123D Catch mesh processing is excellent if data set is composed of a range of 30/200 photos. The number of the dataset photo collection depends on the scale of the object [23].

There are two strong conditions to carry out a useful mesh: 1) use the same camera and the same focal length; 2) have a structured photos data set collection where each image captures the entire object. These latter two conditions are mandatory to have a regular geometric and metric mesh without any distortions. The second condition is an unfavorable limit in architectural buildings application but in archeological, architectural element, museum collection or small scale objects the output mesh is in almost cases excellent [18].

Below there is a pipeline to use image-based modeling techniques for architectural heritage digitalization.

Data set:

- 123D Catch photos dataset is structured and its development is easy to get. The number of images goes from 30 to 200 and depends from the object scale;

Running time and hardware resources:

- 123D Catch calculation take place on cloud and so you do not need of particular hardware resources;

Output:

- 123D Catch output is a mesh file and this is an advantage; nevertheless, Catch tends to automatically close all the holes and does not declare where this operation happens, one should be very carefully into covering the whole object and into inspection the output mesh;

Metric accuracy of architectural element:

- 123D Catch 2.71 mm

Metric accuracy of architectural building:

- 123D Catch 0.03 m

2.2 Bronze tile 123D Catch Model of S. Cristina urn in Palermo Dome

The data set, to carry out the 123D Catch model, is composed of 21 photos made on two different paths around the object with two different gradients.

The number of photos has been designed according to the real dimension of the object. The output carried out, as you can observe in the figures reported below, shows a good visual accuracy.

Furthermore, its metric accuracy has been verified through a comparison with a direct survey: the horizontal and vertical sections, between 123D Catch model and the drawing obtained from direct survey, result perfectly overlapped.

The 123D Catch OBJ model has been exported in standard resolution: I did not use the maximum one because the goal of the research was to analyze the geometrical aspects of the urn in its perspective construction and not to have the best resolution. The imperfections that you can see in the 123D Catch model are in the real object and that is because it has been created in bronze material [4, 15, 16, 27, 28, 29].

123D Catch mesh	793,736 triangles 468,357 vertices

Tab 1: parameters values

Once I exported the 123D Catch OBJ model, I can use it in other 3D packages to make the perspective return. I have chosen Rhinoceros5.

3. Rhino elaboration for perspective return

In order to perform the perspective return in the geometric space, it is necessary to reconstruct the trunk prismatic box that contains the tile. Therefore, it is necessary to find the planes that form the walls of the tile. To do this, I had to dissect the 123D model with horizontal and vertical planes with the same step away in Rhinoceros 5 (Figg. 3, 4).

The intersection between the level curves, obtained by bundles of horizontal and vertical planes, intercept the exact points on which to pass the four planes that make up the tile (Figg. 5, 6, 7). In this way, I obtained profiles that generate the geometric shape in the space.

Extending the carried out planes, we obtain the pyramidal solid through their intersection (Fig. 8). Within the solid, is identified the trunk prism and the straight line where there is $F'_{n\pi}$, the vanishing point of the straight lines perpendicular to the framework.

As you can see in Fig. 9, the extended straight lines of the lateral walls are not aligned. This happens because in the figure the object is not read from the perspective point of view.

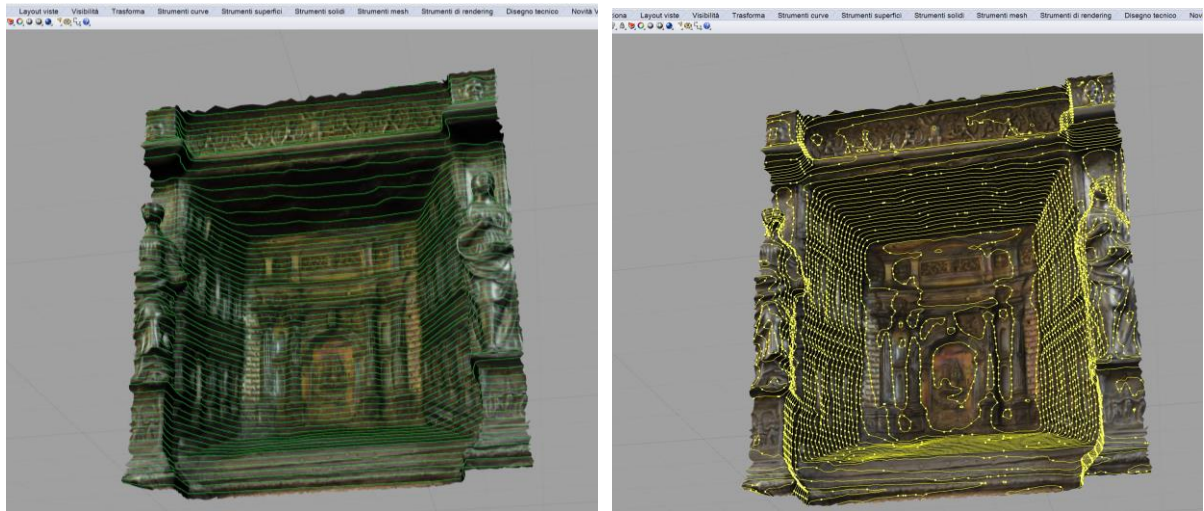

Fig. 3: 123D Catch OBJ model in Rhino5: horizontal and vertical sections.

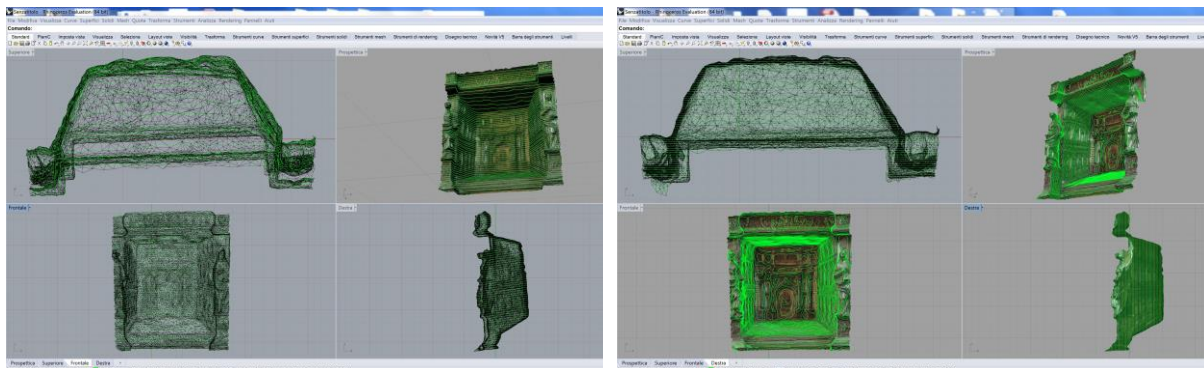

Fig. 4: 123D Catch OBJ model in Rhino5: horizontal and vertical sections.

Fig. 5: 123D Catch OBJ model in Rhino5: rendered model and intersection between horizontal and vertical sections.

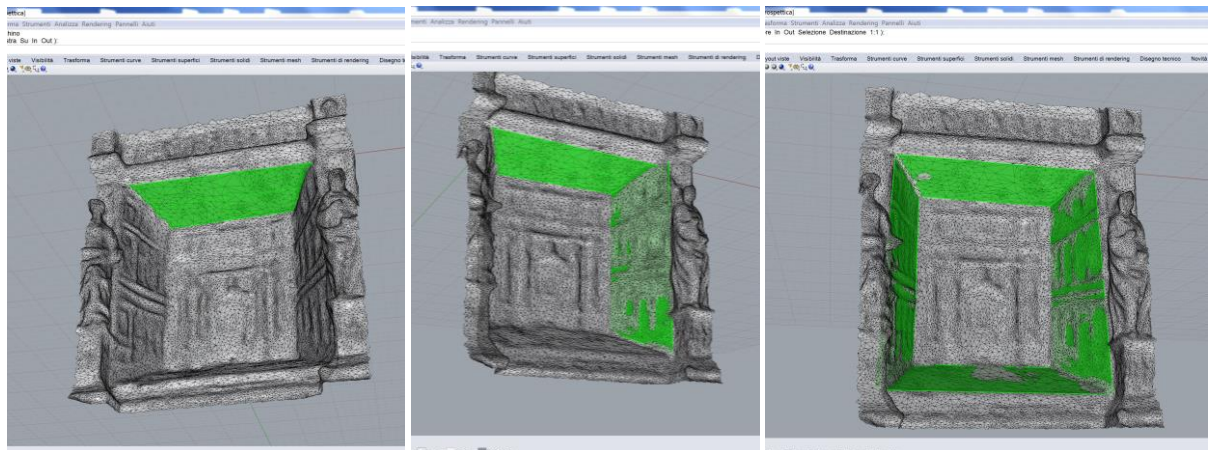

Fig. 6: 123D Catch OBJ model in Rhino5: planes that make the prismatic object.

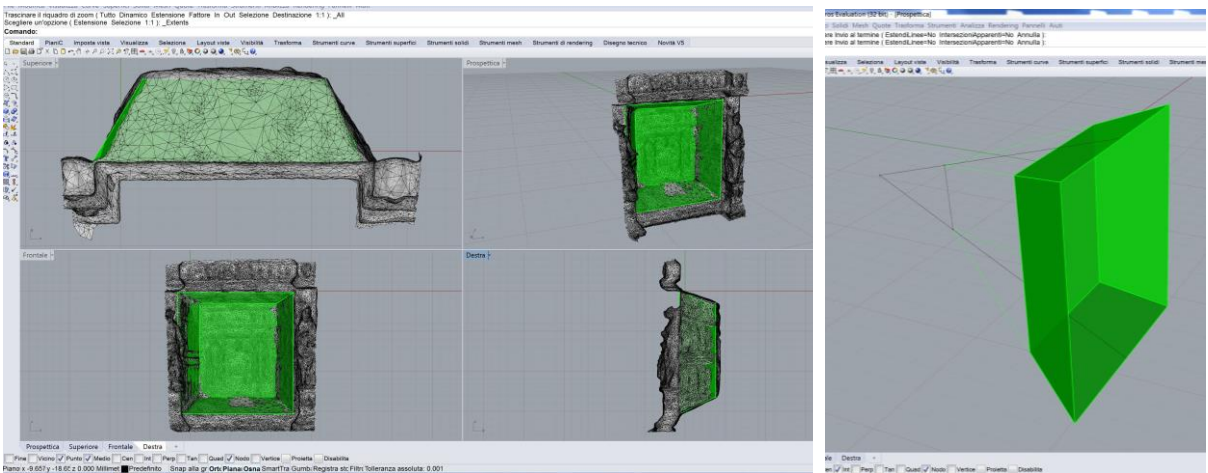

Fig. 7: 123D Catch OBJ model in Rhino5: planes that make the prismatic object in the four views and pyramidal solid.

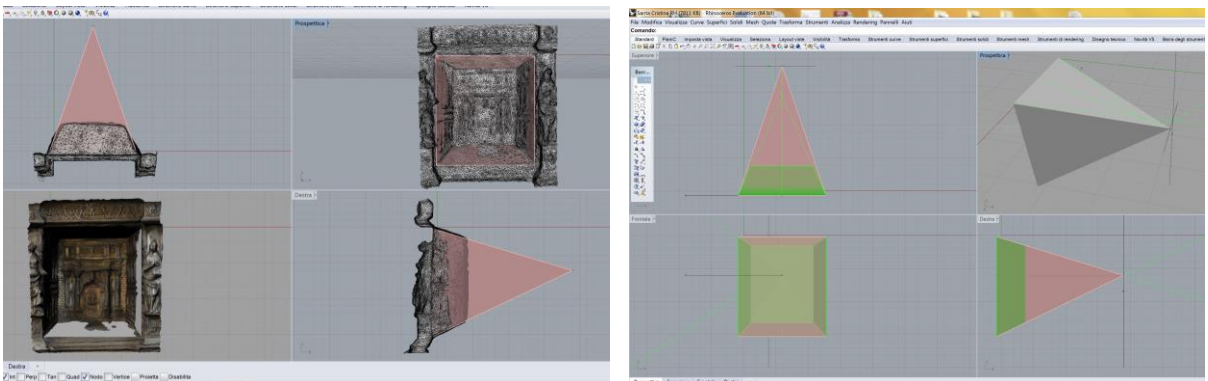

Fig. 8 123D Catch OBJ model in Rhino5: geometric analysis for perspective return.

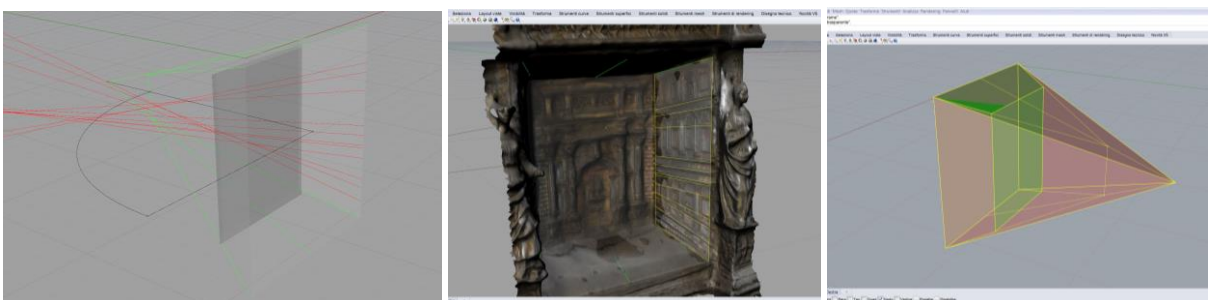

Fig. 9: 123D Catch OBJ model in Rhino5: geometric analysis for perspective return.

This paper was aimed to verify the reliability of the image-based modeling techniques applied to architectural elements in order to make a return perspective.

The result obtained showed that these techniques were entirely satisfactory, at zero cost and with a very low processing time. The metric and visual accuracy allowed me to follow all steps from data acquiring to 3D modeling, to geometric analysis, to return perspective, with a result (Fig. 10) quite satisfactory.

Using of 123D Catch is a suitable choice when you have to elaborate architectural elements or museum items.

MULTI CRITERION DECISIONS IN A FUZZY LOGIC ENVIRONMENT

Maria Cristina MIGLIONICO¹

⁽¹⁾ Department of Architecture and Industrial design "Luigi Vanvitelli" Second University of Naples (SUN), Italy mcristina.miglionico@unina2.it

Abstract

The past few years have witnessed a rapid growth in the number and variety of applications of fuzzy logic, ranging from consumer products, industrial process control and vision systems to medical instrumentation, information systems, signal processing and decision analysis. The foundations of fuzzy logic have become more stable and its impact within the basic sciences - and especially in the mathematical and physical sciences - has become more visible and more substantive.

The choice among several alternatives in a social context depends on the values that the linguistic variables take, with respect to the selected criteria. These values indicate the satisfaction degree of the alternatives with respect to the criteria.

Keywords: Linguistic variables, fuzzy numbers, extension principle

1. Introduction

A great deal of effort involved in the design of fuzzy logic-based applications are expended in the determination of the rules and membership functions. The rules are usually better known than the membership functions. The difficulty in determining the membership function arises from the same factor that makes fuzzy logic attractive, that is the usage of linguistic labels and descriptors on variables. Linguistic descriptors are highly context-dependent. For example, what is considered "high temperature" in chemical processes may correspond to just a "mildly high temperature" in nuclear processes when both are expressed on an absolute scale. In this sense, the experience of skilled human process operators can be considered to be a measure of the degree to which the operator understands the meaning of the descriptors in the context of the plant or process he is operating (membership function). This, coupled with his knowledge of the process behaviour and control procedures (rule base) enables him to control the plant.

Even within the same application domain, the embodiment of the rules and membership functions in the operators' knowledge may vary from one operator to another. In the early stages of developing fuzzy logic applications, it will be advantageous to first try out the fuzzy application on a simulated model of the process. A set of basic rules and membership functions can then be built as the starting point. To this end, the code described has the following characteristics [1]:

- I allows to test out different combinations of membership functions and rules;
- II interfaces to different processes or models; and
- III can be used for fuzzy logic modelling, control or pattern recognition.

These features are accomplished without rewriting the fuzzy logic codes that are tailor-made for specific applications.

2. A fuzzy model for multi criterion decision

There are situations that are decisional situations. In this case, it is more natural to deal with uncertainty by using fuzzy set theory instead of probability theory. A model for decisions in a fuzzy based techniques for linguistic approximation is presented. The proposed model represents the strong subjective value choices dependent on fuzzy information.

The problem consists of choosing between the alternatives of a set $A = \{a_1, \dots, a_m\}$ starting from fuzzy information on the appropriateness of each alternative, based on a fixed criterion. This information is provided by a family of fuzzy sets $S = \{S_1, \dots, S_M\}$, where each S has a membership function defined on the real axis and represents a linguistic term. Starting from this point, it is assumed that the fuzzy sets are fuzzy numbers, preferably of triangular or trapezoidal type.

The adequacy is interpreted as a measure of decision-making, with the criteria being met by the alternatives.

This method consists of choosing the preferred alternative, starting from S , and then to express in linguistic terms the reached decision.

As an example, consider the problem of choosing between four alternatives on the data represented by $S = (S_1, S_2, S_3, S_4)$, as depicted in figure 1.

Fig.1 : Choice made between four alternatives.

The descriptive ambiguity is intuitively reasonable to suggest the choice of a_3 or a_4 . In order to formalize this choice, a concept of dominance based on the separation between two fuzzy sets is introduced.

The σ **separation** between two convex fuzzy sets A and B is:

$$\sigma(A, B) = 1 - \sup_x (\mu_A(x) \wedge \mu_B(x))$$

The δ **dominance** of A on B is:

$$\delta(A, B) = \sup_x (\mu_{\leq A}(x) \wedge \mu_B(x))$$

where $\leq A$ is the fuzzy set "less than or equal to A set" defined as follows:

$$\begin{aligned} \mu_{\leq A}(x) &= 1 & \text{if } x < x^* \\ &= \mu_A(x) & \text{if } x \geq x^* \end{aligned}$$

where x^* is the smallest value of x like that $\mu_A(x) = 1$ as shown in figure 2.

This definition of dominance is not the only possible one, even if it represents in a satisfactory manner the separation of the peaks μ_A and μ_B . The aim of this paper is to determine the subset of S associated with the non-dominated alternatives.

The set in which the elements of S are defined is linearly ordered. A not dominated fuzzy set is the one whose peak is on the right with respect to all the others. It is seems clear that δ does not provide information on the overall shape of the functions of ownership. Therefore, there could be situations, as shown in figure 2, where $\delta(A, B) = \delta(A, B')$, despite the peak μ_B is markedly to the right of that of B .

This means that it is not possible to base it exclusively on δ to order the elements of A .

Fig. 2: Situations where $\delta(A, B) = \delta(A, B')$

By indicating with $R_\delta(i, j)$, the dominance relation on S by using the data of figure 1 results:

$$R_\delta = \begin{vmatrix} 1.0 & 0.5 & 0.0 & 0.0 \\ 1.0 & 1.0 & 0.8 & 0.5 \\ 1.0 & 1.0 & 1.0 & 1.0 \\ 1.0 & 1.0 & 1.0 & 1.0 \end{vmatrix}$$

Note that the third and fourth rows have all the elements equal to 1 and the corresponding alternative (a_3, a_4) are not dominated, as previously argued. The next step is to find a method to identify a single alternative as not dominated.

First of all, an array of weights is introduced whose components are defined as follows:

$$W_i = \bigwedge_j R_{\delta}(i, j) \quad i = 1, \dots, M$$

where W_i is interpreted as the global degree with an alternative, the i^{th} element, that dominates the others. At this point, it is possible to build up an algorithm that allows to define the fuzzy set associated with each of the alternatives that are not dominated. The algorithm is based on the average deviation of all the other alternatives.

The first step is to introduce the following functions of m independent variables:

$$g_k(x_1, \dots, x_m) = [x_k - (\sum_{i \neq k} W_i)] / (\sum_{i \neq k} W_i),$$

where k denotes the positions in W such as $W_k=1$ (in this example $k=3,4$) the x are chosen in the S_i domain.

The second step is to replace x with the elements of S . Determining, by means the extension principle, the Z_k fuzzy sets associated with each alternative not dominated.

$$\mu_{Z_k}(u) = \bigvee_{g_k(\cdot)=u} (\bigvee_i \mu_{S_i}(x_i))$$

It is possible to carry out $Z_k = g_k(S)$ by interpreting it as the fuzzy weighted difference between S_k and the $\{S_i: i \neq k\}$ set.

The introduction of g_k and then of Z_k , can be justified by noting that the alternatives clearly dominated have a low role in the achievement of the final decision. In particular, if $W_i = 0$ for some i , the alternative correspondence is not preferred at all.

The array of the weights referred to the example of figure 1 and $W=(0 \ 0.5 \ 1 \ 1)$ and then in correspondence with $W_k=1$ ($k=3$ and $k=4$) make it possible to determine Z_3 and Z_4 (figure 3). From this figure, it is possible to observe that a_4 is preferred to a_3 . The trust, in this case, is rather low. The trust can be measured in fuzzy terms as depicted in the next paragraph.

Fig. 3: Determination of Z_3 and Z_4 with $W_k=1$

3. Linguistic accuracy and truth qualification

The problem is how to represent the preference of an alternative on the others by expressing linguistically the perception of the truth on the choice made. In this context, a decision can be expressed, for example, using the following proposition:

“is very true that a_k is marginally preferred to all the other alternatives.”

Formally, it is possible to carry out:

“ a_k is P with respect to all the others is τ ”

where P is the intensity of preference and τ is the qualification of truth

supposing P is a fuzzy set defined on the same population of Z_k . In addition, τ is fuzzy, this proposition can be translated into a fuzzy set semantically in the similar manner. First of all, it is to build up the fuzzy set L :

$$\mu_L = \mu_{\tau}(P(u)).$$

in order to determine L in a similar manner to Z_k from the semantic view, by means of a process of **linguistic approximation**.

The first step is to define the set A of linguistic terms that represent the possible decisions and the possible fuzzy representation of P and τ . For the latter, for example, it is possible to choose the fuzzy sets depicted in the following figures:

Fig. 4: Fuzzy representation of P .

Fig.5: Fuzzy representation of τ .

At this point, it is possible to choose the element of Λ , semantically, nearest to Z , where Z represents any element of Z_k .

Each $L_i \in \Lambda$ is represented by an array $P(p_i^1, p_i^2 \dots p_i^k)$ of characteristic parameters, chosen in order to describe, sufficiently, in the correct manner the shape of the function of belonging.

This step is particularly critical because the choice of parameters determines the success or failure of the linguistic approximation. The experience suggests choosing the following four parameters:

- i) $p_i^1 = \sum_{k=1, \dots, N} \mu_{L_i}(x_k)$, where $N = |\Lambda|$
- ii) $p_i^2 = \sum_{k=1, \dots, N} (H^2)(\mu_{L_i}(x_k))^{1/2}$, where $(H)h = h, \quad 0 \leq h \leq 1/2$
 $1-h, \quad 1/2 \leq h \leq 1$
- iii) p_i^3 : first moment of μ_{L_i}
- iv) p_i^4 : second moment (dispersion) of μ_{L_i} .

These four parameters are calculated for Z and then a weighted Euclidean metric introduced to calculate the distance (semantics) of Z by each of $L_i \in \Lambda$:

$$d(L_i, Z) = (\sum_{k=1, \dots, 4} w_k^2 (p_i^k - p_z^k)^2)^{1/2} \text{ (the weights } \pi^1 \text{ are chosen by the decision maker).}$$

It is possible to determine the L_i elements in order to satisfy:

$$d(L_i, Z) < \varepsilon,$$

where ε is a tolerance measure subjectively prefixed.

By indicating with $\Lambda(Z)$ the set of L_i evaluated in this manner, it is possible the optimum search by solving the following problem:

$$\min_{L_i \in \Lambda} d^*(L_i, Z)$$

where d^* is a metric not necessarily of the same d type.

4. A problem of choice of investments

A private investor has a capital to be invested by choosing between five possible areas, taking into account four criteria. Alternatives and criteria are in the following order:

a_1	products market
a_2	share market
a_3	gold and/or diamonds
a_4	real estate
a_5	Bondholders
c_1	risk to loss the equity capital
c_2	vulnerability of the equity capital
c_3	amount of interests
c_4	realization of the cash capital

The rating of the alternatives to respect the criteria is expressed linguistically in tab. 1.

	c_1	c_2	c_3	c_4
a_1	high	more or less high	very high	fair
a_2	fair	fair	fair	more or less good
a_3	low	from fair to more or less low	fair	good
a_4	low	very low	more or less high	bad
a_5	very low	high	more or less low	very good

Tab. 1

It is possible to select one option taking into account that the criteria have different weights as linguistically expressed in the following table:

c_1	c_2	c_3	c_4
moderately important	more or less important	very important	more or less unimportant

Tab. 2

The first step is to determine the suitability of each alternative with respect to the criteria. It is supposed to calculate the adequacy as a fuzzy weighted sum of ratings (figure 6):

$$S_i = \sum_{j=1, \dots, 4} \alpha_j r_{ij}$$

where the sum and the product are performed by using the extension principle.

Fig.6: Calculation of the adequacy as fuzzy weighted sum of ratings.

The use of fuzzy numbers (triangular or trapezoidal) allows to simplify greatly the computational phase by using parametric representations. At this point, it is possible to determine the dominance relation R and the array W of weights, respectively:

$$R_g = \begin{pmatrix} 1.0 & 1.0 & 0.81 & 0.49 & 1.0 \\ 1.0 & 1.0 & 0.90 & 0.58 & 1.0 \\ 1.0 & 1.0 & 1.0 & 0.85 & 1.0 \\ 1.0 & 1.0 & 1.0 & 1.0 & 1.0 \\ 0.77 & 0.79 & 0.63 & 0.34 & 1.0 \end{pmatrix}$$

$$W = (0.49 \quad 0.58 \quad 0.85 \quad 1 \quad 0.34)$$

Fig. 7: determination of $Z_4=g_4$, by finding an appropriate linguistic approximation L_z

It can be noted that S_4 (real estates) dominates the other alternatives therefore it is possible to proceed to the determination of $Z_4=g_4$, by finding an appropriate linguistic approximation L_z (figure 7). In the calculations, it has been tacitly assumed a set of linguistic terms Δ in order to choose the best "approximate". Recalling that the standard form of a decision is a proposition like this:

" a_k is P all of the others is τ ".

In this case, it results a_k = "real estates" and L_z is equivalent to:

P = "from indifferent to marginally better off"

τ = "more or less true".

By comparing the linguistic statement with the weights derived from R_{δ} , it is possible to observe that it is rather prudent. Confirming that a decision is based on uncertain fuzzy data it is itself uncertain. This circumstance can be moreover highlighted by changing in marginal mode the data of the problem. By supposing to modify the importance of c_4 from "more or less important" to "not be less important to moderately important", it generates an alteration of S_i (figure 8) and R_{δ} :

Fig. 8: Alteration of S_i and R_{δ} due to modification the importance of c_4 from "more or less important" to "not be less important to moderately important"

The array of weights becomes $W = (0.58 \ 0.72 \ 1 \ 10.51)$ and thus the dominant alternatives become a_3 and a_4 . There are two sets of preference, Z_3 (gold/diamonds) and Z_4 (real estates). By calculating the corresponding L sets, it is possible to find that they coincide (figure 9) and then a_3 and a_4 are indifferent. Looking at figure 8, it is possible to deduce that a_4 is dominant. At this point, in order to choose between a_3 and a_4 other criteria should be introduced, for example, it could suggest the alternative with the least "fuzziness".

5. Conclusions

This methodology starts from the assumption that in those situations in which the fuzzy sets are used effectively to represent the uncertainty. Making a decisions is an action typically based on fuzzy logic. It is not appropriate to give the final choice as artificially defined precision.

The decisions must assume a linguistic connotation rather than a numerical one. The developed procedure presents a computational complexity that requires the use of computers, with it being essential that all the stages in the decision are put interactively against the decision-making structure which is resolvable in the following phases:

- Phase 1: Problem formulation (alternatives, criteria and basic linguistic terms definitions);
- Phase 2: Definition of decision set (building of A set starting from the linguistic labels assigned to P and τ);
- Phase 3: Initialization of the approximation linguistic procedure (array parameters, metrics and of the E tolerance definitions);
- Phase 4: Decisions revision (linguistic evaluations modification and sensitivity analysis on the dominance).

THE HISTORICAL DRAWING AS A SYSTEM OF IDENTITY OF A TERRITORY. THE VOMERO IN THE EXPANSION PROJECT OF THE NINETEENTH CENTURY TOWN

Maria MARTONE

Dep. of History, Drawing and Restoration of the Architecture, University "Sapienza" of Rome, Italy
maria.martone@uniroma1.it

Abstract

The transformation project of the city of Naples, performed in the second half of the nineteenth century, was characterized mainly by adhering to the theoretical concepts and operational set in Europe in the programs of expansion and rehabilitation of the city. Between areas of the urban expansion, the project, curated by Adolfo Giambarba, also involved the Vomero hill. A uniform mesh of parallel roads and radial overlapped to the land of the hill, giving rise, in the plateau, to a new neighborhood, as opposed to existing villages, provided for a building curtain based on the intensive use of the lot. In the current urban fabric of the Vomero the image of the nineteenth-century city is strongly marked from speculative building of the contemporary city, which reads the stratification of urban and architectural interventions of the past.

The paper aims to identify on the basis of a comparison of survey drawings of the 1872 - 1880 and drawings of project of Giambarba the overcoming of the topographical criticalities of the hilly terrain for the construction of the new neighborhood, to identify actions hinge with the ancient villages which still you perceive in the urban landscape of the Vomero. The historical drawing becomes an indispensable tool for documentation - aimed at the protection and preservation of an architectural and urban heritage - through which it is possible to identify the history of a territory.

Keywords: historical drawing, architecture, city, territory, protection

1. The orography of the Vomero hill before the expansion of the town of Naples

At the end of the nineteenth century it was still possible to admire the hill of Vomero for its ancient beauty, as well as it was celebrated by distinguished poets, writers and painters. Praised in the most famous guides for visitors for the healthy climate, the productivity of the fields planted with orchards and especially for the landscape of the gulf that could be perceived from its top, the hill was characterized by a vast plateau that stretched old villages including the Vomero, Case Puntellate, Belvedere, Antignano, Arenella and Due Porte, which included houses, farms and mansions. Numerous were villas scattered along the crest of the hill overlooking the Riviera di Chiaia. Surrounded by lush gardens and orchards were villa Salve, villa Belvedere, villa Giordano, villa Regina, villa Floridiana. Other important and large villas were located within plateau and in the vicinity of the fort St. Elmo [1]. The Vomero was accessible from the lower town, to the west, across the road of the Infrascata, the current Salvator Rosa. In addition, some streets with steps: la Pedementina di San Martino, Calata San Francesco, la Salita del Petraio, vico Cacciottoli, passing, with very steep paths, the difference in height that divided the hill from the plain, reached the Corso Vittorio Emanuele, built in 1852 and from here the lower part of the city until to arrive the sea level. To the east, via Tasso, opened in 1884, starting from St. Stephen's square, at the beginning of the road Belvedere, arrived to the Corso Vittorio Emanuele, following halfway up the slopes of the hill of Vomero, which still remained a rather isolated from the rest of the city.

The orography of the Vomero hill, before the expansion of the town of Naples, made at the end of the

Fig. 1: *Map of Naples*, Federico Schiavoni, 1863-1869. Sheet 12 (Arenella) [2]. Detail of the area between the village Antignano, to south, and Arenella to north. Original graphical scale 1: 2000.

nineteenth century, finds its most important representation in the plant of the city of Naples drawn by Federico Schiavoni, between 1863 and 1869 (fig. 1) [2]. At sheet 12 (Arenella) are represented the villages of Arenella and Antignano; the sheet 8 (the Archetello) shows the village of Case Puntellate, while at sheets 17 (Forte St. Elmo) and 16 (Villa Ricciardi) is represented il Casale di Vomero, whose name, however, does not appear in the nomenclature of places, unlike in the plants of the Duca di Noja (1775) and Rizzi Zannoni (1790). The plan of the whole city, drawn to the graphic scale of 1:2000 in 24 sheets engraved on copper plates, formed the basis on which it was drawn up the plan of risanamento and expansion of the town of Naples by Adolfo Giambarda, chief engineer of the 1st technical direction of the City [3]. The building fabric is represented with the contour of the buildings treated with a dense pattern with continuous and inclined lines that are interrupted to represent the entrance hall of the buildings, in which is shown the projection of the coverage and the position of the scale; for the sacred buildings it shows the floor plan. With regard to open space, the map shows the design of gardens and cultivated fields, crossed by narrow paths shown with a dashed line. With the technique of maxiclive it is rapresented the jumps of share and steep terrain. The road system, primary and secondary, is enhanced by a careful and meticulous existence of a detailed quoted plane that valorizes the whole plant of the town. Federico Schiavoni, professor of geodesy, University of Naples, was charged, in fact, from City Hall to prepare a geodetic network for the triangulations of the

Figg. 2, 3: Left, *Map of Naples*, Rizzi Zannoni, 1790 [4]. Right: Representation with isopse of the plateau Vomero - Arenella (processing: arch. Floriana Papa). In red the plateau.

plant; documented are, moreover, the mareographic observations along the coast that predisposed to achieve greater precision in the drafting of the plan quoted.

The plateau of the Vomero-Arenella stretched from north to south: from the ancient Via Confalone to Via Cimarosa, the ancient road of the Vomero that led to villa Pietracatella and Floridiana, rising from an altitude of 180 mt. above sea level at an altitude of 195 mt., reaching an intermediate level of about 170 mt., in the area where today stands piazza Medaglie d'Oro. Then, the plateau was characterized, along a stretch, by a narrow compluvium, where it developed the ancient Via dell'Infrascata, whose route ran at an altitude of about 160 mt, along the slope of the hill Arenella. To the east, the plateau was limited by vico Acitillo, located perpendicular to the road Belvedere, while to the west the land sloped down towards the ancient center, reaching the Corso Vittorio Emanuele at an altitude of 100 mt with the road by Girolamo Santa Croce, which ran halfway up the hill. Only in some parts of the plateau was barely visible the height of S. Martino, who reached an altitude of about 250 meters. These height differences in the territory of the Vomero, documented in the plant of the Schiavoni, are well represented in the sole of Rizzi Zannoni [4], in which the technique of chiaroscuro allows you to view three-dimensional position of the plateau in the territorial context of the city. In a representation with isopse the territory of Vomero-Arenella is summarized in its physical configuration, which highlights the height differences that separate it from the rest of the town (figg. 2 - 3).

1.2 The Vomero in the iconography of the nineteenth century. The view of Heilmann

Many were the views made from the fifteenth century until the nineteenth century, of the town of Naples whether painted or engraved, where you can find the profile of the hill of Vomero, that characterized the urban landscape, with the presence of the fortified building of the St. Elmo.

The point of view chosen by painters makes it difficult to read the plateau that stretched inland, on top of the hill, focusing on representations of the lower part of the city, with the exception of some views, such as those implemented in nineteenth century by Alfred Guesdon, who performed the first representations of the city from above, on board a hot air balloon, during his many travels in Europe [5]. In his views can be glimpsed with more information even of the plateau on top of the hill (fig. 4).

A view special and unusual, for the choice of point of view, is that of Heilmann de Rondechalet, followed in 1841 by the square of Castel S. Elmo, in which you can read at 360° the town of Naples (fig. 5). The view, single sheet folded several times, consists of six parts, each with a nomenclature from which it emerges the location of many buildings and places of the hill, the town and its surroundings. Thanks to the use of a perspectograph, tool used by painters of the period, consisting of a squared frame in which it was framed the scene to represent, the artist, gradually turning the tool, drawn six contiguous views of the entire scene of the urban landscape, having as reference the Hermitage of Camaldoli.

Most important is the legend of the view composed of 366 entries, published for the first time in 2000

Fig. 4: *View of Naples*, Alfred Guesdon, 1849 [5].

with his title, edited by Giuseppe Zampino, providing detailed documentation of how it appeared the city and its surroundings in the middle of the nineteenth century [6]. The city is drawn between the Camaldoli and the Vesuvius, between Pizzafalcone and Posillipo, having as background the outline of the mountains Lattari, the Sorrento Peninsula with Mount Faito, the island of Capri, up to the mountain Epomeo of island of Ischia. In the representation is sacrificed the part immediately below the hill, not being it included in the cone of vision of the observer.

The hill of Vomero is drawn in the sixth table, in which, referring to the legend, it is possible to identify in the foreground, from left, The Belvedere of Villa Floridiana, then called, later, Villa Lucia; after the bridge on the road to Belvedere, it is possible recognize the villa Floridiana; below there are the villa Ruffo Palazzolo Haas, Villa Belvedere, and to right Villa Giannone with the Salita del Petraio.

2. The drawing of extension of the town on the hill of Vomero

The highland area of Vomero-Arenella was concerned at the end of the nineteenth century by a planned expansion of the city of Naples provided simultaneously to the intervention of risanamento the slums of the city. The hill still represented a mainly agricultural territory with few and sparse episodes of building constructions than those related to farms and farmhouses, linked to the work of the land, and villas that were the second homes of the Neapolitan nobility. The project of 1885 provided for the center of town the thinning of the existing housing through the demolition of warehouses and alleys and the reconstruction of the area through a new road network with the creation of "blocks" of the building fabric, while the outlying areas, including the Vomero, were involved in the expansion plan of the city, which provided new districts in the plains and hills. A neighborhood in the plains was built to the east of the city and was planned in a marshy area, then reclaimed by backfilling works. Were built affordable housing, for the inhabitants of the houses to be demolished. In addition, it was also planned an extension to the east of the city at the Riviera di Chiaia, formed by Amedeo district. The planned neighborhoods in the hills arose, however, in the area of the Vomero-Arenella-Antignano, between Via della Salute, extension of the Corso Vittorio Emanuele, and Salita St. Raphael to Materdei to the Vomero, and finally on the southern slope of the hill of Capodimonte (fig. 6).

Figg. 6, 7: Napoli. Left: Extension plan and the risanamento of the city of Naples, 1885. The carmine color indicates the area of cleansing, the red indicates the expansion plan [3]. Right: Extension plan of 1886, particular. [7]. Are highlighted the principal axes of the system of roads with names that were subsequently allocated to them and the system of squares that you will later configure: 1. Piazza Vanvitelli. 2. Piazza Medaglie d'Oro. 3. Piazza Muzji. 4. Piazza degli Artisti.

The project of risanamento and expansion was characterized by adherence to the theoretical concepts and operating targets established in Europe in the programs of expansion and consolidation of the towns, oriented on the improvement of sanitary conditions and urban development. The project of risanamento and expansion was characterized by adherence to the theoretical concepts and operating targets established in Europe in the programs of expansion and consolidation of the towns, oriented on the improvement of sanitary conditions and urban development. The design criteria were inspired by the models already performed for the major European capitals and especially for Paris of Haussmann, those models feature a new report road-block.

On this concept were written many development plans in Europe and in Italy. Recall that in addition to the previously mentioned Hasmann of Paris, one of Cerdà for Barcelona in 1859, of Lindhagen for Stockholm in 1866, the Ring of Vienna from 1859 to 1872, the plan of Antonelli in 1852 for the city of Turin, the plan Trotti for the town of Bari in 1867 and Poggi's plan for the city of Florence in 1885.

The Law on Risanamento and expansion of the city of Naples was based on a rough draft, and there were numerous proposals for the definition of the implementation plan: we remember those produced by Lamont Young, Pisanti and Cassitto, Carelli, Giambarba, Folinea, Fantacchioli, Cozzolino. In 1886 it was finally approved the draft prepared by the engineer Adolfo Giambarba regarding the construction and the urban planning and by engineer Gaetano Bruno for sewer and aqueduct. The tender was won by the Company pel Risanamento of Naples, who undertook to carry out the proposed works within a decade, a term that was not respected, especially for economic conditions and the special conditions in which they poured the banks. The work officially began June 15, 1889

and different were laws that followed for the implementation of the plan. The initial project underwent several variations especially in relation to the road layout of the east area.

The basic concept of the expansion project that also affected the Vomero hill was to make the roads as much as possible straight, alternate with a system of squares and square lattices forming and radial, with blocks of regular size, in the logic of academic models. This policy was carried out both in the flat part of the city, in the districts to the east and on the Riviera, both in the hill, showing little sensitivity to the problems of landscape and orography of the area, focusing on building a curtain coded according to the typologies of the period.

New roads were built in the hill of Vomero superimposed on pre-existing ones, while also providing the demolition of some old buildings and road layouts. He remained, however, unstable the link with the town center, despite the realizations of the funicular railways, already provided for ten years before the construction of the new neighborhood. In the plan attached to the expansion plan of 1886 is represented the project of Arenella Vomero district on the basis of the status quo of the area. The design of the new district has a road system with a mesh orthogonal having as axes main the current streets Bernini and Scarlatti, in the which intersection was then designed a square called Piazza Vanvitelli [7]. The upper section of Via Scarlatti, because of the steep slope, it was designed with two bends (now Via Morghen) and a stairway for pedestrians, through which you can reach Castel St. Elmo or the funicular Montesanto (fig. 7).

Figg. 8, 9: *Napoli*. Left: building between Via Scarlatti and via Luca Giordano, in a current photo. Right: architectural detail of a building on Via Luca Giordano, in a current photo.

The axis perpendicular to Via Scarlatti, exceeded with a flyover the ancient road Infrascata, that ran along the compluvium between the hills of Vomero and Arenella, flowed into a large octagonal square, to achieve, always in a straight line, the Arenella, today Muzji square. From the large octagonal square (now Piazza Medaglie d'Oro) departed eight radial roads, including via Tino di Camaino which reached an old stone Village Antignano. The orography of the place, however, has conditioned the drawing in the neighborhood, although currently a first impression of what the area is not perceived, because everything is now hidden by a stratified building that over time has become more and more dense, causing loss of contact with places. Via Scarlatti, for example, was built near the crest of the hill, in the stretch that extended above the Riviera di Chiaia. The nineteenth-century neighborhood, with its towering curtains of the isolates, has represented a closure to the external environment and especially to a landscape that was supposed to attract the eyes and not be an obstacle to its perception. However, the visibility of the gulf from Via Scarlatti would never have been possible given the slight slope of the land on which the road was built and the considerable distance from the point of maximum slope of the land. In parallel to Via Scarlatti ran it yet another road: Via Cimarosa along which there was the garden of the villa Floridiana, before you get to the lookout over the sea. "It's not a different design of the neighborhood, but a much looser building intensity and different typologies would have been desirable, but this would be at odds with the idea of nineteenth-century capitalist city" (Alisio, 2000, p. 61). The hill of Vomero found its point of greatest altitude in the vicinity of the fort of St. Elmo and slowly degraded while to the east to the west its slopes were quite steep towards the Conte di Cerra and Salvator Rosa.

The banks that invested capital for the construction of the new district were before the Tiberina Bank and after the Bank of Italy. Following numerous economic difficulties and above all to the fact that there was now a strong demand for housing in the hills, proving the population is not immediately in

favor of leaving the lower town of old town to reach the upper area, the Bank Tiber, which he had bought soils for the construction of the new district, was forced to give up the full implementation of the ward and to divest its ownership in 1899 to the Bank of Italy, that in order to facilitate private investment adopted the process of splitting lots, for a quicker sale and convenient. Inside the checkerboard pattern, which provided regular blocks, developed a buildings, of which there are still some examples along Via Scarlatti and a Bernini, characterized by an enclosed courtyard, or type in the form of a "C" with an inner courtyard / garden. The facades are almost always surmounted by a projecting cornice, were treated with neo-Renaissance stucco; in them were opened imposing portals and balconies that showed a generally triangular gable or curved. On the ground, a rusticated base ended the facade (figg. 8 - 10). The imposing neo-Renaissance style buildings were joined in the first two decades of the twentieth a building designed for small lots with buildings of two or three floors with architectural features outstretched affirmation of a new floral taste and eclectic. Many of these buildings were then demolished and replaced with speculative interventions that have unfortunately significantly altered the image of the first quarter. The new ward Arenella which was realized in continuity with the Vomero district, was realized after a few decades. In 1931-32 was opened via Mario Fiore, that, surpassing with an overpass the old compluvium of Street Count of Cerra, put in communication the two new districts representing the extension of Via Bernini.

Fig. 10: *Napoli*. Piazza Vanvitelli. Current photo on isolated between Via Scarlatti, left, and via Bernini, right.

2.1 The overcoming the critical issues orographic

The urban plant proved very hard for a territory that had a very varied orography and characterized by significant jumps in altitude and various differences in height. Many were in fact some fittings to overcome some critical issues orographic.

The relief of the plateau did not appear, in fact, uniform, but consists of numerous depressions and valleys; to overcome some of which was necessary to build bridges and overpasses some also monumental. In order to achieve, for example, the connection between the hills of Vomero and Arenella were built two overpasses to overcome the underlying ancient road of the Infrascata. The first, built in the vicinity of Antignano it was necessary to carry out the extension of Via Bernini towards piazza Medaglie d'Oro, and the second most impressive in the structure and decoration was built near the Salita Arenella. Along the continuation of Via Scarlatti at Belvedere, after passing the intersection with Via Luca Giordano, it was necessary to build a flyover on way Annella Massimo, so that the road could go to St. Stephen, in the Via Cilea. To the west, however, to overcome the compluvium defined by vico Cacciottoli was necessary to build a bridge to carry the road Girolamo Santacroce. Another bridge already existed along the Corso Vittorio Emanuele to overcome the height difference of Vico Cacciottoli (figg. 11 - 12).

Only later, in the most steep hill of the Vomero, were instead built roads with hairpin bends to allow views of the Gulf. Via Aniello Falcone, built halfway up the hill, starting by Floridiana, reached to via Tasso; were built Luigia Sanfelice and via Palizzi, on land sloping down to the sea. On the opposite side of the plateau, to the north, was built via Giacinto Gigante, also with hairpin turns, steep path that replaced the ancient Via Confalone.

Figg. 11, 12: *Napoli*. Left, top: Plant of Naples, Federico Schiavoni, 1863-1869 [2]. Sheet 12, particular. Via dell'infrascata. Left, bottom: the two overpasses/bridges in current photos. Right, top, the Schiavoni Plant [2], Sheet 12, particular. Vico Cacciottoli. Right, bottom: the two overpasses/bridges in current photos.

3. The hinge points with ancient villages

During the extension work, the Tiber Bank undertook to respect, consistent with the needs of the plan, the existing noble mansions. Some, however, were destroyed, such as the Villa Doria which stood surrounded by a large garden situated between via Solimena, via Annella Massimo and via Scarlatti; a different fate had, however, the Pontano villa, which it remains today incorporated into the building fabric. To avoid, in fact, its demolition, it was decided to change the direction of the new straight road, via Luca Giordano, designed within the new urban street perpendicular to via Scarlatti, making her fall back in the last stretch towards the church of San Gennaro. In the urban planning of the city, was planned at the beginning of the twentieth century, the development of certain areas for public parks, in the new district, some of which probably also planned to mediate the coupling between the existing fabric and the planting of new urban district. Some of these green areas, even for small parts, have been preserved, such as the gardens of Via Ruoppolo, others, however, were built as a result of further variants of the plan. These nodal points that can be defined as "hinge" between the old and the new, are still visible today where once stretched the old Country. Antignano probably is the village where you can still recognize the identifying characteristics of the ancient village. We find, behind Via Luca Giordano, streets and parts of the ancient building fabric, among which is the house of John Pontanus, built in 1472 and then rebuilt in the early nineteenth century, survived to the subsequent work of expansion (fig. 13). In addition, a plaque on the building, with large arches, which looks out on Antignano, testifies the presence in the place of a bourbonic "duty" in the nineteenth century. With the nineteenth-century expansion is suppressed a major artery of the ancient road system: the second part of the "road of Vomero" from Via Belvedere that cut the plateau from south-east to north-west and, after changing direction, forming almost a right angle, leading to the hermitage of San Martino, with the name of "Road to the Castle."

Fig. 13: *Napoli*. Left: Village Antignano. villa Pontano, followed by a picture of the ancient urban fabric. Right: Building on Via Torrione di S. Martino, 39, followed by the sanfeliciano portal.

With the construction of the new neighborhood has been preserved a section of the old road with the new street name Filippo Cifariello, where there is the ancient church of St. Gennariello the Vomero, also known as Piccola Pompei. Via Torrione di S. Martino is yet another stretch of "road Vomero" which probably ended in the current path of via Caccavello Antonio, close to Villa Giannone. Along the path of via del Torrione there is a beautiful sanfeliciano portal at number 39, surmounted by a coat of arms of an important ancient palace and numerous old houses.

Also Salita Arenella, which connected the plateau with the lower part of the city onto the street dell'Infrascata, preserves along the way some testimonials of the existing building fabric, saved from the urbanization nineteenth-century.

4. The current image of the Vomero in the late nineteenth and early twentieth century

The first buildings constructed by the Bank Tiberina were built along the main roads of Via Scarlatti, Bernini and forth via Luca Giordano, respecting the new building regulations which set constraints on the design, defining a specific architectural rules. The buildings followed the installation of the block with the typology of large stately apartment buildings or villas which were built mainly in the most scenic parts, such as the villas's Maria and Elena, in via Angelini. Of the buildings constructed at the end of the nineteenth century remain today only a few examples, some of them even having been demolished to make way for other buildings speculative. Flanked by tall buildings/containers sometimes also worthless architectural, built without preserving the environmental and urban value of one of the most important district of the town, are recognized in the current building fabric, the buildings of the nineteenth and early twentieth centuries for their monumentality and for details character and architectural styles that characterize their facades (fig. 14).

Fig. 14: *Napoli.* Modern and ancient buildings in (from left to right) Via Scarlatti, Via Merliani and piazzetta Durante (via Kerbaker).

At the beginning of the twentieth century, it completes the construction of the lots included in the plan of expansion in 1885, with buildings less monumental and more related to the new architectural trends. While remaining unchanged the road system, the building facades change and changes the consistency of the block which is fragmented into small buildings and it loses the homogeneous character of typology uniform of a chessboard, now emptied of its original style solutions.

Many buildings in style Liberty were built mostly in via Bonito, in via Angelini and via Morghen. Is, in fact, in this part of the hill, immediately in the vicinity of Castel S. Elmo, that it is preserved the image of the urbanization of the late nineteenth century - beginning of the twentieth century. Recall, in Via Cimarosa, Villa and Villa Rosalia Elena, the latter characterized by decorative elements in iron and, in Mancini, Villa Angelina Adele 1909. Along Via Luca Giordano and in the secondary roads of the plant nineteenth century, as via Solimena, via Merliani, via Kerbaker, via Torrione di S. Martino, still remain in their original appearance, some buildings of the era. In via Luca Giordano, corner via Solimena, well preserved, thanks to a recent renovation, is the villa Casciaro, residence of the Neapolitan artist, built in 1910. The detached house, plastered red, presents, in front, balconies with balustrades and columns and decoration with motifs in style liberty. A white band with stucco flowers runs under the eaves, along the perimeter of the villa (fig. 15). On the south side of the Vomero hill, from which it is possible to perceive a wide view over the Gulf of Naples, was built via Palizzi where he worked since 1886 the builder Gaetano Marcolini. Thanks to the presence of the funicular of Chiaia, the road had considerable housing development. Among the oldest buildings we remind villa Villa Pugliese and villa Esposito Lau, built in the vicinity of the sharp slope of the land toward the sea (fig. 16).

The history of the image of the Vomero hill is graphically represented through numerous views, watercolors, etchings and prospective system of representations in the plant that over the centuries have been produced by artists, architects and travelers from every nation, through which you can read

Fig. 15: Napoli. Left: Via Luca Giordano, the villa Casciaro. Middle: Via Scarlatti, modern and ancient buildings. Right: Via Merliani, modern and ancient buildings.

the drawing of the transformation of a territory that for its particular configuration has characterized the image of an entire city. Today are radically altered the Vomero hill and its plateau. No longer a hill covered with green fields, far from the chaos of the city below, but an "extension" of the city, it itself city.

The drawing of the Vomero old, whether it be a plan, a view or a table, it returns what has been and what it could in the future be permanently deleted, assuming thus a fundamental value of the testimony of a story that should be known to be preserved. The drawing, therefore, plays a key role in the iconographic documentation of a place and important for the protection and preservation of the built environment, testimony of the life of man.

Fig. 16: Napoli. Via Palizzi. Left: The drawing of the facade of Villa Pugliese [8]. Right: drawing of the facade of the villa Esposito Lau [8]; Middle: current views of the two villas.

The “diaeta” in the roman home

Rossella BICCO,¹

⁽¹⁾ PhD Student of “Environment and structures representation, protection and safety and land management”, Department of Architecture and Industrial Design “L. Vanvitelli” SUN, Aversa, Italy
rossellabico@live.it

Abstract

6 century B.C., the diaeta was a room used as a receiving area and also where they partook of meals in the roman home, the diaeta often opened outwards to a small garden, where they grew fresh produce attempting an alimentary self reliance, this was added to the production of medicinal herbs and ornamental plants. Some examples are the house of Fauno or the Villa Imperiale and others. The diaeta held a section reserved for the atium, a small space used during the day, where the family gathered to study or relax, listen to music and a place where they could be together and out of the public eye. Vesta a roman and latin divinity, who was attributed the cult of the family and public hearth, reflects that which in a home is the centre of care and needs, and daily qualms and activities. The meeting place for those who share an area. The hearth, the centre of all activities.

Keywords: diaeta, domus romana, kitchen

The home is the place of the domestic hearth where a family co-habits. Italy is one of the countries with the highest percentage of (80%) people who are apartment owners. In this context a single family home represents the most sought after property because of its independence from the other units and the freedom from condominium regulations, combined with having more privacy and a garden. A single family home, more so than multifamily homes has deep anthropological and historic roots and symbolisms: one of the oldest man made manufactured articles, it is the place of auto representation, of memories and social and personal identification.

The predecessor of a single family home was the *domus* romana that even though slightly different defined the concept of a single villa. Limiting to an architectural point of view and going through some of its aspects like bio architecture as in rain water gathering and a correct exposition to the sun, without forgetting the use of natural materials of the time like wood, stone and blocks.

The absence of multi floor buildings can be seen in Pompei *intra muros*, the highest home preserved thus far has two floors plus the ground floor. You can see that most of the insulae that occupy the western quarters have not been constructed on but are occupied by enormous gardens. In the year 79 Pompei had not been completely occupied within its walls, and so there was no reasons to edify vertically.

The *domus* was the most prestigious and richest home this type of building had a rectangular building plan. The entranceway of the *domus* romana, was a pathway from the outside to the atrium, in most homes it didn't bring you directly to the outside however most were slightly set back from the hallway. The atrium was the most important place in the home, it was a rectangular or quad angular form, set in the centre of the home. The hallway was divided into two parts: the vestibule and the fauces.

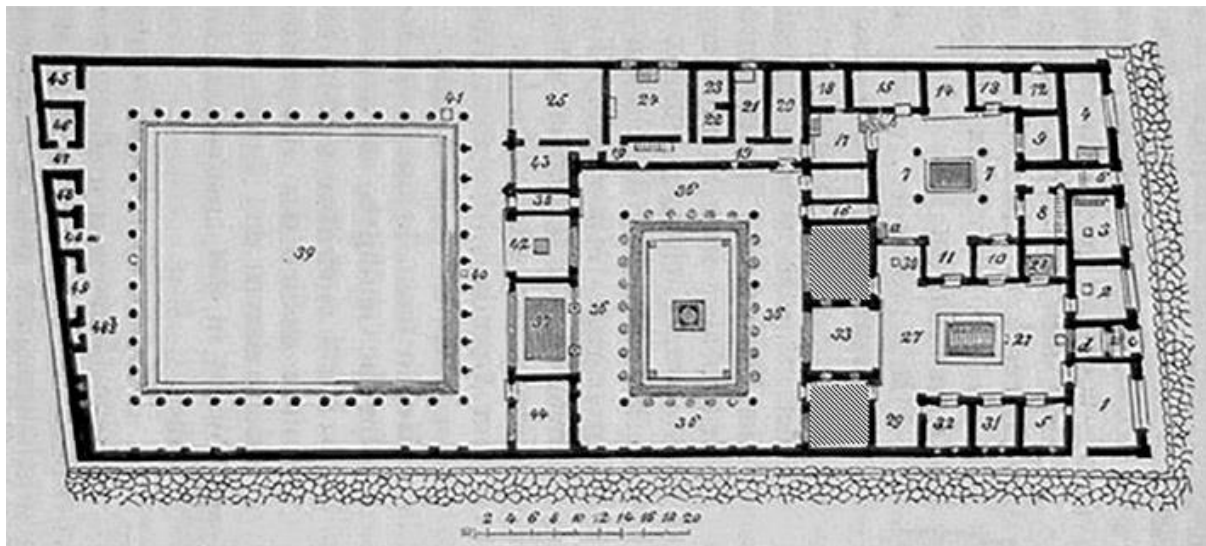

Fig. 1: Plant “Casa del Fauno” in Pompei.

“some friends arrived, and in their honor a column of smoke spiraled to the sky, of course not as dense as the one that comes from the kitchens of important people and puts the fire station in alert, a modest smoke column, that announces the arrival of guests” Seneca in *Lettere a Lucilio*.

Seneca describes a scene from daily life, and gives us essential information, the *culina* was an indicator of the social status of the owner. Even the most modest house had its own kitchen. In homes of antique Italy this was not always the case, because originally the kitchen was situated in the atrium, in other words in the central part of the home. The word atrium reminds us of the origins of this word, it derives from *ater*, black, the color of ash with which smoke rose and covered the walls of the house. In the republican era the hearth was moved in most homes to the kitchen, which became a room of its own. Because of the vapor, it was often placed to the side as long as it was not too far from the dining area.

The size of the Pompeian kitchens was between 6 and 20 mq. A fireplace was always present, it was the centre of all the kitchen activities; on average it was of stone and angular and was often about 120cm high and 80 cm deep. In a round niche of stone under the fireplace they would keep the firewood.

Before becoming one of the most important places that opened to the atrium and the peristylar, the dining room of the older homes was on the upper floor and was called the *cenaculum*, a name which in the following years came to mean superior level, in the absence of an upper floor, meals were taken in the *tablinum*, a custom often continued in the more modest homes. However most often the homes had a vast area exclusively dedicated to meals. The *triclinium*, a name derived from the triple bed on which, as in the Grecian style, guests would lay.

Around a table or a serving table three beds would be placed, each of three places, on which the guests would take place according to a precise hierarchy; on the left bed, the *lectus imus*, the host and his family would sit (or in the absence of a son, a *liberto*); the bed in the middle, *lectus medius*, was reserved for guests of honor or in the grand homes, the place near the host, would be called “*posto consolare*”. On the right was the *lectus summus*, reserved for the other guests. Children would eat their meals with the adults but they were seated at a smaller table where they sat and did not lie on a bed; this system was uncovered in a house behind the “Terme Central”. If the room had space for only two places it would be called *biclinium*; in that case the beds would be placed at right angles, as could be seen in many modest homes. Outdoor summer dining areas were organized like the *biclinium* and summer meals were often arranged in the gardens, shadowed by a patio, and between the beds fountain water would flow. The beds of these summer dining rooms were of stone, plastered and painted. Indoors the beds were made of wood and only fragments remain of the carbonized wood and some bronze ornaments.

Fig. 2: Part of the plant "Villa San Marco" in Castellammare di Stabia.

The ever present garden (*viridarium* - *hortus*), guaranteed a partial self sufficiency insured by cultivation, in the garden there was every type of vegetable, and courtyard animal. The vegetable garden of the Pompeian homes (*hortus*, *hortus viridarium*, o *hortus et viridarium*) was conceived as an extra element in the back of the home, never in the front yard or anywhere else. The *Hortus* is the field, the mini farm, in which not only did they cultivate home grown foods so that they could be self sufficient but also herbal medicinal plants and ornamental plants, and also cages for the animals. When the area around the home was sufficient enough, to the *hortus* was added a *viridarium*, in which a pleasure garden was set up. This idea of a garden, as an expression of the private aspect of roman architecture, expresses the need to include nature into the living area, placing the garden at the same level as the living area, so much so that when there is no space for a real garden it is reduced to becoming an element of the house creating tall rigid forms, forming berry bushes and hedges like short vegetable walls.

It was necessary to include inside the *domus* an area dedicated to the family and relax. The *atrium* was usually situated inside of a *diaeta*.

The *diaeta* was a small room used during the day, where the family reunited to study or relax and stay together away from public activities. This room was more or less isolated, usually it was open to the outdoor architecture or a pergola. For further understanding, in villa San Marco near Castellammare di Stabia we can see many examples of *diaetae*. The villa was situated near Castellammare di Stabia. This city disappeared along with Pompei and Ercolano during the eruption of the Vesuvius in 79. The

Fig. 2: Representation of the goddess Vestia.

villa, was set on the confines of this antique city, and can be included in the residential urban villas, where the landscape becomes an important element of the structure and conditions the development. Inside the villa we can see clear examples of living rooms in fact on the edges of the green area to the side and in front of the ninfeo there are two groups of structures made of three diaetae very similar to each other in shape and distribution of the openings that have large windows on to the gardens and the panorama, they demonstrate the will to exploit the closed rooms as rest areas directly connected to and to benefit from nature. In the first group of diaetae, which can be reached through three gardens, the walls are decorated with small sculptures of high artistic value, among which Perseo with gladio a Medusa head and Ifigenia with the Palladian on her shoulders, then the triclinium which opens onto the garden, the walls are decorated with lively scenes, and is connected to the inside diaeta.

These living rooms were always carefully decorated with mosaics and a frescos. This way the diaetae became places where the family could isolate themselves tranquility outdoors. The *domus* roman can be read like the *ante literam* of the farm houses. In this typology there is an in extractible chain of cultural, economic, social and historical aspects that include architecture, function and technique that originally defines the relationship between the people who live in the country and the reality of the territory, that varied thru the centuries and in the various themes, testimonial of transformation of the territory and society. In a farm house where living and production spaces are two

realities that co habitat together there is an evident representation of environmental sustainability and integration with nature that we talk about today but is difficult for us to create, the court yard has a fundamental importance, especially the open court type, because besides being the centre area it separates the living area from the fields while remaining an important part of the house, it can be defined as a small private universe. What is now the center of the house in the family? Vesta a roman and latin divinity, who was attributed the cult of the family and public hearth, reflects that which in a home is the centre of care and needs, and daily qualms and activities. The meeting place for those who share an area. The hearth, the centre of all activities. Modern day architecture gives a lot of importance to parts of the house where we spend little time during the day, the day to day stress of modern life has brought us to forget the healthy principal of sitting down together for a meal at least once a day, meals have become meager and often eaten while standing or eating things that are very different from those traditional ingredients of our heritage.

Abstract

The letter "Gamma" (Γ, γ), the third of the ancient Greek alphabet, conceals a number of suggestions interweaving glottology, symbolism and graphics. A lot of words starting with "Gamma" refers to the concept of motherhood and birth: "Γῆ", the Earth, but also Gaia, the primordial goddess which gave birth to Olympus gods by parthenogenesis; in this last word, "genesis" is "γένεσις", the beginning, the creation; besides, "γίγνομαι" means "I'm born", "γενεά", is the birth, but also the lineage. All these words can find a sort of linguistic hub in "γυνή", the woman. As a matter of fact, the graphema of the minuscule "Gamma", "γ", reminds the mystical /mythological chalice, i.e. the female womb, and its triangular shape, with the vertex downwards, sketches the Water, "▽", and the Earth, "▼", the cold and female among the four alchemic elements. On the other hand, "γηράσκω" means "I grow hold". The word "γλῶσσα" is "tongue", but also "language", "γινώσκω" means "I learn, I understand, I know", and "γεωμετρέω" "I measure the land". Actually, the graphic of the capital "Gamma", "Γ", calls up the shape of a knee, which in turn finds its etymon in "γόνυ", but also the shape of a set square, "γωνία", one of the most ancient tools for measuring and drawing.

This paper runs across a first approach investigating the associations among linguistic and graphics meanings of "Gamma" as the "root" of the two fundamentals of mankind: life and knowledge.

1. Introduction

The letter “Gamma” (Γ, γ) [1], the third of the ancient Greek alphabet, conceals a number of suggestions interweaving semantics and glottology, mathematics and geometry, symbolism and graphics. Indeed, a lot of ancient Greek words starting with “Gamma” refers to the concept of motherhood and birth. This paper runs across a first approach investigating the associations among linguistic and graphics meanings of “Gamma” as the “root” of the two fundamentals of mankind: life and knowledge.

Fig. 2 “Disclosures of Gamma .Pasqualina Luongo

2. Conception, birth, life and senescence

In the ancient Greek language, the most simple, full-sense and famous word (but also a phoneme and a logatome) starting with “Gamma” is “Γῆ” [gē]: the Earth, but also Gē-Gaia, the primordial goddess which succeeded Chaos (the extreme disorder) to give birth to Olympus gods by parthenogenesis; in this last word, “genesis” is “γένεσις” [gēnesis], the beginning, the creation. Besides, “γίγνομαι” [gígnomai] means “I’m born”, and “γενεά” [genēa] is the birth, but also the lineage. “Γάμος” [gámos] means both “marriage” and “wedding”, and “γάλα” [gála] signifies both the “human milk” and a “nursling”. All these words can find a sort of linguistic hub in “γυνή” [güné], the “woman”. As a matter of fact, the graphema of the minuscule “Gamma”, “γ”, reminds the mystical/mythological chalice, i.e. the female womb, and its triangular shape, with the vertex downwards, sketches the Water, “▽”, and the Earth, “◀”, the cold and female among the four alchemic elements. It is noteworthy that the concept of “womb” is also expressed by the term “γαστήρ” [gastér], which, in turn, denotes the “stomach” too. On the other hand, “γηράσκω” [geráskō] means “I grow hold”.

Fig. 3 "Millenial Gaia Statue" . Oberon Zell

3. Intelligence, knowledge, science and technology.

The verb "γινώσκω" [gignōskō] signifies "I learn, I understand, I know", and the term "γνῶσις" [gnōsis] denotes "cognition", "wisdom", but also "survey", "inquiry". These terms also address to other fascinating words as "γνώμη" [gnōme] and "γνώμων" [gnōmōn]. The former represents a "countermark", as well as the "intellect" or a "judgment". The latter implies even more multifaceted meanings: an "indicator", a "ruler", the "judge", a "gnomon" in the strict sense of the word, i.e. the pin of sundial, or, from Euclide, a "parallelogram complementary to another parallelogram", viz. the part of

a parallelogram remaining after a similar and smaller parallelogram has been removed from one of its corner. The word “γλῶσσα” [glōssa] is “tongue”, but also “language”, and the verb “γράφω” [gráfo] represents both “I write” and “I draw”. Furthermore, the verb “γεωμετρέω” [geōmetréō] indicates that “I measure the land”. Actually, the graphic of the capital “Gamma”, “Γ”, calls up the shape of a “knee”, which in turn finds its etymon in “γόνυ” [gónū], but also the shape of a “set square”, “γωνία” [gōnía], one of the most ancient tools for measuring and drawing.

Fig. 4 *God as architect of the world* Miniature from a moralized Bible [Österreichische Nationalbibliothek](#), Wien.

4. Gamma in notational systems and mathematical symbols.

If on the one hand, linguistic analysis suggests the semantic association of the letter “gamma” to the many concepts so far highlighted, on the other hand – and somehow not in contradiction with the previous one – the use of the letter “gamma” from the Greek alphabet in both its lowercase and capital forms (γ , Γ), is full of meaning even in the complex system of mathematical and geometric notation [2]. The symbol γ' , in which the juxtaposition of an apostrophe to the letter of the alphabet highlights the fact that the sign has no phonetic and numeric value, primarily represents in the system of mathematical notation of the Greek world the number “three”. A number full of magical and symbolic values that occurs countless times in the theoretical speculations of ancient classical thought. On the other hand, the number “three” is also referred to as ghimel (γ) of the Hebrew alphabet in its various forms (Samaritan Hebrew, Rabbinical) and the symbolic dimension of the capital gamma reappears several times in ancient notation systems.

The introduction of the Arabic numerical system in Western culture has completely replaced alphabetic-numeric notation, leaving, however, over time, some letters of the Greek a significant role in geometric-mathematic notational systems. Not only because of the habit of associating the lowercase letters of the alphabet Greek to the concept of angular width (in Euclidean geometry) or in the case of descriptive geometry notation relating to “plans” or even for the use of certain Greek letters to indicate particular concepts such as, for example, the ratio of the circumference to its diameter, the well-known π , introduced by William Jones in 1796, or the golden ratio represented by the letter ϕ . Moreover, Gamma function or Euler function $\Gamma(n+1) = n!$ is the mathematical model represented by the “meromorphic function, continuous on positive real numbers, which extends the concept of factorial to complex numbers”. However, what is especially interesting is the presence of “memories of signs” linked to a letter gamma in some mathematical symbols whose origin has still to be investigated. This is the case of the square root of the surprising symbol of ancient origin which is still not certain. In several Egyptian hieratic papyri from Kahun dating back to the fourteenth dynasty, there is a hieroglyph similar to the corner of a square in the upper left corner to indicate the square root of a number. In fact, Cajori in his seminal *A History of Mathematical Notations* clarifies how the symbolism of the square root was not always unambiguous [3], but the interpretation that is more functional to the discussion being developed is what can be seen in the symbol $\sqrt{}$, especially in the version with the prolongation of the horizontal line memory of a right angle not too far from the capital gamma (Γ).

The association between the right angle and gamma is also offered as a starting point for further interesting graphic analogy between the sign Γ and the set square ($\gamma\omega\nu\iota\alpha$). Perhaps the most ancient geometric drawing instrument.

5. Between the sign and instrument Γ and the set square.

As part of the tools required for technical drawing, the set square falls into that category that can be defined as “guides” (along with rulers, curvilinears, etc.), a category alongside that of “outliners” (pencils, pens, compasses...) and that of “supports” (papyri, paper, tablets...) and “measurers” (line goniometers, protractors...) represent the tools of technical drawing.

Geometry, grouped by Euclid in an organic body that is still indispensable today, is based on logical rigor and graphical verification; abstract science interacts with geometric drawing, which uses only tools that allow for accuracy in drawing and measurement: above all the ruler and compass. Archaeological findings are valuable witnesses of the instruments that were already adopted by the Greek and Egyptian civilizations. In addition to rulers and compasses, in the several museums it is possible to see set squares, protractor calipers (to enlarge or reduce the measurements to scale) as well as drawing pens. An instrument that did not undergo substantial changes until modern times, with the introduction of the orthogonal projections of Gaspar Monge the use of set squares and T-squares became indispensable for a geometric representation that showed fundamental support for industrial design.

With regard to the set square, created to draw straight lines at right angles, in the Roman and Greek period it had the form of two locked arms. The set square sometimes had a base (the so-called set square with base) widely used also in factories and on construction sites. From the 1600s, it became triangular (either a filled triangle or formed by three rods, as today) with particular degrees (45° , 30° and 60°) with it being difficult not to associate the idea of the Pythagorean triangle that has sides measuring 3,4,5 and is also called the sacred Egyptian triangle [4].

It is based on this very highly symbolic representation of the right angle and geometric figures, with it worth noting the similarity between the sign Γ of the Greek letter and the set square and therefore the relationship that somehow can be seen between the Γ and the right angle. It is the angle of excellence, the origin of the main forms of architectural space since ancient times, somehow “origin” of the elemental form of the set square and therefore also of the circle inscribed in it. The set square is the fourth of the fundamental geometric figures. Symbol of the Earth, as opposed to the Sky, it also symbolizes the Created Universe in opposition to the Non-Creation and the Creator. As an anti-

dynamic figure par excellence, the meaning of the Set Square is one of the arrest, the isolated moment, stability [5].

However, the significance of the Square is also expressed in the terrestrial element, intended as the Created, as a manifestation of the divine as the creator, the one who gives birth. It is no coincidence that in Pythagorean tradition, to which we owe the experimental discovery of the relationship between sounds and the analogy between the perfection of numbers and geometrical figures, the circle and the sphere as well as the regular polygonal figures and those of the solid geometry, all constructible with the set square ($\gamma\omega\nu\acute{\iota}\alpha$) and compass, were the elements with which the Supreme God made the Universe in harmony .

Fig. 5 *St. Thomas the Apostle, patron of Architects* Fresco (16th century) of Venafrò (Isernia, Italy).

Cathedral

Fig. 6 *Ancient of day* William Blake, 1794. London _British Museum London

Thus, retracing the suggestions from which we started, the association between the sign Γ and the set of meanings that may be associated to the right angle is not entirely inappropriate, which represent the geometric and conceptual genesis of the set square. From the most iconic of the bent knees upon which the woman ($\gamma\upsilon\nu\eta$) rests her baby "stable" to the more symbolic linked to the genesis ($\gamma\acute{\epsilon}\nu\epsilon\sigma\iota\varsigma$), to the Earth ($\Gamma\eta$) to the idea of "order" that follows the original Chaos. Even more general to the theme

of knowledge understood as awareness of the origins, the beginning of all things, and somehow the end when considering Le Corbusier when he wrote in a letter published in his Praise of the right angle "Death is the exit for each of us. I do not know why you want to make it atrocious. It is the horizontal of the vertical: complementary and natural".

6. Concluding remarks

Symbols, signs and graphs - including letters - frequently are more communicative than the language itself, and they can last for a so long time to survive to their inventors. This is perhaps one of the first reasons for their emotional charm and scientific attractiveness. Linking present concepts and meanings, or even tools and objects, to their past linguistic and graphic roots can reveal surprising and intriguing ways networking imagination, material word, existence, learning and mastery. The above argued theses clearly are deeply rooted in the classical humanities. However, they undoubtedly support - should there be any needs - that the knowledge and the interpretation of our heritage is one of the stepping stones - may be the foremost - for our future socio-economic and scientific-technological development.

Note

[1] The capital and minuscule "Gamma" letter "Γ, γ" respectively corresponds to "G, g" of the Roman alphabet currently utilized by most of modern western languages; however, "gamma" always sounds as an occlusive "g" (as in go), never as a fricative "ɣ" consonant (as in gentle).

[2] For a brief summary see: S. Giulini, *Il simbolo della matematica* in M. Falcidieno Parola, *Disegno*, Segno, Alinea, Firenze 2008, pp141-189.

[3] Cajori notes how the symbolism of the square root can be divided into four groups which have as the letter R (first letter of radix), the letter L (first letter of latus with reference to the side of the square) and the sign $\sqrt{\quad}$ and the fractional exponent $\frac{1}{2}$ as basic elements.

[4] The triangle is connected to the various symbols of the ternary. It expressed mainly the Ideal of the Divinity, that of the ascent of man towards the divine transcendence, the Universal, the Macro-Cosmos, as well as the idea of the projection of the Divine or heavenly powers to Humanity and Nature.

[5] Among the geometric shapes, the Square and the Circle are continually recalled. The Square represents Space and the Circle (or Spiral) represents Time: the division of a Circle with the Cross of two perpendicular diameters represents the Quadrature of the Circle

The design of the architecture, of the sculpture and of the botanical in the “Villa Comunale” in Naples.

Paolo GIORDANO

Department of Architecture and Industrial Design Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Aversa, Italy
paolo.giordano@unina2.it

Abstract

At the dawn of the eighteenth century the Riviera di Chiaia looks like an urban promenade overlooked by monumental religious buildings, large and small residential buildings, a long row of trees extending from the promontory of the block triangular Pizzofalcone up on the top of which is located the tower of Mergellina. This applies to the urban on which, during the eighteenth century, we will work a substantial modification of the design of places based on the design of a "Royal Villa" settled, first, on the coastal area available and, later, in the course of Nineteenth Century, expanded to the sea through the prior construction of a filled artificial. In the course of about two hundred and fifty years the continuous process of growth and change in this area has helped to set up an area of great landscape value testimonial consists of monumental architecture as the Zoological Station, pavilions en plein air as the Rotonda of Errico Alvino, sculptural groups in mythological theme or simple marble busts as well as a plant vegetation consists of rare botanicals. The research aims to document graphically, thematic categories and for different time sections, the cultural environment present in the Villa Comunale of Naples in a historical moment, as the current one, which seems to have lost its sense of responsibility due in respect of a landscaped area of great testimonial value.

Keywords: architecture, vegetation, sculpture, relief, drawing.

1. The Villa Comunale between nature and artifice

At the dawn of the eighteenth century the Riviera di Chiaia looks like an urban promenade overlooked by monumental religious buildings, large and small residential buildings, a long row of trees extending from the promontory of the block triangular Pizzofalcone up on the top of which is located the tower of Mergellina. This applies to the urban canvas on which, during the eighteenth century, we will work a substantial modification of the design of places based on the design of a "Villa Reale" settled, first, the coastal area available and, later, in the course of 'nineteenth century, expanded to the sea through the prior construction of a filled artificial. In the course of about two hundred and fifty years the continuous process of growth and change in this area has helped to set up an area of great landscape value testimonial consists of monumental architecture as the Zoological Station, pavilions en plein air as Rotonda of Errico Alvino or the Temple of Virgilio sculptures depicting mythological or marble busts dedicated to famous people as well as a plant vegetation consists of rare botanicals. The research aims to document graphically, thematic categories and for different time sections, the cultural environment found in the Villa Comunale of Naples at a historic moment, as the current one, which seems to have lost its sense of responsibility due in respect of a landscaped area great testimonial value.

2. Chiaia, the origins

A long slightly curved beach, relaxing between the headlands of Pizzofalcone and Posillipo, characterized in part by the presence of a median island and tuff wall, in the north, from the back slope of the hill of Vomero: this is the new suburban area on which attest in the Augustan period, the main line of development of the western Greek-Roman Naples. On the principle of establishing a connection between Neapolis and Puteolis through the valley of Chiaia and the opening of the crypt neapolitana, makes the Riviera di Chiaia area on the fringes, an enclave nature, protecting, for a long time, the characteristic vegetation, mainly in the Mediterranean, type semiboschiva. Subsequently, between the eleventh and thirteenth centuries, the creation of small farms located tangentially to the slopes of the hill of Vomero in the so-called field Canineo, and, on the waterfront, the building of the church of San Leonardo in insula maris, built on the islet bedrock, producing a sparse urbanization based on the agricultural use of the soils and on the fish dell'antistante gulf. Not only farmers and fishermen during the fourteenth century, the realization in the plain of Chiaia three buildings for worship - located respectively to the east, Santa Maria Chapel, to the west, Santa Maria of Piedigrotta, and in its central part, the Ascension, - provide for the entire area to a sober densification of residential building that also will integrate also with the existing defense structures such as the Torretta and the Tower of Alarçon. The balanced mixture of nature and artifice is found in the second half of the sixteenth century, through the view, engraved from the east, by Etienne Duperac and given to the press by Antoine Lafréry (1566), as well as both etching through the bucolic George Hoefnagel (1578) and it is through the scenic perspective illustration of Jan van Stinemolen (1582) with a double vantage point located to the north of Naples. This is a very unusual image, outside of any previous tradition of landscape painting. Naples appears as if seen from the hills north of the city, rather than being taken up by just one point of view to the north and apparently lying on the alignment between the Castel dell 'Ovo and the silhouette of Capri on the horizon, appears to be the combination two images obtained from different locations.

The view is, therefore, unreliable as a reference topographic overall. It does, however, provides us with a faithful documentation of urban areas more limited, such as Chiaia, the Largo di Palazzo, the area of the Old arsenals, still built in views. Only in the third decade of the seventeenth century, as shown in *Fidelissimae Urbis Neapolitanae cum omnibus et nova* for soloists accurate delineatio Alessandro Baratta 1629, Borgo di Chiaia looks like a building curtain continuous and compact.

In the view was clearly visible long and narrow beach that fronts, from Pizzofalcone to Mergellina, Borgo di Chiaia. On the coast line are detectable both the House of Invitti and is the church of San Leonardo in insula maris. While appearing as a simple beach area, in truth it was already infrastructured by the presence of the Angevin road, which later in 1698 will be adorned by a row of trees interspersed with monumental fountains at the behest of Luis Francisco de la Cerda and Catalina de Aragón, Viceroy and the Duke of Medinaceli. The son of Juan Francisco de la Cerda and Catalina de Aragón y Cardona, inherited the titles of his father, the Duke of Medinaceli, Duke of Alcalá de los Gazules, Marquis of Cogolludo, Marquis of Tarifa and the Marquis de Alcalá de la Alameda; and his mother, the Duke of Segorbe, Duke of Cardona, the Duke of Lerma, Marquis of Denia, Marquis of Comares, Marquis of Pallars, and twice Grandee of Spain, making him one of the most important Spanish aristocrats of his time.

Morphological continuity and homogeneity of the urban backdrop that will be reinforced at the end of the seventeenth century by a promenade lined delimiting the long, narrow beach in front as it is shown in the so-called view Medinaceli, by noon, entitled Naples. Excellency Mr. Duke Medinaceli, Viceroy and Captain General in this kingdom "of 1698.

Fig. 1: The Villa Comunale of Naples, eastern entrance.

3. Chiaia in the eighteenth century

In the first half of the eighteenth century the Riviera di Chiaia proposes the same way as a garden city built on a system of urban road layouts defined by the primary and secondary, either parallel or perpendicular to the coastline. A charming urban enclave, characterized by a strong scenic waterfront overlooking the Gulf of Naples sull'antistante framed, to the east, between the dark bulk of the Castel dell'Ovo perched fortified islet of Megaride and to the west, the lush hill of Posillipo by the widespread presence of palaces and suburban villas. Carlo Celano, in his "News of the curious and beautiful of the ancient city of Naples," describe it, during the seventeenth century, the Mediterranean beauty of Chiaia: "On the side of the East has a marina placidissima The shoulders have the Monte Posillipo fertile, that principia, as was said at the Castle of St. Erasmo, or with the common people of St. Elmo, below which the Church stands or Monistero de Certosini. In this mountain, on the side of the East, it seems that nature is studying with careful effort to keep it green, and always in bloom being that in this, at all times, and also among the most horrid winter there are bunches of work fresh flowers fruits, when in every other place are rural, here s'hanno perfectly ripe, and with a flavor more palatable to the taste of each other then I do not speak of 'gardens of cedar, orange and lemon trees, which when bloom, which are mostly twice in every year, fans coll'odore a terrestrial paradise sea that lies ahead is fertile smelling of fish in each species.

Hemispherical domes, massive palaces, terraces and viewpoints, city gates and steep ramps, pedamentine and narrow winding country roads: this is the diverse morphological abacus that makes up the urban fabric of the Riviera di Chiaia strongly compressed between the Vomero hill and the waterfront. This is the urban structure of the Riviera di Chiaia as documented in the "Topographical Map of the city of Naples and de'suoi contours" written by Giovanni Carafa, Duke of Noja and printed in 1775. Ten years before the release of the Map of the Duke of Noja, Carlo Vanvitelli, on behalf of Ferdinand IV of Bourbon, will receive, in 1765, the task of designing the "Real Passeggio": a long, narrow rectangular strip, characterized by two pavilions symmetrical input located on the eastern end - and on the west in the design of the project - marked by the presence of a double row of trees forming double five avenues parallel to Chiaia Street and tangent to the coastline. Carlo Vanvitelli elaborate different solutions tending in turn to relate or less with the geographical site of belonging. The project of Carlo Vanvitelli for the "Plan of Lido di Chjaia from the Church of the Madonna della Vittoria to San Leonardo with the delineation of the new Public Garden" is preserved in the Historical Archives of the Municipality of Naples (ASMUN). As a whole, the project vanvitelliano is composed of twelve tables that illustrate different solutions. A first solution is given knows a garden parallel to the coastline which deflects at an obtuse angle to the height of the Piazza San Pasquale (ASMUN, Cart.II, Chiaia 11); a second solution, the one closest to the one realized is characterized by the plant to five avenues symmetrical with respect to the main one (ASMUN, Cart.II, Chiaia 10); also a solution of the double extension of the public garden is documented by two artifacts that illustrate a further expansion to the west (ASMUN, Cart.I, 6 and Cart.I Chiaia 13). For a detailed analysis of the design vanvitellian see also: Cirillo O., Carlo Vanvitelli, architecture and the city in the second half of the eighteenth century, Alinea Editrice, Firenze, 2008. Eventually, the designer of the court will opt for a solution strongly characterized by formal autonomy, clearly influenced by neo-classical, all resolved within a footprint planimetric rigid, rhythmic and compact: a floor plan in the shape of elongated rectangle defined to the east and west, two heads monumental input characterized by the presence of two low pavilions neoclassical joined together by a railing tripartite wrought iron which open at the center, through two doors signers in their central axis, in plan, as well as the input also the main axis of symmetry of the rear garden. With regard to the northern perimeter of the new "Public Garden" project by Carlo Vanvitelli included a fence formed by a low wall in the basement which s'impostava a deleted profile with more than double concave semi-elliptical profile interspersed with generous pilasters rectangular base characterized by the presence of niches with allegorical statues neoclassical bordered laterally by double pilasters bugnate. Tale linear structure is interrupted by Carlo Vanvitelli in five places where you can enter as many side entrances to the long linear park.

In this way, compared to the fifth built in the Riviera di Chiaia, the "Public Garden" became a vegetative filter permeable to pedestrian cross between consolidated city and natural beach. A permeability accentuated by the characterization of the fully open southern slope of the garden is not defined on the beach front, by any fence but by inviting a structure consisting of a long bench that artificializzava, with great hardness but with equal sobriety, the difficult transition between the natural sandy of the beach and the decking on the ground tuff of the "Public Garden" designed by Carlo Vanvitelli, the son of Louis, who designed the Palace of Caserta.

As written by Arnaldo Venditti, "[...] The" real site", opened in 1781 with the celebration of the Fair, had its own regulations; open day and night to people decently dressed (they were excluded from the poor, people in uniform, the barefoot), the villa was the meeting place of good Neapolitan society, becoming animated in the summer of festivals and concerts, in the light numerous lights, which, mirrored in the sea, accompanied with lampare Mergellina."

The design of Vanvitelli be able to act as a first founding act of the successive expansions thanks to the careful planting and cultivation of natural essences originally entrusted to the gardener Felice Abbate. The track vanvitelliano well as the availability of an additional coastal area on the western side of the beach of Chiaia, as documented in the plant of the Regia Officina di Naples Rizzi Zannoni 1790, represent the environmental conditions for the successive enlargements of the "Real stroll" both towards the coast line, with implemented a progressive and extensive production of filled at sea, and it is towards the western area through a reclamation of the shoreline and an additional land policy based on further filled large areas of the sea area between the Torretta and Mergellina.

4. Chiaia in the nineteenth century

Stefano Gasse, in 1807, is the architect responsible for launching the revival of the old system and to develop a project proposal for its extension. Extension which is implemented in two phases ie, the first in 1810 and the second in 1834. The first extension proposed by Gasse interested in the area from the western end of the "Public Garden" goes up to the height of the of the abutments of the existing Church of San Leonardo: a narrow strip of land with a trapezoidal floor plan, no more linear as the previous arrangement vanvitellian neoclassical, characterized by an arrangement for "grove" with parterre flowerbeds heterogeneous to "bean" or in line with the trend Anglo-Saxon era that favored the sublime and picturesque garden rather than rational mold of Franco-Germanic.

Simultaneously with the construction of the new "Grove", Stefano Gasse, along with the gardener of the Royal House Federico Dehnhart continued the work of redefining the vegetation started in the first five years of the nineteenth century by the gardener Antonio Cardone within the green rectangle vanvitelliano: citrus, plantains Carditello, weeping willows, oaks and acacias are integrated, or even replace, the earlier eighteenth century vegetation systems based on the use of lime and vine. Not only species of vegetation but also new architectural pavilions able to enrich the dynamic environmental perspectives produced by the apparent irregularity of the bean flower beds in the new "Grove" in 1819, the circular temple host the bronze bust of Torquato Tasso.

The bust is the work of Torquato Tasso Angelo Solari and six years later, in 1825, the Temple classical columns and pilasters with Ionic dedicated to Virgil. The large head of Virgil housed in the Ionic Temple of Stefano Gasse is carved by Tito Angelini. both made and designed by Stefano Gasse. Even outside the fence of the "grove" some episodes architectural, residential and infrastructural nature, emphasize the environmental evolution made the Riviera di Chiaia enlargement designed by Stefano Gasse: on one hand the construction in 1830 of the magnificent neo-classical and Acton Villa or the current Pignatelli Museum, designed by Pietro Valente and, secondly, the realization in 1834, on the northern side of the "Public Garden" vanvitelliano and the "Grove", a dirt track for trotting horses namely the so-called "Trottoir".

Only in 1858 the construction of an imposing architectural structure, the Winter Garden, will re-launch the construction of architectural objects, real "object Trouvée", on the edge or inside the fence coastal vegetation. The Winter Garden will be short lived in the scenic natural surroundings of the Riviera di Chiaia having been demolished after only fourteen years old, in 1872, from its implementation together with the two entrance pavilions of the former "Public Garden".

Two proposals for the accommodation of the Riviera di Chiaia mark the theoretical background to the project of enlargement towards the sea area of coastal land base of the garden: the draft Gaetano Genovese. The main panel of the project by Gaetano Genovese, entitled "Enlargement of the Riviera di Chiaia district that includes the transfer of the Royal Villa" shows, in the bottom left corner, the signature of the Municipal Francesco Paolo Capaldo and, in the lower right, the signature of the Municipal Commissioner Gaetano Genovese.

This difference in the shape of Genovese explicit roles as a member of the Building Board of Naples of 1858 and the one signed by Errico Alvino in 1862. Genovese If the project raises the question about noon the progress of the coastline through a sea filled in parallel to the rear of the Riviera Road to Errico Alvino formalizes graphically, for the first time the hypothesis of a road on the beachfront not able to completely erase the relationship with the underlying beach of Chiaia via a narrow strip pedestrian service activities related to the use of the sea. The project to Alvino, processed free of charge, is part of a master plan for the city of Naples. The project designs, very rich in details and views and floor plans of the whole, they represent a first point of reference with respect to future delineation of the Naples seafront.

The presence of a high wall breakwater, to round to the sea located in places where, subsequently, Verrano really made the viewpoint della Vittoria and Diaz, the great influence of explicit Errico Alvino for the real infrastructure of the waterfront west of Naples. For some designs elements porticos along the promenade or the fascinating metal structure at the entrance of Villa Reale renewed should start to reflect on the influence played by Alvino of younger architects of him as, for example, the work of Lamont Young. In fact, the construction of the new waterfront western, made in two separate batches between 1869 and 1879, will take into account both the need to expand around noon assumed by Gaetano Genovese and infrastructure of both the foreshadowing of a new road on the sea drawn graphically by Errico Alvino. Between 1869 and 1870, two new buildings, to small and medium scale architecture are made, not far away from each other, on either side of the main avenue of the original "Public Garden" on the northern side of the so-called Casina Pompeiana, and on the south, the zoological Station, or an aquarium, biologist Antonio Dohrn wanted by the architect Oscar Capocci. Specifically, the creation of two lots relating to the redefinition of the coastline from Molosiglio until Largo Sermoneta - in the stretch to the east, between the Molo San Vincenzo and to the west, the hill of Posillipo - will not be the result of a clear and definitive project of urban planning and landscape but the compromise between political forces and business based on requests for concessions for infrastructure projects having as their first objective the construction of new residential volumes for the new Neapolitan bourgeoisie.

Among the various requests for grant administration reached Naples and the relevant Commission responsible for examining applications was chosen, August 5, 1869, that the entrepreneur Giletta Annibale took over as licensee of the work to which the Belgian Baron by Ermanno Du Mesnil. Annibale Giletta is one of three participants in grant requests for interventions in different areas of the city: for the installation of the western waterfront were in fact examined by the appropriate Municipal Commission - consisting of Rodolfo d Afflito, Federico Travaglini and Ettore Capacelatro - a proposal Scognamiglio of Martorelli, discarded, the first, for delay in delivery of the proposal and, second, because it operates by the financial unknown.

The first batch of the new promenade by the Panatica in Saint Lucia pushed up to Victoria Square was completed in two years or nel1872. The second batch, which included an expansion of the Villa Nazionale towards the sea and the construction of a new coastal road between Piazza Vittoria and the Fontana of the Lions in Mergellina, was built between 1872 and 1879 thanks to the creation of an infrastructure project, a concave wall subjected to the new roadway and separated from it by a parapet volcanic stones and brick, clay brick, high-impact construction and aesthetic but very vulnerable to the power of the waves of the sea, especially with south wind and the south-west, there impacted against. Gaetano Bruno writes: "[...] when there was a gritty beach, the waves there is flaked running on the beach, or if certain times stronger climbed over the wall of the villa and the road towards Mergellina; but now the waves arrive with energy until the new wall, which stops them, reject them and part them fringes receiving the insistent pressure hydrostatic and hydrodynamic [...]"

Defined and implemented the new shoreline stone that the Panatica - close to the monumental steps from the opposite corner at the intersection of Via Saint Lucia and the new Corso Partenope connect the latter with the quay below Castel dell'Ovo - reached up to Mergellina and performed reclaiming land needed to set up your new decking enlargement towards the sea, we proceed between 1880 and 1885 to define architectural and landscape of the Villa Comunale. First, to the east, the Villa Comunale reconquest, albeit through a completely different configuration, the lost landscape and architectural homogeneity owned by the plant originally defined, a hundred years before, by the presence of the two symmetrical halls vanvitelliani. Specifically, the new eastern end of the Villa Comunale is characterized by the presence of a fence parallel to the facing building curtain on waterfront overlooking Piazza Vittoria, in its central part, it comes back a second concave geometry: a symmetric fluid that is punctuated by the presence of eight statues in white marble depicting mythological and placed on high pedestals decorated with rectangular frames and classic cantilevered shelves or in high relief. The eight architectural sculptures placed on the piers, built between 1765 and 1767 by the Garden of the Royal Palace of Caserta are sculpted by Andrea Violani and Tommaso Solari.

Fig. 4: The Villa Comunale of Naples, the Fountain of the Lions, the prospectus.

5. Chiaia in the twentieth century

Over the past few decades, consistent choices, a lot of mistakes and a general neglect have affected the "cosmic" beauty of the western coast of Naples, the last speech of reconfiguration of the Villa Comunale, designed by Alessandro Mendini in 1998, has proved incapable of reading font identification of the places opting for a transformative hypothesis that introduced, riding on a new fence punctuated by slender golden streetlights three architectural fragments made from synthetic materials and ipercolorati of yellow, blue and red. A choice in total discontinuity with the obvious material characterization of the sites in question based on the dark tones of the stone from Vesuvius, and the density of the porous tuff.

Fig. 5: The Villa Comunale of Naples, sculptors groups of four seasons located around the Fountain of the Lions, plans and elevations.

6. The Villa Comunale: Carlo Vanvitelli, the central avenue and side areas

On the western side of Piazza Vittoria is located the fence of the Villa Comunale, designed by Alessandro Mendini in 1998, decorated with eight statues carved in the course of the eighteenth century by the sculptor Andrea Violani and Tommaso Solari. Specifically, from the southern side to the northern one, are located in the following sculptures: the Fauno performer of Andrea Violani (1763) The Apollo Licio of Thomas Solari in 1761, the Hercules Fauno by Andrea Violani in 1766, the Antinoo of Andrew Violani in 1765, the Sileno with Bacco child to Andrea Violani in 1763, the Hercules with a Telefo by Andrea Violani in 1765, the Apollo Belvedere in 1767 and Fauno playing the flute in 1761 both of Tommaso Solari. The sector represents the area of the abutments of the project originating by Carlo Vanvitelli: an open floor plan with a rectangular measuring 500 x 50 meters. structured along a central avenue flanked on the north by a line of wooded siliquastrum Cercis (Judas tree) and a system of flower beds to "bean" that closes the Villa Comunale to the Riviera di Chiaia, and on the south by a double row of trees, Cercis siliquastrum and Quercus ilex (holm oak) in turn flanked by an avenue of small size: this is what remains of the splendid plant vegetation to five parallel avenues conceived in 1775 by Carlo Vanvitelli. The main entrance to this area opens onto Piazza Vittoria: a double-leaf gate, part of the fence of the general public gardens designed by Alessandro

Mendini in 1998, flanked by two of the eight statues which adorn the eastern side of the coastal garden or the Hercules with a Telefo by Andrea Violani in 1765 and the Apollo Belvedere in 1767 by Tommaso Solari. From the standpoint of vegetation, over the fence entrance, the open space is characterized by thick sets of banana trees (belonging to the family Musaceae) that make up the composition of basement in the north, high and low palms *Phoenix dactylifera* *Arecastrum romanzoffianum* (Cocco feathery), *Brahea roezlii* (*Braea*), *Black burniana* (*Sabal*) as well as a splendid specimen of *Eucalyptus* (*Eucalyptus*). In the central hall, circular flower bed within seven *Washingtonia filifera* (California Palms) towering in height and providing a strong open space east of the Villa Comunale. At the center of the avenue stands the Fountain of the four lions surrounded by two low semicircular benches flanked by four sculptures symbolizing the four seasons, Spring, Summer, Fall, Winter, probably carved in the eighteenth century by an unknown author. The Fountain of the four lions, designed by Pietro Bianchi in 1826, is located in the place where the first, 1775-1791, was placed a large circular bath complete with statues of Sebeto and Sirena Partenope, by Giuseppe Sanmartino, and later, from 1791-1826, was placed the Toro Farnese from the Roman Baths of Caracalla currently housed in the Archaeological Museum of Naples.

Specifically, the Fountain of the four lions consists of a circular tank containing a quatrefoil base on which are placed four large stone shells and four marble lions holding up a big tub of Egyptian granite monolith from the excavations of Paestum. Symbolic theme, that of the lions, very dear to Pietro Bianchi that uses the same type of sculpture to define the end of the hemicycle colonnade in front of the Basilica of San Francesco di Paola in Piazza del Plebiscito designed by the architect Swiss in 1817. The area of the fountain of the Four lions is characterized by the presence of centuries-old *Platanus orientalis* (*Platano*) beading also, in some places, the fence on the northern Riviera di Chiaia. On this side of the central avenue are placed, from east to west sculptures of the Faun with a Kid by Andrea Violani in 1759, the Gladiator fighter by Tommaso Solari in 1759, Bacco with a cornucopia of Andrea Violani in 1759, the Fountain of flora capitolina and the Fountain of flora farnese of Tommaso Solari (1760), the Rape of Proserpina by Andrea Violani carved in the second half of the eighteenth century, the Hercules wrestling with a the lion Nemeo by Andrea Violani (1767), the Fountain of the rat of the Sabine Women by Tommaso Solari (1762-68) both Marsia tied to a trunk of Andrea Violani (1760). Among these last three sculptures and fourth, or the Rape of Proserpine, the Casina Pompeian is located low neoclassical building built in 1870 and flanked on the west by a leafy *Cupressus* (*Cypress*). Conversely, on the southern side of the central avenue stands the Fountain of Lucio Papirio with a his mother, sculpted by Andrea Violani in the third quarter of the eighteenth century and surrounded by a thick grove of *Quercus ilex* (*Ilex*) and *Pinus pinaster* (*Maritime Pine*). In addition to the groups and sculptors at the Casina Pompeian a series of semi-elliptical volcanic stone benches are placed on both the northern and southern ends of the Vialone central, west, with an open-air pavilion designed by Enrico Alvino in 1887. This element architectural design and located in the area bearing that divides the area of the implant abutments vanvitelliano original by successive enlargements of the Villa Comunale made in 1810 and in 1834, designed by architect Stefano Gasse with the help of the gardener and Federico Dehnhardt subsequently, the botanist Giuseppe Antonio Pasquale.

7. The Villa Comunale: Stefano Gasse, "Grove" 1810 - 1834

The area in question corresponds to the first and second extension of the "Public Garden" designed in 1775 by Carlo Vanvitelli. Both extensions, made in 1810 and in 1834 by Stefano Gasse, propose a design based on the areas flowerbeds to "bean", irregular shapes and sizes and different, that is capable of interrupting the neoclassical symmetry present in the garden vanvitelliano. Made with the help of a gardener before, Federico Dehnhardt, and a botanist, later, Giuseppe Antonio Pasquale, the "Grove" is today an enclave dense and shady vegetation punctuated by the abundance of statues and architectural pavilions. Among the latter, the Cassa Armonica by Enrico Alvino, built in 1887, is the most valuable architectural object within the enlargement designed by Gasse. In addition to Cassa Armonica, two other architectural objects, designed by Stefano Gasse in 1819 and in 1825, characterize the balanced relationship between nature and architecture within the scope of the "Grove" of the Temple of Tasso and the Temple of Virgil that is two small pavilions containing the bust of the playwright Sorrento and a sculpture of the head of the poet from Mantova. Both in shape and are characterized by the classical language circular the first and for the implant to the second rectangular base. The "Grove", from 1810 until the first decades of the twentieth century, has been enhanced by the placement of statues in marble and bronze - from clearing where is located the Cassa Armonica with the statue of Giambattista Vico, sculpted by Leopoldo di Borbone in 1862, up to Piazza della Repubblica, where in 1969 he was placed at the Monument to the four days of Marino Mazzacurati - characterized by points in the flower beds "bean".

Specifically, from east to west, as well as the imposing monument dedicated to Giambattista Vico, the sides of the winding paths of the "Grove" are placed the sculptures dedicated to Enrico Pessina by Luigi De Luca (1925), Enrico de Marinis by Gaetano Chiaromonte (1920), Luigi Settembrini by Domenico Pellegrino, Gioacchino Toma by Jerace Francesco (1922), Eduardo Scarfoglio by Giuseppe Renda (1923), Giorgio Arcoleo by Francesco Jerace (1918), Giuseppe Semmola by Leonardo de Candia (1923), Francesco de Sanctis by Achilles D'Orsi (1893), Virgilio of Tito Angelini (1826), Francesco Del Giudice of Torello Torelli (1923), Alfredo Cottrau by Francesco Jerace (1900), Pietro Colletta by Gennaro Cali (1866), the Fountain of the Rape of Europe by Angelo Viva (1798), Enrico Alvino by Giovanbattista Amendola (1884), Torquato Tasso by Angelo Solari (1819), Vito Fornari by Leonardo De Candia (1911), the four talking heads symbolizing Bacchantes and satyrs dancing made at the end of the eighteenth century and, finally, the monument to Sigismund Thalberg by Giulio Monteverde (1879). These sculptures and sculptural groups are surrounded by woods vegetation of great interest that, in the area behind at the Press Club, a *Quercus robur* (Farnia) soaring between low and shady *Quercus ilex* (Ilex) and a rare *Jubaea spectabilis* (Palma de Chile); in the area of home gardeners, two high *Pinus halepensis* (Aleppo pine) flanked by several *Cupressus* (Cypress) and surrounded by the applicants *Quercus ilex* (Ilex) that constitute the spot predominant vegetation in the field. On the back of the Temple of Virgil a leafy *Eucalyptus* (Eucalyptus) defines the background vegetation of the small neoclassical pavilion designed by Stefano Gasse. Finally, in the terminal area, near the sculpture dedicated to Sigismund Thalberg, *Pinus halepensis* (Aleppo pines), *Washingtonia filifera* (Palma California) and a continuous row of seven *Washingtonia robusta* (Palme Mexico) characterize the consistency vegetation offshoot of the extreme west of the Villa Comunale of Naples.

Fig. 6: The Villa Comunale of Naples, the Temple of Virgil in Grove of Stefano Gasse, the southern facade.

8. The Villa Comunale: Gillette Du Mensil, from Victoria Square to the Zoological Station

The area in question is the last expansion, built between 1782 and 1789, the Villa Comunale towards the front of the Gulf of Naples: an audience defined by paths in the land of tuff beat, dotted with flower beds to "bean" host trees various species such as *Quercus ilex* (ilex), *Pinus pinaster* (maritime Pine), *Platanus orientalis* (Platani), *Phoenix canariensis* (Canary Island Palm), as well as other species of wood. The profile of the Posillipo hill, the shape of the the eastern side of the Zoological Station by Anton Dohrn, the thick foliage of the fifth pre-existing tree on the northern side of the Villa, the presence of the Caracciolo seaside promenade characterized by the transparent railing waterfront overlooking the Gulf of Naples represent, as a whole the artificial and natural elements of an architectural and landscape of great environmental value. A value enhanced by the presence of fountains and sculptures of great artistic interest, that is, from east to west, the Fountain of Castore and Polluce by Tommaso Solari (1762-68) and that of Saint Lucia of Michelangelo Naccherino (1606),

the sculptural group of Pelican Francesco Jerace (1884), the bust of Giovanni Bovio made by Enrico Mossutti in 1915 as well as that of Giosuè Carducci sculpted by Saverio Gatto in 1913. Also this area is characterized by the presence of vegetation common trees such as *Quercus ilex* (Ilex), *Pinus pinaster* (Maritime Pine) and *Olea europaea* (Olive) as well as exotic species such as *Erythrina corallodendron* (Coral Tree) located near the sculptural group of Pellicano and on the eastern front of the Dohrn Zoological Station, a beautiful *Chorisia speciosa* (silk Tree). Also in this area, on the southern side, were made in 1998, is the chalet Yellow, Blue one that both built and designed by Alessandro Mendini. Architectural Elements conclusive in that sector are represented, to the west, from the monumental dedicated Zoological Station to Anton Dohrn, created and designed by Oscar Capocci in 1870, and the modern Circolo della Stampa designed by Luigi Cosenza in 1948. Finally, the presence of the third and last chalet by Alessandro Mendini, the red represents the most western seafront entrance of the new fence designed by the Milan designer in 1998.

Fig. 7: The Villa Comunale of Naples, Via Chiaia statement of review (above). The Villa Comunale of Naples, the round Errico Alvino and cantonal corner of the Zoological Station (left) and the eastern side of the Casina Pompeiana (right).

9. The Villa Comunale: Gillette Du Mensil from the Tennis Club to the Piazza Repubblica

The sector is one of the latest expansion to the sea filled built between 1872 and 1889. Fronted by the the round to the sea more representative of the western waterfront, the latter is an area yield varied by location, in the twentieth century, of Tennis Club made for the area of land owned by an eclectic, but decent pavilion to house a thematic exhibition within the Esposizione d'Igiene of 1900. In the present state the true public space of this heterogeneous sector is represented by the presence of the large square dedicated in 1936, the Neapolitan General Armando Vittorio Diaz, Chief of Staff of the Army during the First World War and the War Minister and Marshal d'Italy: a square characterized by the equestrian statue of the great leader of Naples that, over the roadway Via Caracciolo, full the architectural composition and scenic dell'antistante Rotonda Diaz enriched by three rows - respectively on the perimeter of the east, west and north - low palms Black family burniana (Sabal). Specifically, the equestrian statue dedicated to Armando Diaz, built by Francesco Nagni, stands on a tall rectangular stained both in high relief with scenes of battle and both with a long inscription carved on the southern facade. This sculpture group stands on a low base of square shape, also raised with respect to the floor of the Square through three continuous steps on all four sides, and is flanked on the west and east ends of two large circular tanks protected by a low parapet.

Abstract

We started an interdisciplinary study, involving pedology and architecture sciences, aimed at recognizing and reappraising those we call “*agri+cultural*” Borbone sites in Italy. This paper deals with the “San Silvestro vineyard”, once cultivated within the homonymous farm in the San Leucio “Royal Site” in Caserta. Such a vineyard, whose original terracing structure is still perceptible, is a very valuable, but almost unknown record of Borbone farming. The vineyard overlooks the little court bounded by the buildings of the king's residence, and laterally by two symmetrical service bodies, built on the hill of Parito by the architect Francesco Collecini between 1797 and 1801, establishing a system conceptually similar to that of the royal palace of Carditello, but on a reduced scale. Through advanced GIS-based interpretation of original maps and bibliography sources, the “San Silvestro vineyard” has been redrawn in its initial topography, thanks to the comparison of historical and actual maps and through the identification of traces still visible in the present landscape design. Historical maps record the geographical information, that is fundamental to reconstructing past places, holding information retained by no other written source, such as place-names or boundaries. The fertile, volcanic soil of the vineyard, developed from the Phlegraean Campanian Ignimbrite, shows a 1st class suitability to vine cropping, thus testifying the pedo-agronomic expertise of Borbone House.

Keywords: “San Silvestro vineyard”, Borbone House, *agri+cultural* heritage, applied pedology, LIS-GIS

1. Introduction

Borbone House ruled, with twists and turns, the Southern Italy, *i.e.* Naples and Sicily States, or “Two Sicilies”, from 1734 to 1861, with an interruption between 1806 and 1816 due to domestic crises which favored a French interregnum. Aside from any political judgment and ideological feeling, it is undoubted that Borbone House pursued, with modern and innovative perspectives, the implementation of large-scale engineering, architectural and artistic projects, also promoting cultural and socio-economic development, of which the “San Leucio” community was an outstanding model. Worldwide scientists and experts well know and value the “Acquedotto Carolino”, the waterworks built between 1753-1770 to bring water from the foot of Taburno mountain (38 km far) to the Royal Palace assembly in Caserta, also feeding other places; and it is just the case to recall the construction, in 1839, of the first Italian railway, from Naples to Portici, another royal residence. On the opposite, the various rural Borbone assets still are poorly investigated, and most of them languish in the neglect and degradation, notwithstanding they are formally protected by *ad hoc* local laws, as well as by the patronage of international Institutions. A patent epitome of such a paradoxical pattern is provided by

the old agricultural estates of San Leucio and San Silvestro, within Tifatini Hills (Fig. 1), annexed to the Royal Palace in Caserta City, which are considered as world heritage by UNESCO, but are substantially ignored. Indeed, the rural Borbone assets yet represent a priceless cultural heritage, definitely worthy to be restored also as an attraction for profitable and sustainable tourism. On these bases, we have started an interdisciplinary research among pedologists and architects, aiming at identifying, restoring and repaying dignity and value, in the present or in the memory, to those we have called “agri+cultural” Borbone sites. A previous investigation [1] has been focused on a very interesting record: the so-called “Fan vineyard”, an exclusive, now lost, standard of the consideration of Borbone House for both productive and artistic management of soil resources and landscape features. This paper focuses on the vineyard once cultivated in the San Silvestro farm, on the homonymous peak within Tifatini massif.

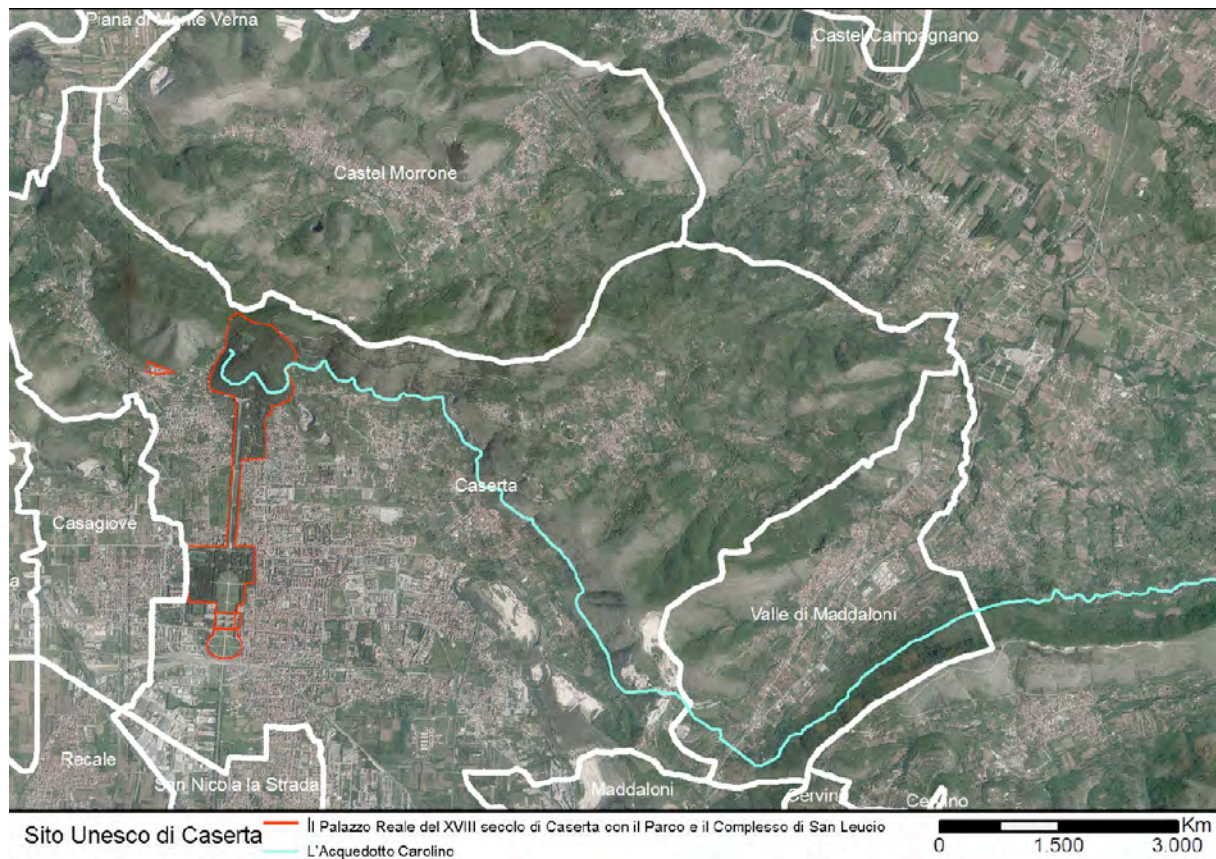

Fig. 1: The Unesco Site of Caserta

2. Study area: historical documentation and iconography, and present scenery

A wide and accurate overview about the onset and development of the “Royal Sites” of Borbone House, and on their role on the socio-economic progress and on the transformation of rural landscape is found in bibliography [1, 2, 3, 4, 5, 6]. The most important historical documentation and iconography is represented by a map painted during the first-half 19th C by D. Rossi [7] (Fig. 2a), and the “Platea”, an index of royal goods compiled by A. Sancio (1826) [8] (Fig. 2b, c). The bailey and the major buildings, structures and facilities of the old “San Silvestro” farm are today well-preserved and, broadly, still in use. The farm is located on the top of San Silvestro hill, belonging to Tifatini massif, just behind the Vanvitelli’s waterfall which feeds the Royal House beneath (Fig. 3) in Caserta. The most relevant building of the farm is the “Casino” (Fig. 4), which is taken as a reference structure. It lies at coordinates UTM 33 T 443721 m E, 4550487 m N.

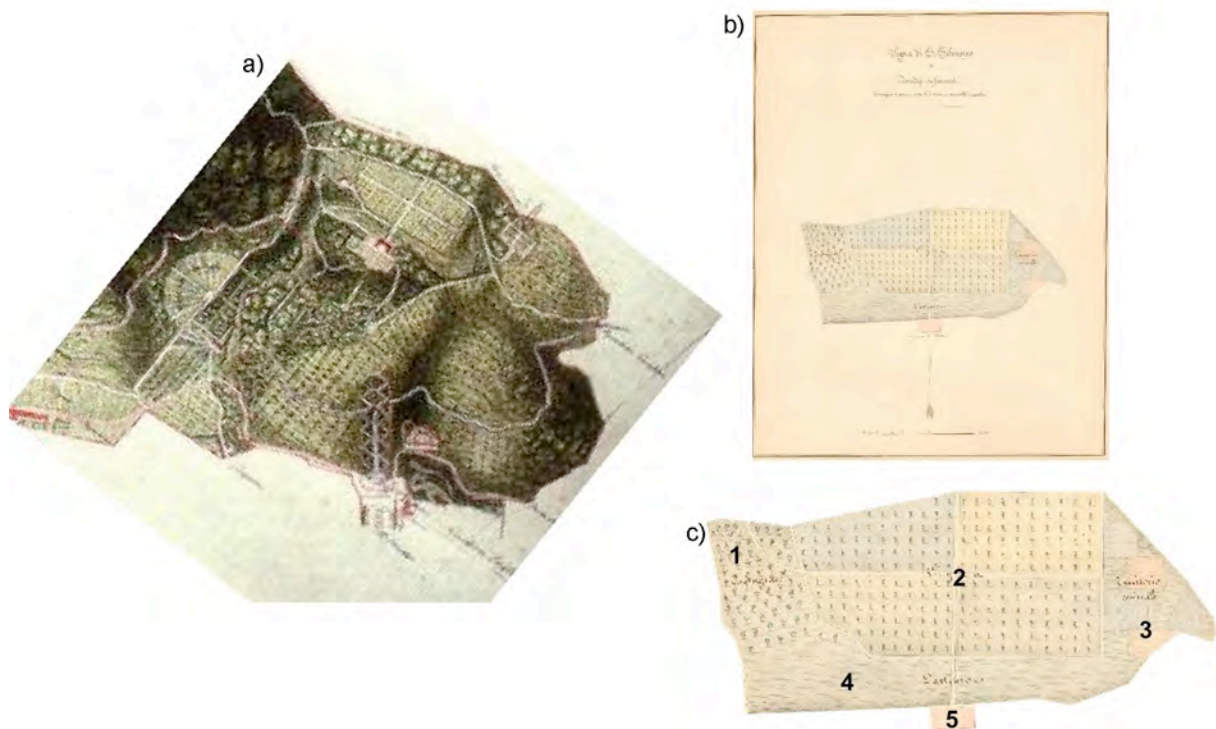

Fig. 2: a) The map of D. Rossi (first-half 19th C) “Pianta del recinto del Real bosco ...”; b) «San Silvestro vineyard and adjacent territories» from “Platea...” by A. Sancio (1826); c) a detail showing the chestnut grove (1), the actual vineyard (2), the “cesinale” grove (3), the parterre (“parterro” in original, 4), the “Casino” (5)

Fig. 3: Location of «San Silvestro» farm and of Royal Palace assembly on the present satellite image.

Fig. 4: The boundaries of San Silvestro farm. The «Casino» (white circle) and the location of the lost vineyard (white rectangle) are highlighted.

3. Historical background

The Royal Site of San Leucio, purchased by the Borbone in 1750, and especially considered by researchers for the silk industry, was organized as an efficient farm, which consisted of arable land, orchards and gardens, stables and fences for the rearing of cattle, goat and sheep, reserves for the breeding of wild animals that were introduced in the hunting areas [9, 10]. Under this system, viticulture was a priority area for the personal interest of Ferdinand IV of Borbone. The same sovereign in the pages of the Statute of the Royal Colony recalls the presence, close to the Belvedere palace, of the ancient vineyards of the Acquaviva family, lords of Caserta in 1509-1634, probably planted in the early decades of the seventeenth century, in which were cultivated indigenous varieties of late-ripening white grapes called "*vernotiche*" grapes.

Beginning in 1786 until the mid-nineties of eighteenth century, the period in which the young King of Naples Ferdinando IV decided to reorganize the Royal Site, together the construction of the silk factories and residences for the workers, he did repair the old vines and planted new vineyards, in which were cultivated grape varieties mentioned for their high quality by Lorenzo Giustiniani in the "Dizionario geografico-ragionato del Regno di Napoli", 1797-1805 [11].

Around 1830, the administrator Antonio Sancio, in the "Platea" [8] of the Royal Site, described six different vineyards, located within the walls of the enclosure, built in 1773, or close to it: the Fan Vineyard, in which were cultivated grapes named "Delfino" (white), "Procopio", "Piedimonte" (white and red), "Lipari" (white and red), "Siracusa" (white and red), "Terranova" (red), "Corigliano" (red); the Vineyard named "Torretta", near the district of San Ferdinando, in which were cultivated varieties of "Lagrima" (red), "Aliatico" (red) and "Aglianica", interspersed with a few fruit trees; the Vineyards named "Pomarello" and "Arcone", at the sides of the Belvedere Palace, in which the ancient white grapes called "*vernotiche*", "Aglianica" (red) and "Lagrima" (red) were cultivated; the "Zibibbo" Vineyard, formed in 1790 by a division of the "Arcone" Vineyard, in which were planted vines from Calabria and Sicily; the Vineyard named "San Silvestro", rear the "Casino", the only one where the vinegrapes have Hedge Maple trees as training stakes, and in which wine of poor quality was produced (*vide infra*).

Among all, the most interesting is the Fan Vineyard, so named for its shape, that was located between the Belvedere Palace and the San Silvestro farm, and placed on a natural slope like an amphitheater, the subject of a careful study of a group of researchers led by Andrea Buondonno [1] presented last year at the 11th International Study Forum "Le Vie dei Mercanti" and published in the Proceedings of the Conference.

Another very interesting vineyard, located at the northeastern end of the fence of the Royal Site, is “San Silvestro”, in the homonymous area close to the waterfall of the “Acquedotto Carolino” and the Fan Vineyard. The site includes, in addition to the San Silvestro Vineyard, object of the present research, a farm house – the “Casino” - surrounded by terraced gardens used to grow fruit and vegetables, and served by an irrigation system built using the waters of the direct conduit to the factory of the Belvedere. The building of the “Casino”, designed by the architect Francesco Collecini, likely with the contribution of his assistant Giovanni Patturelli in 1798, has obvious similarities with the Royal Palace of Carditello (Fig. 5) [12], as both buildings are composed of a central double height body and symmetrical pavilions of service to it grafted, while the decorative log repeats in a simplified form the solutions already adopted by Collecini in the Royal Palaces of San Leucio and Carditello. Differently from these, and also from the farm house built by Collecini on the promontory of Sarzano in 1773-74, commonly referred as the Casino Vecchio (Fig. 5) [12], in the San Silvestro Site the focus of the architectural composition is centered in the vineyard, exactly in the intersection of the avenues that cross it, but not in the building of the “Casino”, reversing the usual relationship between architecture and nature established in the buildings constructed by Borbone House in the territory of Caserta.

4. “San Silvestro” vineyard and its relationships with the territory

Primary importance for studying “San Silvestro” vineyard is the comparison between the historical maps and current ones. The comparison of multi-temporal representations could help in the research of existing tracks and in the recovery of deleted ones. The techniques of land representation, supported by contemporary and innovative systems, are an additional input to the studies of modification of the territory. Specifically for this case study, the comparison is accomplished through the georeferencing of Rossi map through the identification of control points recognized both in aerial photo and in the historical map. In particular we considered the “Casino” of San Silvestro (*vide supra*) because it is really recognizable in both maps.

Fig. 6: Control points on aerial photo

We also noticed the shape and the structure of this building in the context: you can see, in fact, some references about the vineyard and the Casino. In particular, there are some traces recognizable like the axis and the crux generated from the bow of the axis. (Fig. 6)

Fig. 7: The traces recognizable like the axis and the crux generated from the bow of the axis.

This operation between diachronic maps allowed a metric control on the extension of the vineyard and its productive potential. Georefering the map of the Rossi within a projection system and to a geographic coordinate system has allowed to operate on the historical map in a similar way that is possible on contemporary cartography [13].

The survey mapping, however, has been useful not only for a check of the quantity of land used for growing grapes but also for a qualitative verification of the positioning of the cultivated area in relation to the local context. In fact this kind of investigation cannot be separated from the geomorphological assessment of the area and its surroundings, as well as its variations in height. These considerations have supported, for example, evaluations related to the current climate and the sunshine affecting the area planted with vines (*vide infra*).

The most appropriate instrument to support such an investigation is a DTM (Digital Terrain Model), a 3D representation of the terrain surface characteristics from which derive all information of the elevations of the soil. Considering that the area covered by the vineyard has not undergone substantial changes from its plantation until now - with the noticeable exception of the invasion of Mediterranean shrub - we can conduct our analysis on a current DTM. Therefore, working on a georefered DTM of this area, we are able to draw vertical cross sections of the land on which operate qualitative assessments of territorial context.

Among the different sections carried out, those of most interest is that performed in NW-SE direction, thanks to which we can calculate the elevation of the vineyard and that of the hills immediately close to it. The vertical plane of section oriented according to the above arrangement has been conducted, in particular, along the axis that identifies the cross which divides the allotment of the vineyard. The section of the DEM (Fig. 7) show us that the vineyard located at an average altitude of 230 meters above sea level is dominated at NW by the presence of a hill of over 320 meters and at SE with a hill of about 275 meters. Therefore the vineyard was in a depressed position with obvious climatic problems that will be discussed below.

5. Pedo-agronomic features of “San Silvestro” vineyard

5.1 Geo-pedological setting

The geological substrate below “San Silvestro” farm is formed, deep, by calcareous-dolomitic successions, mainly belonging to Trias-Early Cretaceous, mantled by the Campanian Ignimbrite, the so-called “(Campanian) Gray Tuff”, a sturdy pyroclastic fall (cinder, pumices, and scoriae) erupted during the 1st Phlegraean Period about 39 ky b.p. Taking into account its geographical location, geomorphology, and geo-lithology, the study-site is ascribed to the Great Land System “Calcareous Mountain”, System “ Calcareous pre-Apennines reliefs with pyroclastic cover”, sub-System “Low slopes of pre-Apennines reliefs on “Campanian Gray Tuff” and deposits [14]. Soils in such sub-System belong to the Order of Andisols. Andisols [15] are soils developed in volcanic ejecta (such as volcanic ash, pumice, cinders, and lava) and/or in volcanoclastic materials, the colloidal fraction of which is dominated by short-range order minerals or Al-humus complexes. One of the outstanding features of Andisols is their high natural productivity. There are exceptions to this very general statement, but the dominance of physical properties that favor the growth of most plants, allied to the most common occurrence of the soils in areas of considerable rainfall, has resulted in volcanic soils being generally regarded as highly fertile soils.

5.2 The vineyard: a “married grapevine”

The vineyard as such is lost, and the remnant of the old terraces (Fig. 4) are now invaded by Mediterranean maquis shrubland, with prevailing Holly Oaks (*Quercus ilex* L.). However, the principal directrices of terracing are reported on a 1:25000 topographic map (Fig. 8). Figure 2 shows the location of the old vineyard overlooking the “parterro” and the “Casino” to its south-west, with the chestnut grove to its north-west, and the “cesinale” grove to its south-east. The chestnut grove provided valuable poles, widely utilized as main beams in buildings. The “cesinale” (from Latin *caedo*, I cut) was a coppice with a particular rotation with an alternate bearing of hay, thus allowing to graze the goats bred within the farm with fresh pasture grass.

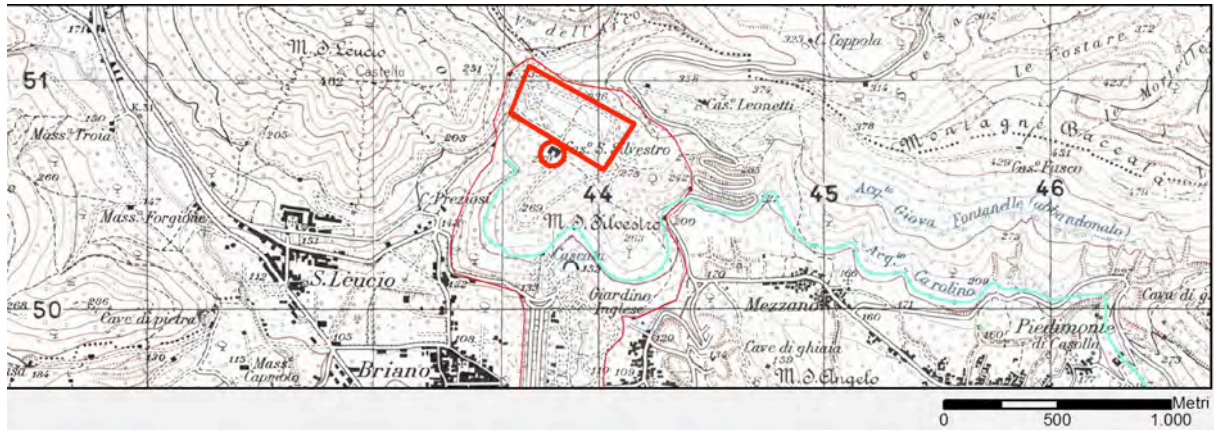

Fig. 8: The «Casino» (red circle) and the principal directrices of the vineyard terracing in San Silvestro farm. From the original 1:25000 map by the Geographic Military Institute.

In its “Platea” [8], Sancio describes the management of the vineyard. In particular, he states that the “temperament” (“*indole*” in the original text) of the soil does not allow crop grapevines pruned “Italian-style”, i.e., short, as a small tree, as instead it was possible in the nearby “Fan vineyard” [1]. On the contrary, the grapevines of San Silvestro were cropped as “married”, i.e., staked to trees named “oppi”, the old name of the Hedge Maple (*Acer Campestre* L.). As a matter of fact, the total of grapevines and trees was 6300 and 1023, respectively, with a mean ratio grapevine-to-tree of about 6 to 1. Such a cropping system deserves a closer examination. Indeed, the so-called “vite maritata”, viz. “married grapevine”, where the “husband” is a tree which acts as a training stake, likely is the first grapevine cropping system [16] spread in the world. The ancient agronomist Tanara, in 1644, discriminates two main “grapevine-marriage” systems: the so-called “arborata” or “alberata”, viz., a grove of trees, and the “piantata”, viz., a planting, a row of plant [16]. The former is the typical trees grove system, where trees to which grapevines are staked are arranged either with a regular spacing or random, the latter is a trees row along the boundaries of an allotment, with the grapevines between trees along the same row, the vine-shoots held by ropes tied between two successive trees (Fig. 9).

Fig. 9: «Piantata». «Asprinio» vineyards managed by «Piantata» system. Left: vegetative stage. Right: state of repose.

Sancio does not clarify whether the “grapevine-marriage” system was the “alberata” or the “piantata”. We are strongly inclined towards the latter. A first reason arises from the ratio grapevine-to-tree of about 6 to 1. The Hedge Maple is a small tree, with a trunk diameter usually less than 1 meter, too small to host 6 grapevines around together. A second motivation is that the “piantata” is presently widely adopted in Naples, Caserta and Benevento provinces, and it represents the distinctive features of the “Asprinio” vineyards cropping systems in Aversa, Caserta province. Indeed, the “piantata” is not only a grapevine cropping system, but also a crops association, especially when the stakes are fruit trees, and the open fields among stake trees are tilled with other crops. However, we also believe that the “piantata” system had another functions. In the “piantata” system the vine-shoots can reach 15-20 meters height; it implies to control the microclimate, by gaining much more insolation and, on the other hand, avoiding stagnant humidity, a mortal enemy to grapevine. Finally, a “piantata” is aesthetically very appealing, and provide natural wings or curtains to host shows and entertainments. Finally, a puzzlement seems to persist: why Sancio did assert that the “temperament” of the soil was not suitable for grapevine cropping? If truth be told, such a statement appears inconsistent with the fertile nature of Andisols which mantle the Tifatini chain. Furthermore, the same Sancio also emphasizes that the wine produced in San Silvestro was “mediocre”. Taking into account that, within same pedological features, the quality of wine is strongly affected by the inclemency of weather conditions [17], we can actually infer that the poor quality of wine was likely depending on the cold-humid climate at that time, under the so-called Little Ice Age (about 1350-1850). Furthermore, we can also assume the negative contribution of geomorphology. In effect, a cross-section along the NE-SW directrix (Fig. 10) clearly shows that the vineyard is located in a depressed site behind a relief, so that the air circulation is constrained and fog and humidity can persist.

Fig. 10: Cross-section along the NE-SW directrix.

6. Conclusions

San Silvestro farm was one of the numerous rural assets of Borbone House which still today enriches the land of Caserta province, and of Campania region on the whole. Indeed, San Silvestro farm also testifies that the knowledge of rural lands was already spread during the previous Acquaviva seigniory. The re-allocation of the historical map by georefering procedure allows to appraise the skill of Borbone drawers in land representation. It is noteworthy that the option of “piantata” as vineyard cropping system most probably arises by a landscape architecture design, rather than from an agronomic plan. In fact, as also clearly showed by the digital geomorphological analysis, the position of the vineyard was unfavorable for a satisfying wine production.

Once again, people is astounded for the neglecting of such heritage, and we strongly expect that the appropriate authorities and the local government act to restore the ancient functions, dignity and pride of the “**agri+cultural**” Borbone sites.

Abstract

Interventions on cultural heritage have always involved the technological expertise of the time. Applications in historical monuments have in fact been prolific stage exhibition and case studies for the sponsorship of producers and technicians to improve commercial use in the more diffused ordinary buildings.

The technology of reinforced concrete, since the early decades of the twentieth century has been widely used in the restoration of historic monuments and archaeological ruins. The reinforced concrete interventions have been used and abused for over 50 years starting in 1930. There are several examples of concrete as the favorite solution to repair important monuments.

The first structural interventions in many Pompeian *domus* involved the replacement of old wooden or collapsed roofs with concrete structures similar to the old ones. Several of these roofs (realized in particular on the atriums) are nowadays visible. In some cases the heavy structure on the top of ancient masonry walls, not designed for similar loads, combined with the effects of weather (rain, change of temperature, pollution) and low -quality materials, has created the damages actually present in the fragile structure of Pompeii *domus*. Emblematic cases are the Vettii *Domus*, the Julia Felix *Domus*, and the Nozze d'Argento *Domus*. Actually several studies aimed at assessing the state of degradation and evaluating the vulnerability of the structures are in progress. In all the case-studies here presented the structural durability of reinforced concrete is a key point in the safeguard of a fragile and precious cultural heritage. This paper presents an analysis of these cases, discussing the role of reinforced concrete durability in the protection of monuments.

Keywords: cultural heritage, durability, reinforced concrete, Pompeian *domus*

1. Introduction

In recent years almost all the developed countries have created free electronic archives and have made relevant attempts to portray their Cultural Heritage. The representation of this artifacts becomes dynamic and interactive: it is the user himself who can directly choose the dimension, the level of detail and also the viewpoint to access each single artifact [Guttentag, 2010].

In this technological landscape fit interventions in reinforced concrete that since the beginning of the 30's for about 50 years have represented privileged expedient in the consolidation of historic monuments.

Once the concept of a monument as a document forming part of the archive of a civilization's material history has been accepted, we are faced with the problem of conserving the monument in its material integrity in the interests of future historical research. This problem affects the whole of our historical building heritage, but is particularly crucial for archaeological remains, which owe their existence and conservation entirely to their documentary value. The archaeological heritage is subjected to a number of natural and man-made hazards inducing continuous degradation. As time goes by, measures have to be taken more and more often to ensure conservation, and this tends to modify the status quo and

compromise the artefact's integrity. Hence the methodological requirement for the durability of any conservation measure. Unfortunately however, even when durability finds consensus in methodological terms, it comes up against resistance both at the planning stage and on site, so that in reality most of the interventions carried out today are not lasting.

In past centuries, as we said above, ancient ruins were often reused in new constructions, or else subjected to major operations of reconstruction. More recently they have undergone wholesale interventions of consolidation which have altered their rationale and static behaviour.

It is rare for archaeological constructions to have come down to us in their original configuration: they have almost always been profoundly altered by successive mutilations and transformations, giving them a new configuration and state of equilibrium as ruins. It is this characteristic which makes archaeological remains the object of complex, interdisciplinary studies involving archaeologists and applied scientists. What is more, in previous centuries characterized by a different, more limited view of history, ancient ruins were frequently incorporated into new constructions, making their anamnesis even more complex. In the light of our scientific understanding of history, we view a ruin as a multi-faceted document, and its integrity and conservation take on crucial importance.

Unfortunately archaeological sites have been subjected to far too many ill-considered, invasive interventions in the name of conservation in flagrant contrast with the ancients' construction culture. This was especially the case during the second half of the 20th century when, thanks to post-war reconstruction and the boom in house building, a shamefully cavalier approach to building prevailed. Moreover, some restoration projects have been closer to an architectonic reinterpretation of the ruins than a scientifically grounded reconstruction [Modena and Valluzzi, 2001].

From this an abuse of the use of reinforced concrete was born in these archaeological ruins and beyond. Several interventions were made by reinforced concrete which covered not only the archaeological ruins, but the cultural heritage in general that, unfortunately, by the time revealed somewhat precarious.

There are several examples of concrete as the favorite solution to repair important monuments that we will discuss in more details later.

If the prime objective is to safeguard the historic monuments and archaeological ruins, it is obvious that the concept of durability plays an integral part in achieving this objective, and must inform both the restoration project and the process of programmed maintenance.

There are two criteria for ensuring that principle:

- safeguarding the construction rationale of the archaeological artifact;
- employing materials and techniques compatible with durability.

These criteria must be adopted as methodological tenets, even though their application in practice can come up against a lot of difficulties.

The brutal insertion of new structural elements in an ancient building context has frequently occurred over the last century. In such cases these should be eliminated whenever this can be done without seriously affecting the archaeological fabric.

Some recent theories of restoration highlight the importance of tracing a historical profile of the successive interventions, in the interests of the building's value as a historical document, and go on to insist on the over-riding importance of the current status quo. Many interventions, and not only in the past, have in fact been highly prejudicial to an objective reading of the original document [ott and Pozzi, 2011].

An anamnesis of the alterations and adaptations carried out should be performed, including any previous evidence of restoration or conservation and the discernible episodes of degradation, whether due to natural or human causes. In addition it is important to determine the material composition of the ruins by establishing the quality of used stones and their provenance, the nature and quality of mortar or other adhesive agents, the stratigraphy of the walls, the way in which they were laid down, the successive alterations and the conditions of degradation.

Finally developments in the realm of technology may require the elimination of unsuitable materials; or again, as we have begun to see recently, progress in elaborating complex virtual reconstructions can lead to the dismantling of ill-conceived restorations in the interests of a scientific conservation of the archaeological monument.

2. Durability of reinforced concrete

The advent of reinforced concrete since the beginning of the 30's for about 50 years urges the massive construction of reinforced concrete structures, that replaces the previous masonry and timber structures. The advance in production of construction materials and architectural concepts cause more reinforced concrete structures to be built in this era. As the passage of time shows, this reinforced concrete material once believed to be eternal shows durability problems due to deterioration/distress of the structure on the long term. Some of these reinforced concrete structures built at that time are nowadays considered to be heritage structures by organizations like UNESCO. Over the past decades, there has been a growing awareness in the world of the importance of preserving our

heritage structures. In turn, this has caused more reinforced concrete structures to fall within the classifications of the heritage sector [David and Gizzi, 1993].

Due to the decay of these reinforced concrete heritage structures, their repair and maintenance is becoming indispensable to prolong the service life of the structures. The repair and strengthening of these reinforced concrete heritage structures are challenges to conservation professionals/restorers these days. It is a common practice to repair these structures based on past experience, and with the new materials and techniques available today.

The performance of a building component in concrete can be deduced from the knowledge of its nominal life, the class of use to which it refers, and the reliability of the component.

A structural element to vary the time undergoes a natural fall of performance, in relation to the useful life of the materials employed to achieve strength and to their implementation. Beyond a certain threshold limit, the performance of the component reaches values below which it is no longer able to ensure an effective response, depending on the required function, which indicates that it has reached the end of its useful life [Glasser et al., 2008].

To ensure that this limit is reached in a time sufficiently higher than the nominal life provided by the designer, it is necessary to adequately protect the concrete used for each different component of the work concerned.

There are many causes of degradation and we have tried to summarize them in the table below. It can be said, as of now, the possibility of the occurrence of a change are proportional to the permeability of the concrete. A waterproof concrete does not allow the penetration of any chemical element. In contrast, a very permeable concrete may be subject to any attack brought from the surrounding environment.

Problems	Causes	Laboratory Analysis	Symptoms	Prevention
Accidental loading	Impact, explosion, Earthquakes	No	Spalling or cracking of concrete	The event can't be prevented, but the effect on the structure can be reduced
Acid attack	Highly concentrated acids nearby the concrete structures	Identification of the specific acid present	Loss of cement paste and aggregate from the matrix and attack to the reinforcing bars causing corrosion, spalling and cracking	Concrete with a low water/cement ratio or appropriate surface coating or treatment
Aggressive water attack	Water with low concentration of dissolved salts	Measure of the aggressiveness of the water	Leaching of surface and consequent rough concrete surface	Coating susceptible areas with non-portland cement based coating
Alkali-silika reaction	A solid that expands in the presence of water, due to reaction of aggregates containing silica with highly alkaline solution	Petrographic examination	Random cracking. Map or pattern of cracking and swelling of concrete	Removal or replacement of damaged concrete and/or protective waterproofing render
Sulfate attack	Attack of concrete by naturally occurring sulfates found in soil or in solution in ground water adjacent to concrete structures	Determination of occurrence of reactions	Softening and loss of surface layers. Map or pattern of cracking and disintegration of concrete	Removal of all suspect and degraded concrete, and patch or full repair using a polymer mortar
Construction errors	Poor workmanship and carelessness	No	Enhance the adverse impacts of other mechanisms or accelerate the penetration of aggressive agents (CO ₂ , Cl ₂) into the concrete	Knowledge of the construction errors and following aggressive inspection program
Corrosion of reinforcement	Differences in moisture content, chloride content, oxygen content and electric potential difference	Determination of chloride content in the concrete, to determine the amount of concrete to be removed during repair	Rust staining concrete followed by cracking (following the reinforcement) and spalling	Use of concrete with low permeability, providing adequate cover to reinforcement

Table. 1: Common problems and causes of reinforced concrete heritage structures

It is therefore of considerable importance the evaluation of the effectiveness of specific treatments against degradation recurring, such as the attack by carbonation, chloride attack and attack by sulphates.

This assessment assumes even greater importance in the event that the component in concrete takes part in the consolidation of a monumental opera.

The good durability of reinforced cement compositions in normal service environments has long been studied in the scientific literature. However, cements and concretes made with cement binders can be attacked and, as a result, exhibit a reduced service life. Most of the adverse conditions are recognized from experience and have been the subject of numerous examinations of field concretes as well as laboratory studies. Not surprisingly, research and testing have focused on the areas of underperformance [Gizzi, 1993].

The concept of "service life" is not new. The ancient world used stone, brick, tile and, from Roman times onwards, concrete, because of their permanence. The reinforced concrete has been used and abused for over 50 years starting in 1930 in the consolidations of many structures and also today it is widely used and comprised in the world's major structures. [Modena and Valluzzi, 2001]

The prediction of the "service lifetime" of structures in reinforced concrete is a global challenge. In literature precisely mathematical models have been developed in order to allow a reliable prediction of the behavior of these structures during their lifetime. Among these is the French APPIET project undertaken to improve these models and improve their robustness [At Mokhtar, 2013]. The main objectives of this project was to quantify the various sources of variability (material and structure) and to take these into account in probabilistic approaches, to include and to understand in a better manner the corrosion process, in particular by studying its influence on the steel behavior, to integrate knowledge assets on the evolution of concrete and steel properties in order to include interface models between the two materials, and propose relevant numerical models, to develop robust predictive tools to model the long term behavior of degraded structural elements, and to integrate the data obtained from monitoring or inspection. It is useful to underline that the loss of compressive strength of concrete due to chemical attack can reach very high values as it is visible from the diagram below [Colleparidi et al., 2006b].

Fig. 1: Compressive strength of the specimens stored in water (20 °C) or in solutions of 30% CaCl₂ at 5 °C, 20 °C and 30 °C. [Colleparidi et al., 2006b]

Among the various causes of corrosion there is the carbonation that is one of the most important factors that contributes for the corrosion of reinforcing steel, thereby reducing the strength and durability of load carrying reinforced concrete elements as shown in figure below [Colleparidi et al., 2006a].

The requirement of durability is exquisitely type design and, therefore, must be addressed by introducing the stresses between the aggressive environmental parameters that contribute, together with the static and dynamic loads acting on the structure, the dimensioning of the sections of the structural elements, the identification of the percentages of reinforcement and their disposal. For a long time the problem of minimizing the costs of the interventions, the definition of life and nominal indices of reliability has been largely overlooked (if not completely rejected) and, consequently, the durability of concrete also has been relegated to a secondary role compared to the attention paid to the elasto-mechanical properties of the concrete and, in particular, to the compressive strength.

The result of this bad practice is represented by the numerous reinforced concrete structures that have suffered severe degradation in the form of corrosion of reinforcement bars. Out of significant parts of the concrete cover, deterioration of the aesthetic and functional qualities that forced it to

anticipate maintenance of 15-20 years compared to the canonical time that, for obvious economic reasons, is found in about 30 years after their completion.

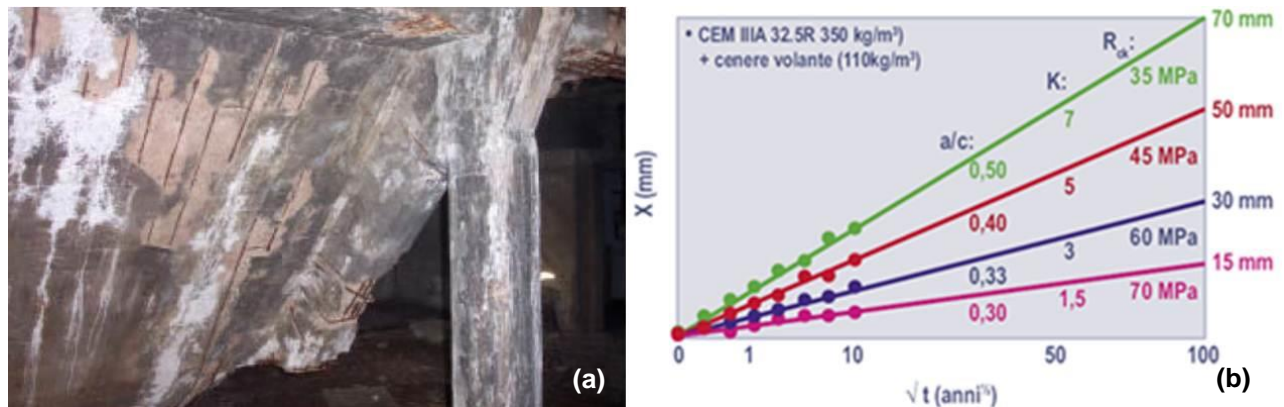

Fig. 2: Reinforcement corrosion caused by carbonation of concrete (a) and carbonation versus the w/c ratio of the concrete (b) [Collepardi et al., 2006b];

To ensure the durability of reinforced concrete structures exposed to the environment, we must take measures to limit the effects of degradation induced from the chemical, physical, and resulting from the corrosion of the reinforcement and the cycles of freezing and thawing.

When operating a restoration project, especially in the case of historic monuments, the environmental conditions of the site where the surgery will be included should be properly evaluated. They must first be established defining the characteristics of the concrete to be used (composition and mechanical resistance), the values of the cover and the rules of curing.

For the assessment of the durability, in the formulation of requirements on the concrete, tests to check the penetration resistance to aggressive agents should be prescribed. The degree of impermeability of concrete should be taken into account too. To this end, the value of the depth of penetration of water under pressure in mm, as indicated in the UNI EN 12390-8:2002 [Roziere et al., 2009], should be evaluated.

Although the statistics show that the poor quality of the concrete is the main responsible for the processes of instability/degradation of the structures, however, it should be noted that the problem of durability of the same needs to be addressed with an engineering approach that takes into account not only the deterioration mechanisms of the material, but also the inevitable implications of a structural type of equipment resulting from the construction. The deviations between the theoretical models and actual behaviors of artifacts, the errors inherent in the difficulty of carrying out the construction details, the distortions produced by thermo-hygrometric variations of the environment are to be taken into consideration. These problems are amplified in the case in which the concrete element goes to integrate ancient structures constructed with materials having different mechanical characteristics.

The engineering approach to the problem of durability cannot be reduced to a mere analysis of the mechanisms of degradation of the material alone, but must take into account that in real structures degradation processes studied in the laboratory using a reductionist approach (analyzing, that is, the various factors acting individually) are not simplistically extensible to real structures where several factors acting simultaneously and together contribute to define the phenomenon as a whole.

The mechanisms of deterioration of concrete shall be construed as one of the anchors that helps to define the general problem of the deterioration of the structures.

3. Some of the most emblematic cases

We shall now look at some practices of consolidation in reinforced concrete which frequently recur in the structural restoration of cultural heritage.

The first structural interventions in many Pompeian domus involved the replacement of old wooden roofs with concrete structures similar to the old ones. Several of these roofs (realized in particular on the atriums) are nowadays visible. In some cases the heavy structure on the top of ancient masonry walls, not designed for similar loads, combined with the effects of weather (rain, change of temperature, pollutants principles) and low-quality materials, has created the damages actually present in the fragile brittle structure of Pompeii domus. Emblematic cases are Vettii Domus, the Julia Felix Domus, and the Nozze d'Argento Domus [D'Amico and Flamini, 2000].

A collaborative effort of the Packard Humanities Institute and the Soprintendenza Archeologica di Pompei (SAP) was launched not only to safeguard and conserve the ancient site but to enhance and advance knowledge, understanding, and public appreciation of Pompeii and its artifacts. One of the

main tasks of the project is a site-wide campaign to address the most pressing conservation problems as collapsing roofs.

As an example the atrium of the Vettii *Domus* in Pompeii has been considered [Altieri, 2006; Di Filippo, 2001]. In the immediate post-war years a wooden roof erected in the late 1800s was replaced with a structure of the same dimensions in reinforced concrete. This intervention was badly flawed structurally and done using an inferior cement, so that it is now in very bad repair: the corrosion of the metal framework is in fact a common problem of interventions using reinforced concrete on archaeological sites. In this case the correct solution would be to replace the roofing, which exerts considerable pressure on the house walls, by a new wooden structure modeled on the 19th century construction, much more in keeping with both the ancient context and the rationale behind the house's construction [Capanna et al., 2000; Sogliano, 1898].

Fig. 3: (a) Poeta Tragico domus' roof, Pompeii, (b) Fabio Rufo domus' roof, Pompeii (photo by the authors, with permission of Ministry for Cultural Heritage and Activities – Special Superintendency for the Archaeological Heritage of Naples and Pompeii. All rights reserved).

The Nozze d'Argento *Domus* is a significant example of an extended atrium house, or urbanized villa, from Pompeii's pre-Roman period. The house was first excavated in 1883–1884 and restored immediately thereafter, with the first roof erected between 1906 and 1909. The house was maintained with periodic cleaning and conservation through the 1960s; its current roof was installed in 1979, after which great intervention on the site ceased. Being made of concrete material, the 1979 roof presents the main aspects of structural degradation of the site. In May 1998, the Kress Pompeii Conservation Project was launched by WMF to establish new standards in site conservation and presentation. Several buildings within Insula V2 -an area the Soprintendenza Archeologica di Pompeii had hoped to one day open to the public -were chosen for demonstration projects. Among them the Nozze d'Argento *Domu*. Methods developed in the course of these projects would be used to formulate a conservation strategy for the whole of the insula. For its part, WMF agreed to provide funding and technical assistance to carry out feasibility studies for the house restoration, enlisting the help of the ace conservators Paolo Marconi and Antonio Pugliano [Marconi, 2007; Pugliano, 2001]. They would develop a structural stabilization plan for the Nozze d'Argento *Domus* that included among other things a plan to replace the roof, the current one some five times heavier than the original. The result was the development of a laminated wood structure that was in keeping, both visually and architecturally, with the original building construction.

Fig. 4: The House of the Silver Wedding Anniversary [Guttentag, 2010]

While all of the conservation research to restore the house has been carried out, plans to construct the new roof have been drafted, and an imaginative method for presenting the site to the public has been developed, the project is currently on hold due to internal management issues within the SAP.

First, the sites require a multidisciplinary team of conservator-restorers, archaeologists, structural engineers, experimental scientists, and surveyors, to analyze the problems, learn from past mistakes and successes, try out and subsequently monitor new solutions. Such a team is beyond the resources and capacity of the heritage agency as presently constituted. Secondly, the rulebook as derived from their work has to be translated into intelligent bureaucratic practice, so that limited resources are not squandered on ill-conceived and expensive projects.

Another case in point is the Roman colonnade in front of the basilica of S. Lorenzo in Milan: during the 1950s the colonnade was dismantled, the segments were hollowed out or drilled through and filled with reinforced concrete, and the ancient crossbeams received the same treatment. This intervention, which is to all intents and purposes irreversible, has destroyed the integrity of the monument, making it impossible to reconstruct its history.

Among other examples that can be cited are those performed in Turin for the Mole Antonelliana where massive reinforcements made of reinforced concrete have been placed since 1931 [Carpinteri et al., 2013]. Engineers Pozzo, Gilberti and Albenga planned to erect a frame reinforcement throughout the building, i.e. structural frame of reinforced concrete pillars composed of independent and isolated element with respect to the Antonelli's masterpiece. Professor Albenga consolidated the foundations considered overloaded and completed his project consolidating the cusp covering the old walls with thin jets of reinforced concrete. In 1953 a hurricane struck 47 m of the cusp and foresaw the construction of a steel structure connected to the old structures with a new reinforced concrete drum. The actual conditions of the r.c. structure is somewhat good, due to the fact that the major part of it is placed inside the Mole, differently from the following exempla, in which the environmental conditions have played a significant role on their durability.

Fig. 5 (a) Great Hall of the Mole at completion of the work of consolidation implemented structural in the '30s. (b) Reconstruction's works of the end the spire after reversal of statue of the Genius winged (c) Half of the prospectus and mid-section of the project spire of 1953 [Gritella, 1999]

The interventions on the floor mosaics of the Roman Villa of Silin, built about 15 km away from Leptis Magna, site of primary importance for the archaeological, historical and cultural heritage of Libya, in view of the uniqueness of the complex are the object of the last considerations. The mosaic floor of the peristyle was at risk because during the 70's it was removed and repositioned on a reinforced concrete slab. Recent interventions have planned, in particular for the most deteriorated part, the removal and replacement of the layer of cement mortar with a new specially formulated and tested by ICR in collaboration with the CISTeC - Center for Research in Science and Technology for Conservation the Historical and Architectural Heritage (University of Rome La Sapienza).

Fig. 11: The interventions on the floor mosaics of the Roman Villa of Silin, Libya

4. Conclusions

The state of conservation of archaeological materials preserved on site depends on many different and changing factors. This significantly influences the effects of restoration actions and makes difficult to predict aspects such as durability or effectiveness of those treatments. However there are still many gaps in our knowledge about the effects of these interventions in the long term. Often, the masonry structures (especially buildings like the Pompeii *Domus*) are consolidated through techniques that provide the using of reinforced concrete, via curbs or beams, to ensure box-like behavior under seismic actions. The effectiveness of these intervention is now widely discussed i.e. after recent earthquakes. The desired box-behavior sometimes was provided, whereas some other times concrete beams caused the collapse of whole masonry walls between the upper and lower curbs.

In many cases, as shown, previous treatments and interventions have become sources of degradation. Moreover, at sites where several interventions have been carried out there could be an overlapping of treatments over the same surface, which can lead to unpredictable and unknown damages.

In these case analytical studies will be essential in order to determine an appropriate solution, as well as knowing mechanisms of deterioration and the validation, or definitive dismiss, of treatments and products. These analyses would be more realistic and practical if carried out in situ, considering their actual exposure conditions.

The conservation principles of heritage structures from recommendations are difficult to attain in reinforced concrete heritages structures. This means that some flexibilities on the principles should be made and it should be combined with the repair principles of reinforced concrete structures to get conducive principles for future interventions.

Durability problems of reinforced concrete have shown that this material does not sustain for long time like masonry heritage structures, and thus repair can't be delayed. The causes of deterioration as the damage or deterioration or distress will propagate easily and reach the reinforcement level, leading to corrosion of the reinforcement and further damages.

For any reinforced concrete structure, and mainly for the r.c. elements placed in cultural heritage structures, preventive maintenance is preferable to repair or replacements of part or all of the structure should taken into account.

Architects and engineers should work together to preserve heritage structures without compromising their identity to pass the heritage structures for the coming generations. In this view the presence of reinforced concrete elements in the framework of masonry structures like those the past generations have left to us should be carefully evaluated in the light of the developments provided by scientific and technological advances.

Designing the country in infrastructure areas. Area highway exit Candela, Foggia

Efisio PITZALIS,

Dipartimento Architettura e Disegno Industriale "Luigi Vanvitelli", Seconda Università degli Studi di Napoli, Italy, E-mail efisio.pitzalis@gmail.com

Abstract

The current scenery near the highway exit Candela imposes a series of interventions to modify the area in the interchange between infrastructure and services.

The lack of space to devote to parking and bus stations has been the driving force of the Municipal Plan of Tratturi. The proposed intervention on the one hand tends to safeguard the property of the herd and on the other hand proposes strategic interventions to change the area into an interregional bus station between Foggia, the Melfi industrial area and the areas "pedeappenniniche daune".

Keywords: Infrastructures, Safeguard, Services

1. Historical background

The "Dizionario geografico ragionato del Regno di Napoli", of Lorenzo Giustiniani, describes the possessory condition of Candela's land in the late XVIII century. From the description were evident two realities: on the one hand there was a privately owned, limited to specialized cultivation; on the other hand, the open fields of the territories under the control of the "Dogana delle pecore di Puglia" of universal and feudal demesne. In the earliest times, it is certainly easier to focus on other forms of ownership in the area. Tracks of the castrum of Candela was in a donation act quoted by Di Meo, with which in 1107, Count Guglielmo granted to the Benedictine monastery of the church of Cava S. Angelo, located outside of its walls, the appliances of the same and the "power to keep the market in May, with exemption stallage."

Apart from the explicit declaration of the existence of the castrum in the early XII century, the exemption from stallage and the ability to hold an annual market at the church of S. Angelo, are indications of extreme vitality of the community, whose territory was to be a sort of focal point for the exchange of the surrounding area.

Unfortunately, even in the case of Candela, the documentation is very incomplete, as to make difficult the identification of the feudal lords of the same place at least until the age of Aragon. In October of 1279 the inhabitants of the "Casale" of Candela are obliged to participate in the maintenance of the "castrum S. Agathes" along with those of the hamlets of St. Antonio of Ascoli, "St. Petrus de Olibula" and the monastery of St. Stefano "in Iuncarico". In 1496, Troiano Caracciolo, Grand Seneschal of the Kingdom, became feudal lord. The Caracciolo leaked early the feudal benefit. In 1487 Ferrante deprived, in fact, the feud owned by Sergianni Caracciolo, accused of felony for having participated in the conspiracy of the barons. Candela was given to the Prince of Oranges "in renumbering of its services." Devolved to the Crown at his death, in 1531, the fief of Candela was given to Andrea Doria together with the fiefs of Melfi, Forenza and Lagopesole. With them he formed what was known as the state of Melfi remained until the abolition of feudalism to the Doria. As often happened, in Candela principles of Melfi had feudal property. Of these, certainly the more important was the farm of Canestrello, whose territory is crossed by the Ofanto, bordered on the estates of the Bishop of Ascoli and was partially subject to the jurisdiction of the "Dogana delle pecore di Puglia".

The Principles possessed almost all the municipalities from which tithes a fee, the “terraggio”, in case they were planted. This also applied to the territories granted to the University of Serra rented for planting. As already underlined the Giustiniani, from the half of XV century Candela was in part subject to the jurisdiction of a magistracy state: the “Dogana delle pecore di Puglia”. This, of course, managed the state-owned large pastures, intended for transhumant herds coming mainly from the Abruzzi and Molise. Mostly located in the Tavoliere area, the duties locations occupied large areas close to the territories of local communities. This it also happened in Candela. In its territory fell one of the “steps” of access to the the Tavoliere’s “tax area” , also known as the “Scaricature” of Candela. Here came also the Pescasseroli-Candela, one of the main “tratturi” used by the people to transfer their flocks from summer pastures in the Apennines to the winter pastures of the plains of Puglia and vice versa. Candela was not, however, affected only the passage of transhumant herds. Large part of it was, in fact, used for the pastures of the “locations” duties. In particular, in the containment of the community fell the territories belonging to the Tufara owned by Feud of Ascoli, the “Correa of Candela” that of this was “rental addition”, the territories of “Canestrello”.

1.2 The Project

Area. The area is located near the town of Candela (Foggia, Italy). Acting on the recommendations regulations at all levels of planning the project intervention is the architectural and landscape design of a complex system comprising a botanical garden, which will be connected and integrated a village tourist accommodation (hotel diffuse) and attached services including a station intermodal exchange. All this taking into account sustainability and eco-friendliness of the intervention.

Masterplan. The concept that defines the structure of the masterplan is born from the encounter and confrontation with the Arch. Carlos Ferrater. The idea is that of a triangular structure that puts in communication the various areas of the intervention, leaving isolated in the center, a pre-existing tower, as if to signify a neuron that part of a structure isolated and then branch out and develop in a series of filaments which in this case become bicycle and pedestrian paths, greenhouses, building hotel and botanical areas.

The entrance building. The building consists of a series of blocks, with sloping roofs that create a bridge that leads to the botanical system. It contains all the activities of first asylum for the services present in the area, a bar area, a bookshop, and a rental bike for bicycle routes through the system.

Albergo diffuso. The hotel consists of housing units in formala two and three, it has a low visual impact and leads to the definition of hidden architecture. It 'also characterized by reversibility, being built on adjustable jacks. Everything is designed to ensure non-introspection and sustainability of the intervention, with particular attention to the mitigation of energy consumption and the use of environmentally friendly materials. In addition, the connecting paths are made of clay and planks of wood embedded in it. The following tables will be useful to illustrate the operation of the entire system.

Botanical greenhouses. They grow to be also integrated into the whole master plan, the logic can occupy less land. It is divided into hanging terraces that make possible the use of tree species present.

This work is the degree thesis of the candidate Paolo Gordon inside of my course and the subsequent contribution of Luisa Costanza.

Davide Pacanowski a significant interpreter of modern architecture in the twentieth century

Riccardo SERRAGLIO

Department of Architecture and Industrial Design "Luigi Vanvitelli"
Seconda Università degli Studi di Napoli
riccardo.serraglio@unina2.it

Abstract

The methodological assumption of this research is the recognition of the importance of many architects exclusively engaged in the profession, but unrelated to the theoretical debate and the academic studies, because they certainly had a significant impact on the environment of the Italian cities during the twentieth century by constructing a number of very interesting buildings. In particular, this paper deals with the long professional experience of the architect Davide Pacanowski. I considered one of the most significant among those who have been active in Naples from the thirties to the sixties of the last century. In his long career he worked in Naples and Rome for private clients, companies and public bodies. The numerous buildings designed by Pacanowski are distinguished in the urban environment of such important Italian cities thanks to the simplicity and the quality of their architectural patterns, where the architect finds the right balance with the adjacent monumental and natural presences. For this reason, they can be considered an adequate solution to the difficult dialectic between the speciality of the historical context and the rationality of the modern architecture. Now, the investigation of Pacanowski's private archive, allows us to study his drawings and his plans, so that we can have a better understanding of his works.

Keywords: modern architecture, built environment, private archives.

1. The professional training and beginnings

After years of research dedicated to the paradigmatic expressions of Italian architecture in the twentieth century, it seems that is the right time to investigate the ordinary buildings in the urban centers, in the suburbs and in the provinces, because they give back the true identity of any context. At the same time, it recognizes the importance of architects exclusively engaged in the profession, but unrelated to the theoretical debate and academic studies. Many of these – like Vittorio Amicarelli, Franz Di Salvo, Sirio Giametta and the same Davide Pacanowski – had a significant impact in the environment of the Italian cities by constructing very interesting buildings [16]. What we are now proposing is to operate the historical recovery of some of these through the acquisition of a documentation supporting the critical analysis in their private archives. In the case of Davide Pacanowski (Lodz, December 29, 1904 - Rome, August 4, 1998), the study of his work has been possible thanks to Mrs. Lydia Sterle, the widow of the architect, who allowed me to investigate his archive [1].

Pacanowski was born in Poland in a Jewish family of artists, naturally projected in an international cultural environment, and led his university studies at the Polytechnic of Milan from 1923 to 1928. During these years, he worked with some of the best architects in the city - Giovanni Muzio, Giuseppe De Finetti, Alberto Alpago Novello, Ottavio Cabiati, Guido Ferrazza, Alessandro Minali – getting by them the interest in the most up-to-date expressions of European architecture dating back to that period [1, 14]. In the twenties, in fact, the professional environment in Milan was characterized by a propensity to the renewal more than in any other Italian city, and in the twentieth century, between 1926 and 1929, the most of the best Italian architects graduated at the Polytechnic [14].

After graduating in architecture and participating in the specialization course on reinforced concrete structures, the young architect settled in England (1929-30), where he treated the accommodation of some shops in Leeds and Leicester [1, 18]. Later he settled in France (1930-1935), where he worked in Paris for the engineering study-office Baffrey-Hennebique and then for a firm engaged in the construction of hotel and sports facilities in Monte Carlo. During his French period, he had a direct contact with Le Corbusier, subsequently in his career the references to the Swiss architect, as regards spatial solutions and architectural details, were so evident to constitute a stretch of continuity [14,15]. Back to Italy, in 1935, the architect designed an innovative residential building in Campobasso, characterized by an early modern language for an Italian southern small city. The building, known as "the Ship", was distinguished for the use of innovative technologies and materials, such as the reinforced concrete in the structures, glass-bricks in the separating walls, linoleum floors, a central radio system (one of the first in Italy), common supply of electricity and water [1, 2, 3, 18]. In the years before the second world war he conducted many significant professional experiences. In 1937 he participated with Domenico Filippone in the competition for the Palazzo della Civiltà in the EUR42 planning, presenting a project that was rejected because of its too modern materials and techniques [1, 18]. In 1938 he designed some residential buildings for the Italian overseas colonies, which show significant similarities with the famous Le Corbusier's Maison Monol of [14, 18]. In 1938-39 he directed the construction of the Banco di Napoli headquarters in Via Toledo, designed by the famous architect Marcello Piacentini. At the end of the work, Pacanowki presented a plan to restore the area opposite the Piacentini's palace, where he arranged a central plaza under the street level, surrounded by symmetrical buildings for offices and residences on the lateral sides and by a building that included a theater and a hotel on the opposite side [1, 18]. This project, however, would have required the dejection of a significant sector of the historical Spanish Quarter. In 1939 he designed the headquarter of the Gioventù Italiana del Littorio and the Casa dello Studente in Acqui, where he arranged the buildings around a high flagpole, that determined the nodal element of the composition [1, 18]. The promising professional beginnings of the architect were interrupted in 1940, when, pursuant to the racial laws of 1938, first he was imprisoned in the Jail of Arezzo, then he was transferred to the Jail of Poggioreale, finally he was sent to internal exile in Sepino, a small town in the province of Campobasso [1, 14, 18]. During the four years of confinement in Sepino, perhaps thanks to the protection of the family Di Penta, the architect was able to enjoy a degree of autonomy. In those years, in fact, he carried out some professional assignment, for example the setting up of the socks shop PRM (Pietro Ruffini Milano) in Naples, where he showed the accuracy in the furnishing design and

Fig. 1: Vintage photo of the residential building named "The Ship" in Campobasso.

Fig. 2: The model of the urban renewal project in the front of the Banco di Napoli headquarter.

architectural details that would be a hallmark of his mature output [1, 18]. In Sepino he gained the confidence of the mayor Alberto Peluso, who gave him the run of the archaeological excavations of “Saepinum”, the ancient Roman city, under the direction of Amedeo Maiuri, the famous director of the Archaeological Museum of Naples. The meritorious archaeological activities earned him the esteem of the population and local authorities, which in 1950 conferred upon him and Maiuri the honorary citizenship [1, 18].

2. The professional activity from the postwar to the end of his life

After the second world war, he resumed his professional activity working for private clients, companies and public bodies. In 1945 he drew up the plans for a twenty-two storey skyscraper, to be built on the ruins of the port of Naples, damaged by bombing [1, 14, 18]. The building was characterized by balustrades of the terraces oriented diagonally and by plants that would have decorated his surface. In fact, in the early postwar years the idea of skyscrapers in the Porto neighborhood was considered as a possible solution to urban development and the Pacanowski's project significantly anticipated the plan for the reconstruction designed by Luigi Cosenza in 1946, which arranged a series of residential towers on the east coast road of Naples.

From 1946 to 1948 he read, with engineers Carlo Cestelli Guidi and Adriano Galli, the technical drawings for the construction of bridges and viaducts in Rome and Florence [1, 18]. Then in the fifties, he devoted mainly to the construction of residential buildings in Naples and Rome.

Figg. 3-4: Views of the Gioventù Italiana del Littorio headquarter and the Casa dello Studente in Acqui.

Fig. 5-6: Plan and view of the skyscraper in the Porto neighborhood of Naples.

The three villas built by Pacanowski on the hill of Posillipo - Villa Crespi (1952) , Villa Bruni (1957) and Villa Maderna (1957) - picked up the legacy of the rationalist buildings made in Naples by Luigi Cosenza in the thirties-forties, such as Villa Oro (1934-37), Villa Savarese (1936-42) and Villa Ferri (1943-49). Villa Crespi, built on a tufa rock between two pine trees at 31 meters above the sea level, was considered at the time of the construction one of the most beautiful villas in the world [1, 7, 11, 12, 13, 14, 18]. The body of the house was supported by a single circular concrete pillar embedded in the tufa rock, designed by the engineer Adriano Galli. The most characteristic element of the building was the roof-garden, that according to the architect constituted the real facade of the villa, which can be seen from the overlying via Orazio. The interior of this house, as the others of the residential buildings designed by Pacanowski in Naples, establishes a special relationship with the surrounding environment through the large scenically windows open on the Gulf, framed by flowers and plants [8]. Villa Bruni, located on the top of the hill of Posillipo, was distinguished by the curved shape, dictated by the form of the road. The contrast between the convexity of the building on the road and the linearity of the parts in the interior side, led to an architecture characterized by the alternation of full light and shadow, that articulated the prospects [1, 10, 12, 13, 14, 18]. The construction of Villa Maderna, located inside the Parco Carelli, was entrusted to Pacanowski after that an interesting project by the famous architect Michele Capobianco, characterized by the transparency of the rooms facing the sea, was rejected by the customers [1, 9, 12, 13, 14, 18]. The building designed by Pacanowski ordered two bodies, joined at the right angles, differentiated from changes in altitude of the site, which determined the different levels of the interior spaces. The garden was divided into various areas, each characterized by different species of trees, while the roof-garden was arranged to camouflage the building from via Petrarca.

In the same period, Pacanowski designed a number of residential buildings in Posillipo, commissioned by Companies Di Penta and Laudiero. The construction of such buildings charged up debates about the morality of the planning architects who were accused of violent alterations of such an astonishing area. As a matter of the fact, the buildings designed by Pacanowski were certainly less aggressive to the surrounding environment than many others, because he integrated the volumes to the morphology of the site, including gardens in roofs and terraces, to preserve, as much as possible, a sufficient amount of vegetation in the new quarters [1, 5, 18].

Stimulants architectural motifs are also identified in other residential buildings in Naples. For example, in the Palace "la Fontana", in the corner between Via Mattia Preti and Via Domenico Cimarosa [1, 18].

Figg. 7-8: Vintage photos of the Villa Crespi in Naples.

Fig. 9: A view of the residential buildings in Posillipo.

The unusual T-shaped form of the Fontana Palace, was probably conceived by the architect to separate some parts of the building from the street fronts, so he could insert small gardens and plants in the free areas.

The Palace of the Società Esercizi Telefonici (S.E.T.), that the architect designed in 1959 and the Di Penta Company built from 1960 to 1966 on the Pizzofalcone Hill, was the last, but not least, work of Pacanowski in Naples [1, 14, 15, 18]. The great concrete volume of the building was constructed partially underground and partially above ground, to allow an optimal use of the morphology of the site, and its C-shaped form was studied to the retention of existing ancient trees, located in manicured gardens in the free areas. In the interior spaces the architect replaced the traditional partition walls, usually used in buildings of similar destination, with modular removable furniture, realized on commission. The building has been recently restored to be adapted to the new destination of the seat of "Parthenope" University and now titled "Pacanowski Palace".

In addition to Naples, Pacanowski has worked in Rome since 1950 for Construction Companies such as Di Penta and SCIE, planning some infrastructures and a number of residential buildings. Also these buildings, such as those of Naples, were characterized by the successful integration of the new constructions to the surrounding environment [1, 14, 18]. An important witness of the architect's ability to report its buildings to the local context, is given by the artist Enrico Prampolini in the architectural review "Edilizia Moderna" in 1954, where, talking about a house built by Pacanowski on Parioli Hill, he pointed out how the architectural solutions adopted in the curvilinear facades and in elements of interior decoration were inspired by the traditional forms of the Roman Baroque [4].

A significant experience in Pacanowski's career, was the task of head-designer for the I.N.A. Casa from 1956 to 1963. In this period he designed a number of cheap dwelling buildings on the outskirts of Campobasso, Agnone, Casacalenda, Termoli, Boiano, Benevento and Secondigliano [1, 18]. The numerous projects of social housing that he prepared for the INA-Casa, although limited by dimensional and economic requirements, carried out logical constructions in the formal and functional aspects. Other interpretations of minimal houses are documented by the residential unit in Casoria for employees of Rhodiatoce, which consists of eight terraced houses (1953); by the houses for Sicilian fishermen (1959); by the houses for single family in Sernobi (1972-75); by the residential district for the earthquake victims in Castello di Cisterna (1983-87); by the prototype in fiberglass of transportable homes, reducible to the telescope, usable in case of earthquake emergency (1979) [1, 14, 18].

In addition to the social housing, Pacanowski designed on behalf of the Istituto Nazionale delle Assicurazioni (I.N.A.) two representative buildings in Caserta and Benevento, where they placed shops on the ground floor, offices on the first floor and residences on the upper floors.

Fig. 10: The model of the S.E.T. Palace in Naples.

Unlimited by the constraints imposed for the cheap dwelling houses, these buildings represent the average solution between the essentiality of public housing and the opulence of the residences in Naples.

In the I.N.A. building in Via Roma (Caserta, 1959) the architect designed a plan similar to that for the palace "La Fontana" in Naples, diagonally joining two rectangular shaped bodies, the first aligned to the street and the other inside to the built-up area [1, 18]. The architectural quality of the main front made the building different from the others of the same urban environment. The rational facade was characterized by the chain-shaped development of external walls, by the small circular columns passing through the terraces, by the terminal canopy crossed by a strip of glass blocks. In the I.N.A. building in Benevento (1966-1973), overlooking the Calore River and next to the archaeological site, the architect designed an L-shaped building developed on five levels, characterizing the main front with horizontal cuts of the long terraces [1, 18]. The simplicity of the architectural patterns found the right balance with the adjacent monumental presences, so that this building can be considered an adequate solution to the difficult dialectic between the speciality of the historical context and the rationality of the modern architecture.

Figg. 11-12: Views of interior spaces in the S.E.T. Palace in Naples.

Fig. 13: Vintage photo of the Istituto Nazionale delle Assicurazioni Palace in Caserta.

Many other achievements and projects of Pacanowski are interesting for different aspects: the high number of interior design interventions in apartments, shops and boats, show a meticulous attention to architectural detail; the plans of the green areas close to the Fiumicino Airport (1958) and to the underground stations in Rome (1960-63) affirmed his intention to surround and cover of vegetation the buildings, in order to lighten their impact in the surrounding environment; the Church of Sant'Antonio di Padova in Foggia (1966-67), characterized by the sinuous forms and the skillful use of the "beton brut", can be compared to the churches built in the same period by famous architects, such as Giovanni Michelucci, Luigi Moretti and Paolo Portoghesi [1, 14, 18]. Finally, the plans of a communal garden close to the waterfront in Fregene (1988-89) and of the underground car park in via Agrigento (Rome, 1990) denote the truly extraordinary intellectual activity of the architect in the last years of his long life [1, 18].

3. Conclusions

In the end, the research on Pacanowski wants to assign to him a role as protagonist of Italian architecture in the twentieth century. The recognition of his value should cause appropriate instruments for the preservation of his works. In fact, we can think that the tampering found on many of his buildings, emerged by the comparison between their current state and their projects and vintage photos, derive from unconsciousness of their importance. New studies dedicated to not well-known architects, despite their numerous interesting buildings in the urban centers, in the suburbs and in the provinces, can significantly enrich the Italian architectural heritage of the twentieth century. This will be possible if the historians of modern architecture dedicates their researches to the investigation of public and private archives, to discover unknown architects and buildings. Similarly, it is crucial the direct knowledge of the territory, to recognize the many buildings worthy of protection. After this challenging preliminary work, we strongly expect that the appropriate authorities will take concrete actions to recover the functional and aesthetic qualities of many architectural complexes built in the twentieth century.

Around the Royal Place of Caserta. The school building “Edmondo De Amicis”.

Luciana ABATE

Seconda Università degli Studi di Naples, Department of Architecture and Design “Luigi Vanvitelli”, Aversa, Italy.

lucianabate.la@gmail.com

Abstract

The primary school Edmondo De Amicis, situated in Pietro Gannone street, close to Vanvitelli square, was designed in the 1922 by the engineer Luigi Fabricat, a professional expert, really active during the end of the 1800s and the first years of the 1900s. It took a really long time to build it, because the Public Administration had to face many problems to find the proper land in the middle of the city. Therefore the building was completed only in 1923 after Fabricat's death. The new institute was opened april the 27st , 1937 by the prince Umberto of Savoia. After the war, the school was named after the writer Edmondo De Amicis. The whole school structure is composed by a main part divided in two floors and another one at the back that has only one floor and where the school's gym is placed. The whole surface of the structure measures 8000mq and it takes off part of the reggia's garden. The building on the side that faces Pietro Giannone Street, has some really interesting decorative elements. Those elements are renaissancial and are elegantly integrated into the surrounding environment.

Keywords: Pietro Giannone Street, Edmondo De Amicis School, Luigi Fabricat.

1. Caserta: The link between the urban area with the agricultural area, through Course Pietro Giannone.

At the beginning of the 19th century, the ruling class of Caserta planned a series of works destined to the urban renovation. This plan was carried out by Vincenzo Memma and was included in the *Piano Regolatore della Città di Caserta*, published in 1924, which presented a new road layout together with the construction of social and residential buildings to be realized in a few years[2].

Among the initiatives destined to the general improvement of the urban structure, it was expected a significant reorganization of the roads which connected the city centre to the northern farmhouses of Aldifreda and Puccianiello. It was composed by Sant'Antonio road (the current Pietro Giannone street) and by the road to San Leucio (the current Gennaro Tescione street)[10]. In particular, along this route, which starts from the end of Vanvitelli square until the Aldifreda village, there is a sequence of very important buildings, which are very esteemed for their architectural value: The Edmondo De Amicis school, the Sant'Antonio church and convent, the Sant'Antonio Casino and the Vaccheria of Aldifreda.

The “Casamento della Marchesa” located between the Vanvitelli square and Pietro Giannone street, was described by the administrator Antonio Sancio in the *Platea del Real Sito di Caserta*, written in 1826[1]. Firstly, this building was occupied by the military troops because of its strategic position, near Palazzo Vecchio; secondly, it was restored and became the residency of the Marquise of San Marco, assuming the name of “Casamento della Marchesa”. Currently, this building is occupied by the Croce Rossa offices. The small building inside the court, between the Acquaviva Palace (more commonly

called Palazzo vecchio) and the De Amicis School, consists of two floors and presents a simplified decorative register.

The Edmondo De Amicis School, situated near the previous "Casamento della Marchesa", was projected in 1922 by the engineer Luigi Fabricat, who was considered an important professional both at the end of the 19th century and at the beginning of the 20th century in several building sites of Caserta. The public elementary school, whose realization was included in the application of Gentile's reform, took a very long period to be completed. This delay was mainly due to the difficulties met by the Public Administration in the process of finding possible building areas near the city centre. This construction was finally ultimated in 1935, after Fabricate died in 1927. The inaugural ceremony took place on the 21st of April 1937, in occasion of the anniversary of the foundation of Rome, by the Prince Umberto of Savoia, to whom the institution was initially dedicated [6].

In the post-war period, after the referendum decision of establishing a republican government and the exile of the Savoia family, the school took the name of the famous writer Edmondo De Amicis. The entire built-up area consists, in total, of 8.000 mq, which are subtracted to the Reggia's park. The architectural organism presents a planimetric U-shaped layout with a central garden and a shed to be used as a gym placed at its back. The configuration of the decorative register was inspired to the neorinascimental style personalized by evident references to the solutions already presented in the near Vanvitelli buildings, the Royal Palace and the prefecture.

Straight on Pietro Giannone road towards Aldifreda, on the right side, there is the Sant'Antonio church and convent. The architectural complex of Sant'Antonio was realized on the already existing, and historically stratified, Santa Caterina of Alessandria church, to which it was annexed the Friar Minor Conventuals convent, founded by the count Giulio Antonio Acquaviva in 1575 [7]. It is actually a common belief that the Conventuals created a first enlargement in the XVII century, after which followed a complete transformation in 1783, while the Convent was ran by the Carmelite friars. Firstly, after the French suppression decree, the Convent and the Church's custody came back under the control of few friars of the Carmelite order. Secondly, the administration of the complex passed in the hands of the Royal Administration of Caserta, which reinstituted the building to the Liguori friars for a royal decision in 1823. The early restoration works of the complex, that did not change its dedication to Sant'Antonio, were carried out under the direction of the architect Giovanni Giuseppe del Gaiso, who was chosen by the friars themselves. However, the rapid growth of the community pushed for new interventions in order to enhance the accommodation capability. A further renovation of the complex could date back to 1843; de facto, it was precisely when the dean of the Sant'Antonio church asked for a licence in order to employ some areas of the church as workshops. The church presents a latin cross plant that represents an original interpretation of the congregationalist type adopted also in the other Liguorini Friars ecclesiastical buildings. The altimetric and planimetric dilatation of the transept and of the broad aisle creates a sort of enlargement of the central node towards the altar. This configuration results into a complex space, which is dense and rigorously controlled at the same time; it is based on the differences among the architectural elements. Outside, the prospectus situated along the axis of the current Giannone road is characterized by the external bell towers, defined by an elegant and measured decorative register, articulated in such a way that it reinstitutes the organization of the internal architectural spaces [4].

Still proceeding on Giannone street, there is the Sant'Antonio Casino. The building was projected around the 1795-98 by Pietro Bernasconi, inside an area called Starza Grande, and was commissioned by the Prince Francis of Bourbon. The Bernasconi planimetries reinstitute the building's original articulation, divided into three different structures. The first building, recognized as the Prince's Casino, delimits a small court through two lateral bodies; throughout geometric and orthogonal alleys it was possible to access to a second building that was destined to the processing of agricultural products, situated around a bigger rectangular courtyard[8]. Finally, the third building, which has a smaller dimension and which is placed at the corner, allows the access to an alley to cross the cultivated lands. Actually, what is left from the ancient rural building is just the articulation of the facade, characterized by the false ashlar of the basement and by lessens that decomposes the prospectus with symmetrical and repeated patterns around the entrance portal, constituted by binate pilasters. Unfortunately, nothing remains of the 17th century garden, that presented a spacious parterre which follows a geometric scheme based on a road intersection.

At the end of the Giannone Street, there is the Vaccheria of Aldifreda, projected by Luigi Vanvitelli in 1753, inside a fraction of the agricultural area called Starza Grande [3]. The early testimoniances prove the existence of a building that was a vaccheria in Rifreda in 1751, whose pre-existing features were included in the Vanvitelli buildings[5]. During the French period, the entire building was transformed into a factory to work cotton threads and then was enlarged adding a new structure destined to the clothes cleaning. Around the 1820, the semicircular part was used again as a Vaccheria, limiting the space of the factory. In 1950 the building was transformed into a barracks and the hemicycle was used as a little military hospital, while waiting for the construction of a bigger hospital which is adjacent the San Francesco di Paola church.

Abstract

In the documentation about the building of the Reggia of Caserta, it's possible to find some references to slaves. Muslim slaves who were converted to christianism were placed in a proper dedicated neighborhood that was more comfortable and had a chapel inside it. The new building was placed inside the Reggia's park, not really far from the royal lakes and close to the village of Ercole. Once the Royal Palace was completed, in 1773 Ferdinando IV ordered to set up a unit of volunteers were all from Lipari's Island and therefore they were also known as Liparoti. The volunteer's unit responded directly to the king and it used to assist him during some hunting and fishing activities, as well as looked after the royal goods. During that period, the houses and the chapel were probability restored under the direction of the architect Francesco Collecini. After the volunteer's unit was discharged, in 1786, some rooms of the buildings were used to train peasants, and some others as doghouses. The neighborhood remains abandoned till 1853, when Ferdinando II wants it to be restored to give it the "passionisti" priest. The restoration was directed by Giuseppe Garzia, the lieutenant of the Genio Militare, who also disposed all the changes to turn it into a Convent. Therefore, the church was restored, and two altars were added on the sides. The convent was opened on the 21st of February 1856, and on the 22nd of May in 1866 the government ordered its suppression. After a further restoration a few years later by the Caserta and Benevento's historical heritage superintendence, the building is actually the society of Storia Patria di Terra di Lavoro.

Keywords: Reggia di Caserta, baptizet slaves, village of Ercole.

The churches of the Bourbon in Caserta.

The Palatine chapel of the Royal Palace represents the most famous among the Vanvitelli churches in Caserta[1,3]. Located at the noble floor of the Royal Palace, at the end of the honor grand staircase, and due to the willing of Charles of Bourbon, it is inspired to the similar ambience of the Versailles Royal Palace. The comparison between the two churches results in favor of the Palatine Chapel of Caserta, which is coherent with the entire architectural organism; the Versailles church was instead added to the Palace many years after its construction and for this reason it appears disjointed with the rest of the construction. In reality, the similarities between the two buildings are limited to the generic analogy in the longitudinal, planimetric layouts and in the narrow perimetral ambulatories. Needless to say, considering autonomously the ecclesiastic room would be a methodological error; for instance, Vanvitelli projected this unit together with the other elements that constitute the Palace. The simple spatiality of the Vanvitelli chapel is enlivened by the articulation of the architectural elements and, in particular, by the rhythm of the binate columns that delimit the ecclesiastic room; by the emergence of the elevated apsidal hemicycle; by the prominence given to the gallery reserved for the royal family

overlying the entrance and opposite the altar; by the opulence of the decorative elements, such as the polychromatic marble floor in which the yellow tonalities prevail; by the refined Corinthian order of the columns, by the dense and geometric design of the intrados of the roofing underlined by an abundance of platings; by the wise use of the natural light, introduced in the rectangular compartment by the ample perimeter windows situated behind the columns and by the buttonholes inserted in the vault on axis with the underlying spans.

The construction of the chapel, started in 1757, took a very long time to be realized and the inaugural ceremony took finally place at the presence of Ferdinando IV on Christmas in 1784. The definition of the decorative register is attributed to Carlo Vanvitelli, who ran the execution since 1777 reducing, probably for economic reasons, the pompous decorative apparatus firstly projected by his father.

Nevertheless, the current ecclesiastic area, completed in the XIX century, reinstitutes accurately the spatiality conceived by Luigi Vanvitelli. Finally, what deserves mentioning are the significant damages caused by the November 1943 bombings, when the sacred furniture and very precious paintings were destroyed. This destruction is documented by the marks in some columns, which remained visible also after the following restorations.

Another important building for worship, in particular for its architectural value, realized during the construction of the Royal Palace, is Santa Maria dei Sette Angeli chapel, erected on the side of the Royal Garden inside the Schiavi Battezzati district [2, 3, 5]. In many documents related to construction of the Royal Palace of Caserta, the presence of an important amount of slaves is attested, who were used for their workmanship. They were mainly Maghrebi pirates caught by the Bourbon Marin, lodged together with the convicts inside the Ercole district, where they were constantly controlled by the armed forces. Many of them converted to Christianity, baptizing themselves through a solemn ceremony during which they acquired their godfather's surnames, who usually were important personalities of the Bourbon court. Generally, they were forced to carry out the hardest jobs (hewers of wood, stone carvers, diggers, cleaners etc.); however, some of them were at the service of the supervisors. For instance, Luigi Vanvitelli himself choosed one slave who took his surname and became his personal servant.

Undoubtedly, if we apply our contemporary evaluation criteria, such a condition would appear unacceptable; by the way, taking into account that in the middle of the eighteenth century the slavery was common and diffused, it can be said that the slaves destined to the Bourbon building sites received more acceptable living conditions: they were sufficiently nourished, they received a modest daily wage, and if they decided to convert to Christianity, they could move to a more comfortable quarter, reserved for them and provided with a chapel.

This quarter was located inside the park of the Royal Palace, not so far from the royal fishery and next the Ercole edifice. Once the Royal Palace was ultimated and the slaves returned home, in 1773 Ferdinando IV ordered to place inside the building a department of volunteers from the Marin Unit coming from Lipari island, and for this reason called Liparoti, that was at the service of the King in order to assist him during his activities of hunting and fishing, and to control his Royal Delights.

Probably, in that period the terraced buildings and the chapel were restored under the direction of the architect Francesco Collecini. After the dissolution of the Liparoti corps, in 1786, some of the building rooms were reduced to cellars while other rooms were used as pheasants breedings[3, 5].

After the Bourbon restoration, the area was left abandoned until 1853, when Ferdinando II ordered a restoration in order to offer this location to the Passionist friars. The restoration works were directed by the lieutenant of the Military Genius Giuseppe Garzia, who adapted the building in order to respond to the needs of the Convent. On this occasion, the church was restored and other two lateral altars were added. After the work, the convent was opened on 21 February 1856 but a few years later, in 1866, the Savoy government decreed his suppression. Currently the old eighteenth-century building, restored a few years ago by the Heritage Office of Caserta and Benevento, houses the headquarters of the Society of National History of Terra di Lavoro [3].

The most interesting aspect of the whole complex is represented by the chapel, dedicated to Santa Maria of the Seven Angels for a decision taken by Ferdinando II of Bourbons. The planimetric layout consists of a unique room that presents a longitudinal development. The facade, overlooking the inner courtyard, is decorated with paired Tuscanic pilasters and with a final triangular tympanum. At the centre, there is a simple gate, decorated with stucco moldings and with an ample arched window on the top. This decorative register is repeated, with some variations, in other churches of Caserta built or renovated during the Bourbon period, in particular in the chapel of Santa Filomena alla Flora (currently known as the Aeronautics Sacrarium), in the Sant'Elena church and in the Sant'Agostino church.

The interiors are decorated by Ionic reliefs, attributable to the architect Francesco Collecini, and articulated by three marble altars. The main altar was adorned with a picture portraying the Virgin Mary surrounded by seven angels that are no longer present. The floor paved in painted tiles of terracotta present an exquisite craftsmanship and was produced in the Santa Maria's furnaces. The area in front of the church is bounded by the low districts that were used to accommodate the slaves, while on the side of the road it is located a unit with two levels, that corresponded to the nineteenth

century convent. Next to the building, near the San Vito Martire church inside Ercole hamlet there was another building to accommodate the slaves, which no longer exists.

The chapel of Santa Filomena alla Flora, that was originally dedicated to Our Lady of Mount Carmel, was built in line with a project by Carlo Vanvitelli short after the construction of the Reggia in the early nineteenth century [4]. In 1806, the architect gave the opportunity to work on the surrounding area in order to improve the traffic flows and the road system towards the city centre; however, the renovation of the area was realized only in 1828, with the opening of the Royal Riders road [4]. In 1806, Carlo Vanvitelli ordered reliefs and site surveys to examine the ground upon which building the Chapel and, after then, carried out a project which involved a trafficable area with a widening in front of the church connected to the urban road network. This urban planning scheme was implemented only in 1828, with the opening of the Royal Riders road. The availability of an undeveloped area allowed the architect Carlo Vanvitelli to adopt the Reggia layout of the Round, not very common in Vanvitelli ecclesiastic works but already used by Luigi Vanvitelli in the chapel realized in the barracks yard near the Maddalena Bridge in Naples. A particular introduction to the main decorations used in the ecclesiastic building with central layout has been also founded in a drawing attributed to Luigi Vanvitelli depicting the allegory of the Religion, represented by a female figure that sustains a small centric temple with an extrados dome, assisted by the dove of the Holy Spirit, wrapped with a cope while she stepping on two books named "Luther" and "Calvin".

The church was completed by the end of the first decade of the XIX century and, in order to limit the costs, during its realization were used some ornamental elements coming from near buildings that were no longer used: the marble altar and the bell were dismantled in 1810, under the direction of the architect Bernasconi, from a small church located in the Royal Grove used by the workers encharged for the maintenance of the Royal Peschiera; the Majolica tiles of the floor, instead, were taken from the Royal Palace rooms in 1814, under the direction of the architect De Lillo. As already said, Carlo Vanvitelli adopted for the small church, originally destined to the religious instruction of the children, the layout Round. From the outside, it was articulated by a plain Tuscanic order and by the bell tower, over the fencing wall; while from the inside it was articulated by three altars delimited by cabling semi-columns and by a continuous entablature that supports the small cover divided into geometric mouldings and decorated by six pointed stars surrounded by a crown of leaves. Inside the chapel, four small compartments are taken from the ring-shaped masonry o contain three altars and an entrance. A sober cornice transforms into units the portions of the curved wall and link the niches with the altars. The coverage, realized with a sail vault and sustained by four pairs of Tuscanic columns placed against the wall, it is adorned with arching lines and geometric panels, with the six pointed star and surrounded by the crown of leaves, a solution which is similar to the one used in the SS. Trinità dei Pellegrini church in Naples.

Beyond the cornice, there are two windowed lunettes, decorated with the usual pattern of the Vanvitelli "shell", while the triangular tympanum at the main bottom supports two winged angels.

The position and the shape of the building underline its "linking" function between the Reggia and the city, while a simple interplay of colors highlights the rectangular panels that constitute the whole external building surface.

Around the Royal Palace of Caserta: the new market square

Pasquale VAIANO

Ph.D. student, Dipartimento di Architettura e Disegno Industriale "Luigi Vanvitelli", Seconda Università degli Studi di Napoli, Aversa, Italy.

pasquale.vaiano00@gmail.com

Abstract

The actual Matteotti Square was realized in postunification period with the construction of the foodstuffs market and is situated on the northern part of the urban area built in the nineteenth century. The new headquarters for fair activities replaced the, previously one held in the square in front of the old palace of the Acquaviva, which was transformed in 1879 into the main square of the city dedicated to Luigi Vanvitelli. This new market involved the construction of an intriguing masonry building used for the daily sale of foodstuffs. On the opposite site of the shops, the large quadrangular space of Amedeo Square (now Piazza Matteotti) was intended to accommodate the weekly fair. At the beginning of the twentieth century, the new market's area established the urban sector placed to the north of Ferdinando avenue (then named Umberto I). During the 1920's, new residences for ICP (Istituto Case Popolari) were built over the market stalls. In 1937, the Casa del Fascio, designed by engineer Giovanni Campopiano, was built on the northern side of the new During the Fascist period and in the years following the square experienced radical changes in relation to the various functions performed. In the second half of the twentieth century the central area of Matteotti square has hosted a fair twice a week until it was replaced by a new foodstuffs market opened in 2008.

Keywords: foodstuffs market, urban planning, Caserta, casa del Fascio, weekly fair.

1. The market square

The market held in the city since the time of the "Villaggio della Torre", has played a key role in the urban development of Caserta, occupying the central areas of the buildings [1,5,6,8,10]. The market square was born following the decree of King Ladislao of Durazzo issued on 9 February 1407 [2]. Since that period and until the late nineteenth century the area in front of the count's palace hosted the local weekly fair. For about a Century preceding that time, the sellers of fresh edible farm produce had not been able to find a stable place in which to hold a regular market, in fact previously they were sold along the roads leading to the market square, at the "Trivio" and in a provisional square built in the garden of a building in Mazzini street. Due to the decision to devote the market square to Luigi Vanvitelli in occasion of the centenary of his death, a permanent home for the daily market in what is today's Piazza Matteotti was created. In 1894 a building designed by the Casertan engineer Arrigo Veccia was constructed of masonry for the use as a Market hall [6]. The need to find an appropriate place for the markets (both daily and weekly) held within the city using permanent structures is documented by numerous incomplete projects, produced from 1765 to 1890. The first project for a building to be used as a market was raised by the Royal architect Luigi Vanvitelli, who in 1765 decided to eliminate «[...] the previous wooden structures, due to their inaccuracy and indecency spoiling the aesthetics of the Royal Palace» and built in their place «[...] solidly constructed shops (starting from the top of the square along the road that leads to Carmine, with an open semicircular form with a view to the Royal Palace. In order to build a more comfortable covered area the inner part of the semicircle building was dedicated for public use whilst the outer circumference of the semicircle small shops where designed to store the merchandise». A letter sent by Vanvitelli to Lorenzo Maria Neroni (land agent of Caserta) refers to two drawings prepared by the architect, a "small one" with the

Fig. 1: Giovanni Battista Patturelli project for the new covered market.

representation of the workshops and related measures (12 spans in height and 20 spans in width corresponding to 3.1 x 5.2 meters) and another drawing "a larger one" «[...] which relates to the building with its elevation» [18,19]. Unfortunately, these drawings have not been found, however, from the brief description of it, we can see similarities with the design of the Mercatello square in Naples, formed by a semicircle of twenty-two brick built shops with apartments above, made by Vanvitelli in 1761 [12]. The Architect drew up the computation of the Casertan buildings, stating that they could be amortized in a short time from the rental income created by the shops situated within the building. However, this was not implemented because at that time there wasn't the available funds [9]. The missed execution of Vanvitelli's project transferred the problem to the successive City administrators. Between 1820 and 1825 the Caserta Mayor Vitelli, appointed Giovanni Patturelli as the architect of the royal buildings and he was appointed for the preparation of the project to adorn the square and streets around the Market Hall, whilst he had already been previously engaged in the design of the new cathedral [3].

The architect drew up the design of the square by arranging to level the area and created a working wooden model of the fountain which was to be built in the center [20,21,22]. In 1825 the Decurionate commissioned the royal architect Teodoro Paolotti to enlarge and beautify Trivio street, by improving the regularity of its condition and also to design a square for the sale of foodstuffs [4]. This project also remained on paper, whilst a temporary solution to the problem was found for the food market it was decided to take advantage of a wide open space surrounding the existing new Main (Maggiore) Cathedral that was used as the venue for the day to day business [7,23]. Later, another Patturelli, Giovanni Battista (the last of the twelve sons of the aforementioned Giovanni [3]), drew up a new project for the construction of the market, documented by an autobiography and sent to the king in 1848, and by some charts kept in the Archive of the State of Caserta [24]. Patturelli configured a building divided by the axial sequence of three courtyards with a fountain in the center of each, ordering the shops around these built up to the perimeter of the plot. Access to eighty proposed shops was provided directly via the urban roads from the North (limited by a newly built road) and to the West (limited by the existing Trivio street) and by the covered area arranged around the courtyards inside the building.

Pianta di un Mercato di commestibili da costruirsi in Caserta nel luogo detto Trivio.

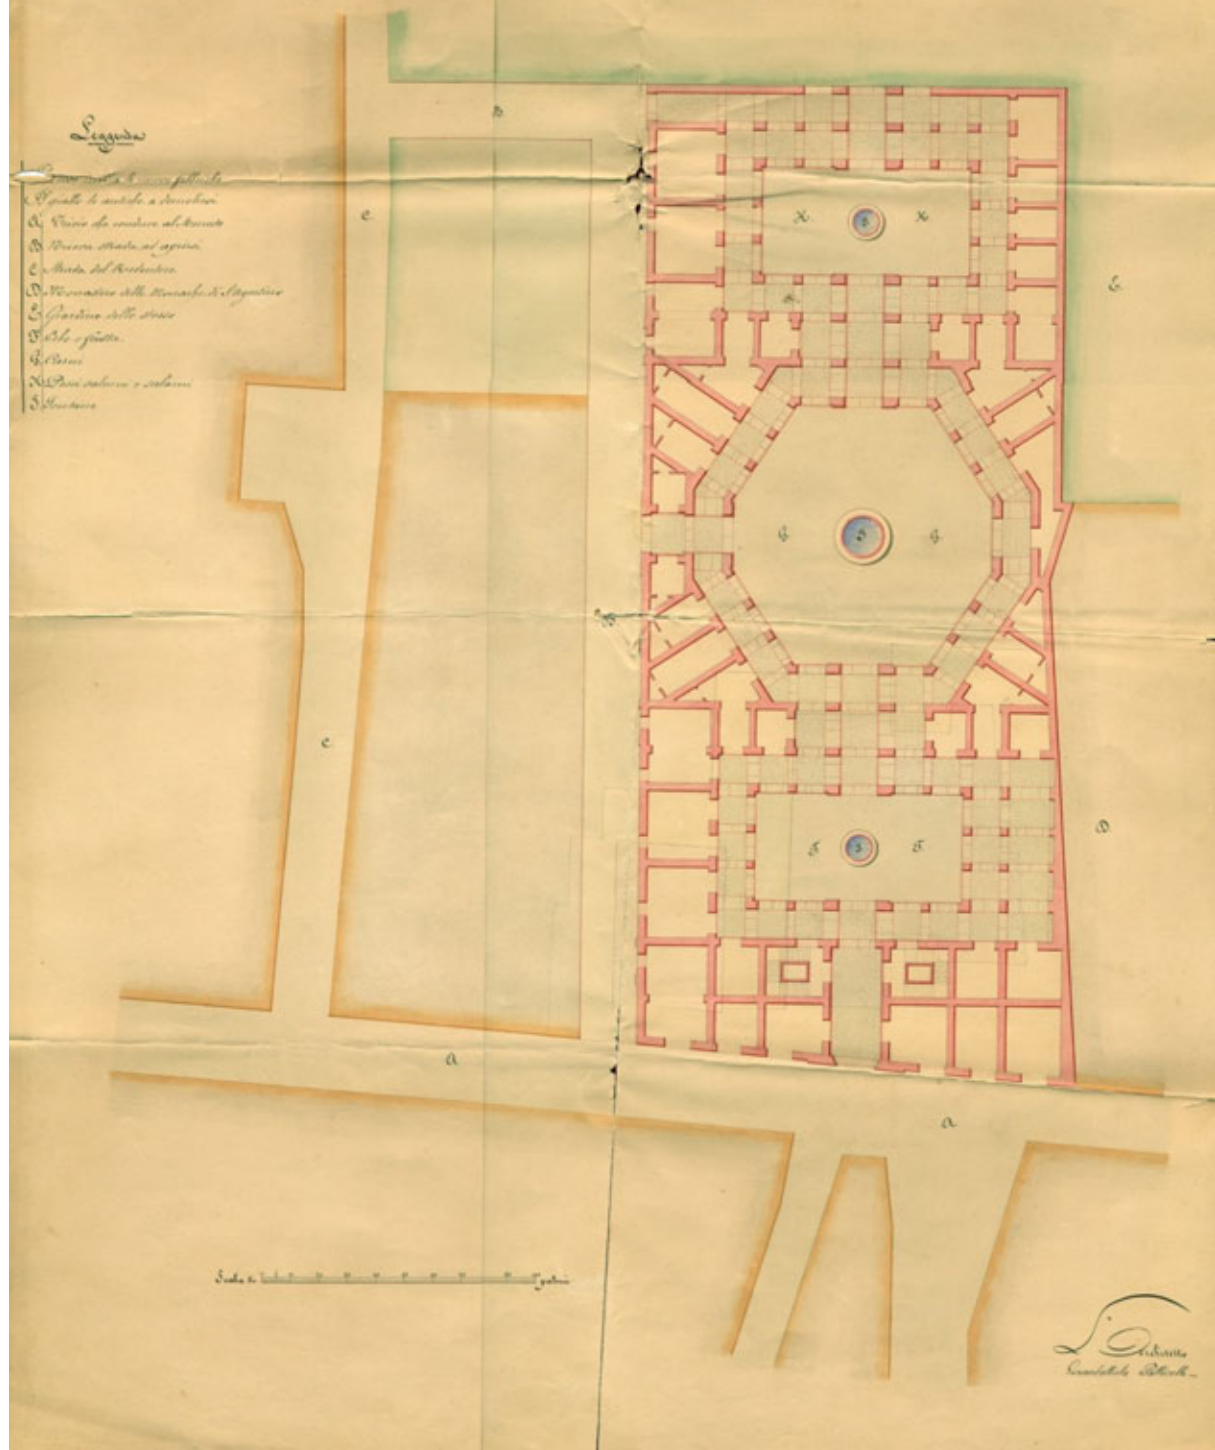

Fig. 2: Giovanni Battista Patturelli project for the new covered market.

Fig. 3: Arrigo Vecchia, the central part of the facade.

The Central element of the composition was a large central octagonal space divided symmetrically along the longitudinal axis around the median with a fountain situated in the center of the architectural composition. The elaborated planimetric's articulation contrasts with the elementariness of the main front in "via del Trivio", characterized by "muratura listata" of the ground floor and by the simple moldings of the windows situated at the first floor. Its central sector, which includes the tilt of the main compartment, it is strengthened by "listatura" extended to the floor, framed by Tuscan pilasters, and the crown set upon a thick sequence of shelves. Ultimately, the geometric register inspired by Renaissance, depict a whole characterized by a moderated elegance, which appears appropriated to the requirements of an architectonic adornment necessary to a public building. However, in spite of a first approbation, the citizen Decurionate denied the execution of the work, maybe with the flimsiness of the previous and well-known disagreements with Giovanni Patturelli on the occasion of the cathedral's construction [25]. In 1850 the Decurionate entrusted a new project to the architects Domenico Rossi and Gaetano De Lillo, which graphic arts, all the same, are unknown, such as the ones edited by Francesco Di Napoli and Francesco Tramunto in 1861 (modified by Di Napoli himself and Vincenzo Mongillo in 1867), by the technicians Contenoire, Rombie and Tarantino in 1869, and by Pasquale Toscani and Giuseppe De Lillo in 1875 [7]. It's supposable, even if it's not possible to comment the architectural and urban quality of the mentioned projects, that their failed realization is due to the problems tied to the expropriation of the chosen area, probably the one identified in Giovambattista Pitturelli's project. The new seat for the market's task, which took place in the square in front of the ancient Acquaviva's palace since the Four Hundred, was transformed in the main square of the city dedicated to Luigi Vanvitelli in 1879, and required the construction of a masonry building, notably interesting from an architectural and urban point of view, which was assigned to the daily sale of foodstuffs.

In 1894 the engineer Arrigo Vecchia, planned the new daily market, composed of two buildings – one in the shape of the C letter and one in linear shape – located at the east side of the square dedicated to the ancient market (now Piazza Vanvitelli), linking it to the bordering areas by a trident of new streets, composed, from north to south, from via Bologna (now via Battistessa), via Genova (now via Alois) and via Firenze (now via Crispi), joined to the curvilinear route of via Principessa Maria del Belgio (now via Turati). Opposite to the small stores, the wide quadrangular area of Piazza Amedeo (now Piazza Matteotti) was destined to host the weekly fair.[14] The project, that for its urban arrangement of connection to the preexistent road conditions, recall the "Tridente" projected by Luigi Vanvitelli for the elliptical square in front of the Reggia, [13] predicted the construction of masonry buildings realized through technique production methods and traditional taste, joined together by modern platform roves realized with iron and glass, covered by pitches which incline towards roof gutters, confluent into empty pillars, joined to an underground system of discharge [26]. During post-war years, the necessity to achieve new low cost buildings, led the Institute "Case Popolari di Caserta" to extend the structure of the daily market, using a ground elevation with the purpose to host new accommodations addressed to the less well-off. In 1924 the engineer Luigi Fabricat projected the restoration of the nineteenth-century's built, transforming it into a three-storey built, made up of seven blocks functionally autonomous; each of them is provided by a central staircase, serving two apartments.[15] In this way, the interior public spaces, destined to the commerce, became a closed courtyard, useful to the real estate, while the access to the small shops – some of these were destroyed to allow the

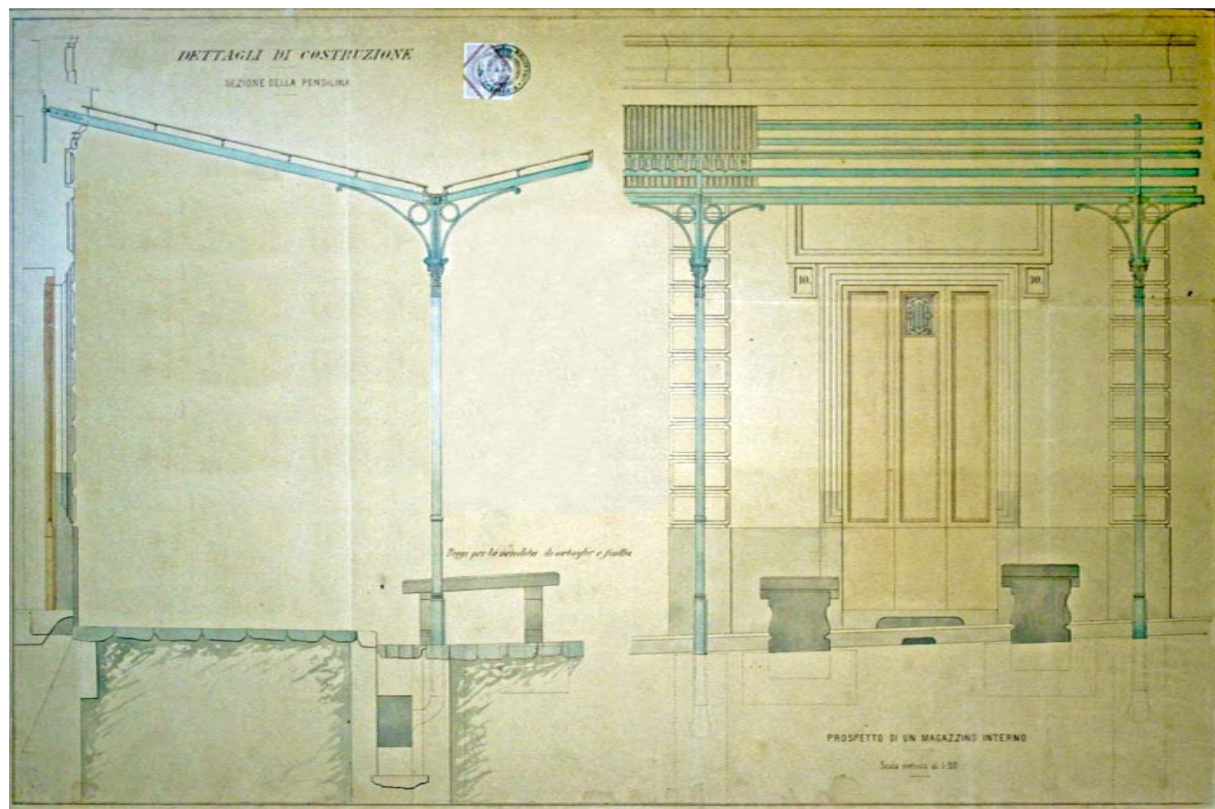

Fig. 4: Arrigo Vecchia, the construction details.

staircases construction – was moved to the external side. Bureaucratic difficulties held the realization of the work, seeing as the contracting firm interrupted its activity in 1925, because of economic problems. Labors were committed to another firm, restarted in 1927 and concluded in 1929.

The initial project was substantially modified by Memma – succeeded to Fabricat, who died in 1927 – to restrict labor costs. For example, was decided to reduce the staircase constructions (from seven to three) and to replace the platform roof with a reinforced concrete landing. At the end, some apartments' entrances were disposed next to the staircases while the other ones were disposed next to the spectacular external landings. By the way, the external landing's continuity was interrupted by the following addition of other parts of it to the residences. On the other hand, the aesthetic of the inner spaces definitely improved thanks to the double arcade, opposed to the building in the shape of the C letter, supported by pillars "a stampella" out of the low ground, and corbels "a gattoni" anchored to the first floor's masonry, both made of reinforced concrete and delimited by an elegant parapet made of masonry. During the immediate post-war period, the building damaged by bombardments, was fixed rebuilding the central part of the main building and realizing a second floor above the isolated house in piazza Amedeo, projected by the engineer Luigi Giaquinto, while the elevation of a third floor above the portion of the central street of the trident (now via Alois) wasn't realized because of economic problems [16].

In addition to the changes of the building, there are changes brought by the lodgers to the internal apartments, the group of "Piazzetta Commestibili" represents one of the best expression of the local architecture of the first twentieth century. Therefore, the conclusion of the restoration of the building, still in action, appears as a target that absolutely has to be reached to improve the character of a crucial area for a urban structure, qualified by the latest recycling of "Casa del Fascio", but impoverished, on the other hand, by the ugly structures of the new daily market in piazza Matteotti. The urbanization of the area began again at the end of the thirties with the construction of the new domicile of the "Confederazione Fascista dei Lavoratori dell'Agricoltura", projected by the engineer Giovanni Campopiano in 1937, arranged on the north side of the square, made up of a two storey house, communicating through a great posterior wing, used as a fruit and vegetables market.

The main entrance at the low ground includes a great central vestibule and four lateral settings; in one of these settings was located the staircase which led to the upper story. The same model recurred at the first floor, with a great salon in the middle and four lateral settings. The great posterior sitting room was divided into three parts by a row of reinforced concrete pillars, with the lateral areas lower than the central one.

Fig. 5: Palazzo Commestibili facade on Vincenzo Crispi Street.

Fig. 6: Palazzo Commestibili interior courtyard.

The building, answering to the description of architectural character based on the functionalist rationalism of Fascist's work, defined the expansion area at the East side of the city, establishing an ideal limit to the road axis of via Vincenzo Crispi, connecting it to piazza del Vescovado. When the work was almost finished, the "Federazione Fascista di Napoli" obtained the property of the entire complex, converting it into the "Casa del Fascio", because of the building size and its location in the great city square. The new project by the engineer Campopiano and Maglio, developed co-operating with the "Ufficio Tecnico della Fondazione dei Fasci di Combattimento di Napoli", was definitely approved by the Segretario Federale Amministrativo di Napoli in 1939 [17].

The change of purpose, led to a reflection about the locations and the connections among them. The central salon turned into a council room and a gymnasium, while the lateral settings were erected to obtain offices. Contemporaneously there was a second thoughts about the configuration of the view that appears on the square, with the building of the typical central tower, which middle balcony could have been used as a stage for possible assemblies in the opposite area. All that legitimate the special care devoted to the external hangings, all the same, because of a restricted financial difficulties, in the lateral areas the building was covered with a plaster panels dyed with a color similar to the local tuff (yellow), instead the tower and the pillars of the arcade were dyed with a color similar to the tuff "pipernino" (grey). The important building, still dominant in piazza Matteotti, has been restored by the architect Raffaele Cutillo in 2009, consolidating the structural elements and redefining the functionality using modern technologies and materials, but preserving the authenticity of the original aesthetic characters [11]. The bi-weekly market, before hosted in piazza Matteotti, moved to via Ruta since the eighties of the last century. Finally the arrangement of piazza Matteotti ended with the construction of the new covered market, projected by the Ufficio Tecnico Comunale and inaugurated in 2008.

This structure, which tripartite and wavy roof is the most connotative element, can be considered as a failed attempt to update the urban environment of the square, inserting new elements marked by a current architectural code. The disposition of the volumes of the new covered market, shows a redundancy marked by the inappropriateness of heterogeneous materials used for structural elements, which appears assembled illogically. The mediocre quality of this building impoverishes the unanimous quality of the pre-existent urban fabric, breaking architectonic and urban balance configured by twentieth-century interventions.

Rural Campania: from the Pantano of Sessa Aurunca to Centore village

Giuseppe Mario INFANTE

Architect. City of San Cipriano d'Aversa (CE), Italy.

Giuseppe988m@virgilio.it

Abstract

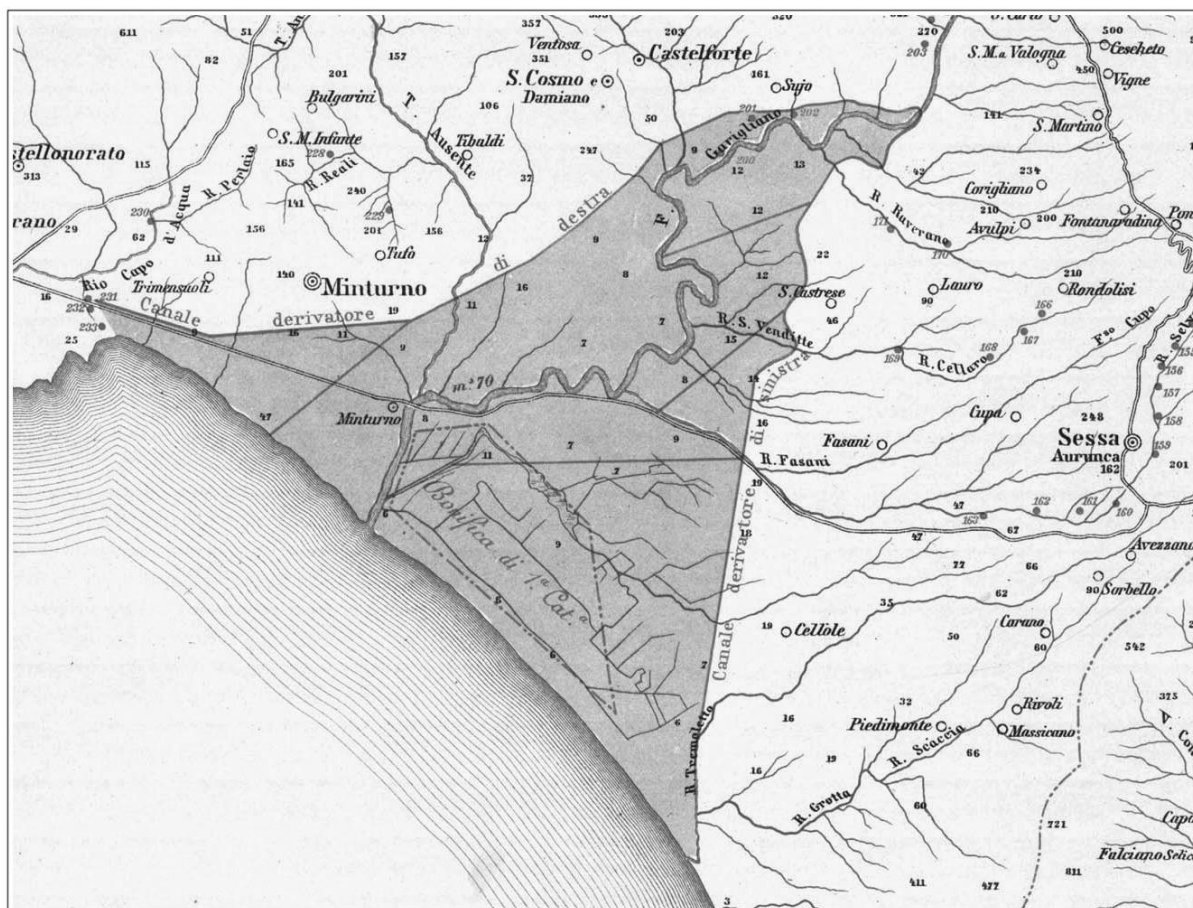

In the fifties of the XX century, after the preliminary operations of land reclamation of the Campania territory of the *Basso Garigliano*, the *Sezione Speciale per la Riforma Fondiaria* built some farmhouses and a rural village named *Centore*, a service center for settlers of the neighboring farms, located on the *Domiziana* street. The village was composed of a church, a bar, an ambulatory, a tobacco factory, a dairy shop, a cheese factory, a professional Institute of agrarian, a service center for agricultural vehicles, a football pitch, a nursery and an elementary school. In 1958, on the occasion of the exhibition of the Italian poultry, in the park of *Caserta* Royal Palace were exposed some models (in miniature) of colonial houses built in the area of the *Basso Garigliano*. In recent years, the complex of village *Centore* was considered, after the attention and scrupulous observation by the municipality of *Cellole*, a residential core of historical interest to be protected. Moreover, it is also considered for possible projects that could propose the functional recovery of disused structures. Currently, the most of the buildings are still used, including the church dedicated to St. Catherine of Alexandria and the restaurant.

Keywords: Garigliano, Reclamation, Pantano (Quagmire), Cellole, Centore.

1. The reconstruction of historical phases and ideas for the restoration of the rural village.

This contribution dedicated to the study of *Centore* (in province of *Caserta*) is part of a larger work conducted by who writes on the colonization of the *casertani* territories during the fascism and after the world war II. We intend to disclose, on the international cultural scenery, the history of the land reclamation of the plain of *Garigliano* in the XX century, reconstruct the phases of its colonization by the *Consorzio Aurunco di Bonifica* [1] and by the *Sezione Speciale per la Riforma Fondiaria* and investigate the potentiality offered by the area in terms of socio-cultural development. For historical research, was recovered archival and bibliographic material, from the archives, libraries, public bodies and private institutions of *Rome, Naples, Caserta and Salerno*. In particular, in some offices were found documents [5] (in some cases saved from waste by passionate employees of history of the territory) and historical photos, such as those relating to the *Manifestazione Avicola Nazionale* of October 5th, 1957 of *Caserta* city [11]. On that occasion, in the park of Royal Palace there was an exhibition characterized by the presence of some prototypes of colonial houses built (as we will see later, in this paper) by the *Sezione Speciale per la Riforma Fondiaria* in the *Basso Garigliano*. No less interesting are the other photographs that immortalize the land, farming vehicles and the lifestyles of the population in those years.

In the early years of the twentieth century, in the vicinity of the estuary mouth of the *Garigliano* river, were present some marshland areas known as *Pantano di Sessa*, *Pantano di Minturno*, *Pantano Doccia* and *Pantano Corso* [2] which were part of a area of reclamation directly controlled by the Italian State. In 1901, a commission of experts prepared a general project, then modified, to ensure the land reclamation of the vast territory, with the restoration of drain ditches (high and medium), whose disordered regime did not allow complete drainage of water from the ground, thus worsening the hydraulic conditions of the depressed areas, near the coastal dune [7]. In the period 1910-1912, to restore the marshy areas of the district, the *Genio Civile* (of *Caserta* city) built the pumping station of *Punta Fiume* which was obsolete respect to the technological possibilities of the time [3].

In the twenties, the *Consorzio Aurunco di Bonifica* was founded and on the February 24th, 1929 it presented a preliminary project of the land reclamation of the area of its jurisdiction, for an amount of work equal to *Lire 33.500.000* [7]. In 1931, on the initiative of the *Società Garigliano* was studied the modality to irrigate part of the district, in both the sides of the river, for a complex of approximately 6000 hectares [7]. In the same year, the *Consorzio Aurunco di Bonifica* appointed the *Milizia Forestale* to study the reforestation of the coastal strip to protect the countryside from the sea salt and for this reason were planted different types of trees, such as: *Pinus pinaster*, *Pinus pinea* and *Populus alba* [7]. In subsequent years, the consortium made other works and potentiated the pumping station of *Punta Fiume*, replacing the old steam engines, no longer efficient, with new ones, powered by electric energy [7]. At the end of the thirties of the twentieth century, various consortia including the consortium *Aurunco*, soon joined and became the *Consorzi Riuniti della Bonifica Campana*. Subsequent, in 1940, this new company presented a plan of land division of the area of the *Pantano di Sessa* and for surrounding, approved by the ministerial decree number 6440. The second article of the decree stated that the area had to be divided in unit, of width, respectively, from ten to five hectares, depending on whether it was private property dominated by the irrigation canal or if it belonged to the municipality of *Sessa Aurunca* [7]. In particular, the plan of transformation included the construction of three types of farms (provided with farmhouses and outbuildings), one for the *Pantano di Sessa Aurunca* and two for the outside areas. The type of farm called *podere del pantano* had to be constructed on a ground deep, fresh, and rich in organic material, belonging to the municipality and subject to an unspecified civic use. In addition, its extension had to be minimal and sufficient to guarantee an agricultural product capable to feed the farm family and the payment of the respective taxes. The farm type one, instead, of ten hectare, was to be devoted to mixed crops, with important breeding livestock. Finally, the type of farm named *Sussidiario* or *predunale* had to be built on sandy land less fertile located close to the coast and a part of its surface had to be grown with vineyard. Moreover, for each of them were studied four types of houses, all with two levels, with the ground floor consisted of a kitchen, the upper one of bedrooms and toilet, then, there was also a porch, a stall, a silo for fodder and outbuildings. All four types, according to the guidelines of the *Consorzi Riuniti*, had to be simple in the distribution of the parties, disposed on farms in order to avoid any unnecessary fatigue for the carriage of goods or equipment, airy, bright, friendly and relaxing and the most important thing is that the houses should have arouse in the farmer's heart, love for the countryside [7].

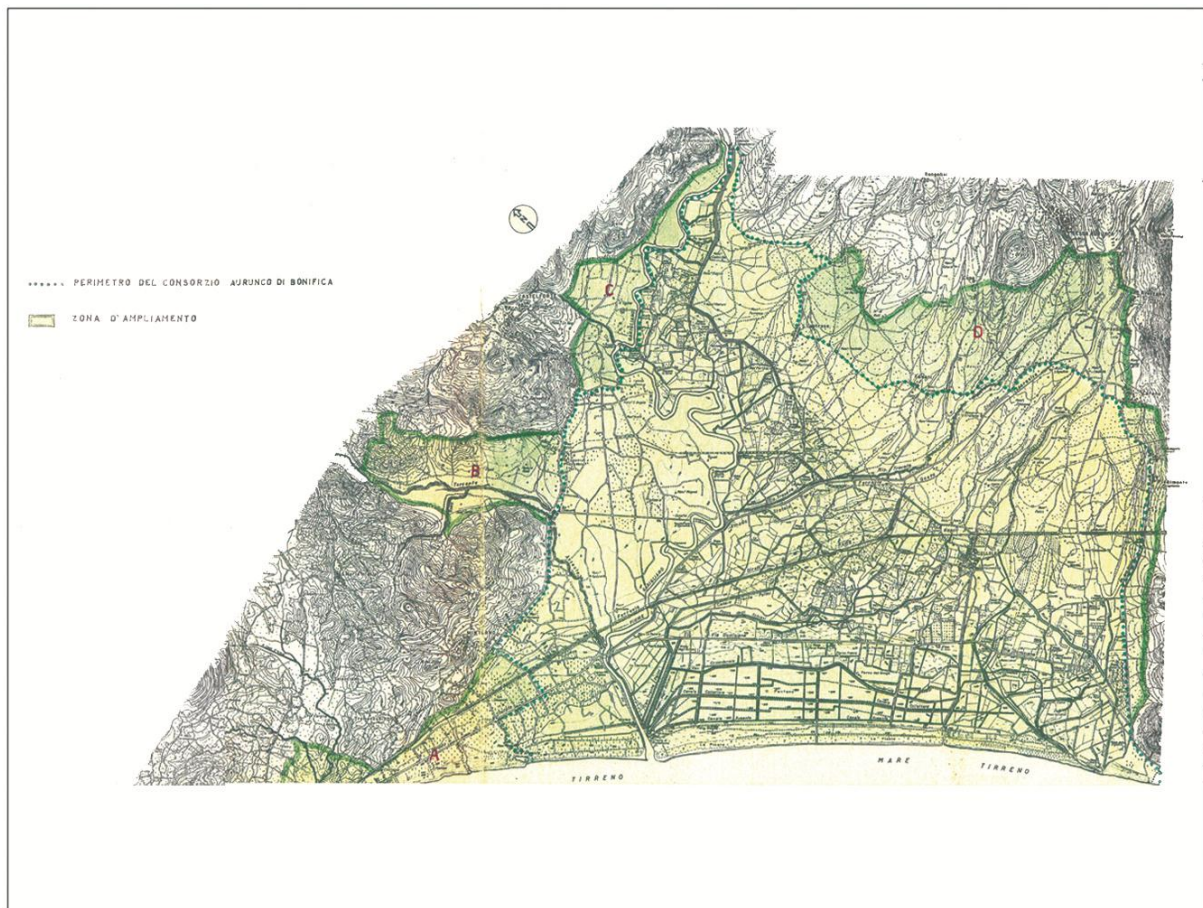

Fig. 2: the perimeter of the Consorzio Aurunco. Prof. Nallo Mazzocchi Alemanno.

In addition, to guarantee the life necessary conditions of the farms, the construction of new rural centers were not calculated since the existing ones were considered to be sufficient, such as: *Cellole* (now, an independent town), *Piedimonte-Rivoli*, *Carano*, *Fasani* and *San Castrese*, but the possibility of having to build others villages successively was not excluded, especially near the *Pantano di Sessa Aurunca* [7]. However, this plan of land transformation drawn up by the *Consorzi Riuniti* was not appreciated by several unitholders renters of plots of the *Pantano di Sessa* and probably also for the physical and verbal clashes between them and the public administrations, this proposed transformation plan was not put into effect [13].

In the fifties of the twentieth century, with the laws *Sila_104/1950*, *Stralcio_841/1950* (entitled, *Norme per la espropriazione, bonifica, trasformazione e assegnazione dei terreni ai contadini*) and *Regionale Siciliana_104/41950*, some Italian agricultural areas were placed under the agrarian reform, including the plain of the *Garigliano* [13;15], near the *Pantano di Sessa Aurunca*. The purpose of the laws, according to the provisions of article 44 of the Constitution of the Italian Republic, was to intervene in some areas of the peninsula where there was still the problem of a monopoly of the land (*latifundium*) or there were situations of particular social hardship and of extreme fragmentation of the management system of private land [19]. In the plain of the *Garigliano*, in the locality *Centore*, near the former *Pantano di Sessa*, the regulations were implemented by the *Sezione Speciale per la Riforma Fondiaria*, a public body established at the *Opera Nazionale per i Combattenti* [10] with the decree n.70 of 1951, the same law that defined the scope of its intervention in the municipalities of province of *Caserta* as *Cancello Arnone*, *Castel Volturno*, *Capua*, *Grazzanise*, *Santa Maria La Fossa*, *Vitulazio*, *Villa Literno*, *Carinola*, *Francolise*, *Mondragone* and *Sessa Aurunca*; and those in *Salerno* area, as *Albanella*, *Altavilla Silentina*, *Pontecagnano-Faiano*, *Battipaglia*, *Capaccio*, *Eboli*, *Giungano*, *Serre e Trentinara* [6]. The agrarian transformation of *Centore* (placename which according to the researcher *Giuseppe Tommasino*, depends on the fact which in that area there was the hundredth milestone of the Appian street) [9] was implemented with the construction of about fifty farms of the total area of hectares 226, served by colonial houses, by infrastructure and by a service center, probably, first called *Borgo Clanio*, then *Borgo Centore* (in Italian language), as the name of the locality in which it was built. The Farms, the colonial buildings and those for unitholders were designed according to criteria of economy and simplicity, but ensuring a respectable settlement for the farm families. Moreover, these farms, even though built in the countryside and therefore far from existing community

Fig. 3: Sezione Speciale per la Riforma Fondiaria in Campania: chorographic map (Garigliano).

centers, have allowed to those families to feel fulfilled since they could count on the services (municipal delegation, offices, churches, schools, etc.) offered by *Centore* village that was a point of reference for farmers. From studies of that period conducted by the *Sezione Speciale per la Riforma Fondiaria in Campania*, the village had to offer public services to about 1.000 people in the surrounding rural land characterized by an area of 2,700 hectares of which 226 divided from the *Sezione Speciale*, 135 divided into lots and the remaining in private ownership [12]. An initial project of the *Centore* village, from what emerges from a planimetry constituent a private collection of documents [4], is dated 1955 and drawn by the engineer *Claudio Corini*. Of this plan, we notice that the main village square, triangular, was to be built at the intersection of the streets *Domiziana* and *Pietre Bianche*. In the same years, was designed the final project, in it is obvious that the perimeter of the village is almost a quadrilateral circumscribed on three of the four sides by the following streets: *Domiziana*, *Pietre Bianche* and *interpodereale Centore*. The main entrance to the village is located on the *Domiziana* street, from which you can admire its main square of trapezoidal shape, dominated by flower beds, pine trees and from the church dedicated to St. Catherine of Alexandria [18] with its bell tower, a building certainly of architectural interest. In addition, on the same square there are the former elementary school (today, hotel management school), the bar and infirmary (today, bar and restaurant) and the former office of the *Ente di Riforma* (today, highway police station). The Church, slightly raised above street level with a base, has a rectangular plan and a single nave ending with a semicircular apse. Its facade has a large arched portal and a series of vertical cuts on the top [5;18], the inside is very rational and enlightened by a series of openings at the top, the roofing is composed of wooden trusses. In the decentralized position of village, there are some abandoned buildings, accessible by internal road network, among which we distinguish the former tobacco factory of the cooperative *Santa Caterina*, the former cheese factory, the former service center for the agricultural vehicles, a vocational institute inside a former experimental farm [8] and a basement theater built recently, that apparently gets flooded during heavy rains. In addition, from what emerges from a magazine of the 1988 named *L'Achitettura*, *Centore* village has been a topic of interest for a contest sponsored by the *Ente di Sviluppo Agricolo in Campania*, which concerned the design of a public park for the promotion and the safeguard of agriculture [14]. Finally, a few years ago, the whole village of *Centore*, after the attention and scrupulous observation by the municipality of *Cellole*, it was considered a residential center of historical interest to be protected. It was a correct decision if you think that the village was built just after World War second and reflects a particular historical phase of

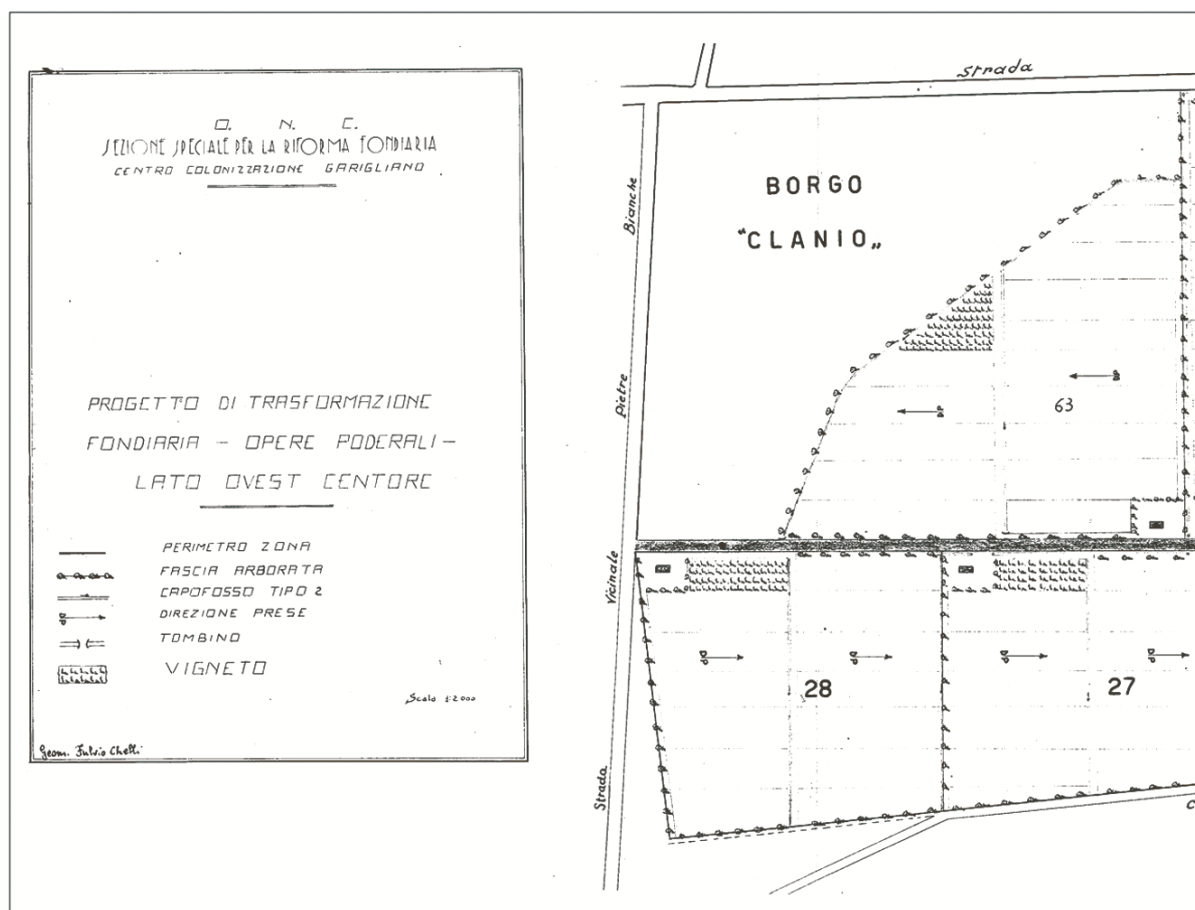

Fig. 4: Sezione Speciale per la Riforma Fondiaria in Campania: Centore land transformation, surveyor Fulvio Chelli.

the territory. *Centore* village, is now a place easily accessible from the *Domiziana* street, that connects the province of Naples to the *Basso Lazio*, a reference point and stopover for tourists and truck drivers from *Naples* and *Caserta* and directed, through aforementioned street, to the various companies of the area or to the renowned beaches of the *Basso Lazio*. The village is very busy at rush hours, in the summer and on Sundays, in addition, it is also considered for possible projects that could propose the functional recovery of disused structures, some of which have already gained a new use, for example, in the former offices of the *Ente Riforma* there is the highway police station; in the structure of the former elementary school and that of the old dairy has been placed the branch of the Hotel Management School of the city of *Teano (Caserta)*, which differently from many other Italian schools situated in critical areas with heavy traffic, can enjoy of a relaxing geographical context for pupils, characterized by numerous trees and green areas. However, some buildings have not yet found a new destination for their use and are in a pitiful state of disrepair, it is the case of the former service center for agricultural vehicles, the former dairy factory, the former tobacco factory and the former agrarian institute. Future projects for functional recovery of abandoned structures must have as its objective the protection of economic interests and to appreciation the area. In this sense, the possible opportunities for economic development, of tourism and culture offered by the geographical location of the village are many, considering that it is located in an area of outstanding scenic interest. In fact, just a few kilometers away we find the natural park of *Roccamontina - Foce del Garigliano*, the archeological city of *Minturnae*, the historical center of *Sessa Aurunca* and the *Ager Falernus* with its wines known since ancient times [20]. In addition, it would be interesting if in one of the abandoned structures (such as the former agricultural institute) will built a library and a museum of land reclamation and colonization, a place characterized by books, photos, documents and models of reconstruction of the works of transformation of territory, in order to pass on this particular segment of history to future generations. Finally, we hope that all these initiatives can ensure the protection and enhancement of these artifacts, without forgetting the existence of other rural villages situated just a few kilometers from *Centore*. These include, *Domizio* village (unfinished) in *Castel Volturno* town and *Appio* village [16;17;18] in *Grazzanise*, both built in the late thirties of the twentieth century by the *Opera Nazionale per i Combattenti*. These villages have undoubtedly a high historical and social value but are destined to perish if we continue to neglect them, for this reason, will be necessary new ministerial measures for consider these as assets to be protected, just as it has been for the *Centore* village.

Subsidiarity and sustainability as a widespread cross-cutting approach to different anthropocentric events and aggregations: land government, fiscal federalism and geo-intelligence as international heritage of knowledge, scientific progress, land government and law enforcement policy

The legislation ruling the territory consists of a complex set of technical, administrative, environmental and fiscal laws. The government operator needs the support of the most advanced scientific research knowledge in order to enforce administrative, criminal and taxation laws. Tax legislation extends its field of application in environmental legislation and must be considered a suitable instrument to anticipate and maybe avoid the complex criminal case of environmental disaster. The trio made by science, technology and taxation can be a solution: it should be established a background of knowledge generated by the synoptic representation of high density and multidimensional datas. A shared, total and diachronic knowledge of a territory allows an effective management and sustainability of its own exploitation. Scientific and governmental interlocutors in the survey, knowledge, analysis, representation, defense and requalification of the territory should be a triple point for all human beings. The scientific knowledge, law enforcement and repressive powers, should converge to outline standard discretization procedures in order to glean individual contributions and to integrate them into a complex and upgradeable platform of extended knowledge. This multidimensional and multiple layer 'cornucopia' has to be at disposal of all social community and the legal system, forever, as our heritage to the generations that will come.

Keywords: Geointelligence, government of territory, fiscal federalism, sustainability, law enforcement

1. Geointelligence as an international heritage of knowledge, scientific progress, land government and law enforcement

The legislation ruling the territory consists of a complex set of technical, administrative, environmental and fiscal laws. The government operator needs the support of the most advanced scientific research knowledge in order to enforce administrative, criminal and taxation laws. Tax legislation extends its field of application in environmental legislation and must be considered a suitable instrument to anticipate and maybe avoid the complex criminal case of environmental disaster. The trio made by science, technology and taxation can be a solution: it should be established a background of knowledge generated by the synoptic representation of high density and multidimensional data. A shared, total and diachronic knowledge of a territory allows an effective management and Sustainability of its own exploitation. Scientific and governmental interlocutors in the survey, knowledge, analysis, representation, defense and requalification of the territory should be a triple point

for all human beings. The scientific knowledge, law enforcement and repressive powers, should converge to outline standard discretization procedures in order to glean individual contributions and to integrate them into a complex and upgradeable platform of extended knowledge. This multidimensional and multiple layer 'cornucopia' has to be at disposal of all social community and the legal system, forever, as our heritage to the generations that will come. Fiscal law also can be also enforce with airborne remote sensing technology: the knowledge of our territory and its modifications it has to be something that our government and police must know, control and dominate everyday, everywhere, seamless. High density and multidimensional data acquired through the activities of airborne remote sensing technology conducted by economic and financial and economic police may be established as a basis for an activity of geo intelligence. Those informations, essential to control the territory and for application of tax law, are aimed at providing essential elements to the operator of the tax and criminal police enforcement activity. For example, one for all, a national geo-intelligence awareness offered by remote sensing police aircrafts may constitute a strong boost to contrast systematic and large-scale illegal housing: scans acquired by financial police equipped with airplanes in configuration Airborne Remote Sensing also could overcome all the difficulties in application of the fiscal federalism laws due to local governments fragmentary actions. A depth knowledge of the urban fabric, in the first place, allows to contrast criminal organizations: those criminal realities acquire power and acclaim on the full knowledge and control of their territory. They exert that control in the forms of 'ownership', imposing themselves as an alternative to the State power. This systematic scanning of portions of the territory allows the creation of spatial database, whose data can also be used for scientific research and police investigations. The creation of digital and multidimensional maps lays establish the correct pattern to create and implement geo-information databases, a fundamental tool for all the citizens and the daily activities of the national institutions. The famous social network Facebook has revolutionized the web world just to have paired and connected personal data to one or more digital images: bind a huge and widespread amount of textual data in possession of the various national, regional and local government in a single map database, georeferenced and always implementable, spread new intelligence frontiers with geo-economic law enforcement purposes. Effective policing financial enforcement is a '*condicio sine qua non*' in achieving fundamental principles of fiscal fairness and tax progressivity: that goals would significantly meet the justice expectations of the majority of taxpayers who contribute with their income to the survival of the legal and democratic nation. Tax fairness have the positive effect of increasing awareness and participation of the taxpayer in national and european contributory system: to increase the sense of individual responsibility that binds the tax levy to cover public spending allows the entire community to raise the level of negative social value that comes from the commission of offenses related to tax evasion and fiscal avoidances.

2. Land Management through legal and geographical representation of its territory: concepts of tax fairness and contribution capability applied to local analysis. A case study compared between Italy, Spain and Germany

Fiscal federalism is now, in its multidisciplinary approach, the focus of national and European policy debate: it is the backbone of the form of government, both national and Community level, determining the forms of operation and financing. The federal tax rules the purposes and mode of operations in which jurisdictions manage the national tax levy and its allocation between the central state and sub-state levels of government.

The supranational governments today are widespread and highly representative in international contexts: same national states, confederating in various ways, have transferred part of their sovereignty to supranational entities and to the sub-national levels of government at the same time. This reduction of centrality and sovereignty of national states is a consequence of an inevitable process, simultaneously centripetal and centrifugal, accelerated by the globalization of financial markets and the institutional subsidiarity.

The federal process is not limited to the split of national unity: it is the attainment of equilibrium in the process of development, in the diversity of local autonomy, strengthening the national identity through cooperative and mutual policies.

2.1 Fiscal federalism as a new legal dimension for land management and representation

Fiscal federalism, widespread among the forms of State all around international community, isn't an immediate consequence or a unique form of development of a typical federal state. In fact, as the following analysis, fiscal federalism can be institutionalized in a federal system such as the regionalized one; however, in the form of a federal state, it may be replaced by a financial derivatives system without any provisions of fiscal federalism principles. Today, many countries with a federal system, regardless of their form of State, have adopted the federal form of the tax system by institutionalizing the full correspondence between federalism and fiscal federalism are an example the United States, Canada, Brazil, Argentina, India and Australia. Fiscal federalism is also a solid

institutional reality in various European countries: systems of fiscal federalism are in charge, often politically institutionalized in a federal State as Germany, Switzerland, Austria and Belgium. Among the European countries with a fiscal federalism form of government and without a federal constitution, there are for example Spain, the regional state with a strong fiscal autonomy given to Autonomous Communities.

Even the Italian Constitution has identified as a form of recognition of local autonomy, the state regional decentralization in the programmatic intentions of the settlor was not then followed by coherent legislation. The approval of the necessary legislation, at least for the ordinary statute regions, took place only after 1970. A significant time delay was also caused by the harsh political opposition of central government to the possibility that regional governments ruled by opposition forces, such as in Emilia Romagna and Tuscany, from reaching autonomy. Even after 1970 national State has considered the regions only a mere kind of decentralization instead of state-entities with a proper autonomy.

2.2 Germany and Spain: different way to represent subsidiarity and sustainability in land management

The objective of this section is a comparative analysis of 'living' fiscal federalism in Germany, Spain and Italy, three quite autonomous legal systems very different but also very similar for law and cultural traditions. A essential element that distinguishes them and at the same time joins strongly them is that they are European Union Member States. The legal systems of Germany, Spain and Italy are particularly changeable in time and space: the legislative reforms are ongoing and relentless legal research is to define models of fairness and healthy public management.

Fiscal federalism, as a complex fiscal instrument for a proper territorial government, calls for a strict regulation of the financial relationships stability between all government levels providing reward or sanction mechanisms aimed at empowering national and local public management. The choice of a nation-state in establishing a system of fiscal federalism, such as last reforms of Germany, Spain and Italy, need to rule and set all those laws and legal institutions aimed at irresponsibility prevention in the financial management of local and national. Laws must bridge the accountability deficit that has always been present in multilevel government. A well structured system can ensure the sustainability of public spending, initially parameter for entry into the European Union but today it has become a prerequisite for the very existence of the EURO currency.

The experience of the territorial government in place in Germany is well important: land government features of German system develop since world war II until its evolution into being reformed by *Föderalismusreform I* and *II*, respectively, approved in 2006 and 2009.

The Spanish model implements a government of the territory through a particular form of asymmetric decentralization. The Spanish Constitution is the most recent among those considered in the present study: despite its approval in 1978, it was the subject of deep reforms, including that of 2009 which radically modified laws ruling land government. It has extended the powers reserved to local governments, Autonomous Communities, at the expense of the Spanish nation state.

2.3 Fiscal federalism in the *iure condendo* Italian experience

The Italian model of fiscal federalism, in a phase of uncertainty that has lasted since its inception, has to be analyzed through every implementation phase till its current progress. Its analysis should take into account the particular Italian regionalism: this proved to be a legal phenomenon of extreme avant-garde at the time of inclusion in our Constitution, although initially created through the form of mere administrative decentralization. To understand the perspectives of our territorial government should be carefully analyzed also the purpose of the last fiscal federalism enforced by Title V reform of constitutional law n. 3/2001, which found its first application in law n. 42/2009. Fundamental principles and objectives are also analyzed in the eight legislative decrees issued on basis of the delegation law n. 42/2009. Fiscal federalism as well as drawn by the Italian Constitutional law in order to become fully operational requires a number of steps to be issued over a period of 7 years : 2 years for the implementations and 5 years for transitional arrangements: timing for the implementation have undergone delays and accelerations due to the fluctuating fortunes of the national governments.

The analysis and the understanding of how the land government is being enforced both at the national and local law level needs to define legal and fiscal concepts such as equalization, budget sharing, shared responsibility, which highlight and outline how land government, through the structure of fiscal federalism, designs relations between the territorial and national public institutions. Furthermore, the nation-state provides tools for the sustainability of the public debt and for management control of entities responsible of public spending through fiscal federalism mechanism.

2.4 Compared analysis for a land government common model: social and economic sustainability of local government policies

The common model among German, Spanish and Italian form of fiscal federalism that emerges from the analysis carry us to understand how the federal-land government developments follow, unavoidably, evolution of fiscal taxation enforcements and land management. It is important to highlight how the elements common to all three countries, aimed at a full complexity of redistribution and equalization sustainability phase giving high role to national constitutional jurisprudence as high courts monitoring compliance with constitutions. Full analysis of the provisions regarding revenue, transfers and 'revenue sharing', control of accounting and public expenditures sustainability become fundamental to outline how land management is close to citizen in according to subsidiarity principle. In the analysis of the peculiarities of the different systems emerges throughout the centrality of the German element of taxation and its fiscal executive decentralization time against the particular dynamics of the strongly 'autonomic' spanish system.

An efficient territory government enforced through fiscal federalism laws needs to avoid any economical distortions and requires predetermination of sharp financial responsibilities held by all government levels with revenue or expenditure capacity, constitutionally guaranteed autonomy in the supply of resources, abstract ability in getting a balanced budget, compliance with the principles of equalization and solidarity.

In outlining salient aspects of fiscal federalism in Germany, Spain and Italy, it become obvious how much the implemented reform processes have been marked by severe difficulties and resistances both in legislative phase that during its application. Their complexity is further exacerbated by an extensive multi-disciplinary approach that distinguishes fiscal federalism enforcement to all other public law branches.

Germany, Spain and Italy are three examples which, although similar in a geopolitical and institutional point of view, have taken different paths to the approval of their fiscal federalism land government model.

Germany today is recognized among the states of the Union, as one of the major economic and institutional actors. Despite the delicate economic and financial environment, this country shows to be able to control its debt, earning a spread on the financial markets much lower than the European average. After World War II till today, german land government has been reformed several times: embryonic provisions of fiscal federalism came right from the Weimer Republic in 1919. Nowadays the German fiscal federalism is a mature, centered in the fiscal determination of taxation but strongly autonomist in equalizing redistributions : it guarantees full respect of local solidarity institutions and the pursuit of uniform living conditions throughout the whole national country.

Spain stand out, in world institutional landscape, as a young advocate of a asymmetric and reinforced regionalism: the spanish Autonomous Communities, as a strong asymmetric constitutionally guaranteed autonomy, identify in "*diferencial hechos constitucionalmente relevantes*" (differential constitutionally relevant facts) the heart and the protection of national identity and integrity. This form of asymmetrical land management among various levels of government counterparts is now gradually conforming by identifying many jurisprudential constitutional principles, even if not expressly stated in the constitutional text. The financial autonomy focuses mainly on two fundamental statements: the resources equalization in a cooperative and jointly responsible perspective and Autonomous Communities self-determination.

Italy has recently approved a major institutional reform after Constitution became law in 1948: the whole reformation process was started in 2001 by the Constitutional Law n. 3 and had to wait until 2009 for the approval of fiscal federalism main law. After almost three years after the delegating law, were issued by the Government all eight planned legislative decrees that completed the framework of Italian fiscal federalism. It is clear that the legislator has turned his attention to the Spanish model in preparation of law texts adding original and innovative solutions. The Italian constitutional system does not allow an institutional hierarchy among the various levels of government: this entails greater difficulties in adjusting the institutional relationships between a plurality of autonomous entities with respect to the laws that rule power and responsibilities between the Federal State and the nation state. As for Spain, the financial autonomy, limited and promoted by cooperative and solidarity principles, finds its foundation in institution resources equalization and regions and local authorities self-determination with respect to the State.

3. Subsidiarity and sustainability as a widespread cross-cutting approach to different anthropocentric events and aggregations

The analysis of those three jurisdictions come across that financial autonomy, for all three national government allocated to the respective sub-state government levels, has been a common proposed solution against a major cause of political-administrative indebtedness: the non-coincidence between taxation determination conditions aimed to cover costs with own revenues and unlimited spending capacity of third-party resources. This dichotomy has led to widespread forms of managerial irresponsibility, often shared with virtuous levels of government, that resulted in serious financial difficulties and defaults. To fight this accountability deficit were been voted provisions that impose to

level of government, as a fiscal autonomy holder that implements policies of exemption or concession arrangements and facilitations unsustainable, to suffer the full consequences of their financial management.

The analyzed systems are aimed at looking for a natural balance between the guarantees offered to territorial autonomy and guarantees for the protection of national integrity and uniformity both social and political conditions of life in the whole territory of national State. These values, which test the legal and logic stability of a complex regulatory system as land government, must comply with a further hierarchy that is struggling to form in a centripetal and supranational direction: the European Union. The stabilizing function, which in a federal arrangement typically is assigned to the central government, is to be progressively and inexorably absorbed by the Community institutions.

It's important to underline that excessively equalization policies could lead to distortions that would empty and overturn constitutional principles as solidarity and cooperative. Even excessive state aids can determine outgoing cash flows and incoming poverty, further aggravating the discomfort of areas already suffering from reduced financial capacity.

Fairness and solidarity management, strictly imposed by the fiscal federalism land management, inalienably determines continuous and relentless pursuit of efficient and responsible policies in the management of all public affairs. Those criteria cannot be only points of political programs proposed during the election campaign but must impose the exact fulfillment of provisions on keeping and preparation of public accounts.

Federalism and land government, as analyzed in Germany, Spain and Italy, open to a general sharing of fiscal policy, even if there hasn't been directly attributed fiscal territorial power in taxing to local government. Fight against tax evasion is one of the main tasks to be pursued in the field of sincere cooperation between national, local authority and central government. Tax evasion, such as derivative finance or excess of equalization, is a danger to correct assessment of distributed resources and services provided territorially. National government and fiscal police need to represent on databases and digital maps all fiscal value related to their own territory to fight locally tax evasion. To do this government must join all resources from fiscal operators, citizens information databases, research center and all available technology.

Today is related high importance to all processes reforming national land managements: fiscal federalism, having a look to Italian or other European country experience, could be identified as different allocation in a subsidiary way of power; but, at the same time, excluding internal federation processes of European member states, the unitary dimension of land government is given by Europe Union institutions.

Surely the target of the modern European institutional reform proceeds towards unity under European Union, suggesting that it could be considered improper to attribute the term of "federalism" in those internal reformist processes in national states under EU. No doubt that fiscal federalism can be summarized as a subsidiary reorganization of national powers: it is certain that this seemingly simple institutional reorganization is an opportunity to put an end to decades of reckless and irresponsible management of local and national public resources.

At the moment one of the greatest resistance that meets the EU as a federative process is precisely the lack of waiver by the member states of national tax powers: a fiscal federalism land management imposed to all EU member states, as a similar patterns in common but differentiated geographically, could be the common key to continue on the path of political institutions growth. That path of political and institutional EU reform, currently at a so uncertain stage, needs to be sharply improved: maybe one of the possible land government model would be offered by Germany, Spain, Italy or by a further common and shared model as an 'institutional interpolation' between these three ones.

In this context, the Spanish model, in particular, stands out among those in cooperative federalism and solidarity, since it concerns a national legal system in which local identities and local historical origins have very old but whose strong contrasts are still alive actuality.

Why not imagine a greater Europe Union, politically united, composed of 28 or more States or autonomous communities, through a european cooperative and supportive fiscal federalism confers extensive autonomy to local levels of government?

Abstract

The objective of this article is to contribute to the enhancement of natural and environmental heritage present in the territory of Formia in view of the disclosure and sharing of cultural-historical and architectural aspects typical of some local areas sometimes poorly understood - especially by younger generations - but still intended to arouse interest and useful stimulations to understand the present as it unfolds. In this section we propose a digression on the history and evolution of the city of Formia - garden city and area of great scenic and environmental interest because of its topography and hydrographic features. The Roman Cistern of Formia, located below the present Piazza S. Anna, is a wonderful example of hydraulic engineering. This irregularly-shaped underground structure is characterized by impressive architecture: 65 meters long, 25 wide, with more than 60 large pillars measuring six and a half feet high. This chapter provides a description of the history, discovery and recovery work through the consultation of documents from local and national archives and the classification of the main methods of analysis suggested by scholars who, over time, made the Cisternone their object of study. The last part of the paper illustrates a possible scenario for the realization of an integrated tourist route in which the Roman Cistern of Formia has its rightful place and promotion.

"Prima di entrare nel deserto
i soldati bevvero a lungo l'acqua della cisterna.
Ierocle gettò per terra
l'acqua della sua brocca e disse:
Se dobbiamo entrare nel deserto,
io sono già nel deserto."
(Jorge Luis Borges)

1. Introduction

The objective of this article is to contribute to the enhancement of natural and environmental heritage present in the territory of Formia in view of the divulgation and sharing aspects - historical, cultural and architectural characteristics of some local areas sometimes poorly understood - especially by younger generations young - but still intended to arouse interest and useful stimulations to understand the present as it unfolds.

2. Formia and its History

"Il mio Paese è curva di terra ove l'arancia profuma di mare." (F. Miele¹)

Formia, a city garden and land of great scenic and environmental interest characterized by the imposing limestone Aurunci mountains, which, extending as far as the promontory of Gaeta, frames and protects the splendid gulf.

According to a false etymology (Strabone, Festo, Servio), the city was founded by the Laconi, who called it *Hormiai*, moorings (cfr. Palermo: *pan-hormon*, "tutto approdo"), and *kajadas* the cavity formed by the promontory, Latinized in *Formiae* and *Caieta*.

Even the events of the pre-Roman period are uncertain. Some sources refer to the settlements of ethnic groups such as Ausoni and Aurunci, which overlapped in the beginning of the fifth century B.C. with the presence of the Volsci, though still not supported by archaeological evidence. The oldest evidence of colonization of the territory can be traced back to a series of terraces of polygonal walls placed along sheep tracks converging towards the urban center, a sign of an original settlement of rural and pastoral civilization.

The presence of a truncated ogive coverage places them in the period of the Punic - Etruscan influence, in the late seventh century B.C. The center of the urban settlement is located in the area between Castellone, separated by a proto-urban core near the natural inlet of Sarinola and including the Cascio hill, primitive part of the city.

The dock becomes the key element of the subsequent development of the Roman town of Formia. In this new historical-social context the nodes of trade are increased with the passage through the city of the Via Appia in 312 B.C. and trade plays an important role with the production of olive oil and renowned "Formiano" wine.

In 188 B.C. Formia received full citizenship (*civitas optimo iure*) and was registered to the Aemilia tribe, entering thus into the Roman-Italic communities.

During the reign of Hadrian, Formia is transformed with the idea to reproduce and replicate the image of the 'City'.

The opportunities offered by nature, the richness of the soil, the mild weather and the landscape of rare beauty made it a popular destination of prominent personalities of the City and the entire coast was built with villas plants, fish farms (piscinae), among which that of Mamurra on the promontory of Gianola, a forerunner of the open terraces and porches, and one at the port Caposele with excellent prototypes of vaulted structures on columns Formia making a sought after and prestigious center of *otium*.

Imposing mausoleums and stately villas, such as those by Lucio Munatius Plancus, Lucius Sempronius Atratinus and Cicero, in whose estate was reached by the executioners of Mark Antony on December 7, 43 B.C., after a useless attempted escape by sea. In addition, it is likely that Formia was home of the architect Vitruvius, author of the famous treaty of ten books "De Architectura" dedicated to Augustus.

The decay of Formia dates back to the year 867 as a result of the transfer of the bishop's venue in the *Castrum Cajetanum* and the translation of the relics of St. Erasmus - subtracted to the attack of the Saracens and the continuous raids - when the fate of the city, "no longer able to ensure the safety of the prelate and the performance of its functions" (Miele-Freccanese) changed permanently.

After his near-total destruction, which occurred in the second half of the ninth century, the inhabitants of Formiae took refuge partly in Castellone - close to the cathedral which became a powerful Benedictine abbey - and partly in survived homes which stood between the Via Appia and the sea giving life to the district of Mola di Gaeta, so named because of the presence of numerous water mills. In the district of Castellone, the natural gradient of the land was regularized through works in large blocks, which gave origin to a variety of platforms on which the buildings were erected, mostly sacred ones according to the planning of special effects, which, given the high flow, did not come to fruition before the first century B.C.

In its place, at the end of the thirteenth century, on the occasion of the fortification built in Gaeta by Charles II of Anjou, a castle with a high, cylindrical tower was erected, and strategically diverted along the coast a stretch of the Appian Way.

After the Norman Conquest (1140), part of the territory of Gaeta, the village of Castellone and Maranola was assigned to the county of Fondi, was passed to the powerful Onorato I Caetani, who proceeded to reorganize the defenses and the construction of new strongholds (Castellonorato); then with the Aragonese conquest of the Castle of Mola lordship became a branch of the family who assumed its title (1460).

During the Spanish viceroyalty, the renewal of consular in 1568, and the increased security with the end of the maritime supremacy of the Turks in 1571, gave new impetus to trade and erudition of travel. Mola became a Grand Tour post and destination renowned for its amenities and comfortable accommodations. In addition, with the further strengthening of the fortress of Gaeta, the nobles and bourgeois, disadvantaged within its walls, built many stately homes and villages between the two of them along the Via Appia, with a gradual recovery of the urban fabric. This revival made the administrative autonomy an aspiration, first reached with the invasion of Napoleon and then ratified by the Bourbon resettlement with the City of Castellone and Mola di Gaeta.

During the events of the unification of Italy in 1860-61, the municipality was siege-based to the fortress of Gaeta, whose capitulation marked the end of the kingdom of Naples, and was awarded the ancient

name of Formia in 1862, which was followed in 1865 by the crest of the mythical Phoenix rising from its ashes, with the motto "Post fata resurgo", and in 1866 reached the title of "city".

Between the late nineteenth century and the subsequent thirty years, there was a significant boost, especially related to the mills and pasta factories, the brick kilns, agricultural production, favored by first rail link Sparanise-Formia-Gaeta (1892) and then by the Rome-Formia-Naples (1922, 1927), as well as the simultaneous construction of the port, which made it a center of commerce servicing a vast area. In 1927, Formia passes from the province of Caserta to that of Rome, and in 1928 it is increased by a mountainous territory and population with the aggregation of the areas of Maranola and Castellonorato. At this stage it becomes a location of "resort and care" with a regulatory plan and taking on the role of a center of higher education. Then in 1934, it is inserted in the province of Littorina, today's Latina. In the last conflict, thanks to its position in the Gustav Line it inflicted terrible destruction and mourning, and for this reason was decorated with a silver medal in 1961. The reconstruction plan has improved its road network through the expansion of the railway and the port.

3. The Roman Cistern

The Roman Cistern of Formia, situated below St. Anna's Square, is a wonderful example of hydraulic engineering. The supply of water has always been a major concern and a decisive factor in the emergence and development of human settlements. As amply documented by the ruins of Pompeii, as early as the sixth century B.C. dwellings and public buildings were equipped with tanks designed for storage of rainwater, with a typical Mediterranean regions, which were joined later for direct funding from the permanent springs. The "Castellone Cistern", dated to the first century B.C. is a massive underground structure 65 meters long, 25 wide with an irregular plan divided longitudinally with rows of pillars (about 60) twenty feet and a half tall that set the environment in 4 aisles covered with pseudo-cruise vaults with a total area of 1,200 square meters and a capacity of at least 7,000 cubic meters.

Fig. 1: Entrance to the Roman Cistern in Formia.

The water followed a long and complex sloping path fully integrated and responsive to the morphology of the site. The pipeline at 217 meters above sea level with a first section at 1450 meters underground, wound behind the town walls in the vicinity of the square of S. Erasmo, at an altitude of

54 meters above sea level, then, probably on a stretch of arches, reached the Castle Square, where it entered the tank through *fistulae* located in the ceiling.

Fig. 2: Architectural plan.

In this way, public buildings (baths, fountains, nymphs) and private buildings (residences, craft shops, commercial facilities) of the city's plain receiving water reserves steadily thanks to a simple but effective system that was in use for many centuries until the finding of a new system in the mid-nineteenth century when the Bourbons inserted it into an aqueduct which came from the Valley of Santa Maria la Noce feeding a fountain beneath the Tower of Castellone and Villa Real Caposele.

Fig. 3: Overflow regulation.

Fig. 4: Cross vault.

Fig. 5: Fistulae with water regulator.

From a structural point of view the Cistern is one of the hydraulic underground Roman wonders which adds to the few examples which have come to us from ancient times, as the “Piscina Mirabilis” of Miseno, dating from the Augustan age and the famous “Yerebatan Sarayı” of Istanbul, built under Constantine, in which the jewel of Formia has many typological affinities.

Fig. 6: Piscina Mirabilis of Miseno

Fig. 7: Yerebatan Sarayı of Istanbul

The walls are in *opus incertum*, bound together by mortar and cocchiopesto that assured that the water seal, along with the vaults preserved in perfect condition.

In addition to historical-architectural detail, it is interesting to analyze the phases of discovery and recovery work through the consultation of documents from local and national archives and the classification of the main methods of analysis suggested by scholars who, over time, made the Cistern their object of study.

3.1 From Discovery to Retrieval

The underground building, after centuries of oblivion, was brought to light around 1994 thanks to the interest of a group of researchers² who conducted the preliminary investigation by some directions and testimonials - passed down in oral form - by the locals and some related work carried out in 1930 for the restoration of a sewer, although some attempts had already been made previously as evidenced by the words of Pasquale Mattei³.

.... "Mr. G. Paone with some masons descended in the basement vault of Castellone and finding a large stagnated water sewage where they could not proceed, made a small boat which crossed the vast vaulted corridors. For the first time it was discovered that the houses had been built on the overlying straight by massive pillars that rose from beneath the stagnant waters. Two of these pilasters were huddled onto two huge bronze lions that rested on two travertine bases surrounded by the waters ..."

These were followed by those of Felice Tonetti⁴.

... "The next morning an opening allowed me to descent as well. I descended, in fact, and was faced with a show of enormous magnitude. A long series of triple pillars of stone and earthenware piston, still like new, stretched as far as the eye could see, and held four times a barrel of at 2.90 meters wide and the pillars measure 0.90 meters sideways. The huge underground is partly filled with crushed stone that the older masons recall being laid down more than thirty years ago, after having been removed from the cable run for the large sewer of Castellone. Where the soil does not reach, the underground is full of clear water. It has not been able to fully explored ..."

On January 6, 1994, climbing down a manhole, the Friendship Group of St. Anna "Castellone", accompanied by the inhabitants of the place, found themselves in a huge underground basilica, which for years had been used as a dump and was almost completely filled with mud and water.

Only in 2003 the difficult task of emptying it was accomplished, returning a piece of the past to the city.

Fig. 8: The Cisternone before the emptying of mud, water and debris.

... "Above the central plateau of the ancient Arce of Formia, St. Anna's Square in the center of Castellone, you can hear the voices and the noises ringing. But underneath, I went a bit of steps and entered the heart of the earth, reign supreme silence and wonder. The cistern seems to re-emerge like magic from a legendary past ..."

Paolo Brogi (Corriere della Sera newspaper, 29 July 2003)

A further step aimed to the recovery occurred in December 2010 through a regional funding which has enabled the creation of an innovative lighting system aimed at highlighting the features of the architectural structure, enhancing its historical aspects and its function within the city. The 1,200-square-foot cistern was covered by a system of lights that consume only 170 watts.

The entire system emphasizes with a light and dark relationship that has its origins in the mists of time between water and man. Warm, red lights indicate the walkway of the ancient man who went to draw from the well and the contemporary man who now admires the work of the ancient past as well as the practical function of the cistern, white lights enhance the purity and transparency of the water. A striking encounter between "flesh" and nature that gives the idea of the ancient Roman world divided between its origin in the rural community of shepherds and intelligence to be able to take advantage of an ingenious nature like few others.

Fig. 9: Scenic effect with the new, innovative lighting system.

4. Reflections and Conclusions

The last part of the paper illustrates a possible scenario for the realization of a tourist route where the integration of the Roman Cistern of Formia will have its rightful place and promotion.

4.1 From Conservation to Management

For a long time in Italy the main objective related to cultural heritage has been that of its preservation. This dominating attitude clearly exercised a "passive viewing" of cultural heritage, not seen as a potential engine of economic development, but purely as a heritage to be maintained, considering that this was the best way to ensure its survival over time. But the sharp increase in the demand for knowledge and enjoyment of cultural heritage, quantitatively relating to a "tourism resource" has gradually led to a change in their social role.

In this context, driven by new and more modern beliefs, the challenge is to be able to return the Roman Cistern to a new life giving it an adequate place in the present and making it a living part of an integrated tourist route, accessible and visible to the historical - cultural city of Formia. From the two Cryptoporticus of the Villa Comunale to the Antiquarium opened in 1997, and the nymphs on the beach of Caposele 'domus' Cicero located below Villa Rubino, a 'tower' whose tradition identifies it as the tomb of Cicero - and the Villa Mamurra in the site of Gianola.

A new territorial concept, a renewed culture of the coastal city meant not only as a vacationers' destination in the summer months, but a place full of suggestions, destination of dreams suspended between history and nature.

Risk Management Planning. Phlegrean area and the case study of Bacoli¹

Giuseppe GUIDA,¹ Giovanni BELLO²

⁽¹⁾ PhD - Department of Architecture and Industrial Design, Second University of Naples, Italy

E-mail guidagiu@unina.it

⁽²⁾ Urban Planner - Department of Architecture, University of Naples

Abstract

The coastal region from Bacoli to Sorrento Coast contains, besides an alternation of fine landscapes and large areas of unplanned urban sprawl, different natural risk elements, object of planning tools that affect substantially urban policies and urban plans

In fact, if a Civil Protection and Emergency Plan is a project of all activities and procedures that need to be adopted to deal with an expected disaster in a region, it is evident that the coordination with urban planning is fundamental, especially in sensitive areas such as the coastal ones.

In the article, using the case study of the Italian city of Bacoli (near Naples), I'll explore the possibilities offered, in the emergency planning, by the sea as a specific escape route in case of natural disaster. The reflection starts from an examination of the particular orography and geography of the Phlegraean coast, the area topography, the level of interconnections and infrastructures. The strategies developed during the preparation of the emergency and civil protection plan, from which this article starts, identify in the waterfront, especially adapted, infrastructured and safe, a fundamental option in the management of major emergencies of the Phlegraean area.

Keywords: safety & security, large scale plans & projects, social practices

1. Introduction. The risk as a variable

The contextual nature of risk perception and response is very typical of contemporary society and of a "second kind of modernity" (Beck, 2000), in which the risk factors "described by science" are relativized by the cultural background of the society in which they occur, exposing to oblivion some obvious risks or, conversely, believing that anything is potentially dangerous, according to the perspective from which the events are observed (Lupton, 2003).

Throughout the metropolitan area of Naples there is an overlap of risk factors that periodically generate more or less serious events: landslides, soil pollution, earthquakes, bradyseism and volcanic hazards, which are quite infrequent but extremely dangerous.

The latter is a real evolving risk (among the biggest all over Europe), connected to the volcanic activity (Vesuvius and the Phlegrean caldera), that weighs significantly on spatial planning, on its possibilities and on direction of its development paths.

The relativization of this risk and the characteristic cultural approach held by population (Douglas, 1996), have almost reduced its perception and only in the last decade, institutions have undertaken preventive works, planning actions and regulatory constraints.

Regione Campania (the authority appointed to territory administration and coordination of risk prevention) has been promoting longstanding actions and instruments of coordination-prevention on

¹ The present paper is research result of a joint reflection of the two authors. However, paragraphs 1, 2 and 3 can be attributed to Giuseppe Guida, paragraph 4 to Giovanni Bello.

many different levels of cogency and institutional spheres which converge in order to form a strategic reference frame in dealing with natural disasters.

The final outcome will be a network of plans and programs connected to emergence, whose core is the writing of Emergency and Civil Protection Municipal Plans meant as planning instruments of all the organized activities and all the procedures adopted in case of expected disasters in a given area, in order to ensure the effective and immediate use of needed resources required to overcome the emergency.

Therefore those plans may define both the risk scenarios for a proper management of crisis situations, and the explanation of planned urban actions that can be integrated to and complementary with other types of plans and policies for the area (especially the municipal urban planning).

In this scenario land resources are the central point of reference for emergency control, in terms of safe places, waiting areas, infrastructures and equipment, both existing or proposed.

In this regard the Civil Protection Plan can have a strong connection with urban and territorial planning, partially overcoming the intrinsic sectoriality of the approach.

This paper will use the case study of Bacoli, near Naples, to describe the path of Emergency and Civil Protection Plan associated with the various forms of risk caused by the Campi Flegrei caldera as well as its acting as a strategic and complementary instrument in urban planning.

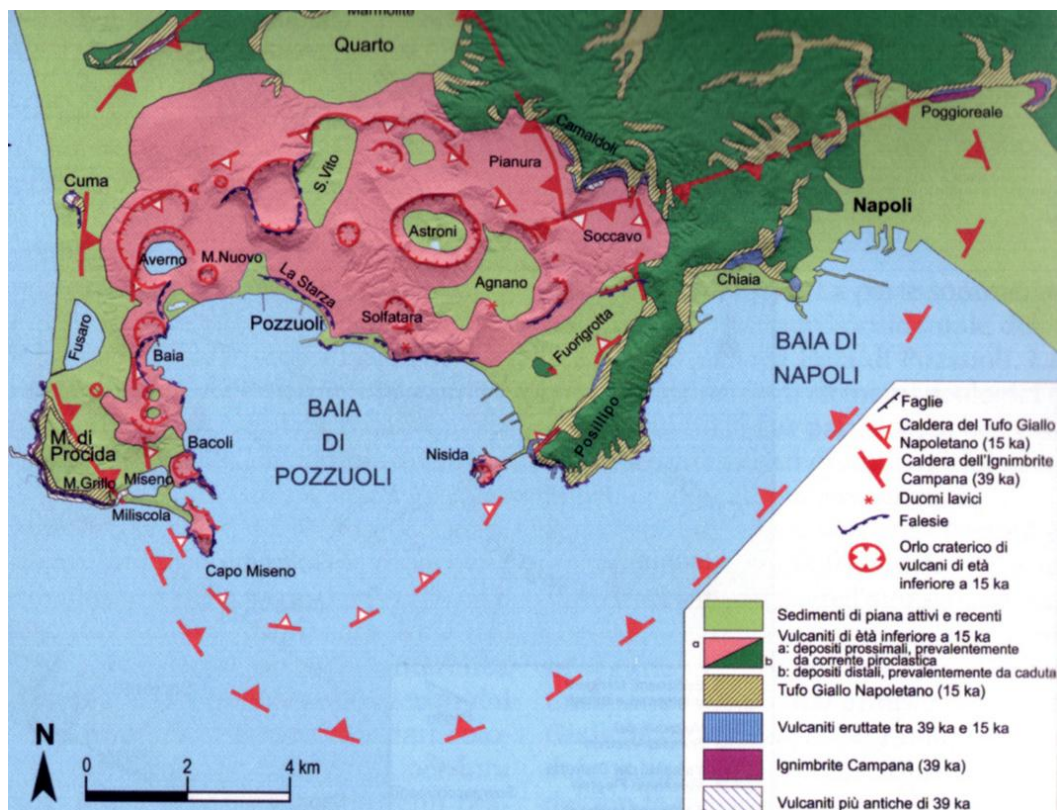

Fig. 1: Schematic geological map of the Campi Flegrei caldera (Source: Orsi *et al.*, 1996).

2. Morphology of the risk in the Phlegrean Area

The whole Gulf of Naples is characterized by the presence of four volcanoes: The Somma-Vesuvius system, Campi Flegrei and Ischia resurgent calderas, Procida volcanic field (Orsi & Zollo, 2013). For what concerns Campi Flegrei system (whose last eruption took place in 1538), the activity is proved by intense and millennial fumaroles, by hydrothermal waters and frequent bradyseismic events, which cause ground deformations together with seismicity and variations of chemical-physical characteristics of the fluids emitted from fumaroles (*ibid.*).

The most recent bradyseismic activities occurred in 1970-72 and in 1982-85; the 1970 one took by surprise the unprepared scientific world and the emergency apparatus. Indeed up to that moment the area was not monitored, and the only precedent related to ground motion phenomena was in 1538, as already mentioned.

In 2012 the alert level of that area grew from "basic" to "attention" on a scale of four levels defined by the 2001 Area Flegrea Emergency Plan.²

This new standard was adopted by the Civil Protection Department after a consultation with the Major Risks Committee, as a result of the new parameters detected by the Vesuvius Observatory, even if there aren't many elements which may help to predict a short-run evolution (Martini, 2013).

Despite this risk scenario, the urbanization of the whole Phlegrean area and specifically of the town of Bacoli grew up along the second half of the 900, in a fragmented, uncoordinated and, of course, partly abusive way, considerably increasing the load settlement³. All this occurred in spite of several planning instruments operating on the municipal area: the 1976 General Plan, the 1999 Campi Flegrei Landscape Plan, the establishment of Campi Flegrei Park, four S.C.I.'s (Sites of Community Interest) and Regional Basin of Campania Centrale predictions.

At the same time, the chaotic building of many areas of the city produced as a consequence the lack of infrastructural system, which is poorly interconnected and not adequate to cope with natural disasters, even the smaller ones, as often reported and repeated by media.

3. Emergency Planning as a urban strategy. The case study of Bacoli

Emergency and Civil Protection Municipal Plan is a planning instrument able to assess and prevent the effects of common risk factors that can statistically affect a territory.

The goal of this Plan is to define scenarios for an incisive management of crisis situations. It is in this sense that goes the recent amendment of the Law 225/92 (already complemented by the Law 401/2001) that introduces specific requirements for municipalities through the Law 100/2012.

The Bacoli Emergency and Civil Protection Plan is currently only a "preliminary project"⁴, and it establishes as pivotal matter of the planning the risk connected to bradyseism and to all other kinds of risks (geological, seismic, fire risks and so on), and primarily all their possible interaction.

With the aim of satisfying these needs we must at first define the risk scenarios basing our consideration on the vulnerability of the territory (areas, involved population, damageable structures etc.) in order to have overall and reliable information related to the expected event (above all in the specific case the volcanic and bradyseismic risk) and therefore be able to assess in advance the operational response required to overcome the emergency stage. All that will be considered in terms of resource allocations, infrastructures sizing and forecasts that are realistic and compatible with the spending power of the local authority or with projects funded by other institutions (especially those actions financed by Structural Funds and European Investments).

² The bradyseism, which is characterized by a slow lifting motion (negative bradyseism) or a decreasing motion (positive bradyseism) of the soil, happened on September 7, 2012 with a low energy earthquake swarm and some events perceived in the area located between the historical center of Pozzuoli and Arco Felice. The statement issued by the Vesuvius Observatory showed that the swarm was not an isolated phenomenon, but an event connected to a larger process that involves the whole Phlegrean Area. At the time of writing this article, the phenomenon seems to have settled down with a clear decreasing of significant events.

³ In the four cities of the area (Bacoli, Monte di Procida, Pozzuoli and Quarto) the population has increased from about 70 thousand inhabitants in 1951 to almost 160 thousand in 2013. In the metropolitan area, the city of Naples has decreased from 1.004.577 inhabitants of 2001 to 959.574 of 2012, whereas during the same decade some of the Vesuvian countries (Somma Vesuviana, Ottaviano, San Giuseppe Vesuviano and Terzigno) and those located Northwest of Naples (Giugliano in Campania, Pozzuoli, Bacoli and Monte di Procida) recorded the highest average growth of all the current Province of Naples (Guida, 2014).

⁴ The Bacoli Emergency and Civil Protection Plan is being drafted by Municipality Urban Area (SPM arch. Gennaro Ciunfrini), with scientific advice of the Department of Architecture of the University of Naples "Federico II", prof. arch. Michelangelo Russo (Scientific Responsible), arch. Giuseppe Guida (Scientific Adviser), arch. Giovanni Bello (Collaborator). The final plan will identify in details what has been established at level of strategies. Additionally, the project will adopt an analytical approach of ELC (Emergency Limit Condition) which concerns the test of behavior of the various components with the intent of urban emergency management (Bramerini *et al*, 2013).

Fig. 2: Emergency and Civil Protection Preliminary Plan of the Town of Bacoli Areas and facilities for emergency (excerpt).

Provincial and regional plans are less detailed than municipal plan, which allows citizens and Civil Protection workers of different sections to have a frame of reference corresponding to the real size of expected event, involved population, alternative roads, possible evacuation routes, waiting areas, temporary lodging camp, gathering places and so on.

Proper planning strategies for mobility and evacuation routes are critical to the success of the plan. Strategies must include provision of new projects of reorganization, adjustment or increase of the current network and standing areas. Notably, Bacoli Emergency Plan identified the sea resource as a specific evacuation route for expected catastrophic events.

In this sense, one of the basic elements contemplated here is population and its distribution on the territory. Through the interpolation of Istat data and their georeferencing, it has been possible to graphically and dynamically identify the different "weights" within the geographical subdivision.

Subsequently local territory has been divided into 5 "micro-areas", representing section of territory characterized by uniformity of positional, urban, historical, cultural, environmental, socio-economic factors, as well as of delivery of service and infrastructure related to mobility. Table 1 describes the entity of the gathering places previously located in the plan for each micro-areas.

Further refinement of data and follow-up inspections of the effectiveness of the evacuation routes, especially the maritime ones, and of different types of risk dimension will lead to identify or modify what have been indicated and downsized.

Microzones	Gathering place	Surfaces	Population
Microzone 1	Miseno/Fondi di Baia	37.402mq	10.581
Microzone 2	Torregaveta	27.620mq	9.803
Microzone3/4	Porto di Baia	9.925 mq	882
Microzone 5	Fusaro	15.125mq	5.369
TOTALE		90.072mq	26.645

Fig. 3: Entity of micro-areas (microzones) in terms of surface and population

4. Evacuation routes and planning strategy

The available data about Bacoli infrastructural level show a mobility system that doesn't seem to be insufficient, but barely interconnected, fragmented and consisting of a limited intermodality among different kinds of transports. For example, it's clearly showed how the mobility network, both road transports and iron transport, can't assure presently evacuation and safety measures not only for the most of Bacoli inhabitants, but also for the nearby town Monte di Procida, whose whole flow converges on Bacoli's territory, and then gather with Naples' Ringroad routes and Domitiana's routes, passing through the Town of Pozzuoli.

Additionally, in case of significant natural calamity, the iron transport can't be seen as crucial in evacuation plan, due to railroad's risk of deformation.⁵ Emergency and Civil Protection Plan, here partially explained, tested and prorated ponderal incidence on maritime transport's infrastructure network, that is a strategic system in the management of evacuation routes.

Geographic and morphological location of Bacoli's territory has led Emergency Plan to provide as preferential evacuation route, especially for certain micro-areas (1, 2, 3, 4, where 4/5 of 27 thousands of Bacoli inhabitants live), the maritime way, trying to locate from time to time the best destination for each path.

On Bacoli territory there are three small harbor areas: Baia, Miseno and Torregaveta.

Presently, Baia harbor has a 4.5 meters of maximum draught and it is generally used by leisure boats for docking and laying over. The harbor, which can contain approximately 600 boats, with 25 meters of maximum length, is adequately equipped for assistance and nautical service. There are commercial docks, also used by local shipbuilding. Porto Miseno, further South, is essentially subdued to Finance Police's boats; here there aren't leisure boats, but it's possible to drop anchor and moor to buoys, which are usually granted to licensed private citizens, who during the summer, may create a congestion of people and vehicles, provoked by the excessive number of leisure boats. Additionally, it should be considered also the risk caused by the huge presence of mussels breeding at the harbor entryway.

Therefore, it's evident that even in this case, specific spaces assigned to emergency use must be provided in case of need. Lastly, on the West part of the Coast, the small Torregaveta harbor is located; it is endowed with a dock and well linked to the nearby Cumana Railroad.

The ponderal rate of evacuation routes given by these landing places (especially the one in Torregaveta), will be able to absorb in perspective also part of the charge of the neighboring town of Monte di Procida, which, as already said, weighs completely on Bacoli territory in matter of mobility.

Thanks to initial tests, done on location of waiting areas, reception and gathering places, it is possible to quantify, in regard to the involved micro-areas, that almost ¼ of Bacoli population may be engaged in a generalized emergency exodus through the sea (about 5000 people, together with a variable index given by Monte di Procida citizens).

⁵ Railway transportations are provided by Cumana railroad, which connects the centre of Naples with Campi Flegrei area.

The Emergency Plan identifies for the whole evacuation routes system some necessary adaptations. This orientation is going along and simultaneously with the redaction of the new PUC (City Urban Plan), so that to obtain planning previsions which at the same time can be univocal, more feasible and effective.⁶

Figure 4 shows in form of concept the first strategies derived from the preliminary plan. These strategies summarize data at the present stage, and use them to draw possible configurations, related particularly to the connection network and tools, be they already available or in progress.

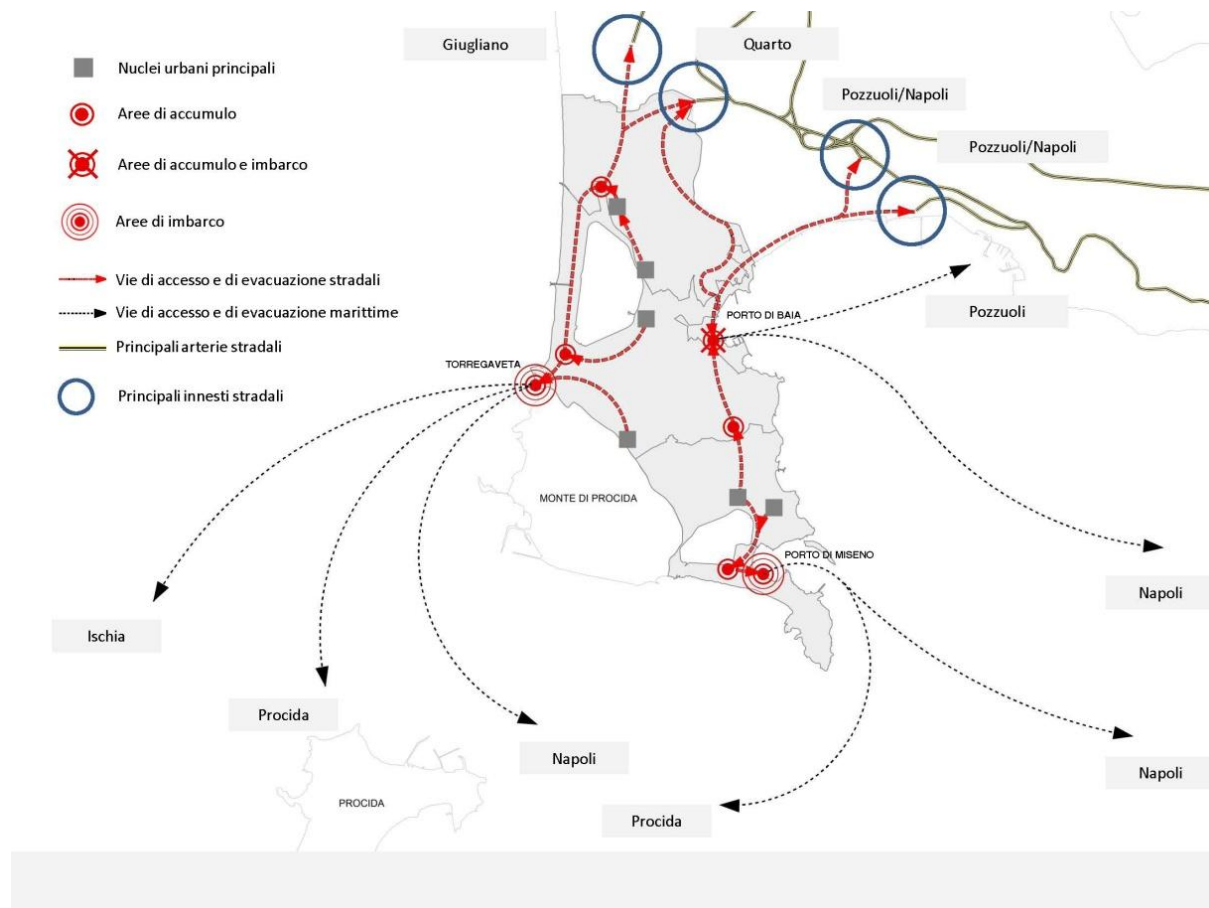

Fig. 4: Emergency and Civil Protection Preliminary Plan of the Town of Bacoli - Outline of strategies for evacuation routes.

5. Conclusion

Emergency planning, *ex ante* and *ex post* event, can also give the opportunity to think over the planning models and urban strategy in certain territories which are subject to natural hazard and to a misuse of territory and resources that have considerably increased the so-called “exposed value”. Additionally, this risk is at the mercy of social and cultural variables which may modify its perception beyond scientific evidence, negatively affecting in particular the phase of prevention and priority definition. Therefore, risk management is not an issue that should be addressed uniquely to the limited field of emergency plan, but on the contrary it should be connected with a wider territorial and urban planning in cognitive, planning and operative way.

In this sense, emergency plan must accurately take into account urban and geographic condition of territory and its ongoing planning and development. The example here exposed is hinged precisely along this project, and Bacoli is the first of Phlegrean towns to be endowed with an emergency plan in which different parts of urban system are evaluated according to a relational approach, able to better identify strategic elements (strategic buildings, emergency areas, accessible and connecting infrastructures, by integrating in the specific case, evacuation ways, etc), using the available civil protection resources in a more effective ways.

⁶ In 2014 Municipality of Bacoli started, together with Emergency and Civil Protection Plan, the redaction of the New Urban Municipal Plan, committed to Studio Architetti Benevolo with Goldstein Architettura and arch. Guido Riano.

DESIGN AND REPRESENTATION OF LANDSCAPE OF “TERRA DI LAVORO”

Vincenzo POLLINI¹

⁽¹⁾ Dipartimento di Cultura del Progetto, Facoltà di Architettura Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Italia
vincenzopollini@gmail.com

Abstract

The territory of Campania, which is within the larger boundaries of *Terra di Lavoro*, occupies the part of the region that once the Romans called Campania Felix, also known as *Ager Campanus*, that is "the prosperous Campania". Today it corresponds to province of Caserta, which is smaller than it has been for centuries in the historical context of the Kingdom of Naples. The province of *Terra di Lavoro* infact also included parts of the current provinces of Naples, Avellino, Latina, Frosinone, Benevento, the town of Venafrò and adjacent areas until Capriati al Volturno, Molise.

The entire province, since ancient times, has always been characterized by the extraordinary proliferation of cultural, historical, artistic heritage but also by the wonderful landscape of *Campania Felix*. The landscape of ancient *Terra di Lavoro* manifested its beauty through nature, the splendour of this territory has attracted the attention of the famous poet Pier Paolo Pasolini who, in the poem "The Ashes of Gramsci," writes these pithy lines: "It is now near the *Terra di Lavoro*, some herds of buffaloes, a few bunch of houses between tomatoes plants, ivy and poor planks. Every once a rivulet, sleeping in the ground, appears between branches of the elm trees full of vines, dark as a drain. Inside, in the train that runs half empty, the frost».

Keywords: Represent, Terra di Lavoro, Drawing, Landscape

1. Drawing and representation

We revered and throw open our eyes when we see him but we never stopped to think what is the landscape. It derives from the French *paysage* which in turn derives from *pays* and indicates the appearance of a place, the totality of its forms and interactions between them.

On what the landscape, debate different schools of thought, but the official definitions are two: the European Landscape Convention "defines a certain part of the territory, as perceived by people, whose character is derived from the action of natural factors and/or humans and their interrelationships, and the cultural heritage of the landscape" defines a homogeneous part of territory whose characters derive from the nature from human history and interrelations between them".

Represent a landscape means penetrating in its complex reality, analyzing all aspects, without stopping to its appearance, but account should be taken of a number of essential elements: it is therefore to put in place a complex procedure, which will lead to "deep" knowledge of the landscape, through a careful and reasoned analysis. The term "representation" is derived from the Latin *re-ad-praesentare*, which literally means re-submit, make (again) present. In all civilization man has always sought to represent reality drawing to express an emotion, a feeling, a message or simply to convey what his eye received.

Leonardo da Vinci described the eye as the main instrument of knowledge, and the design as the most suitable to register the objects observed, but also to create new images. The design was considered a method to know the world, to understand, to design new things and finally to transmit the knowledge acquired. Similarly, Le Corbusier called the drawing "a means to observe and discover",

but also to remember, and then to "invent and create". The design comes from the need to communicate the characters, the identity, the quality of a particular spatial situation, with its distribution, technological implications, construction and image; but also by the need to communicate spatial transformations within the evolutionary dynamics of each project. "Drawing" should be construed according to its oldest academic tradition, such as "design" metalanguage (shared between the Arts), how to know concerning the figurative dimension-and therefore "communicative" (representative) – architectural construction. Scrolling texts dedicated to the masters of architecture from Palladio to Aldo Rossi, from Leonardo to Le Corbusier, our interest is drawn from images of the works but, often, even more so from the drawings, the graphical representation of their ideas. The design should be understood as the ability to understand and convey the knowledge of urban transformations, evolution of the territory and of the environment variables and constants.

The urban and territorial representation is defined specifically to describe not only the landscape, but also the dynamics (expected or desired existing) concerning it.

The real knowledge of the architecture and the landscape is achievable only through a geometric analysis of the spaces designed to emphasize the close relationship between the configurative genesis of surfaces (and their intersections) and their translation in its pictures, as Aristotle already knew in the 5th century a.c. "the soul never thinks without not an image."

Only knowledge, understanding of the genesis and succession processes allows a correct representation and, with it, the design of spaces and also amenities of figurative high complexity. To re-establish the identity of a place like an architectural artefact becomes increasingly need a real work of knowledge representation, which can be done only through discretization and measurement of all those tangible and intangible values of the territory which are essential for traces of the past in the present action. Discretization and measure are the only actions that allow to pass from a knowledge of "natural" type a "cultural" type and their interaction gives rise to a result that has a value added otherwise unimaginable.

The landscape is the set of elements characterizing and distinguishing features of an area. In order to know a "landscape" we must know it represent. Here I should like to emphasise how can no longer suffice a geometrically defined, but it is increasingly necessary a kind of relief which prospect the n dimensions of product and territory, multi-dimensional relief, a relief that assumes a multi-criteria analysis, integrating the multiple skills, return the right value to the heritage of cultural and environmental heritage.

My research-study is based on the method of reconstruction of the territory moving from simple geometric relief to the relief of all its constituent components: this is, precisely, the purpose of the multi-criteria analysis. Multi-criteria analysis [Fig. 1] puts in motion a complex process, a process of accumulation of knowledge and of knowledge, based on the relationships between technology, society, politics and economics, and it is precisely the set of these relationships to give life to that quid that becomes physically measurable and quantifiable and that returns to render the role and dignity of the designer. Therefore the major task of this analysis is to measure and discretize reality: be it an object, an artifact, a piece of a whole city or more generally an entire environmental system. The environment, as we know, is a complex and articulated system, consisting of territories which are nothing but the environments defined by legal and administrative areas.

For this the action of the multicriteria analysis aims at deeper knowledge of the suspect through the complete expertise to contribute to the deep knowledge of the environment. A method to reconstruct the territory is a cultural attitude that enables the detector to understand both generators of signs that the object context to be analysed. Discretization of architecture, in its parts and its entirety, constitutes the essential methodological basis for each hypothesis.

The detector which operates using multicriteria analysis, through the operation of land measurement, interprets and discretizes the event, reconstructs the relationship between the parties, between place and space, between territories and between economics and architecture project, because knowledge of the signs of already allows us to design the future border.

Multidimensional knowledge as a fundamental tool of balanced and sustainable development of the territory, which can be implemented only through a serious and clear operating relationship between man and environment, based on the desire to recover the historical memory and conscious recovery of each sign and artifact that characterize and founded the identity of a place and retrieve its essence. The eco geometry can therefore be understood as the discipline that allows you to manage the representation of complex system of the territory and by relating individual know-how, redraws a new identity as integral of knowledge.

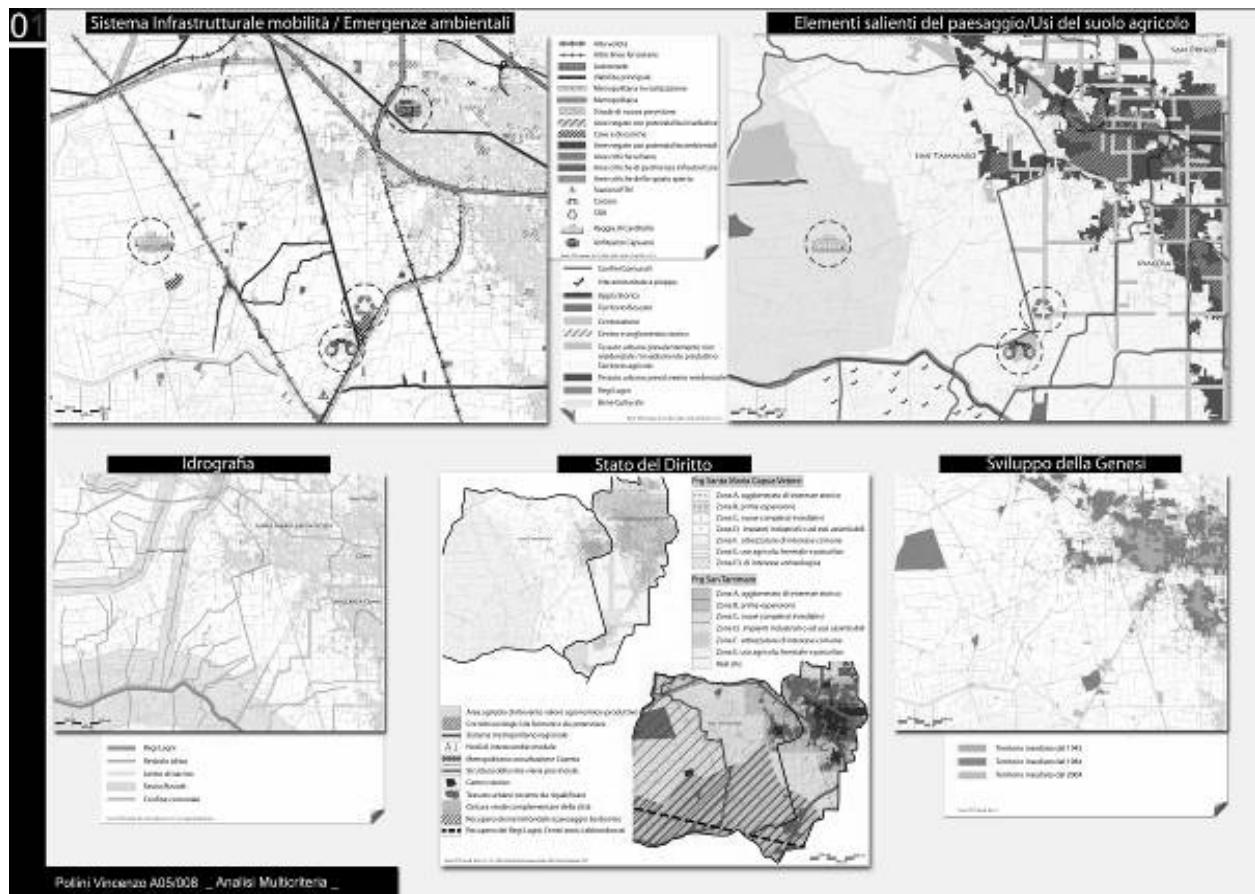

Fig. 1 Analysis Multicriteria

Another key step, is given by the study of the aspects that have damaged his image, the changes that have taken place over time and those that have changed positively or negatively the environment due to natural factors and/or human. The latter can only from the analysis of the physical, biological features (Lakes, rivers, mountains, etc.) and anthropogenic (city, houses, roads, etc.) and continue with an investigation of theoretical knowledge, cultural, historic, town planning, storage and cataloguing of urban heritage.

The analysis of the changes, however, must have some logical antecedent to the study of the roots in order to explore the area and find traces of its evolution and its components. Traces of the past, in fact, assume a value of testimony, integrating together with transformations and changes of this, outline the fate of the territory.

The complexity of today's issues related to land management and the environment "safety, quality, efficiency" involves an ever increasing demand for knowledge on the State and on the territorial transformations in all its aspects — physical, institutional and socio-economic.

Today there is a need for a new commitment to cultural and political level-to achieve a better institutional and systematic knowledge of the territory and the environment of the country, aiming at its preservation and enhancement. Therefore, the concept of representation can no longer be traced nor belong to a single discipline, but must relate to different sectors, different disciplines, which cannot be taken into account in their individual specificity, but as parts of a whole.

A complex representation that, starting from an analytical phase, discretize the unit and then entrust it to the various skills. A project of knowledge integrates knowledge, both for "already done" and the "what to do" ensuring quality. Only in this way, the added value will be born from their integral, thus creating a real table of knowledge.

Today, we are equipped with formidable terrestrial tracking tools [Fig. 2], aereophotogrammetry [Fig. 3] and satellite [Fig. 4] with high technological content, supported by sophisticated software able to return the 3D environment subjected to investigation.

Fig. 2_3_4 survey methods: terrestrial, photogrammetric and satellite

Among these, particular software is the GIS (Geographic information system or GIS stands for Italian Territorial Information System "), considered by many to be one of the most powerful tools of all information technologies, because it allows to integrate knowledge from multiple sources [Fig. 5] and create an environment of collaboration.

GIS systems are fundamental tools to evaluate, analyze and represent each type of spatial phenomenon; question then of a computer system can produce, manage and analyze spatial data associating to each geographical and scenic element one or more alphanumeric descriptions. In essence, therefore, the minor times you get quality and results.

Discretization of architecture in its parts and its entirety first is the essential foundation to any hypothesis of constructing a genomic data base. It is therefore appropriate to analyse the diversity of every artifact within a general field to identify the various elements, going up to the limit of minimal units of meaning, to be included as part of an organized structure according to flexible and paths that allow reading multiple routes. This indicates the need for storage systems, in addition to quantitative data and identifying information, including data about the formal qualities of architecture, able to explain the shape of the parties, in relation to a reading of the constitutional architecture and character of its elements first. The city as a complex system of relationships is proposed as a field of experimentation and analysis and reflection articulated on multiple levels of knowledge. Definitions that valences and identify constituent traits that characterize the collection, decoupling and recomposing, is an operation that must be carried out within a cognitive structure that allows global then lunges on specific connectable as appropriate. In this sense, every investigative structure, knowledge, should be conducted through relief operations, processing, cataloguing, valuation and management of all components of the tangible and Intangible Cultural Heritage, the environment and Built in order to allow a reading for each unit construction is related to the context (theoretical, historical, cultural, urban, formal, legislative) which outlined the morphology. Next to this if the development of new technologies for the relief and the representation of architecture are now a boost to configure complex information systems, you must counter that each major project, processing, cataloguing, valuation and management of the natural and built heritage is set to theoretical bases related to specificity of architecture. Geographic information systems (Geographical Information System – GIS) [Fig. 6] computer systems are specifically designed to support the implementation of geographic information systems (GIS), which require the use of information "specialized" to achieve their goals.

Fig. 5 Environment of collaboration

Fig. 6 Stratification of the layers

A SIT is in fact an organized set of geographic data and human resources, planned and prepared to capture, store, maintain, manipulate, analyze and illustrate all forms of geographically referenced data. A system of organizational, informative resources capable of managing and using data describing these phenomena on the Earth's surface, to the service and for the purposes of a specific production process. The relevance of the location and geographical component/territorial for the activities of the research organizations, public administrations, institutions and enterprises in almost all areas (Central and local governments, public goods and services, utilities, agriculture, manufacturing, trade and services, etc.) is highlighted by the growing importance that go assuming the distinctive characteristics of the "local system" territorially identified and defined, albeit "fuzzy" terms, scope, boundaries of land or area; In addition, the possibility of having knowledge and information detailed geographical scale up to the level of architectural artefact is often an essential element of knowledge bases research bodies, enterprises, institutions, local administrative entities, public and private operators that provide services in many areas.

Finally, with the spread of interest in economic dynamics, social, political and environmental factors that affect the territories of most of the planetary system growing importance, availability and rapid access to data and information available on regional.

Geographic database systems, generally known as GIS (geographic information systems) or sometimes SIT (territorial information systems, although this name is used mostly in reference to planning applications and environment), constitute the innovative component, both from the technological side/side methodological information/information, the collection, organization and use of that data type. For some years in Italy, a little late compared to other European countries but with a good recovery trend, the use of GIS had a remarkable increase, especially from public (State, regions, local authorities, territorial institutions) "holders" of georeferenced data both "hard" and "soft". Relevant examples include zoning and land information (such as the use of GIS-SIT, which was followed by the adoption of CAD, is practically generalized), the system of infrastructure and technological networks, transport and communication (including logistics), the mapping of environmental, cultural heritage, landscape, and industrial production, until the recent development of several "portals" to promote territorial areas (although the latter may not produce desired effectseven for the current fragmentation that reduces its effectiveness).

In different disciplines and applications, GIS have become indispensable tool and widely used not only for storing data, but above all for their analysis, development, implementation, evaluation and management that fully exploit the spatial nature: think of the problems of the Government of the territory, or more generally the use of soils (including agricultural crops), nature and environmental protection hydrological research, geological and geomorphologic characteristics, (which are also used 3D GIS), remote sensing up to archaeological research.

Ultimately the representation plays a major role in the design process, through the draft or other forms of representation the project defines and is transmitted as know formalized during the various stages of implementation, using all the technological opportunities that allow us to enter the body of the natural and built environment in order to discretize, to measure it and evaluate it for any size multidimensionality with the scientific expertise that identifies.

In a landscape, we must investigate and reconstruct reality, describing his childhood, places, objects, the points of view of memory, all the material and immaterial components, this represents a eco geometric model of reality, a paradigmatic model of environment and built.

Behind the gradual change of human needs, there is a biological significance of design: the biodisegn. It is an echo of geometry, which is the knowledge of what exists and what it will, through the transformation of all the components that make up the reality.

It consists in the knowledge of what exists and what will be, becomes the most fascinating part of the architecture and landscape architecture, because we will find during our linear path that surprise, that deviation, that will put in crisis the ideas of our imaginary journey.

1.2 The landscape of Terra di Lavoro

The territory Casertano, which is within the larger boundaries of Terra di Lavoro, occupies that part of the region that once the Romans called Campania Felix [Fig. 7], also known as Ager Campanus, "the prosperous of Campania". Its territory coincides with the historical and geographical region of Liburia, also known as (hereinafter the Decree Rattazzi, the law October 23, 1859) Terra di Lavoro, which had as its capital before Capua until 1818 and then Caserta. Land of fires? No, to tell the truth is Terra di Lavoro. Yes, because this was the name of a vast region which also included the present province of Caserta. It is thanks to Terra di Lavoro that the Campania earned the nickname of "felix". Since 79d.c., was the most fertile area of Campania, and Plinio the elder coined the nickname just to distinguish it from other areas. Then, over time, through the Middle Ages until you reach at the time of the Kingdom of Naples, he took with him the whole load of an area of Campania florida and happy, that in 1221 Frederico II wanted to even make.

The whole province, since ancient times, has always been characterized by the extraordinary proliferation of cultural, historical, artistic, but also material goods, products of the land known to the world as an essential part of Campania felix.

The splendor of this territory has attracted the attention of the famous poet Pier Paolo Pasolini who, in the poem "the ashes of Gramsci", refers to these pithy words:

"It is now near the *Terra di Lavoro*, some herds of buffaloes, a few bunch of houses between tomatoes plants, ivy and poor planks. Every once a rivulet, sleeping in the ground, appears between branches of the elm trees full of vines, dark as a drain. Inside, in the train that runs half empty, the frost».

The name of this noble and ancient province immediately evokes the notion of intellectual energy and lots of manuals, which empowered the natural gifts of a fertile land, pleasant and ideal for human settlement since prehistoric times. The landscape of Terra di Lavoro constitutes a document, an idea, an image, a word, but especially an emotion. In fact, the complex set of factors and processes denudation processes that determines the different nature of soils, landscapes and their different capacities and aptitudes.

Fig. 7 J. Jansson, "Terra di Lavoro olim Campania Felix" from "Atlantis majoris", Amsterdam 1660

The study started from the analysis of soils, precisely from their sub-layer, and to do so have been reported all the symbolism of the *geological map* produced by Regione Campania soil conservation Sector. On the basis of the available data you can notice the prevalence of sandy, dunes and beach and silt-clayey deposits, outcropping in a wide band about 1-3 miles above the sea; and silt-Sandy fluvial deposits-associated deposits peaty marsh, that crop up in most of the area concerned and reach the highest heights in the vicinity of the Volturno River. [Fig. 8] are the geomorphologic phenomena to characterize a soil and the soil which determines the development of civilization and that makes the work so fertile Land. From privileged pleasant climate and the fertility of the soil, the region is characterized by a mostly hilly territory, with mountainous areas on the border with Basilicata and Molise. Vesuvius, among the few still active volcanoes in Europe, the Gulfs of Naples and

Salerno, separated by the Sorrentine peninsula and the islands of Ischia, Capri and Procida offer landscapes of rare beauty. The soil is therefore a living body in continuous becoming, composed of inorganic particles, organic substances, air and water, which affect biogeochemical cycles are necessary for the maintenance of the living beings on the planet's surface. It derives from continuous phenomena of complex interaction between the air (atmosphere), water (hydrosphere), geological substrate (lithosphere), living organisms (Biosphere), human activities (anthroposphere) and represents the ' membrane ' through which take place exchanges of energy and matter with the lithosphere and other environmental compartments. The " pedo landscape " is a " new ideas " cross: we may think of the pedo landscape such an enrichment of the classical concept of landscape, such a " landscape of which you are also understood the soils supporting it, " or as the " dynamic combination between the outward appearance of the landscape and its intime the pedo genetic roots. " The pedo landscape function is the most extensive and complex of functions that soils play in the ecosystem, beyond production or protection objectives, involving the balance of the environment as a whole, including cultural aspects, also sociological, historical and naturalistic itineraries.

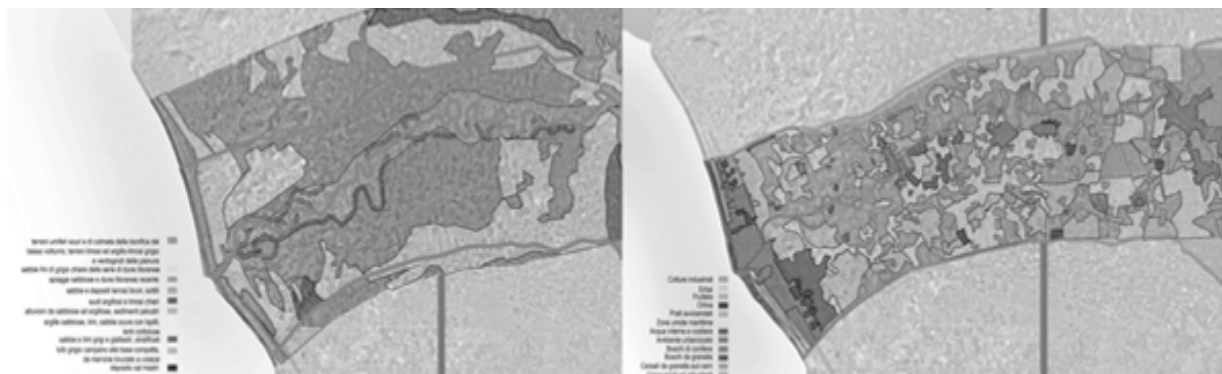

Fig.8 Geological map produced by Regione Campania soil conservation Sector.

From relative swot analysis of air (also known as SWOT Matrix), is a strategic planning tool used to evaluate the strengths (Strengths), weaknesses (Weaknesses), opportunities (Opportunities) and threats (Threats) of a project or in a business or in any other situation where an organization or an individual must make a decision to reach a goal. It can be seen as the most important strengths of this area are characterized by the presence of an environmental heritage, landscape and natural history of great importance.

Another strong point is given, by the high presence of numerous farms buffalo, from which arises a major agri-food excellence in analysis: buffalo mozzarella. Of secondary importance is not even from a warm temperate climate, which, as already mentioned, makes this area one of the most fertile of the whole region, creating a favorable environment in the presence of fauna and flora found along the lower reaches of the river Volturno. [Fig. 9]

Fig.9 Medium temperature and sunny hours of Campania

Although we have described the strengths on the other are opportunities that must be regarded as the greatest awareness of men to protect the enormous wealth that our land has to offer. Within this analysis were also highlighted the weaknesses as well as the strong presence of clayey soils, the high percentage of degraded areas, which can lead to threats such as the abandonment of traditional agricultural activity and increasing pollution. We can observe the magnificent beauty of the landscape of terra di lavoro through works of PhilippHackertun master of landscape of cultural life and more specifically the artistic landscape of terra di lavoro. Jacob PhilippHackert was a landscape painter of Brandenburg, who did most of his work in Italy, he traveled throughout Italy, gaining a reputation as a

talented landscape painter. In 1786 he went to work for Ferdinand IV, King of the two Sicilies in Naples, where he commissioned various paintings. The depiction of the landscape Hackert the ground paints inside the Real site of Carditello, appointed by Ferdinand IV of Borbone to the direction of the work of decoration and furniture of the Real site of Carditello. [Fig. 10]

Fig.10 Paintings of Jacob Philipp Hackert in the Royal Site of Carditello, depicting the Terra di Lavoro in the year 1780

The estate of Carditello, also known as the real site of Carditello, or palace of Carditello, was part of a group of 22 sites of the royal dynasty of the Bourbons of Naples, which also included the Royal Palace in Naples, the Royal Palace of Portici, the Reggia di Capodimonte and the Reggia di Caserta. These places were not only dedicated to recreation (mostly hunting) of the Bourbon Royal family and his court, but in some cases constituted real companies, entrepreneurship expression inspired by the not important ideas in vogue at the time. The estate is an elegant architectural complex of neoclassical style, originally designed by Charles of Bourbon to hunting and breeding of horses and later, at the behest of Ferdinando IV di Borbone, turned into farm model for grain cultivation and breeding of fine breeds of cattle and horses. It was surrounded by a large estate of Woods, pastures and land for cultivation. Carditello was one of real places which possessed the title of "real Treat" because, despite its function as a business, offer a pleasant stay to the King and his court to the special hunting thanks to rich and numerous woods which possessed. The structure was built by the architect Francesco Collecini, a pupil and collaborator of Louis Vanvitelli. La Palace has a plan to double "T" designed with the alternation of long bodies with eight octagonal towers in the factory body joints, the King, President of the King with the façades decorated with greater sophistication. A view coeval of the Palace and the area in front of view appliances agricultural and clay slope with fountains and obelisks and a podium without the circular temple built at a later date. Buildings was entered through three entrances, two lateral and one central. All around a vast wooded area. [Fig. 11]

Fig.11 Royal Site of Carditello

The current state of disrepair, the crumbling plaster from time, defaced the frescoes and the ill use have failed to erase the beauty of architecture of attacked improper urbanization of ancient feud, in fact, are still guessed the richness and artistic and architectural beauty of the Palace and the magnificent overview of the place.

The Campania Felix still enchants the visitor with the aroma of Mediterranean pine trees, orange groves and lemon trees, the cliffs overlooking the sea, golden beaches, clear sea, the same age-old charm that won the mythical heroes, Greece, the Romans and the imagination of the whole world.

But Campania is also rich in history and a rich and diverse architectural heritage. In fact the Campania, Sicily and Tuscany, is the region with the largest number of Unesco sites. The five sites of Campania are: The Royal Palace of Caserta, the aqueduct of Vanvitelli and the San Leucio; the historic Centre of Naples; Pompeii, Ercolano and Torre Annunziata; the Amalfi Coast; the Park of the Cilento, Paestum, Velia, and the Certosa di Paluda.

The man who observes the landscape of Terra di Lavoro remains fascinated by what he is facing, arousing in him inner emotions and sensations that converge in the recognition of the landscape. This recognition is subjective, because each of us, in the face of a landscape sees the latter way, filtering with personal experiences, with its cultural background, things that other people do not notice, and converse.

The mental processing of forms and aspects of what we see, is different for each of us even though the elements that constitute the landscape exist and are physically present at the place. We could say finally, mediating, that the landscape is the product of the tension between subject and object, between the cultural filter of each observer and natural field. Should be suggested to think about landscape as aesthetic places entities; with this statement we want to emphasize the aesthetic aspect is a member of the physiognomy of the territory, intending to say that its appearance contributes to individuality of the place as that specific place. You still want to put emphasis on the uniqueness and individuality of each landscape and characteristics on membership of nature and history. The landscape is not subjective aesthetic sense but rather as intersubjective all cultural and aesthetic values in particular. Having said that the definition of landscape has been established by the European Convention considering the landscape of Terra di lavoro: *"defines a certain part of the territory, as perceived by people, whose character is derived from the action of natural factors and/or humans and their interrelationships"*.

Abstract

Masonry towers constitute a huge amount of the Italian built heritage. Therefore, their safety assessment against earthquakes has a significant social importance. They are unique architectural typologies, usually conceived in ancient time exclusively to withstand vertical loads. On the other hand, the recent national and international codes require the actual ultimate behavior of these structures under strong horizontal excitations to be deeply studied, encouraging the use of sophisticated non-linear methods. Recent Italian earthquakes (Umbria and Marche 1997, Puglia and Molise 2002, Abruzzo 2009, Emilia 2012) provided wide observational information about the recurrent behavior, the damage patterns and the intrinsic vulnerability of bell towers. The mechanisms of damage and collapse of this type of structures are varied and depend on both the geometry (slenderness) and the structural characteristics (quality of masonry walls and constraints). The development of mechanical models able of analyzing the failure mechanisms for all types of bell towers is not always viable, so it is suggested to carry out specific checks too, even though approximated as specified in the Italian Guideline “Cultural heritage seismic risk assessment and reduction with reference to the Italian national building code NTC/2008”. This paper presents the results of seismic analysis carried out on a seventeen-century masonry tower in Italy, the “Corpus Domini” bell tower in Maddaloni (Italy). The results of linear and nonlinear analysis are compared and discussed, in order to provide general guidance on the main structural problems of this specific type of bell tower (recurrent in several earthquake zones of Italy).

Keywords: Seismic Safety, Bell Tower, Masonry, Code provisions.

1. Introduction

Most of historical structures has deteriorated over time by natural and environmental effects, such as earthquakes, because of inadequate preservation, which is considered a fundamental issue in the cultural life of modern society. Therefore, if the actual behavior of structures is known, protective measures can be supplied. In bell towers, the systematic observation of damage caused by recent earthquakes highlighted the high seismic vulnerability of belfries, located in their upper part. This is due to the presence of top mass and wide openings that imply slender pillars. The vulnerability consequently rises from their modest vertical-load bearing (related only to dead weight) that does not ensure stabilizing effect with respect to overturning. Quite frequently, bell towers are in contact with other lower structures. Customary cases are towers built as part of or next to churches, towers incorporated in various ways within the urban setting and towers built into city walls. In these structures, the presence of horizontal constraints at different heights can deeply modify the seismic behavior: limiting the slenderness, introducing localized stiffening elements and producing stress-concentrations, thus the vulnerability is greatly increased. In the literature, there are several research studies dealing with the seismic assessment and the vulnerability analysis of masonry towers, with regard to different aspects: mechanical and numerical analysis by computational [1,2] or simplified

approaches [1,3], experimental testing methods and structural identification [4,5], modal identification through experimental data of full-scale environmental vibration testing [6,7], seismic assessment by nonlinear static analysis. In the Italian National “Guidelines for evaluation and mitigation of seismic risk to cultural heritage” [8], different simplified mechanical models are identified for the most diffuse types of historic structures: buildings, palaces and other structures with bearing walls and horizontal diaphragms [9], churches and other structures with large halls, without intermediate diaphragms [10], towers, bell towers, and other tall and slender structures. The adoption of these models, though affected by uncertainties, permits to supply a homogeneous evaluation on territorial scale and, thus, a preliminary design of future strengthening interventions. The analysis based on simplified mechanical models (LV1) allows the evaluation of collapse acceleration by means of a method based on a limited number of geometric and mechanical parameters or utilizing qualitative tools (analysis of the construction characteristics, critical and stratigraphic surveys). Seismic behavior of towers depends on certain specific factors: structure slenderness, degree of connection between walls, presence of adjacent structures in the lower portions (which may create horizontal constraints), presence of slender architectural elements at the top of the structure (steeple, towering gables, battlements, etc.) or in any case belfries. For towers, the Italian National Guidelines [8] propose a simplified model based on failure hypothesis due to combined axial force and bending moment. The model considers towers as cantilevers which, if loaded by lateral forces in addition to their dead loads, may be subject to crises in a generic section due to crushing in the compressed zone, after the reduction of the effective un-cracked area due to non-tensile-strength. In this paper, the “Corpus Domini” bell tower is studied applying the LV1 level proposed in [8]. The results of linear and nonlinear analysis are compared and discussed.

2. The “Corpus Domini” bell tower

The “Corpus Domini” Basilica in Maddaloni is situated in the oldest part of the city called Olivet, near the ancient S. Aniello Church, on the slopes of the Maddaloni Hill. The building is very articulated and seems oversized as compared to the surrounding urban context. The Basilica was built in the eighteenth century on pre-existing late sixteenth [11]. The bell tower was designed by Orazio Salerno in 1781, on the right side of the main entrance of the church, about one meter from the front side. There is little historical information on the designer, but it is known that he worked in the years when Luigi Vanvitelli was directing the building of the Royal Palace in Caserta and the Carolingian aqueduct in the Maddaloni Valley. Also a wooden model of the tower, along with the graphics and the technical report, was commissioned to Orazio Salerno. The construction began on May 13, 1781 and was completed in 1790. Because of the damage caused by lightning on February 12, 2010, a restoration design was drafted by the architect Mariano Nuzzo; and the interventions ended on 2012. Although the tower shows good structural conditions, its safety against potential future earthquakes is of primary importance. The bell tower is about 49.12 m high, and has nine portions with both square and circular cross-section. Table 1 shows the dimensions of each portion, and the material by which it is made.

N.	Height [m]	Material	Section [m] side or diameter	f_{mc} [MPa]	Weight [kN/m ³]
1	0 – 0.75	limestone	8.02	4.5	22
2	0.75 – 10.25	brick	8.02*	2.4	18
3	10.25 – 11.05	limestone	8.40	4.5	22
4	11.05 – 20.65	tuff	7.66*	1.4	16
5	20.65 – 21.48	limestone	8.40	4.5	22
6	21.48 – 30.55	tuff	7.66*	1.4	16
7	30.55 – 31.38	limestone	8.02	4.5	22
8	31.38 – 39.86	tuff	6.44**	1.4	16
9	39.86 – 49.12	tuff	6.44**	1.4	16

3. Simplified mechanical modeling and analysis

The assessment of safety, as well as the necessity and the suitability of eventual retrofits, has to be determined from the comparison of the structure capacity, evaluated as the result of qualitative and quantitative knowledge and analysis of the building, and the seismic action demand [9]. This assessment can be performed by simplified methods, that are different from the specific ones used in the strengthening design. Safety index I_s greater than 1 indicate structures able to withstand the required seismic forces, provided by the seismic code; on the contrary if I_s is lesser than unity, the

safety is lower than that prescribed. Similarly to the index I_s , it can be defined an acceleration factor f_a , defined as:

$$f_a = \frac{a_{SLV}}{a_{g,SLV}} \quad (1)$$

where $a_{g,SLV}$ is the design ground acceleration, corresponding to the assigned return period of the earthquake, related to subsoil A. The acceleration a_{SLV} is the ground acceleration leading to the achievement of the structure ultimate limit state (SLV), computed as a function of the fundamental period of vibration T_1 of the structure, as defined in the Eqn (5.26) of the “Guidelines for evaluation and mitigation of seismic risk to cultural heritage” [8,12]. The simplified model proposed in the Guidelines [8] is based on the assumption that towers are structures with cantilever-behavior.

The analyzed bell tower was divided into n sectors with uniform geometric characteristics and the checks were performed in correspondence of each section change. The ordinate of the elastic response spectrum $S_{e,SLV,i}(T_1)$, required by Eqn (5.26), corresponding to the ultimate limit state SLV in the i -th section of the bell tower (taking into account the confidence factor F_C) is calculated by:

$$S_{e,SLV,i}(T_1) = \frac{q \cdot g \cdot M_{u,i} \cdot \sum_{k=1}^n W_k \cdot z_k}{0.85 \cdot W \cdot \left(\sum_{k=i}^n W_k \cdot z_k^2 - z_i \cdot \sum_{k=i}^n W_k \cdot z_k \right) \cdot F_C} \quad (2)$$

where:

- q is the behavior factor;
- g is acceleration of gravity;
- z_i is the height of section i with respect to the foundation;
- W_i is the weight of the i th sector;
- $M_{u,i}$ is calculated as described below.

Where the tower has got squared rectangular cross-section, under the hypothesis that normal forces are not larger than $(0.85 \cdot f_d \cdot a \cdot s)$, the resistant moment at the base of the sector may be computed by:

$$M_{u,i} = \frac{\sigma_{0i} \cdot A_i}{2} \cdot \left(b_i - \frac{\sigma_{0i} \cdot A_i}{0.85 \cdot a_i \cdot f_d} \right) \quad (3)$$

where:

- a_i is the cross-section side orthogonal to the direction of the seismic action, depurated of any eventual openings;
- b_i is the cross-section side parallel to the direction of the seismic action;
- A_i is the total area of the section under analysis;
- σ_{0i} is the average normal stress of the section;
- f_d is the design compression strength of the masonry, opportunely reduced in relation to the knowledge level achieved.

Where the tower has got circular cross-section, the resistant moment at the base of the same sector may be calculated as:

$$M_{u,i} = A_{set} \cdot 0.85 \cdot f_d \cdot y_G \quad (4)$$

where:

- A_{set} is the area of the sector of the circular crown;
 - y_G is the distance of the point of application of the resultant from the center of the circle.
- For each cross-section, the peak ground acceleration (demand) that causes the resistant moment (capacity) is estimated. The minimum value of the peak ground accelerations, among those obtained for the analyzed sections, represents the acceleration corresponding to the ultimate limit state for the bell tower.

3.1 Seismic safety of the “Corpus Domini” Bell Tower

According to the above briefly described procedure LV1 outlined in [8], by considering the geometric features of the “Corpus Domini” Bell Tower, the acceleration factors (f_a) of nine portions were computed. These portions are the most representative in terms of geometries and openings; their plans are reported in Figure 1. Seismic safety was evaluated according to the only one direction because all the examined portions are symmetrical. The safety verification was performed at different heights because it was not possible to identify a priori the most critical section, due to the tapers in wall thickness and the opening impairments. The acceleration factors f_a are computed through Eqn (1), according to a seismic safety level corresponding to buildings of limited relevance and to a class

of normally crowded use (Class III), and assuming a ground motion acceleration $a_{g,SLV}$ of 0.202 g and a B soil class. The fundamental period of vibration was computed as $T_1=C \cdot H^{3/4}$, where H is the tower height and C is equal to 0.05. In addition, in computing Eqn (5.26) of Guidelines and in Eqn (2), the S coefficient was assumed equal to 1.197, the F_0 factor equal to 2.519, and the behavior factor q is equal to 3.6. The indexes are computed assuming a confidence factor of 1.35 (corresponding to a complete survey of the geometries and a limited one for constructive elements and mechanical properties of materials). The analyses led to F_a values lower than one for the tuff portion number 4 and 6, with values ranging between 0.4 and 0.6, and for the brick portion number 2, where is equal to 0.7.

4. FEM modeling and analyses

The safety index of the tower was also evaluated using a finite element modeling. The analyses were performed using the "strumas" model of the computer program MidasGen®, specifically developed for the study of masonry structures. This a "micro-macro" modeling based on the hypothesis of homogeneous equivalent material [13], where, starting from the definition of a representative elementary volume and different constitutive models for the three constituents (brick, bed and head mortar joints), the properties of the equivalent masonry material are computed through a homogenization procedure. The technique of homogenization is the one proposed by Pande [14] and is based on the equality of the deformation energy. The properties of the equivalent masonry material depend, therefore, on the size of blocks, the thickness of horizontal and vertical mortar joints, on the Young's and Poisson moduli of blocks and mortar, on the tensile strength of blocks and mortar. The model assumes a indefinitely elastic behavior in compression. The analytical procedure is linear in each step, but if the principal tensile stress exceeds the strength of a constituent, its contribution to the new stiffness matrix of the homogenized material is reduced or canceled. The reduction depends on a parameter of stiffness abatement, assumed to be equal to $10e^{-4}$, which corresponds to a nearly elasto-plastic behavior [16]. The FEM model of the "Corpus Domini" tower is composed of 47976 brick elements (Fig. 2). Eight node solid elements of size about 0.3 x 0.3 x 0.25 m, with isotropic behavior were used for modeling the masonry structure. The material parameters, including the compressive strength, were selected according to the Italian National Building Code [15], and the selected values are listed in Table 2.

Material	E [MPa]	G [MPa]	f_{mt} [MPa]
brick	1200	840	0.15
limestone	2400	1560	0.30
tuff	900	630	0.10

Table 2: Mechanical properties of the bell tower materials.

Figure 2: F.E.M. model of the "Corpus Domini" bell tower

4.1 Modal characterization

In order to assess the seismic response of the bell tower, initially a multi-modal simplified analysis was performed, even though the ability of such an analysis to represent the actual behavior of masonry buildings is limited, due to the largely nonlinear behavior under dynamic seismic action. Moreover, the knowledge of eigen-values, eigen-modes and activated masses is needed for determining the shape of the horizontal load forces to utilize within the subsequent pushover procedure. The first three period of vibration are listed in Table 3.

Mode	Frequency [Hz]	Period [s]
1	4.196	1.278
2	5.009	1.254
3	15.424	0.407

Table 3: First three frequencies and periods of the "Corpus Domini" bell tower.

4.2 Pushover analysis

The nonlinear static analysis was carried out applying loads in two stages: first the vertical loads and then the horizontal ones. Several distributions of lateral loads were applied. The corresponding capacity curves were subsequently converted to capacity curves of single-degree-of-freedom systems. Following the procedure described in [15], it was possible computing the safety indices in terms of capacity/demand ratio, to be also compared with those determined through the LV1 simplified analysis. The tower capacity was identified with the achievement of the maximum stresses in compression, thus making a conservative assumption. The control point was placed at the mass center of the ninth sector. This occurred for the Z-horizontal direction of loading; the corresponding maximum displacement is equal to 69 mm, showing a noteworthy large deformation capacity. Fig. 3 shows the vertical stresses in the entire bell tower at the above maximum displacement: the figure highlights that the maximum strengths are achieved in the lower tuff sector. Usually, the tall and slender shape of towers makes them more vulnerable at the base settlements, limiting the maximum allowable displacements under earthquake. In addition, the boundary condition of cantilever type makes them unsuitable for redistributing stresses and dissipating energy. The characteristic limited ductility of the masonry accentuates this brittle structural behavior [17], which is often accompanied by a concentration of stresses at the basement and can be amplified by the brittleness of deteriorated masonry. In the "Corpus Domini" bell tower, the noteworthy difference in terms of material properties between the intermediate diaphragms in limestone, the lower sector in bricks and the main portions in tuff, besides the achievement of the maximum stresses in the tuff portion, allowed larger deformation capacity of the whole tower. Fig. 4 shows the stress distribution in the tuff portions only, which are the most representative. The cracked zone is concentrated at the base of the pillars. Following the

Figure 3: Vertical stresses in MPa.

Figure 4: Vertical stresses in the tuff masonry [MPa]

procedure provided in NTC/2008 [12], the displacement demand in the Z-horizontal direction is equal to 180 mm, and then the minimum safety index is equal 0.38. Therefore the safety assessment of the bell tower under horizontal loads is not verified also for the pushover procedure.

5. Conclusions and safety assessment remarks

Masonry towers constitute a huge amount of the Italian built heritage. Therefore, their safety assessment against earthquakes has a significant social importance. They are unique architectural typologies, usually conceived in ancient times exclusively to withstand vertical loads. Many of these buildings are then characterized by structural schemes not suitable to withstand seismic events. This paper presents the results of the seismic analysis carried out on a seventeen-century masonry tower in Italy, the “Corpus Domini” bell tower in Maddaloni (Italy). The results of the LV1 simplified procedure and nonlinear static analysis are compared and discussed, in order to provide general guidance on the main structural problems of this specific type of bell tower (recurrent in several earthquake zones of Italy). The results obtained through FEM analysis essentially confirm those of the LV1 analysis. Moreover, the safety indexes obtained by the simplified analysis are larger than unity, except for the tuff portions. The response obtained by the FEM model confirmed the exceeding the allowable stress levels in the tuff masonry portions. It has to be considered, however, that in both models the brick coating of the tuff masonry was not considered, and then the possible increase in strength was not taken into account. Finally, the seismic safety evaluation of masonry towers should be performed both by global seismic analysis, controlling the entire structural system capacity, and by local failure mechanisms analysis, controlling all the possible out-of-plane mechanisms.

Paper's Title Rural design and territorial development

Caterina BELARDO

Dipartimento di Architettura e Disegno Industriale, Seconda Università degli Studi di Napoli,
Aversa(Ce), Italy
caterinabelardo@gmail.com

Abstract

The topic of this study is the redesign of the agrarian landscape of Caserta (Terra di Lavoro). The redesign is about the experimentation of new projects, which don't try to be a solution, but an array of possibilities capable of triggering a new growth. The target of the research is the redesign of a territory for the creation of "new cultural landscapes". The aim of the plan is to allow for sustainable development, so that the characteristics, heritage and qualities of the rural settlement may be preserved. The project involves the formulation of theoretical models applicable in the territory. The result will be an atlas of models useful to design new landscapes. There will be multiple project proposals which are part of a dictionary. Projects were done on three areas of the territory. Each model has different features formal, geographic and orographic. Planning and developing, in its various contexts, as a unique form of rural life with a distinct character. The proposal studies several solutions to the problems using three rural design strategies. These are examples only and, therefore, contain only very general guidelines. But this lack of rigidity makes the proposal very flexible and adaptable on all territory. Models leave space for future sustainable growth of the rural landscape.

Keywords: rural, landscape, sustainability, model.

1.The place. Terra di Lavoro

The place of study is a part of Campania, the flat area between the slopes of Mount Massico and Campi Flegrei . The ancient Romans called this part of Italy Campania Felix (happy Campania) . This area is rich in of mythology and history. Is famous , as always, for the fertility of the land. It is described by poets and writers as a Garden of Eden . Here lived Strabone , Virgil, Pliny , Goethe, Pasolini, Maiuri . All of them talked about the beauty and the fertility of this rural landscape. The presence of the Regi Lagni, antique reclaimed Clanis, and the temperate climate have made these lands so fertile. Those have been a source of the population for centuries. Here was born a peasant culture that currently is almost completely lost. Actually, the rural characters are still very strong, but the area is highly degraded. Industrialization, the loss of rural life and the spill of toxic waste have transformed the area in a negative way.

Today we can still see the presence of centuriatio, a system for the division of land that used by the Roman surveyors. The rural areas still retain the courtyard houses, typical buildings of the place. The houses were farms, the spaces were marked by the agricultural products working.

Fig. 1: Hackert Jacob Philipp, Palace of Caserta and Vesuvius, 1793.

1.2.The Idea: " The rural landscape project"

The research project is the redesign of the agrarian system of Caserta (Terra di Lavoro). The project has a complex structure. This experiment with new design solutions for the development of the landscape. It is a series of exercises design made on sample areas of the territory. The result will be an atlas of models useful to design new landscapes. The proposals are always reversible and adaptable to future needs related to the growth of the territory and society. The atlas will be based on a dictionary of elements: the pre-existing and new interventions. The design of the new agricultural system is based on two main actions: the reactivation of the existing elements and the new project that brings together all the characters. The quality of rural development can be influenced by many factors.

The new focus on rural landscape centers on three key questions:

- searching for identity
- reduction of landscape deterioration
- definition of a new development model

The design of the new rural system is based on two main actions: the recycling of the existing elements and the integration of multiple characters. The integrated system will be made of green areas supporting urbanized areas, production areas inherent to the new agrarian system and a network of "elements" that will connect all the existing and future systems.

The model studied is applicable and extensible to all landscape.

Models for areas:

1. flat area
2. coast area
3. river area

Fig. 2: Areas.

The theoretical model will be applicable in the territory through the formulation of an abacus of elements divided by macro-systems.

Fig. 3: Models.

The model will acts on various systems: infrastructure system, agricultural system, production system and architectural system. A service of multiple uses:

- production
- cultivation
- collection products
- homes
- transport
- import-export
- agro-tourism
- receptive
- social
- cultural
- didactics

The actions are so many. Possible solutions have the focus to consolidate the existing agricultural activities and introduce new production systems. There will be a new agricultural landscape that will take advantage of all the resources of the place. The First actions are: strengthening of tracks of

centuratio and reactivation of farm roads. Then, the recovery and re-naturalization of watercourses, allow to create an optimal microclimate, and to increase the water supply for irrigation of fields, and in some cases real river parks.

The rural centers , numerous cottages and farmhouses in the area, forming between them a dense network in the area, are the basis for the proper functioning of the new system .

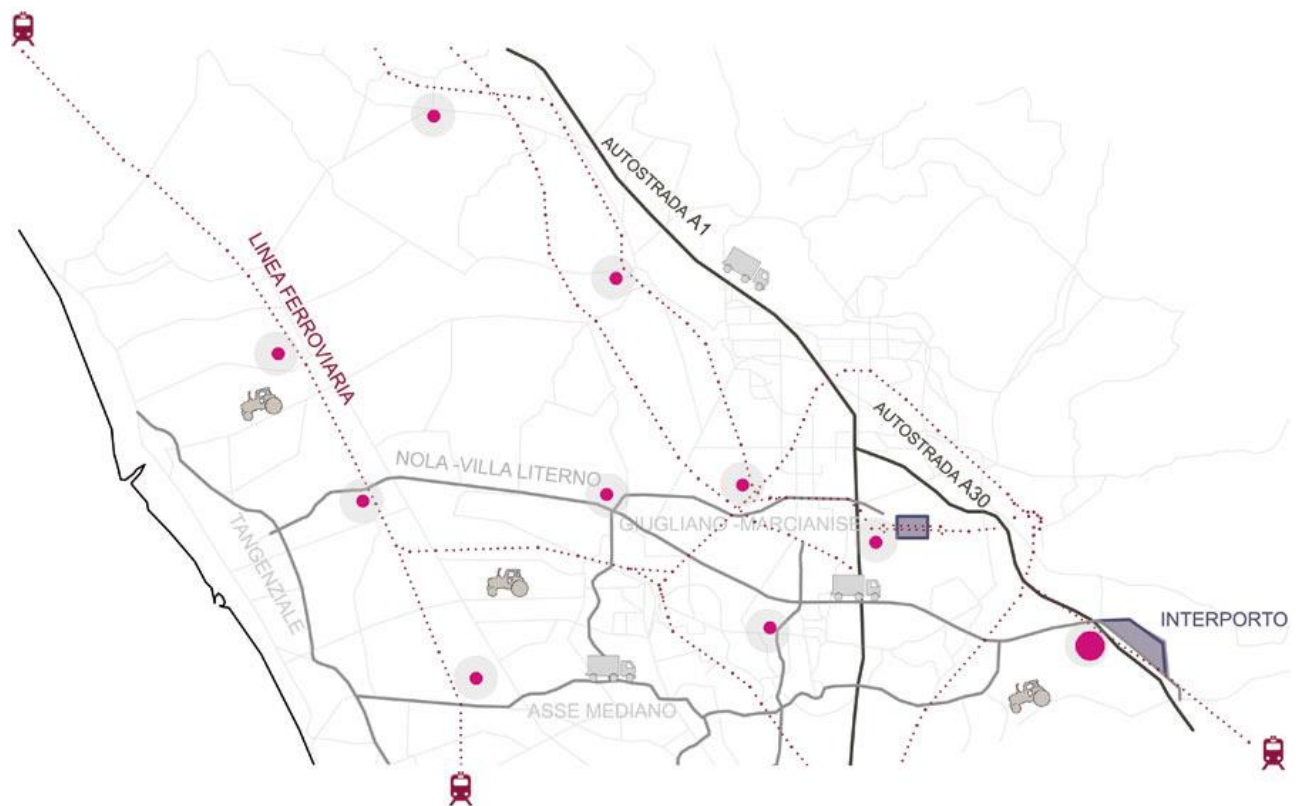

Fig. 3: Mobility

Those buildings sometimes become the place for the production and storage of agricultural products, information, education and refreshment. The centers will be preserved in their rural character and peripheral areas transformed. In highly urbanized areas the project involves the development of agricultural areas through the formation of interstitial green promenade. These green belts suburban centers will bring into connection with the surrounding agricultural mosaic. In some of those areas it will be possible the creation of new residential areas. Near the exit of the main ways of communication technology parks are planned for Renewable Energy and the points of collection of agricultural products. The production will be supported by new buildings for the manufacturing, storage, and export. The architectural heritage, the numerous archaeological sites and natural areas will be part of this project . These are also a good opportunity to initiate activities to do. For this reason it is important to restore the historical paths and insert them into the new system.

Fig. 4: Rural landscape. Terra di Lavoro.

Models Template1: The model of the flat area. A portion of the territory taken in a suburban area of the city of Marcianise, this is densely populated urban center. Here are two important elements: the urban area and the agricultural landscape. The project proposal deals with work on the edge of town. The peripheral area, abandoned and degraded, it turns into green belt. This is an area, serving the towns, where many activities take place. This is made from poplar forests, urban gardens, pedestrian trails and areas for outdoor activities. Here you can also create new residential neighborhoods and new centers for agricultural production.

Template2: The model of the river area. The area in question is near the Volturno River and the town of Santa Maria la Fossa, a small town. Here are the important elements: the river and the rural center. The project involves the creation of a River-Rural Park. The creation of this park will help to save the landslide risk areas. The recovery of the ecosystem configure a new landscape. The park is made up of areas with equipment, farmland and natural areas. This makes it possible to connect the village with the surrounding landscape. Here is the planned introduction of new manufacturing activities related to the river.

Template 3 : The model of the coast zone. The area in question is in the town of Castel Volturno, this is a run-down area characterized by illegal buildings which is exploited mainly in the summer. Here too, the agricultural landscape is still very present. In this area the main cultivation is tomato plants. The coastal strip is separated from the farm by a large pine forest. The proposal involves the redevelopment of the area and restoring the character of agriculture and tourism. A single project where we will design bathing low-impact landscaping, pedestrian and cycle paths alternating those driveways and large pine grove in the park. The poor quality of the existing building will be integrated with the creation of new cottages conceived as a hotel widespread. It will be a tourist activity in rural character.

Sorrina Nova (VT): traces of an intangible city. The contribution of aerial archaeology

Davide MASTROIANNI

davidemastroianni@yahoo.it

Abstract

Sorrina Nova is the name of the ancient Roman settlement of the modern city of *Viterbo*. The centre was located, most probably, in the western portion of the extended promontory of *Riello*, along the road *Baths*, which is connected with the *Via Cassia*. The roman town developed after the destruction of etruscan *Surna*, that was erected on the *San Lorenzo's Hill*, where today there is the Papal Palace and the Cathedral. The reconstruction of the *Via Cassia* determined the development of *Sorrina Nova*, because it was an important connection between Rome and Central Etruria up to Florence. The fall of the Roman Empire caused a period of serious crisis, that forced the residents to return again to the *San Lorenz's Hill*, called *Urbs Vetus*, founding *Castrum Viterbii* in 773 AD. The research aims to integrate the data obtained during the surveys conducted on the ground and collected in the two volumes of the *Carta Archeologica d'Italia*, *Viterbo* (MILIONE A. 2002-2007), with the data achieved with the aid of aerial photointerpretation. The objective of this preliminary study is to define the location of *Sorrina Nova* and the ancient city plan.

Keywords: Lazio, Viterbo, Sorrina Nova, Aerial Archaeology, Ancient Topography

1. State of the art

The uncertain position of the city of *Sorrina Nova*, the ancient roman settlement of the modern city of *Viterbo*, is always argument of research for academics and literates; the earlier studies were continued, in the middle of XIX century, in 1849 [1], by Francesco Orioli, scientist and archaeologist, who supposed that the location of *Sorrina Nova* was on the upland of *Riello*, about 3 km from the centre of *Sorrina Vetus*, the ancient Etruscan settlement, that today stands in *Colle del Duomo* in *Viterbo*. F. Gamurrini, in the writing of *Carta Archeologica del 1881-1887*, republished in 1972 [2], pointed out with accuracy the numerous archaeological ruins on the area of *Riello*, that probably belonged to the ancient *Sorrina Nova* [3]. Also A. Gargana, as Orioli, was convinced of existence of an etruscan-roman settlement [4], that during the Middle Ages developed into the city of *Viterbo*. Later, the theories of F. Orioli were denigrated by M. Signorelli [5]. A. Scriattoli, describing the monuments of *Viterbo*, retail that, near *Palazzo Cristofori*, was conserved a fragment of epigraph, embedded in a wall [6]: the epigraph referred the name "*Sorrina Nova*" (*CIL*, XI, 3010). In the 1966 e in the 1969, around the area of *Riello* [7], two fragments of marble's plate were found, a grave and an etruscan inscribed sarcophagus were found in *Poggio Giudido*. In a document dated back to 797 AD, the *Regestum Farfense* (II, n. 172), emerges the name of "*casalem Surrinem*", not that "*Sorrina Nova*"; the town had almost lost its importance. In 1988, V. Focchi Nicolai [8] asserted that the ancient roman settlement was on the *via Cassia*, near the *Ponte Camillario*, about 2 km west from *Viterbo*. The archaeological surveys which were already conducted in the area of *Riello*, between 2002 and 2007 [9], had established, confirming the regress data and completing the new data, that the area was, probably, the location of the ancient roman settlement, however today the question of real site of *Sorrina Nova* has not yet been resolved.

Fig. 1: *Sorrina Nova* in *Carta Archeologica* 1881-1887.

2. The ancient viability

In ancient times, the territory of *Viterbo* was crossed by so-called *via Cimina* that, in historical cartography, is often the only element representing the ancient local viability. Attested by ca. fifteen inscriptions about *curatores viarum*, which are probably dated back from the I to the III century AD, the way maybe started from *Sutri*, it passed in the neighbourhood of *Lago di Vico* and then it brought back to *via Cassia*, in the North of *Viterbo*, near *Aquae Passeris*. Traces of *via Cimina* were founded also near *Sorrina Nova*; in correspondence of *Strada Bagni*, an arterial road started; it was part stone-paved and part dug in tuff stone. This road ran long a wall section near *Poggio Giuduo* and then it cut the site of *Riello*: it is possible suppose that in this point, the *via Cimina* was divided in two arterial roads: the first passed near *Sorrina Nova* and arrived to the *via Cassia* in the W and the second brought back to consular road, near *Aquae Passeris*. The road that linked to *via Cassia* is now equivalent to *Strada Bagni*, this had four "*diverticula*": the first brought in *Tuscania*, the second in the neighborhood of bath buildings near *Bussete* site, the third crossed the hill of *Sorrina Nova* and the last one continued behind *Poggio Giuduo* and met with the current *Strada Riello* [10].

3. *Sorrina Nova*: the archeological studies of site of Riello

The ancient settlement of *Sorrina Nova* is today attested by numerous inscriptions [11], but only eleven of these, dating back between the I and II century AD, mention exactly the name of *Sorrina* [12]. These inscriptions give very little information regarding the organization of the roman town, which became, probably, a *municipium* in 87 BC; in these inscriptions is attested the presence of several baths, a *macellum* and necropolis. An *ordo decurionum* [13] and a *pontifex iure* [14] are mentioned and this imply the existence of political structures and worship buildings. The area of *Riello* is frequented since the protohistoric age, as the materials found at *Poggio Giuduo* and *Fosso Riello* suggest; the settlement attested a continuity of life, during the etruscan and archaic age, as evidenced by enlargement of the settlement, which extended over a large part of the upland to the W of *Fosso Riello*, and over the necropolis of *Poggio Giuduo* and *Poggio Giulivo*. The finding of a memorial stone, on the site where *Sorrina* was built, confirms the attendance of the area between the fourth and third centuries BC; the presence of necropolis is attested along the cliffs that line, to the W and to the E, *Fosso Riello*. During the early imperial age, in the city was build the baths and the *macellum*; the necropolis of *Poggio Giuduo* continued to be used until the first century BC. The city remained alive

until the fourth or fifth century AD, as attest the attendance of the roman baths in Late Antiquity; the literary sources attest also the martyrdom of Sts. Valentine and Hilary, in 304 AD, near the *Ponte Camillario*. Towards the end of the eighth century AD, the city was abandoned and the *Regesto Farfense* mentions, in the 796 AD, only a “*casale Surrinem*”, while from the middle of eighth century AD, the same literary source attests a “*Castrum Viterbi*” that correspond to the *Colle del Duomo* [15]. The city, therefore, moves again to the site of the ancient etruscan town of *Surna*.

4. The archaeological map of *Viterbo*: summary of the surveys data in the area of *Riello*.

The area of *Riello*, in order to carry out a more detailed analysis, has been divided into four micro areas, called A, B, C and D (fig. 2) with the purpose of summing the study up. Each single micro area contains all data related to the reports of discoveries and archaeological surveys conducted between 2002 and 2007, for the preparation of the archaeological map of *Viterbo* [16].

4.1 Micro area A

The south-western area is characterized by the existence of underground rooms, communicating each other through many tunnels, and various chamber tombs. Sporadic fragments of red and clear clay tiles and fragments of tableware are also attested [17].

4.2 Micro area B

The north-eastern side is bordered to the W by a tuff ridge, at the edge of which a *opus cementicium* wall was found; it was composed by small travertine blocks. Scattered fragments of red and clear clay tiles, some *opus cementicium* wall ruins, few tableware fragments, red clay ware, black painted pottery, italic and african terra sigillata, archaic and renaissance maiolica were found [18].

4.3 Micro area C

In the SW area there were many *hypogea* and many narrow passages communicating each other; these were part of a complex system of tunnels dug into the tuff, performed in etruscan times, to capture the many springs this area was full of. Several fragments of building material [19] and ceramic [20] (VI-V century BC) and numerous paving stones were found in the NW of micro area C.

4.4 Micro area D

The area covers three hectares and is delimited by a tuff ridge to SW, S and S side, by a slope to E and W side and it is reconnected to *Fosso Riello* to N and NE. The presence of shapeless blocks of tuff and fragments of travertine plates were found in all the area. Ruins of a roman building and numerous chamber tombs built in the tuff are today hidden by vegetation. The area is characterized by the presence of numerous fragments of ceramics and building materials (VI century BC-I century AD) [21].

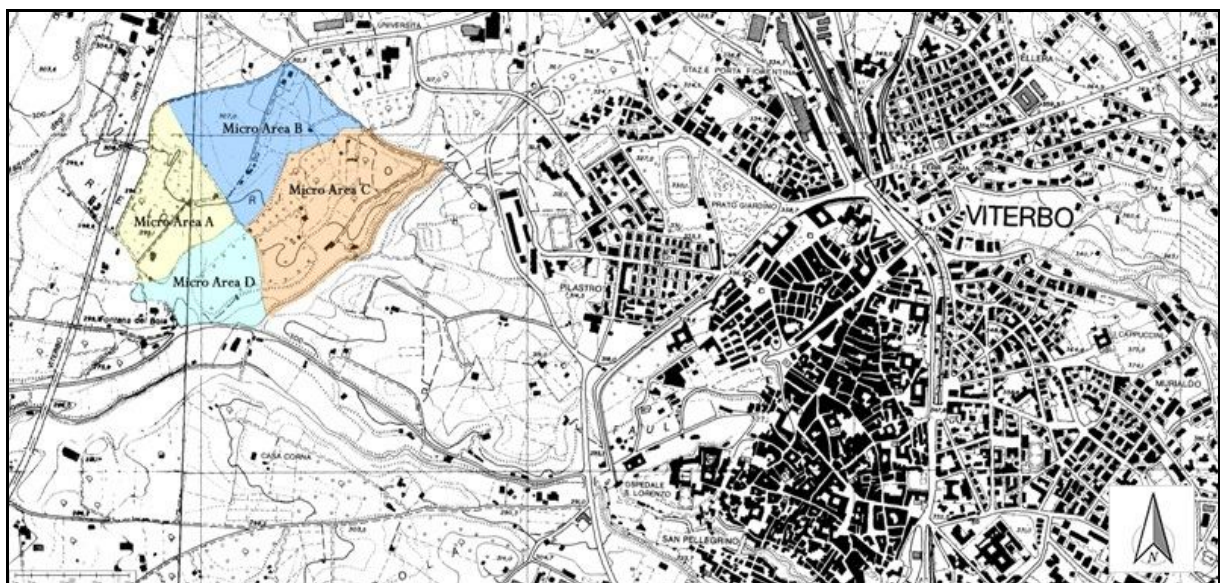

Fig. 2: The area of Riello divided in four micro areas: A, B, C and D.

5. Analysis and interpretation of aerial photos

Aerial photography is used in archeology as tool to documentation and identification of archaeological features that are not visible and are difficult to find, if not from the top. The elements, in the vertical and oblique photography, are called tracks; one or more archaeological objects "impress" the photographic plate to produce some effects on certain elements that surround it, or make it "invisible". These elements act as a mediator and make visible the hidden objects. The analysis of aerial photographs, along with a few visible persistence on the ground in 1849 and identified in 1887, and the materials found during the surveys conducted between 2002 and 2007, have identified part of the ancient roman city of *Sorrina Nova*. It was possible to reconstruct partially the topography and the system of the roman town, thanks to the reading and interpretation of satellite images, using aerial storical photos of RAF (1939) (fig. 3), satellite imagery from Google Earth (2005, 2009), ortophotos of the Lazio Region (1989, 1994, 2000, 2006, 2008) and the vertical and oblique images of Bing Maps (2013). After a careful aerofotointerpretation of individual shots, it was possible to create an aerial photography georeferenced mosaic (fig. 4), overlapping the union of sheets 345130 and 345140, in scale 1:10000, relating to the Regional Technical Map of Lazio, and this has allowed to "vectorized" archaeological visible anomalies. The frame snapped in the 2009 was basic for the correct interpretation of some anomalies and of great importance to the partial reconstruction of the urban structure. In vertical aerial photography are recognizable remains of numerous buildings and many relevant traces of the eastern sector of *Riello* (fig. 5). Of particular interest are the negative cropmarks that show, in the northern portion of the micro area C, the remains of several buildings, with NW-SE orientation: eight quadrangular rooms (ca. 8 x 7 m), an L-shaped structure (20 x 12 m) and an unusual shaped building that has all the characteristics of a burial chamber. In fact this is composed by a *dromos* (12 x 4 m) which allows access to an environment of rectangular shape (10 x 8 m) relevant to the chamber of the deceased. The anomalies of quadrangular and polygonal shape, generated by increased growth of vegetation and by a difference in darker tonal color, would seem to indicate that the structures were dug in the tuff (fig. 6). Similar examples are found in *Vulci* and *Veio* [22] (fig. 7).

Fig. 3: The area of Riello in a historical photo of RAF 1939.

Fig 4: The aerial photography georeferenced mosaic.

Fig. 5: Riello. Micro area C: The structures and the block identified by cropmarks.

Fig. 6: Archaeological area of Vulci: the structures pointed out by cropmarks are similar to those of Sorrina Nova [23].

Immediately to the SE, negative cropmarks are visible: they are remains of two blocks, narrow and elongated in the NE-SW direction, which measure 36 x 48 m. These are divided into batches (12 x 24 m each), three on the short side and two on the long side, for a total of six, for each isolated. Other cropmarks are visible: the remains of a moat (106 x 4,50 m), oriented NE-SW, delimits the block on the SW side (fig. 6).

Fig. 7: The finalized cartography. The area of Riello with restitution of archaeological data. Detail of roman blocks in red and etruscan structures in blue.

6. Conclusions

The results obtained from the study of aerial photographs, along with the data deduced from literature sources and those derived from surveys, it is possible to suggest different phases of the frequentation of the area of *Riello* and, in particular, the micro area C. Obviously, this is a preliminary study performed on a narrow portion of area with high archaeological potential. The investigated section of the area, according to the data mentioned above, seems to have been occupied, in a first phase, in etruscan age, as evidence the structures built in the tuff bank and the ditch, probably belonging to an etruscan “tagliata”, whose presence is attested in the highly territory. In a second step, the area seems to be affected by the existence of a roman settlement, as evidenced by the presence of two blocks. At the current state of knowledge, the consistency of the obtained data is the first step for a series of interventions aimed at verifying future archaeological excavation of the tracks identified during the aerofotointerpretation.

[3] "In compagnia del sig. Medichini ho fatto degli studi sopra il terreno di Surrina Nova. Dalle vicinanze di Ponte Camillario si parte una via romana che doveva percorrere l'attuale dei Bagni fino alle vicinanze di Porta Faul. Detta via passava per una terma, (i bagni del Caio) la cui costruzione accenna ad un'epoca tarda. Sembra che detta via si unisse ad altra che proveniva dal piano del Bullicame, ma di questa non conservasi che lungo tratto incavato nel tufo e comincia precisamente al fontanile dei Bagni di Ser Paolo. Presso questo bivio discendono altre due vie, la cui esistenza è accertata da profondi tagli e da vari selci e frammenti di selci. La prima costeggia la valletta di Riello a destra salendo il fosso; giunto sull'altura piega a d. con piccolo angolo sulla via mulattiera che conduce a Porta al Bove per poggio Giudio. Per questa via sono frequenti tombe di un periodo etrusco romano, cioè non dissimili da quelle lungo la Cassia di Sutri. L'altra via piega a manca verso l'altura di Surrina. A capo all'altura di Surrina lasciava a destra un monumento sepolcrale e discendeva ad un tratto di via antica, che da sopra il Bullicame portava e tuttora porta alla Madonna della Croce (Bivio della via di Toscanella con quella di Montefiascone). La via descritta doveva essere il decumano della città di Surrina. Tanto la via che corre sul fondo di Riello, quanto quella che percorre la via attuale dei bagni mettevano capo ad una strada, di cui si accennano l'esistenza più selci ed un continuo taglio la quale corre parallelamente alla via attuale circondaria da Faul a Porta di Bove. Ecco ora una succinta descrizione della nuova Surrina. Le tombe che vedonsi sopra il gazometro a Porta Faul debbono appartenere a quel pagus etrusco che stava dove ora trovasi il Duomo ed il giardino vescovile, cioè sulla rupe fra il fosso Arcione e il fosso di Paradosso perché sono di un carattere puramente etrusco e lontane e divise dalle altre della nuova Surrina. Queste si estendono lungo la via attuale dei bagni, su pel fosso di Riello ed in quella costa ripida e tufacea di S. Ilario, cioè alla manca dell'arcione a mezzodì di Surrina. Il carattere di queste tombe è etrusco romano, cioè sul davanti sono aperte ad arcosolio, e più di esse sono internamente divise a loculi. Vi sono però delle tombe più antiche, etrusco romane sempre, colla volta divisa a travature, ma queste sono tre o quattro. Della antica cinta di Surrina Nova niuna traccia. Dal lato del Bullicame è lasciata a picco a sud e sud-est difesa e divisa dal fosso di Riello a nord da una vallata ora detta di Ciofi. L'altura entro questi confini non è molto vasta, ma appariscono numerosi segni di fabbricato nell'altipiano attiguo in direzione di Viterbo. Il lato nord di questo altopiano è tracciato con un taglio rettilineo sul tufo corrispondente sulla valle Ciofi."

[4] "In due dei nostri cronisti del '400, Niccolò della Tuccia e Giovanni di Iuzzo da Cobeluzzo, in un atto del Chronicon Farfense e, quel che più conta, in alcune iscrizioni romane (CIL, XI, n 3009, 3014, 3017, 3020) si accenna esplicitamente ad una Città antica di nome Surrena esistente nel Viterbese. Alla delimitazione topografica di tale centro romano si giunge facilmente per le indicazioni dei cronisti che affermano essere stata Surrena situata in contrada "Riello". Uscendo infatti dalla Porta Faul ed inoltrandosi per la vecchia strada dei Bagni, che, in alcuni punti, per essere incassata profondamente nella massa tufacea, mostra la sua pura origine etrusca, si raggiunge a circa un chilometro dalla Città, una collina che si erge, a guisa di altipiano, sulla destra della Via. Anche l'occhio meno esperto non può tardare a riconoscere nel colle in parola la sede di una città antica, oltre che per l'abbondanza dei ruderi, alcuni di pertinenza termale, affioranti il suolo e per il grande numero di grotte sepolcrali scavate nelle colline vicine. Sul pianoro del colle che dovette ospitare la Città – la Surrina delle epigrafi o la Surrena dei Cronisti – si notano resti di antiche costruzioni."

Knowledge and representation as instruments for evaluation of retrofitting in the historic cities. The Jewish *Ghetto* in Rome.

Gerardo Maria CENNAMO

Engineering Faculty, International Telematic University UNINETTUNO, Roma, Italy
g.cennamo@uninettunouniversity.net

Abstract

Approaching with method to the problem of dissipation of non-renewable energy and, in general, environmental pollution is now an imperative condition at the international level.

This issue concerns not only the new urban settlements but also the historic cities, with all the difficulties arising from the need for transformations resulting by retrofitting in the historical heritage.

In the range of the difficult dichotomy between conservation and innovation, the historical city must address the complex path of the research of an equilibrium between its own essence and the new modernity needs along with a development in line with the environmental sustainability.

We can say that now there are already many technologies and procedures applicable for this purpose in the new buildings, so the issue becomes very controllable in the event of new buildings.

Likewise, when it is possible to work in a decisive manner on the building, making necessary changes to the plant and architectural level, the action of retrofitting is a simple application. But in the case of historic heritage, how is it possible to operate?

What choices such as shares, assessments must be implemented in urban areas characterized by historical or however formal and architectural balance structured, in different historical periods?

One possible way could be the analysis of the potential transformations or, better said, analysis of the transformations compatible with the historic cities, resulting by the application of retrofitting techniques, already studied in specific disciplines.

In this direction, the "sustainable retrofit" of the historical city, becomes an element able to initiate policies for restoration and urban innovation of the historic cities, to refurbish of the obsolete housing stock and to implement the construction sector.

This paper is in the interest of PRIN 2010/PEA4H8, supported in part by the MIUR. It is part of a research carried by Engineering Faculty, civil and environmental department, of the International Telematic University UNINETTUNO about the topic of the role of the representation as an instrument for control and evaluation of the retrofitting transformation in the historical cities, principal through the survey and subsequent graphic simulation as a means of monitoring changes of the architectural heritage.

Keywords: Historical cities, survey, representation, retrofitting, architectural heritage.

1. Introduction to the issue

The historical city, harbinger of a cultural, sociologic, iconographic and mnemonic heritage, ancestrally rooted in the conscience of civilization, addresses the complex path of the research of an equilibrium between the own essence and the new modernity needs. Individual buildings or entire urban areas and pieces of city, have begun to deal with a new one (in terms of perception) and postponed requirement, established by the need to embark on a path towards a logic of sustainability in terms of functionality and energy.

In fact the Italian conurbation is characterized by a large number of urban and suburban areas, nucleus and districts of cities that express, most times, a remarkable formal language, a synthesis of morphological and architectural archetypes which have developed in the succession of ages. Many Italian and also European historical towns show a number of features, peculiarities and common traits

to each other which, although in different places, have often contributed to give a common identity and similar conurbation. The real question, in fact, for which this research seeks to identify possible solutions or at least good practices and methodologies, does not affect only heritage and historical areas of most valuable historical interest or, for better said, those areas that are already subjected or protected by specific statutory regulations.

This path is not easy, especially in the pleasant setting of formal and architectural balance in Italy and in Europe, recognized as a historical city; in fact this path cannot be abstracted by the clear definition, from a verse, of the extraordinariness of historical heritage and, from an other verse, by just as important identification of imposed -or deriving from a contemporary historical place- needs, functions, conditions system.

This paper therefore aims to highlight the main procedural issues, planning and management authority relating to regeneration in the historic city, through the reading of an urban environment taken as an example, where specific and relevant formal features.

1.2 Historic city and energetic requalification

The awareness that most of the historical heritage or however built until a few decades ago are the true responsible for a high proportion of environmental pollution and releases of carbon dioxide in the atmosphere, produced by their "lives passive", through the usual and daily use of domestic utilities and equipment has led to the attention of the scientific community and civil society in general the problem of retrofitting of the housing stock.

We can say that now there are already many technologies and procedures to be applied for this purpose in the new building, so the issue becomes very controllable in the event of new buildings.

Likewise when it is possible to work in a decisive manner on the building, making necessary changes to the plant and architectural level, the action of retrofitting is a simple application. But in the case of historic heritage as it becomes possible to operate?

What choices such as shares, such assessments must be implemented in urban areas characterized by historical or however formal and architectural balance structured in a different historical periods?

As we said in the introduction, the scope in the fully interests of research are represented by urban and suburban areas, nucleus of cities, districts and city of pieces that much characterize of the Italian and, in general, European conurbation that express a remarkable formal language, a synthesis of morphological and architectural archetypes which have developed in the succession of ages. It is precisely these the "essences", the genius loci, the most salient characteristics of the conurbation of our territories, Italians and Europeans in general, so that it was not wrong to use the definition of "historical city" wanting to synthesise, in this expression, the sum of the characters and archetypes we have mentioned. This is the test, this is the place of confrontation in which explore how annul, or at least moderate, the conflictuality and criticalities resulting across the great value of cultural heritage, to be preserved as it is, and the demands, not be postponed, of a contemporary living environmentally friendly and conscious that natural resources are quickly running out.

Andreina Maahsen-Milan talks about incessant changeability of the urban scene. Changeability also determined by the ability to translate into physical elements also the formal technical and technological device, like form and matter. *«Whether it be "armed scenes", ie looms or light materials however detached from the space functional, from the main structure, or changing - screens, either physical or virtual - the urban scene wetsuit incessantly. Different instead is the evaluation of what the outcome will, the sum of retrofitting energy in the overall image of the city and landscape. Given as a fact the failure of any practice aimed at hampering such phenomenon, it is that the only possible way is the "virtuous use" of practices and technological devices required and imposed by sustainable planning and design onto design practice. An unresolved issue is still represented by energy upgrading of existing building heritage while there is increasing risk related to the visual pollution caused by the – so called "third landscape"».*[1]

Actually, this complex path through a delicate balance in which the conflict between conservation and innovation cannot be abstracted from that and that a clear definition, on the one hand, the extraordinary nature of the historic and, on the other, the equally salient identification of that system requirements, functions, conditions imposed by or derived from a use contemporary historical site.

How and in what way it can be considered "sustainable" if the historical place related to an ecosystem characterized by the current conditions?

How and to what extent can change the perception of the site in relation to the pursuit of these objectives in terms of sustainable energy?

It's necessary to determine the priority of values, defining rules of conduct such as moderate, if not cancel, the resulting conflict that inevitably comes from the prelude and comply with the same, including the value of the past and expectations of the contemporary.

The identification of these "rules" and practices inevitably passes through the design of context that, as the primary instrument of knowledge and simulation, takes the value predominant in these specific transformation processes. [2]

1.3 Main problems and criticality

The issue, especially in Italy, it becomes urgent if not impelling, partly because of common sense of people and partly because the many directives (UNESCO Recommendations HUL, the Directive 2009/28/CE "20 20 2020", Horizon 2020). But this question is not already enabled and, especially, not systematically implemented by the Italian statutory regulations that interest urban development and construction industry. Yet it seems that in recent times the attention of regulators is still paid to aspects that do not appear to address the issues under discussion, which still are of interest exclusively of scientific communities. Continuing our main interest in the representation as an efficient instrument of knowledge, monitoring and analysis of the transformation of cultural heritage, we have sometimes researched items of interest in the urban planning area, but without satisfaction.

We would like to clarify that the scope of interest of this research is not precisely the project, (it would be in a specific field of competence of scientific sectors discipline already extensively studied with excellent results), but priority of knowledge, survey and analysis.

Thorough knowledge of the areas of intervention, in order to learn and recognize the most salient constitutive characteristics, the essences, the fundamental archetypes.

The genius loci, but also through a systematic approach, recognizing the momentous layers, influences that exist and can be found in the historical building.

Define the scope of intervention, representing the conurbation, the space complexity, the architectural composition, the compositional language, the colorimetric quality. That 's the first fundamental step of the work. Analysis of the potential transformations or, better said, the transformations compatible with areas of interest, the historical city, resulting across application of the techniques of retrofitting already, as before mentioned, notes, studied in specific disciplines and of which are we take note of the results useful for our specific research, through the modelling and the graphic simulations the most better methodologies and the best practices. [3]

2. The case study

The Jewish ghetto in Rome is a great place for our research; few roads, the subject of numerous descriptions and representations, viewed as a city within a city, always dodges from the influence of the Vatican, expression of Jewish otherness, but also bearer of roman "authenticity", even during the dramatic event of Nazism. Few streets that retain and return the ancient memory of the epochs, recognizable through the residual parts of the native urban plant or otherwise "old" in the morphological characteristics of the architectural heritage, in the archetypes constructive hidden or visible in the fabric of the buildings, the monuments, in the names. Everything in continuous relationship with a path still in place that you see the evolution of the place from the conclave introverted to a kind of organism in permanent osmosis with the outside, the full expression of the contemporary social dynamics, highly productive thanks to an uninterrupted cycle put in act by a variety of exercises and economic activities such as restaurants, bars, shops, small-capacity accommodation, crafts and much more, where the evolution has strongly reversed the proportional relationship between living - so a place of protection, limited socializing - and produce - then place open to flows "external" and the widest use.

The morphology of the Ghetto, as it appears today, the result of four basic stages of processing, three of which made for exclusive the will of the Vatican and only the last, the modern one, dictated by a planning approach.

First phase: 1555 Paolo IV imposed the construction of a boundary wall accessible by only three doors that go to delimited an area of approximately three hectares in the valley of the river Tevere.

2nd phase: end of 1500 beginning of 1600, Sisto V ordered the expansion of the area in southwest direction near the Tevere, going to be a new settlement, accessible by two new doors.

3rd phase: 1830 Leone XII imposed the closure of the insula that facing Via del Portico di Ottavia, Piazza Mattei, Reginella's street and St. Ambrogio street in north - south direction.

4rd phase: 1800, intervention rather radical urban transformation that has given us the current morphology. [4]

It's clear that the evolution of the urban area of the ghetto into a period of about four centuries, derived solely from the application of religious dictates. This of course until you reach the conformation "modern", which saw the implementation of a project on urban development over most of the area between the Tevere and the axis of via del Portico di Ottavia, handing down to us today, such as residual areas the original system, some urban blocks upstream of the street Portico di Ottavia as, in particular, the aggregate bounded by the axes cross street of the Reginella, and so Sant'Ambrogio.

It must be pointed out that, although under the morphological and typological aspect can certainly be understood as an integral part of the system "ancient" of the Ghetto also some areas immediately surrounding the area between the Reginella's street and Sant'Ambrogio is ultimately, only to return

again the vision of the original Ghetto, intense according to the physical boundaries of strictly imposed by the Church.

This does not mean that truth in the "new" Ghetto has lost the genius loci so distinctive and peculiar; the place, although in the wider conurbation which now identifies it as an area in the historic center part of the district of St. Angelo extended between Monte Cenci, the Theatre of Marcello and Piazza Mattei, preserves the legacy of a widespread manner redolent of the original memory essence.

In addition to the architectural and cultural aspects, for the purpose of our research is necessary to take into account the high energy dispersion and consequent environmental pollution resulted from a place like the Jewish ghetto. In fact, as mentioned in the introduction, the peculiarities of the place, its location, its historicity, mainly its beauty and charm, has led to an economic process of "inversion" of the original functions. An area that for centuries has maintained a predominant feature of settlement to inhabit, although almost made it "forced" as we have said previously, in contemporary times has had a strong boost production quickly, becoming a real center of productivity, including economic, based primarily on accommodations, restaurants and subsidiary activities. (Fig. 3 – 4b)

This has determined to be able to welcome visitors and new streams of visitors to almost continuous cycle, the need to fortify the various exercises, the production equipment of its stores (kitchens, plants and equipments), on the one hand with a consequent increase in the energy requirements, for another the need to equip with thermal regulation systems increasingly powerful acts to regulate the climate temperatures, but above all to counter the rising thermal determined by its production facilities (electric motors, cookers, refrigerators, freezers, heat pumps) more and more powerful.

A sort of paradoxical vicious circle, which leads to the need of enhanced energy to be able to adjust the effect by itself procured or otherwise increased.

For this reason that the scientific communities are starting to verify that the only recourse to the type of plant technologies will not be sufficient to achieve the levels of reduction of energy dissipation that the Community directives (and common sense) dictate to the society soon.

2.2 Possible solutions

We will need to move towards more complex interventions that take into account the possibility of a practical and concrete use of natural resources; naturally obtaining a good yield deriving from natural resources need for a much longer metabolic process or, in terms Inverted, more extended quantitatively.

So the boundaries between visible and invisible, between perceptible and imperceptible, inevitably will vanish, and the society will be responsible for establishing criteria and procedures for the correct but decisive approach of retrofitting on the historic heritage, causing necessarily exterior changes but reaching to check out the original characteristics, in order to preserve the readability of the good and the place. You will have to develop the right knowledge to be able to use in our historic towns photosensitive roofing, ventilation chimneys, solar greenhouses and any other device that, in warm climates, make the most of the solar resource effectively controlling the temperature rise liabilities.

For this issue becomes a priority the role of knowledge, through the survey, the modelling and representation, as a fundamental instruments in the evaluation of the exterior modifications. [5]

2.3 Survey and representation as instrument of evaluation

Considering the solar exposure, urban structure and construction type orientation, conurbation, the dimensions and characteristics of general climatic, as the winds in summer that are prevailing direction from quadrants SW, NE and NW, with average temperatures of 23 at 31 degrees for three hours in a day, the entire area has characteristics of high energy dissipation. (Fig. 1, 2)

For a site like the one selected as a case study, the main aim so, for the purpose of upgrading the energy efficiency of action, is to moderate the thermal dissipation due to the particular exposure and climatic conditions of the area especially in relation to the type of construction, if that does not achieve of significant architectural quality particular performances in terms of transmittance. The main issue is that it does not negatively affect the view of the architectural features the district and define the right choices in this regard. A valley so of the analysis phase is fundamental the ability to simulate, through the representation of some hypothetical transformations, the possible forms in order to control the transformations and analyze the right responses.

We have analyzed four different applications, singly and combined, and simulated through the representation of the effect of the changes on the perception of the architectural heritage.

Among these, the common element introduced is the application, upon the original roof, of an energetic roof called "TECU solar system". It is an innovative integrated radiation-absorbing roof system constructed entirely in similar copper. The roofing covers a certified system of tubes in copper, through which runs a vector fluid which captures the solar energy. This latter transfers the heat to the water in a storage tank and thus to the building's heating system. As shown in the image, the architectural perception of the building is not negatively altered.

Besides this, three other different interventions have been proposed:

1 - Transformation implemented through the utilization of trees, positioned in a front and parallel to the curtain of buildings. By the climate data, it is identified the opportunity to use caducous leaves trees, so the positive effects are maintained during the transitional seasons and eliminate almost all the unfavorable effects during the Winter. Therefore we make use of broadleaved large foliage species and in the specific of *Tilia Tomentosa*, (Basswood), originating from Eastern Europe that is resistant to Summer, drought and pollution. This type of intervention allows various results. The first results consist of a totally naturalistic approach. Then, taking into consideration that the area faces on the South, so trees have the effect of shading, the mitigation of temperatures, and a creation of air currents which increase the summer ventilation during the day.

During Winter, the caducous leaf trees lose their shading function. However, the presence of spin (trees with hemispherical shaped crown) allows, even without of leaves, to have a windbreak, like a wind barrier, that has still greater effect if we lower the distance among the trees. In the images is simulated the change made to the visual perception by this change. (Fig. 5 - 6b)

2 - Transformation implemented through the realization of solar greenhouses, working as thermal regulators. Solar greenhouses aim at capturing the light energy of the sun and convert it into heat energy and store it. The solar energy passes through the glass and heats the interiors. What really happens is the short wave infrared waves going in and turning into long infrared waves, which cannot escape. So they just reflect around and get absorbed by their surroundings. They reveal to be very useful during Winter season. They trap solar energy during the day, usually with benefit of south-facing placement and sloping roof to maximize sun exposure. Once the sun goes down, they are able to retain that thermal heat and use it to warm the house at night. In Summer, users can open up the double line of windows and let fresh air go in. Thus, these changes modify the visual on average perception of the site, introducing changes that, in certain territory or places, do not adversely alter the architectural and formal balance of the site. In the images is simulated the change made to the visual perception by this change. (Fig. 7 – 8b)

3 – Transformation implemented through the introduction of thermal chimneys, built upon the facades, as independent and reversible elements from the buildings. Solar chimney is a way of improving the natural ventilation of buildings by using convection of air heated by passive solar energy. A simple description of a solar chimney is that of a vertical shaft using solar energy to enhance the natural stack ventilation through a building. During the day, solar energy heats the chimney and the air within it, creating an updraft of air in the chimney. The suction created at the chimney's base can be used to, naturally, ventilate and cool the building below. (Fig. 9 – 10b)

Finally, through the representation techniques it is possible to evaluate and analyze the result of the combined application of the three interventions. [6] It's sure that this methodology introduces changes that strongly modify the visual perception of the site. This does not mean that these modifications negatively impact on the formal and architectural balance of the site, but surely they modify, also thanks to new compositional elements of the facade, the comprehension of buildings, their original characteristics and, generally, of the site. In the images, the change made to the visual perception by the introduction of these interventions is simulated. (Fig. 11 – 12b)

Abstract

The current regulations, which governs the energy and environmental sustainability of buildings, ratifies that the evaluation of building's environmental performances must consider its entire life cycle. Therefore, the assessment in Operating Energy (OE) is not enough; the Embodied Energy (EE), which is the total value of the energy, which a building needs, is very significant.

The choice of construction system, technologies and materials influences the EE. It often happens that technological choices that aim to reduce energy consumption during the operating phase, instead substantially increase the EE.

This paper illustrates the results of a research, which analyzed, in response to this need, the use of straw not only as natural heat insulator, but also as building material, in order to design a farmhouse located in the countryside of Pompeii. The innovativeness of the approach consists in the application of this material in Mediterranean climatic contexts, characterized by warm summers rather than by cold winters.

The straw can guarantee excellent thermal insulation thanks to very low conductivity values, and it can significantly reduce the losses due to thermal transmission.

The benefits are not limited to the reduction of energy consumption during the operation phase of the building. In fact, the straw is a construction material from a renewable source, with minimum energy consumption both in the phase of production, both in the phase of transport (mainly because the material is generally of local production), for both the phase of recovery / recycling and final disposal.

Keywords: Straw ball, Embodied Energy, Energy Performance

1. Durability, zero energy and low cost: fundamental requirements (AV)

The Energy Quality of a building is closely related to the concept of balance between levels of comfort (habitability requirements), consumption of energy and management costs. A new era of buildings and design seems to be starting, responding to increasingly higher standards of performance. The awareness of society to the energy and environmental problems is growing ... the European prospects appear lighter. The need for eco-friendliness, innovation and competitiveness is becoming the long-awaited opportunity to broaden the cultural horizons of the professional, more and more oriented towards an "aware environmental friendly design". It reflects renewed management models of the creative process - constructive that is no longer just tied to compliance with the minimum requirements of the law, but it is susceptible to the recommendations in order to improve the performance characteristics required by common good practice and to increase the comfort requirement and the environmental compatibility.

One of the possible strategies to pursue in order to "force" the industry to respond with an offer of eco-oriented and bio-compatible goods and services, is to orient the market acting on the ecologically thrust qualification of the demand. Only a virtuous circle of influences that originate from below (civil

society) can obtain the evolution of behaviours that allow us to improve the quality of life and to have less waste of resources.

According to this approach, the design is a system of integrated technology solutions based on the fulfilment of three requirements: durability, low cost and zero energy.

Some traditional materials, as straw, were used for thousands years in order to construct buildings. Today these materials are repurposed as innovative construction materials, low-cost renewable material. The straw is a humble material but rich in quality. In fact, it is characterised by simple technological details, sustainable construction processes and lower embodied energy in manufacturing.

The research investigates technological, energy and environmental benefits of using straw bales as building material, according the current regulations, which governs the energy and environmental sustainability of buildings and ratifies that the evaluation of building's environmental performances must consider its entire life cycle (ISO 15392:2008 and ISO 21929-1, ISO 21931-1 etc.).

2. Energy and environmental sustainability of Straw bales as a construction material (MC)

The international standard ISO 21929-1 establishes a core set of indicators to take into account in the use and development of sustainability indicators for assessing the sustainability performance of buildings. One of the indicators proposed by ISO 21929-1 is "Amount of non renewable resources" that includes:

- Consumption of non-renewable raw materials
- Consumption of non-renewable energy

Straw is an attractive building material for both indicators.

The standard states that total amount of non-renewable material resources consumed and the total amount of non-renewable primary energy shall be assessed on the basis of life cycle assessment method and/or information modules following the basic principles given in ISO 21930 and ISO 21931-1. A renewable material is one that can be replaced by natural processes at a rate comparable or faster than its rate of consumption by humans, rather than a finite resource that is depleted through use. Straw is available wherever grain crops are grown, so it is widely available in rural areas, and is annually renewable.

Moreover, straw it is considered an agricultural waste product. Once the edible part of the grain has been harvested, the stalks often become a disposal problem for farmers, and in many parts of the world, they are burned in the fields (causing a great deal of air pollution). By using the straw instead of eliminating it, we reduce also environmental impact of air pollution.

As regards the second indicator, straw's excellent thermal insulation properties reduce consumption of non-renewable energy using for heating and cooling of buildings. In fact, U Values of walls of 45-55 cm made with straw bales typically fall between 0.13 and 0.19 W/m²K (depending on the overall method of construction). Therefore, houses constructed with straw do not require further insulating layer to comply with requirements imposed by the legislative framework for the implementation of the Directive 2002/91/CE (D.Lgs 192/2005 and D.P.R 59/09).

Therefore, the assessment of consumption during Use-Phase of the building is not enough. In fact, the total amount of non-renewable primary energy of a building (valuated according to the life cycle assessment) is made up of two components: operating energy and embodied energy.

Operating Energy is the non-renewable energy requirement of the building during its life from commissioning to demolition (the energy used for heating, cooling, lighting, hot water...).

The Embodied Energy is the non-renewable energy required for building construction (for extraction, processing and manufacture of building materials, for their transportation to building site, for installation and final demolition).

The choice of construction system, technologies and materials influences the Embodied Energy.

3. The straw house: describing construction technology (LDS)

This design has a clear architectural bioclimatic matrix and the specific technological choices are the use of straw and bio-brick. The farmhouse project is located in the Pompeian countryside, a place rich in history and traditions. Pompeii is a town in the province of Naples, situated in the lowland, 14 metres above sea level, between Mt. Vesuvius and the Lattari mountains. According to DPR 457/78, Pompeii is placed in climate zone C, with 1.131 degrees day. In fact, the climate is temperate (mean annual temperature of 16.2 °C); August is the hottest month of the year with an average temperature of 24.1° C, while the coldest month is January with an average temperature of 9.3 °C. The project

involves the construction of a country house with vertical wall plugs made of straw bales and bio-bricks.

The used straw bales have the following dimensions: 35x45x85-120 cm, and a density of 90-120 kg/m³, directly coming from the field to the construction site. Therefore, the straw bales are “zero kilometre” material, which does not require intermediate processing.

Generally, straw bales walls have a thickness about 45-55 cm, included interior and exterior plaster. The straw bale, in order to be considered a efficient construction material, must provide some significant benefits:

- to be dry;
- to have internal moisture contents in the order of 12 % -15 %;
- to be well compressed;
- to have a fairly uniform size.

The construction of straw house is technically very simple; it includes a wooden frame, which is anchored to the ground by upside-down “T” section foundation beams, made of reinforced concrete, which also include the pillars of the structure.

The construction is very fast compared to traditional houses. Once the wooden frame structure is realized, wooden planks are set out in a vertical direction, in an appropriate section and at a distance between 60 to 100 centimetres, in both sides of the structure, from outwards and inwards to form a containment cage, otherwise called “double backbone technique”.

This technique was created in Canada thanks to the work of a group of researchers who studied straw house built with the techniques from the natives as well as constructive methods from Nebraska. Looking for a combination of the different construction techniques, the research group founded in the 1990's an association called GREB (*Groupe de Recherches de la Baie écologiques*), which gives its name to the GREB construction technique, changed by the American Ballon-Frame.

Since then, the building system has spread to Europe, especially in France, where hundreds of buildings have built.

This technique involves a double wood framework, used in order to contain the straw bales. These two elements, combined with the GREB plaster, are the only ones to have a structural value, and from a thermal point of view, they ensure the complete reduction of thermal bridges.

In Italy, the GREB construction system is not widespread because the current law does not attribute straw a structural value. In our country, the construction materials with structural capability include reinforced concrete, steel, masonry and wood. Thus, the GREB technique cannot be used in all of its applications but is used simply as an infill system. The same system has also been adopted for roofs.

In a GREB system, the plaster has an important role. It must be:

- long lasting
- stiffening the system, as support,
- protecting the straw from water, fire, animals and insects
- ensuring smooth, breathable walls.

The characteristics of the composition are:

- _ 4 volumes of sawdust (for lightness and hygroscopic adjustment of the wall);
- _ 3 volumes of sand (for roughness and adhesion of fine plaster with lime);
- _ 1 volumes of lime (for the compression resistance, sound insulation, water vapor permeability);
- _ 1 volume of cement (for its resistance to compression and rapid setting).

The plaster realized provides good breathability to the straw and reaches a thermal conductivity of $\lambda = 0.2 \text{ W/mK}$.

The sawdust, in particular, is a very useful element since it favours the migration of water vapour through the plaster: It participates in the hygrometric regulation, is a hydrophilic material and promotes the breathability of the walls. Moreover, it is used to obtain acoustic wellbeing, too.

The role of the plaster in the “vertical wall” system is relevant and significant because it determines the technological feasibility of the use of straw as an infill.

The plaster is prepared in-situ. After making the wooden frame, the double frame containing the straw bales, having anchored OSB panels to it (which will act as a mould), the plaster is cast creating a layer one each side about 5 centimetres thick. It takes between 12 to 24 hours to set the system. Before casting and laying the panelling, any water piping and electrical wiring should be installed in order to reduce the construction time (unlike traditional practices where they are laid after the infill has been completed). This limits the amount of waste material as well as reduces construction time and costs.

Once hardened, the fine plaster is mixed, using clay as a material naturally present in the raw earth, mixed with fiber (chopped straw or sawdust of a certain size).

Vertical closings made in this way, with a thickness of 50 cm (including 5 cm plaster on both sides) guarantee an excellent performance in terms of thermal and acoustic insulation, breathability and fire resistance.

Fig. 1: A model of straw house (De Simone L., Dell'Aversana V. and Cantone D. designers)

4. Operating energy of a straw bales house in Mediterranean area (AV)

The architecture of the South Italy, like that of most of the Mediterranean basin, has favoured the use of massive construction systems, which consist of thick stone walls with small openings and open spaces such as control elements and climate mitigation.

In relation to the specific characteristics of the climate of southern Italy, the environmental control constructive model was predominantly conservative, based on integrated solutions responding to selective criteria, which are particularly useful for the mitigation of summer temperatures. The traditional (especially what is spontaneous, without architects!) compact and massive construction system was motivated by climatic reasons. Therefore, in a past where the use of plants in order to ensure comfort conditions to the confined space was not possible, the wellness was guaranteed by the building's shape, that had to be compact in extreme climates and pleated in temperate climates. The technological analysis illustrates that compact types of construction characterize the Mediterranean architecture, with small and deep openings, light and reflective colour (white / sand). This system was empirically repurposed to minimize solar gain in summer without compromising the heat gain in the winter season.

The environmental conditions dictate, therefore, rules, templates, and fees to build architecture that otherwise would not have capability to meet the welfare needs of its direct beneficiaries.

The straw ball house is located in Mediterranean area, in a climate zone C, characterized by hot summers (more than 26 ° C); for this reason, a good thermal insulation is not sufficient. The high thermal insulation ensures adequate conditions of hygrometric comfort in the winter season, with significant savings in fuel consumption on energy costs for heating. In order to ensure adequate comfort conditions even in summer, it is necessary to verify that the wall has adequate constructive characteristics of Transmittance and Attenuation in order to reduce the summer heat load and an appropriate phase shift that postpones the input flow in order to allow for the nocturnal dissipation of heat.

Therefore, it was necessary to verify the performance of straw bales wall in terms of thermal inertia. The thermal inertia represents the material's capability to accumulate heat, as opposed to changes in temperature and flow of thermal power that occur in variable thermal conditions (external temperature, sunshine, etc.).

The thermal inertia depends on the density of the material but also by its specific heat. The straw is characterised by a low density (approximately 100 kg/m^3), but also by a high specific heat (1400 J / kgK), compared with other building materials. For this reason, a wall made of straw bales has good heat storage capacity.

The simulations, carried out with the software *Gemavap*, give these results:

- Thermal Transmittance $U = 0.1492 \text{ W/m}^2\text{K}$
- Phase Shift about 15 hours
- Attenuation coefficient of 0.16.

This allows affirming that the straw is an interesting building material, from the point of view of energy efficiency in operational rating, even in places located in the Mediterranean area, even if they are characterized by hot summers. The curtain wall of straw bales in fact guarantees a good control of temperature and humidity conditions in the summer too.

5. Embodied energy of a straw bales house in Mediterranean area (MC)

The project aims to minimize the total amount of non-renewable primary energy, not only Operating Energy but also Embodied Energy: the benefits of choosing a wood construction system and straw bales for building walls are not limited to the reduction of energy consumption during the operation phase of the building, but also during the entire life cycle.

The choice of building materials is very important: the materials with higher embodied energy require more resources and cause more waste, affecting the environment in a negative way.

For most building materials, the major environmental impacts occur during the initial processes. From this point of view, the straw bales have a low-embodied energy.

Straw is a construction material from a renewable source, with minimum energy consumption both in the phase of production, both in the phase of transport (mainly because the material is generally of local production), for both the phase of recovery / recycling and final disposal.

Very little energy was used to manufacture the product (sunlight was the main energy source for growing plant). The only energy needed to make a straw bale is in the bailing process.

Analyzing energy consumptions used to transport building products from the factory gate to the building site, we can say that they are a function of the transport method, of the distance travelled and of the material weight. Straw bales are generally of local production, and are lightweight. In the specific case, straw bales are widely available in rural areas of Pompei.

As regards the phase of recovery / recycling and final disposal, straw bales homes can last over 100 years if properly maintained. Moreover, straw bales are 100% biodegradable. Therefore, they have not disposal problems: when the time comes, the straw bales can be plowed back into the earth.

The Inventory of Carbon & Energy (ICE) is an embodied energy and carbon database for building materials [4]. The embodied energy data provides the energy consumed to make a building material.

In the ICE database the embodied energy of straw is 0,24 MJ/kg. Instead the embodied energy of a common Brick is 3,00 MJ/kg, twelve times higher of straw.

Straw bale walls are typically coated with a thick layer of plaster that is the main structural element, but is also the component of the wall that has the highest embodied energy. In the ICE the embodied energy of plaster is of 1,8 MJ/kg.

Therefore, the research examined the material composition of plaster, in order to determine the most optimal proportions to reduce the embodied energy of this material.

We can say that straw bales construction is an environmentally friendly construction method. Straw is a natural and renewable material that has low-embodied energy, and represents an interesting area of research for the construction industry.

SMART AS INTELLIGENT

Francesca VERDE¹

⁽¹⁾ Department of Architecture and Industrial Design "L. Vanvitelli" - Second University of Naples

francescaverde7@gmail.com

Abstract

The transformation of the built environment requires more and more frequently the use of an intelligent management system that is able to offer multiple and simultaneous responses on the issues about the quality life of modern citizens : Economy, People, Mobility, Governance, Environment and Living.

This paper pointes out some results of a research aimed to highlight , through the comparison of international experiences , the adaptability of smartness concept to a Mediterranean context area characterized by a great cultural value.

There are several models of reference : some examples of sustainable neighborhoods in Europe, the smart street and the smart building in Northern Europe and the Action Plan of Copenhagen, Vancouver and London.

The results achieved from the systematizing of these different study cases shows how the concept of smartness applied to the urban context isn't inclined to assert itself as a template to be replicated in a serial manner in all geographic areas.

However, it is possible in every urban reality read the specifics of the area in terms of strengths and weaknesses; aim at the creation of networked integrative superstructures; focus the propulsion nodal centers of growth and ensure the continuity of the system through the collection of data and information used in short, medium and long term.

In this sense Smart City is an opportunity for the city as a whole. Besides the tantalizing prospect of the access to funding available for the public authorities , it represents a real opportunity to open up to international experiences becoming the protagonist of the transformation.

Keywords: Smart City, Sustainable Neighborhoods, Intelligent management, Connected system

1. Analysis method

The most recent European and National announcements in energy, mobility and life quality put the smartness concept as a top priority objective into the strategic planning of interventions and as essential requirement for the characterization of urban regeneration operations.

But it's not enough to define as *smart* an intervention or a strategy to realize it as that; more often are declared aims which are not translated in actions, especially when it's about operating in built environment.

It's due to the diffusion of the use of the smartness term, which has permeated every cultural sector, in the most cases very superficial and sometimes equivocal.

As it's known we talk about "intelligence applied to the urban reality" since Nineties, when the *urbotics* concept prefigures a daily routine (home, school, work, transports and spare time) controlled and managed through electronic devices.

But, undoubtedly, the affirmation of the "*Smart*" approach takes place in 2006 thanks to the diffusion of the International research "European Smart Cities" from which, for the first time, are pulled evaluation instruments on the attitude of being smart of forty medium size European cities.

The study, even if it's developed into the economic sector, faces up the theme through the rating of categories and thematic requirements but at the same time extremely mutually dependents as: Economy, People, Mobility, Governance, Environment and Living.

This multifocal vision is transferred into the transformation experiences of the built environment, in which smartness, is developed as a digital infrastructure characterized essentially by two particular features: the connection of the effects on a temporal scale and the central position of the user.

Its definition can be read in the progressive adaptation of the urban sustainability concept applied to an environmental awareness and to a connection of social and economic sources of the area.

Therefore, the research goal is to define how the urban system conceives the smartness concept.

This study points out through the use of some examples:

- the organization of the structure derived by the urban action plan (Vancouver, Copenhagen, and London);
- the intervention sectors pointed out from the examples at the settlement scale (Eco Vikki, Kronsberg, BO01);
- the integration perspectives of a smart system through urban punctual interventions (Amsterdam World Smart Capital).

The results of the research point out that the screening of areas, the analytic individualization of strength and weakness of the site as well as the potentiality and the vulnerability of the areas analyzed are the fundamental elements for the correct realization of a smart project.

2. Urban Action Plans: a strategic view of smartness

Cities are the places where is concentrated the most of the worldwide population [1] and for this reason since the mid of Nineties they have been singled out as a point of reference, essential for the economic development and the conservation of the human and social resources capital that gravitates round them.

A lot of cities in Europe and in the whole world distinguish themselves for the introduction of smart topics in strategic planning actions, and also as innovative approaches to local problems.

In the research were studied some examples of cities as Vancouver, Copenhagen and London which empirically translate the concept of smartness through an integrated organization of times and modality of interventions realization.

For the city of Vancouver it's created the Greenest Action Plan in 2009, a plan directed to reach goals of increase and improvement of inhabitants' life qualities according to two temporal sequences: goals in medium-term, achievable within 2020, and goals in long-term, achievable within 2050.

The plan is shared in 11 action themes: Sustainable economy; CO2 Emission reduction; Building energy efficiency; Sustainable mobility; Zero Waste; Green areas access; Reduction of environmental footprint; Reduction of water consumption; Improvement of air quality; Local food promotion; Governance and Participation.

The Greenest Action Plan allows to reflect upon two distinctive aspects of the outcomes organization:

1. The temporal scanning of the programmatic goals, for which are established times and costs of investment.
2. The bottom-up logic for the localization of actions, are shared in development districts (neighbourhood by neighbourhood).

This logic, also present in the United States plans of Chicago and Portland, identifies strength and weakness of an area but above all actively involves the local community which proposes, realizes and controls the established goals by the territorial planning.

The reference model of the Vancouver city is the advanced Copenhagen - it has always been an international reference point on issues of sustainability and environmental awareness - which in 2009 develops its Strategic Plan and the annexed Urban Climate Adaptation Plan.

The objectives of this plan are established on the time scale. Copenhagen aims to be a Carbon Neutral City in 2025, but what emerges from the analysis of Climate Adaptation Plan is the following of continuous improvement objective, intrinsic in smart dynamics.

The actions prospected in the plans, in fact, are rated on a scale of expected impacts and associated risks, in order to create a reference database useful to ensure the feasibility (especially economic and environmental) and the effectiveness of future interventions related.

A very peculiar case, but representing another key aspect of the organization of a smart structure, is provided by the Great Authority of London, through the Action Plan of 2000.

The action plan aims to regenerate, through a the development of an interventions system, the fragments of a city that shows, differently from the two cases examined previously, many of the issues arising from the uses complexity from the needs of a dynamic and multicultural reality.

Also in this case the shares are held in independent territorial units, consisting of municipal districts, and given the spatial extent and sometimes even from urban villages.

What is interesting from an analysis of the plan is the process of local resources screening, which is analyzed to collect information about:

- the energy performance;
- the maintenance of buildings;
- the potential and social vulnerability;
- the characteristics of the settled population;
- the indication of the economic and cultural sources attractiveness.

The survey, as done, identifies the site condition as a necessary element to elaborate effective policies focusing on the main fields which leading the transformation.

URBAN ACTION PLANS	NAME	YEAR	GOLAS ON TIME SCALE	MAIN GOALS	ACTIONS' AREA
	Vancouver Greenest Action Plan	2009	Medium term 2020 Long term 2050	11	Neighbourhood
	Copenhagen Climate Adaptation Plan	2009	Medium term 2025 Long term 2050	6	Single case
	London Climate Change Plan	2000	Short term 2010 Medium term 2025 Long term 2050	5	Municipality/district

Fig. 1: Urban action plans comparison grid

3. From sustainable to smart neighborhood

If on an urban scale, can be specified the program objectives and guidelines, when it's reduced the range of investigation to the district is also possible to evaluate the smartness of design choices and technological solutions.

The neighbourhoods are a place for experimentation and dissemination of innovative technology solutions and best practices, which have become common use through the design experience of the European Framework Program 5th and 6th.

The neighbourhood small scale is ideal to identify areas for application of urban smartness, by encompassing the complexity of functions and dynamic cities, while remaining manageable in terms of size - for number of people and dimensions - and informative - for data collection.

The analysis research phase was carried out by selecting some European sustainable neighborhoods chosen depending on available information (e.g. readability of the planning phases) and technological solutions.

There are evaluated 23 European sustainable neighborhoods, classified according to:

- settlements typologies,
- designed intervention categories,
- performance requirements,
- renewable energy sources used.

This cross-reading was accompanied by some critical considerations that led to the comparison between three particularly significant neighbourhoods: Eco-Viikki in Helsinki, Kronsberg in Hannover and B01 in Malmo.

These districts have adopted some tools to support the strategies triggered in the design phase, from which it can be deduced some of the key aspects of the territorial approach to smartness: the evaluation of interventions, the operational involvement of the local community and the dissemination of results.

Eco-Viikki, is the oldest within those identified, allows to read in the construction of the PIMWAG tool, the dynamics of transparent check of the expected results. With the so-called PIMWAG method, in fact, it is identified a real rating scale that indicates the coherence between the design aspects in the elaboration phases, and the effective implementation of the same. The method identifies a reference

scale and a valuation range on five essential topics such as: pollution, natural resources, health, protection of biodiversity and food production.

The case of the Kronsberg neighbourhood is related to the EXPO 2000 interventions, according to specific quality standards, both in the planning phase and in the buildings and open spaces realization: *City as Garden City as Social Habitat*. Among the sustainability goals for Kronsberg, that stands out for innovation and long smart view is the KUKA project - *Kronsberg Umwelt Kommunikations Agentur*.

The KUKA agency was established by the Municipality of Hanover firstly to coordinate and then to follow until the end of whole operation Kronsberg.

The batch processing has been oriented to a multitude of operators, to transfer them all the ecological concepts of optimization, to inform users and to make understandable the project objectives and, at least, to create transferable outcomes. The centrality of user is the key of an efficient internal communication system to the district - with an interesting documentation centre and a rich production of information on the use of the buildings.

Even more advanced is the experience of the Bo01 district of Malmö, which is structured according to the objectives set out by the Quality Programme Bo01-City of Tomorrow. This tool enables the creation of tested models. Best practices aimed at the dissemination of results.

The document, drawn up by the design team of BO01, in agreement with the City of Malmö and builders, defines the quality targets to be achieved during the planning and implementation phases, the objectives related to the environment, the provision of technological systems, the urban and architectural design, but also the social services and to the citizen.

The preparation of this document not only ensures the realization of the actions defined in the design phase, but in this way sets of best practices that become the benchmark for new settlements of the same type.

4. Amsterdam: smart nodes for smart cities

The city of Amsterdam represents the most innovative tangible application of a smart management system adopted on building and urban existent heritage.

The works organization on cities follows the principles and dynamics that put in practices sustainable urban basics pursuing a goals expressly smart: the policies, undertaken in 2009, aspire to realization of the first World Smart Capital.

The smartness project implementation for Dutch capital pass through five key themes of analysis: living, working, moving, social policies and open data access, developed in good forty-two projects, actually half-realized, especially focused in three suburban zones : Nieuw West, Zuidoost and IJburg, respectively at West, South and East of Amsterdam city centre .

The ensemble of these punctual projects allow the participation of specialized companies and qualified investors able to support all phases of models application and results survey, through computation and evaluation of project validity and dissemination of derived practices.

The close partnership between companies and workers permit to realize project of transversal positive effects, from residential and work sectors to the mobility system.

The projects on residential sector include the application of management and monitoring systems of house energy demand (and so application of home automation and regulation software for control and indication of consumption indicators and also indications for energy and money safety) and also wider initiatives about whole neighborhoods.

It's possible to mainly characterize two typologies of applications, the first on a large and medium scale, further divided in technological orientations and in social and educative ones, and the second on small scale of housing and building interest.

City Zen it's an extremely innovative project localized in Nieuw West district. This project uses for the most part the investments directed from Smart City program, and it's supported by fifty percent European funds.

City Zen it's a *Smart Energy Test Area* of international interest - the biggest in Europe - where are tested well advanced technological solutions and the results derived allow the application of system based on interaction of renewable energy sources and diffusion of that knowledge to communities.

Essentially the project is based on the realization of a combined system for photovoltaic and solar panels home integrated, from these it will be possible to monitor constantly the achievement test on district scale and also to save energy for extraordinary needs.

Besides this, the project consider the realization of a storm water drainage system, used to produce bio fuel as power source for public vehicle, in addition the project is realized with the collaboration and participation of local community, also in requalification of building heritage.

The project is aimed to involve the most of people in order to generate shared vision of the processes and expedite the know-how of new urban practices.

Another interesting project is about the alternative mobility, and it is developed in Utrechtsestraat, for this reason defined as the first Amsterdam climate street.

In matter of this street, very interesting in urban dynamics for centrality of commercial destination is developed an integrated system of vehicular and alternative mobility, that integrates renewable sources in nodal points - bus, bike-sharing and car sharing stops.

But this project involves also some aspects about the street destination including the waste collection, by compactator devices, and the street cleansing with storm water reuse.

The distinguishing feature of the project is undoubtedly the punctual localization of intervention operations: the strategic integration in fact depends on the deep knowledge of surrounding built environment in order to evaluate the produced effects according to the benchmark.

Then the intervention is effective , beyond well-advanced technologies, because it's closely related to the context and in accordance with requirements of user: so the goal is not to define an univocal answer to a current problem but is oriented to create a inclusive and integrated system of solutions.

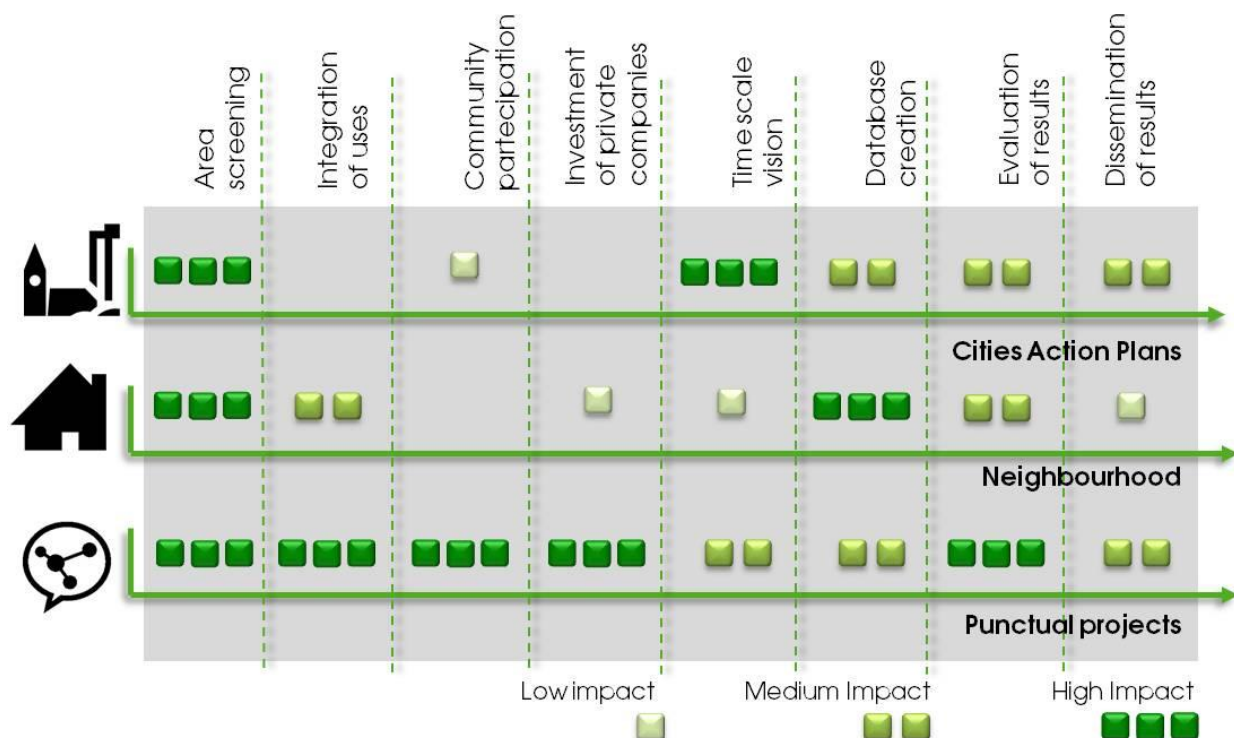

Fig. 2: Impact of main characteristic of smart development on urban different scale.

Conclusions

It's sure that smart cities and smart neighbourhoods' start up are both an opportunity to achieve European funds and to plan new urban demand about sensibility and awareness of the sites.

The most recent best practices teach us how the local characters are converted in smart design requirement, as we can see in Oulu, in Finland, where the municipal authority is creating a smart clean-tech district, according to urban advanced orientation, and also in Heidelberg, where the local community is developing a whole Passive-haus district.

These examples represent the natural evolution of the local awareness about technologies and their potential application in daily life, focusing the territory in terms of current and future needs.

As we can see the most of study case selected are located in the Northern Europe, and also the neighbourhoods are realized as new cities development district, beginning from scratch or redevelopment of brownfield sites.

But our Mediterranean reality it's different from these cases firstly for climatic conditions, secondly for the cultural and historical building heritage where the project might to be developed.

So the real challenge about smart city system applications is the creation of a tool to read the strengths and weakness of peculiar sites, to improve and control the actions specially on the built environment, very far from a model serial clone.

In this way we can note some Italian interesting initiative such as Smart City Med, that is aim to create a cluster between local authorities and enterprise to boost local development specially through the

improvement of cultural heritage knowledge, preservation and economic development specially through tourism enhancements.

Therefore this dynamic research theme is becoming basilar in urban planning and also in application of landscape policies.

But there are some methodological open questions: about the durability of the system, in fact as it's so recent that we can't quantify the chances of effective operational time in order to seek the innovative technologies; and about the gap between the real knowledge of the sites and the tools to evaluate the favourable conditions to operate in.

Gérard Magnin, Executive Director of Energy Cities give us a perspective to answer to these questions : "The technologies we need already exist today. The question is how will we use these technologies? Will we be open-minded enough to incorporate these technologies into our lives?" [2]

ECO-FRIENDLY MATERIALS AND TECHNOLOGIES: the added value of urban transformation

Antonella VIOLANO¹, Lucia MELCHIORRE²

Abstract

The analysis of the urban sustainability's processes is at the center of the current debate about the future development of the city. At building scale, legal standards and regulations were introduced in order to aim the substantially enhancing energy efficiency and environmental impact of buildings, while at the urban scale, with regard to the Italian landscape, there are no specific regulations on this issue. Currently, the Institute for the Innovation and Transparency of Procurement and Environmental Compatibility (Italian acronym: ITACA) is studying a tool for decision support (Protocol ITACA) in order to evaluation of urban open spaces. It can be a very useful tool for the eco-friendly technological design of "non-places" of the city, thanks to targeted analysis, specific criteria and appropriate indicators as land use, mobility and bio-climate. The sustainability, a multicriteria assessment tool of building's sustainability (especially energetic and environmental performance), introduced in 2004, allows defining the quality range of urban complex design and proposing solutions for the own development, with a smart and sustainable view of urban regeneration at European level. Therefore, Public Administration, businesses, citizens and investors have greater assurance and the urban transformation work becomes attractively. The approach of Ithaca is valuable, as it analyses the criteria of sustainability in a systemic way, or considering alternative designs in all their possible implications for environmental, economic and social issues, taking into account the life cycles of materials and works, the interactions with the land and with the markets.

The paper illustrates an experimental design of some urban wreck or unused areas for which the choice was the playground's use.

Keywords: Sustainability, Urban space, Protocol ITACA, Playground

1. Urban Metabolism: the creative transformation of open spaces (AV)

The city is the habitat of modern man and the urban ecosystem is the complex network of interactions between citizen and built environment (abiotic component), in which flows of matter and energy (urban metabolism) are generated. The contemporary city manages these metabolic fluxes basing on its energy -environmental, socio-infrastructural and economic-functional genetic code.

Since today the city is the main collector of material and energy resources and the mainly responsible of carbon emissions on the planet, the major challenges for the urban future include reducing the ecological footprint of cities and fighting for the closure of cycles of urban metabolism on a local scale. (Toledo Declaration, 2010). [5]

The city governs its mechanisms of production, growth and regeneration in synergy and sometimes in contrast both with the surroundings either with its internal residual spaces. [4]

In all cities, there are some worthless anonymous areas, urban spaces of "social diversity" that do not have the warmth of lived, crossing points that could be reabsorbed into the urban metabolism and might become useful spaces. The architecture can help giving quality to these places, in order to make them points of attraction for socializing, public equipment for leisure.

A lively debate has been created about the redevelopment of these urban residual sites and the importance of turning a need into an opportunity: to redevelop converting the current urban "non-places" into playgrounds, vital and comfortable places, useful to the youngest segment of the local community, where children playing can also learn the best practices of environmentally conscious behaviour.

The design experimentation led to the choice of creative keys to open a gate to other dimensions: cultural, social and ecological field.

It is well known that a city is sustainable if is capable of managing "creatively" economic competition, social cohesion and preservation of its natural and anthropic territory, by implementation of strategies and actions that successfully reduce the discrepancy between desirable future scenarios and current conditions in dynamic evolution.

Fig. 1: B.A.B.A. Design: converting the current urban "non-places" into playgrounds (Caso R. and Cicatiello A. Designers)

From the socio-cultural point of view, rehabilitation of degraded urban areas gives back to the city some places that are useful for the conduct of activities in the service of the citizen. If this regeneration occurs with a prior assessment of the needs of weaker social classes or categories of people most in need, the added value will have contributed to the growth of social capital of the community.

From the ecological point of view, every residual urban space, if it was been appropriately designed, can help to reduce the disorders of the urban ecosystem, becoming a core-area of the urban network. The connection between the built areas, expertly designed, can help reduce the microclimatic urban phenomenon of the heat island, thanks to the refreshing effect of the vegetation, it helps to regulate the water balance, allowing greater permeation of rainwater into the ground; it reduces the impact of noise and pollution.

This environmental infrastructure allows relating and connecting different areas with some presence of naturalness or sociality, where it is possible to integrate the development processes of the local communities with the natural processes. The objective is to recover and connect all those urban wrecks and dispersed areas. In this way, those are being ripped to decay and become support to an overall widespread diversified urban quality.

In this project, the concept of environmental culture is associated with the concept of environmental quality and the ecological regeneration not only satisfies the physical, technological and functional requirements, but also includes a process of growth of the knowledge of young citizen user who learns environmentally friendly behaviour playing.

According to this approach, the design of the open space is not only the use of appropriate technologies. It requires a strong analysis and understanding of the relationship between space and technology, the need for complex training and integrated planning processes to achieve sustainable results.

For example, "Baba" (*Baby Area: Big Adventure*) is a design that has transformed a residual urban space in a game area: colors, fantasy, adventure and sharing are the key words of this playground.

The five "stripes" including the games are divided by themes:

- Orange stripe: to learn the flat geometric shapes.
- Red stripe: to learn how to play with numbers. The bowling has tracks like meters for measuring distances; the puzzle indicates the odd and even numbers; the "game of the week" shows the metric system.
- Green stripe: to teach that sport is "all live peacefully", as the team activities encourage collaboration and sharing.
- Yellow stripe: to learn the vowels between slides, tubes, tunnels, wheels and climbing.
- Blue stripe: to play between the planets of the galaxy.

An innovative concept of area for recreation and socialization that shapes a grey corner of the city making it an eco-compatible colourful space where everyone can play and learn.

Fig. 2: B.A.B.A. Design: young citizen learns environmentally friendly behaviour playing. (Caso R. and Cicatiello A. Designers)

The decisive challenge in designing urban spaces of good quality is to combine all the significant requirements: the needs of the weaker sections of the population and the needs of a creative and innovative design that interprets the characteristics not only the place but also of its future users. However, this is not enough! After realizing the transformation and investing resources, we should verify the productivity of investment by checking if the conditions assumed by the project are really actuated. [2]

The ex-ante evaluation of the scenarios is more reliable if the data used for evaluation are truthful. The use of decision support systems can help the designer to verify the technological choices and the public entity to verify the programmatic choices.

Within the heated debate about the future development of our cities, according to the principles defining the premises for a sustainable urban development and smartness, the lack of national guidelines on such an issue is evident. On a building scale, if binding rules have been introduced aiming at improving both the energy and environmental efficiency of buildings, on an urban scale, about the Italian panorama, there are no rules. In order to fill such a gap, the Institution for Innovation and Transparency in government Procurement and Environmental Compatibility (ITACA), is carrying out the *Protocol ITACA Urbe*, based on the methodology focused by the iisBE (International Initiative for a Sustainable Built Environment) in cooperation with the Urban Morphology Lab: a

specific multi-criterion system for the analysis and evaluation of sustainable urban areas (SBTool Neighbourhood).

The *Protocol ITACA Urbe*, introduced in Verona on October 2013 at the Smart Energy Expo, is an evaluation system of urban and landscape quality of the interventions in the urban areas, mixing evaluations of architectural and energy type with sociological analyses, verifying its feasibility in relationship with technical rules and building regulations in force.

The central role of the city established by the European policies (Leipzig Charter, 2007), as well as the place from which they can start for the economic recovery and the development of innovation, created the need to elaborate a *Protocol ITACA* on an urban scale able to monitor and, as a consequence, limit the indiscriminate use of the soil, degradation of the public urban heritage, unchecked urban expansion and scarce quality of suburban areas.

After the first phase when the aim consisted in creating a friendly attitude in each private citizen on the value of an “environmentally friendly behaviour”, acting on the improvement of the energy-environmental performances of the private building heritage, the following step is the systemic control of the energy-environmental quality of the urban eco-system, carrying out a tool able to analyse and rationalise the whole effects deriving from the transformation of the public space on a wider scale. Such a tool may be useful to the public subject both in the ex-ante evaluation phase in order to orientate the planning of the urban renovation towards sustainability, and in the on-going evaluation phase in order to determine the coherence of planning and designs with strategic indications, and in the ex-post evaluation phase in order to monitor the efficacy of the interventions made.

Guidelines and Indicators will support designers in their own choices and, as already happened for the residential *Protocol ITACA*, this method won't be useful only to verify the choices made in order to get a certificate and/or a class of merit, but also a supporting tool to the design in order to help making appropriate choices, that is a quality design. [7]

Thanks to the development of this specific tool, aiming at the evaluation of the environmental sustainability on an urban scale, able to orientate and monitor, in performing terms, the interventions of the urban transformation, an important chance for our Country will be played: that one of the rehabilitation of the existing urban tissue. All that through a process of sustainable development based on criteria not only of urban type, but also of environmental, social and economical type.

2. Protocol ITACA “Urbe”: a new tool improving territories and developing innovation (LM)

Protocol ITACA is an instrument that is presently relevant to the building scale. In case of estimates on urban scale, such as projects of urban recovery or new district constructions, it would be valuable to use a specific instrument whose evaluations are based on appropriate indicators. International iISBE is developing an instrument to evaluate sustainability on territorial level, suitable for the specific features of any city or neighbourhood. The system uses criteria, which allow examining complex problems. The definition of the overall set of criteria and indicators will probably concern the following aspects:

- social and participative dimension
- economic and financial practicability and sustainability
- landscape compatibility of the intervention with the context
- mobility, accessibility and connectivity
- quality of public spaces
- quality of the project proposal: energy, environmental, urban and architectural.

To build this multicriteria tool, which estimates every indicator and its own weight, it has been executed a plan divided into different phases:

PHASE 1_This phase, defined as “the state-of-the-art” stage, is the one in which it has been built a frame of reference both at European and national level. Everything has been arranged through accurate analysis and the examination of the Italian Region documents, and the open database information, which can be used for this Protocol.

PHASE 2_Phase 1 data have been analysed in a critical way and they have been reinterpreted according to the present needs.

PHASE 3_In this phase, an evaluation system has been arranged based on the most suitable multicriteria methodology.

PHASE 4_It has been analysed the compatibility of the instrument with the current regulations in order to prove its validity.

PHASE 5_The Protocol has been tested in different urban areas used as samples.

PHASE 6_At this last point, it has been written the definitive *Protocol ITACA Urbe*.

This definitive Protocol has been realized to be used, first of all, as a tool to help evaluation activities. However, it is also meant to be an instrument for both “ex post” monitoring and “ex ante” evaluation of urban regeneration plans and programmes.

Protocol ITACA is an open tool as it has been built considering open data banks. Nevertheless, at the same time, it turns out to be both flexible, as it is applicable to different urban scales (building, urban block, neighbourhood, district, city), and totally integrated with the context, as its indicators have been particularly created for Italian cities. Indeed, it can also be used as a guideline tool for both urban and territorial planning. Another feature of *Protocol ITACA Urbe* is that it is a public tool as it has been defined and shared by Italian Regions. For these reasons, if wisely used, it can significantly help to raise the project quality as it provides criteria and guidelines useful to answer to public notices and announcements.

3. Indicators system (LM)

The great innovation of the National *Protocol ITACA "on urban scale"* is that it allows to execute environmental, territorial and energy evaluations on different scales, from the block to wider areas, becoming a useful quantitative support tool in the Strategic Environmental Evaluation. In connection with this, it's a good thing to highlight that Torino City adopted the Protocol ITACA on urban scale to approve the Variante 200. Obviously, every building which is part of the project has to conform to the indicators, observing a minimum score established into the Protocol ITACA.

Fig. 3: Evaluation fields

The analysis is carried out on interconnected scales: building – block - neighbourhood. The urban scale criteria constitutes an instrument able to analyse complex urban problems, helping to find the most suitable solutions.

The instrument is used in the following phases [6]:

- *overall urban planning;*
- *executive project of the intervention areas;*
- *realization;*
- *monitoring during the construction.*

In particular, the urban field is considered the overlapping of six layers:

- *interactions: man and his own activities*
- *transports: street networks*
- *building shapes: fragmentation*
- *reliefs and topography: limits and opportunities*
- *land use: flows and settlements*
- *full and empty spaces: air flows, penetration of solar radiation, pollution dispersion, air temperature.*

There are no appropriate evaluation tools for analysis on block or urban scale, nor it is possible to employ the instruments now used for building analysis. On this purpose, scientists are working to find specific indicators able to represent urban problems in a suitable way. Each indicator is expressed in a logic function, which can calculate, according to its typology: intensity, diversity, distribution, morphology, proximity, connectivity.

In this way, the use of the Protocol ITACA allows to obtain indications regarding the most convenient measures of urban regeneration and development, giving the possibility to better understand the effects of both project and political choices.

For its application in a specific geographical context, the evaluation tool, which has been created to encourage sustainability and to give economic aids, must be measured and contextualized considering local peculiarities like weather conditions, executive procedure, technical rules, regulations, etc.

Methodology is based on the interconnection between two research grids: one of spatial analysis and the other of sustainability. The first one includes aspects [6] like:

- *Diversity (mix of activities)*
- *Intensity (urban concentration, occupation, energy, CO2 emissions, etc.)*
- *Proximity (distances between one's own places, transport availability, recreational areas, etc.)*
- *Spatial distribution (concentration or dispersion of activities, parkings, etc.)*
- *Morphology (shape factors of buildings, blocks...)*
- *Connectivity (street interconnections).*

The second grid, regarding sustainability, includes the following topics [3] :

- *Economy*
- *Bio-diversity*
- *Energy*
- *Culture and well-being*
- *Social equity*
- *Water administration*
- *Mobility*
- *Waste*
- *Land use*

Fig. 4: Grid 1_Space analysis and Grid 2_Sustainability analysis

Topics like mobility improvements and accessibility on urban or metropolitan scale, urban regeneration and the project integration with the infrastructural, insediative and environmental network are connected with the evaluation of service efficiency. However, it is also important to consider the relevance of all the social benefits resulting from the project and the environmental and landscape compatibility of the suggested interventions.

In this way, the tool allows to obtain a global vision of the city sustainability level, or of a part of it, and of the better strategies useful to face up to the future challenges.

The result of the evaluation is a sustainability score: global and partial (according to the topic areas), able to express the social, environmental and energy qualities in the urban areas.

4. Game rules (AV)

Among the strategies of action considered as a priority, therefore, that one to “*Create and ensure public spaces of high quality*” emerges in order to attract the industrial investments with a high know-how, skilled and creative human resources tending towards a “Baukultur”. It proposes to create attractive spaces orientated towards direct, indirect and potential fruiters and, why not, future fruiters (in the viewpoint of the intergenerational equity principle), but with actions aiming at preserving and valorising the historical-architectural heritage with a high cultural and environmental standard (Europe 2020 Strategy).

In fact, our cities have got unique cultural and architectural qualities, astonishing tools of social cohesion and excellent chances of economical development. They are centres of knowledge and sources of growth and innovation, but they can't carry out their function as an engine of the social progress and the economical growth (as described in the Lisbon Strategy) unless they can keep in balance the pressures coming from different parts: the social sphere needs equity and legality; the environmental sphere needs protection and safeguard; the economical sphere, that governs all systems inappropriately, should be limited to verify efficiency. Particularly, the economical progress shouldn't be linked with the exploitation of resources definitively, stimulating knowledge, excellence and innovation economy, making the endogenous development stronger and diversifying the local

production systems and, at the same time, arranging the labour market adequately through both education and a continuous workers' training (Toledo Declaration, 2010). [5]

If these presuppositions happened, they would ensure an urban growth and such a level of life quality that would be changed into competitiveness, attractiveness, creativeness and wellness.

Management tools, like *Protocol ITACA*, are useful to make friendly designing choices, according to the principle that a proper and a clever usage qualifies the space.

Starting from such principles, the design experimentation made, based on the demanding-performing approach, put at the centre of the decisions children from 2 to 6 years old. Planning and realization of a playground in an urban non-place addressed to mainly preschool end-users, has been interpreted as the occasion to give environmental knowledge. The whole design is based on the principle of an eco-friendly behaviour: from the choice of materials to the choice of the types of games, as children learn when they play.

Anyway, the type of destination of use put a series of ties, having as main aim that one to ensure the safety of the end-user /fruter. In such a case, talking about safety, it is necessary to make a difference between safety of the child and safety of the game. The former concerns mainly of the use of the game, and the safeguard of the risks coming from either wrong or dangerous behaviours, while the latter concerns of resistance to the deterioration by consumption and/or weathering, safeguard of the integrity of its parts from vandalism and its maintenance. Therefore, we can deduce that the right design of the playground, while the safety of the game depends mainly on the appropriate choice of the materials ensures the safety of the child.

In fact, in order to carry out the design of a playground, the architect must respect not only specific regulatory and legal requirements, with a reference to the building and safety, but also the test of the criteria of eco-compatibility, recycling and renewal of materials to be used being real ties for the technological choices.

Expecting the definitive version of the *Protocol ITACA* for urban spaces, it has been used the National *Protocol ITACA* for schools (2011), because it fits better to the evaluation of the environmental performances of a playground for children, with the opportune corrections, of course. All criteria allowing a right evaluation of the sustainability of an urban space design have been analysed and selected with a friendly attitude, not considering the criteria foreseen for the evaluation on a building scale. The valuable macro-criteria are: Site Quality, Resources Consumes, Environmental Weights and Service Quality.

In particular, the National *Protocol ITACA 2011* for Schools considers, within the evaluation area "consumption of resources", four evaluation criteria for the used materials:

B.4.6 Recycled/ recovered Materials; in fact, in order to limit the consumption of raw materials it is necessary to foresee either the reuse of recovered materials or the use of recycled materials;

B.4.7 Materials from renewable sources, having a meaningful percentage of material of either vegetal or animal origin; their use tends to reduce the consumption of non-renewable raw materials;

B.4.9 Local Materials, whose local supplying allows shortening the distance that components must make in order to get to the intervention site, contributing to reduce the emissions produced by such movements. Loads from the movement of raw materials from 150 to 300 km are considered as *environmentally acceptable loads*;

B.4.10 Recyclable or removable; the chance to reuse or recycle parts of a building at the end of its useful life-cycle in a differentiate way allows to collect a meaningful quantity of materials able to have new functions in the future, minimizing the necessity to use new raw materials.

In accordance with the trends of the present market, the sustainability criteria in the design phase impose to consider the **Life-Cycle Assessment** of each material to be used, so considering the whole process: from taking the raw material to the production cycle, up to the realization of the product and its disposal.

Protocols including a certificate of the materials used in architecture in the evaluation of the performances of sustainability of the building are several and consider the different phases of the life-cycle of the material divided into four main issues:

- Origin of the material
- Use of recycled materials
- CO2 emissions in the working phase
- Pollutant emissions and possible disposal of waste.

The final judgment is not an aggregate judgement, but it is indicative of the design performances in comparison with the single categories of evaluation criteria.

For example, in the design of the "ECO-VOLCANO"(Corselli S. and Graziano G. designer), the Goal of this game is to teach children how make correctly the separate collection of rubbish in order to keep clean and healthy our Earth. Children have to pick up the balls inside a pit situated in the middle of the volcano, and put them inside the cones placed on the top of it on four sides. Each ball have a different colour that represent a different type of waste: green for paper, blue for glass, violet for plastic waste and brown for the organic waste. Each balls had to be put inside the cone of the same colour. Under

those cones, there will be a ramp where ball will slide again to the center of the volcano in order to restart the game. At the same time, children develop the ability to associate colours but also knowledge about recyclable materials. In addition, the whole game is made of environmentally friendly materials: Heolzhof Playlastic layers cover the steel structure; cones and balls are made of recycled plastic materials. All choices are maximally consistent and the result of the Protocol ITACA evaluation is positive:

- Site Quality: 5.00 A
- Resources Consumes: 3.15 B
- Environmental Weights: 1.08 D
- Service Quality: 2.94 C

Fig. 5: Protocol ITACA evaluation

From such an application, it has emerged that the *Protocol ITACA* is an excellent tool supporting the designer's decisions, with the aim to make easier the design choices.

5. Conclusion (AV)

In conclusion, the technological design experimentation has confirmed the methodological validity in leading the technological design as an "action of research" that, through more or less complex models and tools scientifically supported and shared, interprets phenomena and/or problems concerning of the sphere of the human habitat, underlining the links of cause-effect in order to make decisions.

A catalogue of more or less performing solutions is offered thanks to the creative act of design, maximally answering to the needs determining it, more or less adequate to the surrounding conditions that become "game rules". The Leipzig Charter is offered as a platform in order to establish these "game rules", that can be extremely shared and accepted, so that from strategies they can /must become signs, actions, material ... "appropriate habitat". [1]

“Local” in the Space of Reconstruction of Meanings. Ingushetia as a Phenomenon of “the North Caucasus Identity”

Elena SHLIENKOVA,¹ Zarema KALIMATOVA²

⁽¹⁾ Department of Innovation Design, Samara State University of Architecture and Civil Engineering, Samara, Russia

E-mail el.shlienkova@gmail.com

⁽²⁾ E-mail zarema_rus@mail.ru

Phenomenon of “the North Caucasian Identity” by the example of the Republic of Ingushetia

In 2012 the first stage of the research on the topic of “local” started on the basis of Samara State University of Architecture and Civil Engineering: “Global and Local Identity in the System of Visual Cultural Codes of Design (by the example of the Republic of Ingushetia)”. In 2013 the research was continued but this time within the topic which maximally reflects exclusiveness and importance of applied character of this work and also the opportunity of its phased realization: “Local Identity” in Formation of National Strategies and Universal Codes of Project Culture (by the example of the Republic of Ingushetia)”.

Taking into account the special character of the material under study, we decided to include “tribal” community of Ingush people with other highland peoples into the focus of our attention. With those who managed to “retain” their identity and make it the object of interest not only for authentic bearers of the cultural code but an important factor for regional, economic, innovative development. With those who preserved their history, their memory and found an original way of intercultural communication and broadcasting of these “value receptors” outside. With those who did not lose their uniqueness while living in transcultural space of contradictions, in the megaurbanized world, in migration flows and the endless cocktail of cultures, traditions, “blood” and language. With those who made philosophy and culture of their “small homeland” a world asset.

Keywords: Ingushetia, “Caucasian Civilization”, collective identity, local and global, syncreticity

1. Introduction. Local identity in transcultural space

Problems of “big” and “small” nations is currently becoming a complex intersection of deep contradictions of civilization in the global space, which has absorbed and diluted many value factors such as uniqueness and complexity of cultural, social, ethnic and confessional codes. The possibilities to discern “a similar one” from “a different one” and the dialogue on the level of fine vibration of meanings are beyond a historic, cultural and anthropologic model. The space of politics and tough “rules of the game” in the global economy field often irreversibly eliminate the diversity and uniqueness which the presence of “the little” in “the big” gives the humanity.

This problem has recently become particularly critical in the territory of the former Soviet Union which used to be integrated. That is true not only for the borderlands of modern Russia (the Caucasus and Far East) but also for major centers where conflicts based on nationality acquire a regular character. The object of our research is the Republic of Ingushetia that is located in a dangerous region of the North Caucasus. On one hand, one can see all signs of internal commuting, on the other hand, there is unlimited expansion of neighbors. Flashpoints of tension are growing, conflict situations are turning into “combat” operations. These result in escalation of internal and foreign policy situation and inevitable search for the peaceful doctrine for settlement and prevention of possible provocations. That

is certainly not only a problem of one country but also a common global trend of the last decades. Similar scenarios happen practically everywhere with a various degree of aggressiveness and irreversibility.

A famous Russian film director Alexander Sokurov gives the following characteristic to the existing situation: "Russia is the only big country where feudal public structures coexist with democratic ones. It is necessary to work not on the blending of different cultures. The state has to solve another task: the establishment of a noble and respectful distance between cultures... One can not force different ethnic groups to move from one territory to another so sharply and cause a clash between them practically forcing ethnoses to have a war with each other. Many efforts have to be made to keep people in the Caucasus. To provide them with decent work so that there will not be those aggressive raids to the other nations' territories where people with a different lifestyle live. This is a task of a state level. In case it is not solved the process will start with a wave of mutual hatred and end up with a civil war. A true national policy is not a celebration of blending but a celebration of mutual distance and mutual preservation of cultures in their nonaggressive, humane state. That is only one problem. And how many are there?" [12, p. 97]

The nature of demographical and ethnic "vibrations" is complicated and mixed. However, it is possible to make an attempt to solve this growing welter of contradictions and further conflicts on the basis of humanitarian and cultural discourse and establishment of primarily:

- internal dialogue through reconstruction of deep and temporal codes;
- formation of the principles of "soft esthetics" as the space for intercultural communication in contrast to aggression;
- detection of differences through positive competition;
- actualization of cultural codes of identity, verbal and nonverbal, intercontextuality, religiousness and secularity and others.

2. Main reference of the territory: "The Place from where the Horizon is Visible"

The North Caucasus is one of the few historic places where unique monuments of ancient traditional culture remained. They are of genuine interest from the point of view of highland peoples archetypes and philosophy in a complex set of landscape and biospheric, geographic, cultural and genetic, social and political factors. According to philosopher Khazhismel Tkhagaposev, Coaucasian mountain area "serves as a factor of "compression" of space which causes an immense diversity of sharply different natural, climatic and biospheric zones (from severe continental to subtropical) and creates preconditions for coexistence and interaction of various types of cultures, ways and forms of man's existence". [8, p. 8]

Several official data:

- Kabardino-Balkaria, Ossetia, Ingushetia, Chechnya belong to the area of the Northern Caucasus.
- The Republic of Ingushetia is the "smallest" regional and "peaceful" highland part of Russia. Part of the state boundary of the Russian Federation with the Republic of Georgia goes along its southern territory.
- The territory of the republic is 3.6 thousand square kilometers. It stretches 144 km. from the north to the south and only 72 km. from the west to the east. [13]
- According to the data of the National Statistics Federal Service its total population was 442 255 people on January 1, 2013. Altogether 71 nationalities live in the republic, the Ingushes make up over 80%, the Chechens are the second in number, and the Russians are the third. [11]
- Autonomy of the Republic of Ingushetia dates back to July 4, 1992. [13]
- According to the Russian Federation Life Quality Rating carried out by the RIA-Novosti TV channel in 2013, the Republic of Ingushetia is in the "red zone" of regions which are traditionally dependent on federal support due to the lack of economic basis and mineral resources for independent development, which leads to low level of its own income. However, in contrast with its territorial neighbors that also have a negative dynamics of main indicators the Republic of Ingushetia managed to rise two positions up in the rating in 2013. [14]

3. Syncreticity of cultural and historic multilayeredness and invariance

Despite the fact that systematic and detailed study of history and cultural heritage of the Caucasus is usually connected with the end of the eighteenth century (the beginning of colonization of the South of Russia and the Caucasus, active military, administrative and resettlement actions) some sources mention the Caucasus as a "distant geographic province of Ancient Greece". Back then, Homer, Herodotus and Strabo tried to comprehend mythological experience of these places.

The first mention of the man presence in the territory of the Caucasus was at the end of the Paleolithic Era – the beginning of the Neolithic Era (500 thousand years ago). Three thousand years B.C. the

Caucasus “becomes the source of paradigmatic cultural and technological innovations” for Southern and Eastern Europe, Western Asia and the Volga River region. [8, p. 13] Cultural communications with Ancient Greece became a crucial point in the history of the North-West Caucasus especially in the sixth century B.C. (centralized system of government, active trade, new quality of construction, including monumental urban structures, coinage, intensive migration of steppe nomads and others).

Fig. 1: Archive photo, Fatima Kudusova “Family and Family Life of the Ingush”. A married couple in national costumes [6]

Fig. 2: Photo: Dmitry Belyakov. Elders

Fig. 3: Photo: Dmitry Belyakov. Elders

A special place of Caucasian culture of the Early Iron Age holds the appearance of original “historic and cultural encyclopedia” – “Nart Epos” that absorbed and reflected in an amazing way the mythological ideology of practically all representatives of the Caucasus from the peoples of Dagestan and Georgia to the Ingushes, the Adyg-Circassians, the Karachais and others. The world of spirit and mode of life of the ancient times, pagan customs, rites, norms of urban etiquette, poetry patterns and rhetoric are presented in the Epos. It undoubtedly “has not escaped and could not escape different cultural and historical accumulation, topics and images of distant from each other cultures of the East and the West alternated in the world: Hittite-Hurrian, Indo-Iranian, Ancient Greek, Turkic-Mongolian. Figurative and narrative parallels with the Avesta, the Rigveda, Kalevala, Russian epics are found in it, which reflects that complex cultural interweaving that is characteristic of the region’s history”. [8, p. 14-15]

Ancient history of the Caucasus is incredibly rich and diverse but unfortunately it underwent irreplaceable losses as a result of mass migrations and Russian colonization, soviet “integration”, internal discord and attempts to “erase” the memory about ancestry and customs in its newest history. It does not allow to reconstruct an objective picture and carry out a full-value analysis. For instance, the tragedy of the Ingush people which happened in the twentieth century was connected with mass deportation.

Although the format of this article can not go into details of a complex history of the issue under study, it is worth to emphasize the multilayeredness and multifunctioness of various research devoted to the Caucasus and Ingushetia. We can see two key approaches “from outside” and “from within” in available factual material and extended base of sources which make up the platform of subsequent scientific paradigms.

We owe the view “from outside” mostly to the members of academic expedition of the end of the eighteenth the beginning of the nineteenth centuries which participants were military and civil officers who often had European background (I. Georgy, I. Gildenshtedt, P. Pallas, U. Klaprot, M. Engelgardt, L. Shteder, P. Butkov, S. Bronevsky, I. Blaranberg, F. Leontovich and others). [2] This view has an imprint of collision and penetration of worldview positions, civilization models, perception of Caucasian identity in the context of a wide spectrum of eastern cultures.

The view “from within” is characteristic of the first Ingush and Chechen researchers (Ch. Akhriev, A. Bazorkin, U. Laudaev). This view is invaluable, it is built on deep understanding of material and its mental interpretation. Keeping this “from within - from outside” duality in the focus of attention undoubtedly enriches and complicates the system of valuation opinions which are inevitable in any author’s interpretation.

Starting from the 1940s ideological pressing effected the formation of scientific concepts which resulted in concentration of a number of researchers on ethnogenetic approach and the loss of the integral picture of regional specificity.

Over the last twenty years the national issue has sharpened in Russia and inevitably causes a new wave of interest to this topic, to the sources of highland peoples, their sovereign rights, cultural identity and its heritage.

4. Ethnicity as a key sociocode of “Caucasian civilization”

The Caucasian mountain range is a peculiar symbol of an integrated world, the integrated territory for the ethnic group called “the Caucasians”. At the same time it is a dividing line of civilizational and cultural deep collisions in two spiritual spaces: Christianity and Islam. The deviation of what used to be a harmonious pagan picture of the world into the two religions could not go through painlessly for the North Caucasian ethnoses, that is why it continues to reflect religious and cultural syncretism and polyethnicity of the civilization matrix of the highland peoples.

As historian Victor Chernous notes: “The peoples of the North Caucasus were involved in the periphery of ancient eastern, antique civilization, and afterwards Byzantine-Slavic and bivectoral Islamic (Sunni and Shiite) to a different extent. In other words, from the moment of the transfer to civilization the Caucasus has played a role of a contact zone for several regional civilizations instead of becoming a place for development of a mutual Caucasian one (which does not deny influence of other civilization circles on the South and North Caucasus)”. [10, p. 153]

When talking about ethnicity as the key sociocode of “the Caucasus civilization”, the researchers compare a special role of etiquette of such distant cultures as Japan and the Caucasus which demonstrate surprising similarity in clannish and social way of life, functioning and communication with outside world and foreign cultures. They differ in organicity of cultural verbal and nonverbal codes which form an integrated field of meanings and behavior but at the same time they identify themselves in the line of other cultural paradigms.

It is important to understand the syncretism of a culture through the absence of “a boundary between routine, practical, communicational, religious and artistic forms of activity – they are inseparably connected, unbroken in real manifestations; within the framework of a syncretic culture art is also not structured (in types, genres and etc.), it is also syncretic. Within cultural syncretism art (myths, songs, dances, games) is also involved into the life flow and performs utilitarian functions: ritual, symbolic-communicational, practical and cognitive and etc.” [8, p. 47] Continuity of an everyday myth that became a “living tissue” of a culture is that school of life which retains its “pattern”, structure and plasticity. We can see here a succession and a perpetual internal vibration of complementary elements of the etiquette. There is a special intimate character and incredible openness to the world where “...the sources of the most syncretic culture of Caucasian ethnoses, its arsenal of images and meanings, formats of ethnic psychology, that is mental characteristics and archetypes of ethnic cultures of the Caucasus, date back to the Nart Epos, where the etiquette formation processes started” [8, p. 48]

Plasticity of syncretic cultures, which at the first sight seem to be close, evidently demonstrates astounding viability in most contradictory and crucial stages of the mankind. Hidden reserves of creative energy, which have been brought to perfection and integrity by polishing over thousand years, are concealed here. “New” time sets “new” forms of expression. Traditionally researchers studied such types of tribal and intertribal communication as myths, dances, songs, games, music harmony, language. Nowadays semantics of expression is incredibly complicated due to development of information and media technologies. It migrates freely from one genre to another, goes beyond boundaries of styles and creates unexpected dialogue forms, synthetic and interdisciplinary conglomerates from any scenarios and technologies. New formations are born in a natural way mixing and “taking in the wind of change”, cultures and types of communication. Open borders of countries and integrated information space also have inevitable influence on the speed of broadcasting and perception of any information.

Here arises a most important dilemma for working with the cultural heritage, local identity and its mental core: preservation and conservation or development and openness? Or attempt to hold both and strengthen them through preservation? Which decision to consider the right one and which way to choose today? The ethnoses themselves are often not involved in these. The modern world has transformed and assumed this privilege which used to be exclusively genetic.

We see the relevance of this kind of statements most clearly in the national theater, music and cinema of the countries which have been considered intimate, closed, incomprehensible for a long time, and today these countries present the form of dialogue that finds easily a common language with all the world. Appropriateness, symbolism and universality but at the same time complexity and multifaceted nature of such type of communication does not need translation. It is syncreticity that makes intercultural communication with foreign cultures go naturally.

These are some examples: Ki-duk Kim (South Korea): "Hwal" (2005), "Spring, Summer, Fall, Winter... and Spring" (2003); Takeshi Kitano (Japan) "Dolls" (2002); Sergei Paradjanov (Georgia) "The Color of Pomegranates/ Sayat Nova" (1968), "Shadows of Forgotten Ancestors" (1964), Tengiz Abduladze (Georgia) "The Tree of Wishes" (1976) and others. All the above mentioned films are the world's treasures. They do not lose their ethnic strength and expressiveness regardless of time, place or audience. Global communications broaden opportunities of cultural exchange and "soft esthetics".

The "sculpting in time" concept that was introduced by the great Russian film director Andrei Tarkovsky with regard to the cinema reproduces most accurately the meaning of art of communication in general: with the world, history, time and a man in the world, in history and in time.

5. "Local" in the space of reconstruction of meanings

How to revive and discover potential of deep meanings of ancient Ingush people? How to reconstruct syncretic codes in new cultural reality? Which meanings will the space of contemporaneity be filled with due to cultural intervention of identity that was opened once more time?

It should be admitted that a communicative space "is very important for interpretation of sociocultural processes which take place in the territory of local identities. A communicative space is a virtual formation where concepts, discourses and ideas find place. They have different sources of origin,

express differently directed interests and set different programs for constructing the future. A communicative space consists of a collection of individual, personal spaces but at the same time they reflect a common space and are formed under its direct effect and influence". [5]

Fig. 7: Author by poster: Zarema Kalimatova, Highlanders 1.

Fig. 8: Author by poster: Zarema Kalimatova, Highlanders 2.

It is very important that nowadays the study of "the Caucasus Civilization" nature, of its mental core is reaching a new conceptual and methodological level. Duality of perception "from outside" and "from within" is expanding due to the sum of new meanings and possibilities which globalization process offers us. Typical to academic research conservativeness gains the character of a discourse included in a common field of humanitarian values and its polemic nature. If we look at the topics of research works of recent years devoted to identity of Russian regions, including the Caucasus and Ingushetia, we will see a number of trends which are important for our research and its project nature: "ethnoculture as the basis for formation of Ingush people national awareness". [Dzarakhova, 4]; "local identities in the context of sociocultural dynamics of Russian Region" [Dzyakovich, 5]; "ethnoconcepts of Ingush culture" [Zyazikov, 9]; "modern transformation of ethnocultural identity: universal tendencies and Russian specific character" [Shubin, 7]; "dynamics of Ingush culture" [Agieva, 1] and others. Unfortunately, there are practically no possibilities to actualize cultural codes in real life of Ingush people with project means. On one hand, this fact can be considered as unwillingness of the "locality" to go through another deconstruction of the well-established notions about the position and role of the people in their own national history, or an attempt to preserve the established way of life unchanged. But it is already impossible to avoid external influence. Up till the present time one or another form of colonization went in a forcible way and the break from the past was inevitable. Nowadays there is a potential and desire of new generation to influence the projection of their future themselves. Besides, this can go in a natural and delicate way by means which are available for a "common access" and which have proved their consistency from the point of respect and piety for traditions.

6. Conclusion

Phenomenon of the North Caucasus cultures is insufficiently explored and up till now it is an unclaimed part of multicultural Russia project history. Ingushetia as a small locality in complicated processes of newest history of "a big nation" formation has a chance to get an effective instrument for preservation of cultural traditions and their increase by means of reconstructed visual and plastic codes.

Taking into consideration a specific character of our research and its mission – to detect tendencies and contradictions which serve as a driving force for development of the Republic of Ingushetia and

perception of its collective identity – there is much work ahead on development, theoretical and empirical basis for increasing the role of “local identity” concept in project culture and its unique communication code in a transcultural space. The research tasks are constantly defined more precisely in the process of the work, they are expanded and become a serious basis for:

- examination of opposition “global/ international” and “local/ national” in a project culture;
- study of the role of national project schools (architecture, design, art) in the system of global communications;
- exploring special features of cultural interventions at the level of semiotic and semantic codes, formation of style;
- analysis and actualization of new formations, possible project scenarios, visual and plastic games and intrigues, ciphers and decipherments by the example of the specific highland culture.

In order to coordinate the work on the territory of the Republic and gain official support, a cooperation agreement was signed between the University and the Ingushetia government.

The agreement is aimed:

- to organize a number of meetings with representatives of ethnic, cultural, scientific and educational communities as well as with political and economic spheres of the republic in order to develop a mechanism for promotion of an international cooperation idea and establishment of a permanently working research group;
- to hold a series of field studies in the territory of the Republic to detect Ingushetia’s ‘value receptors’ as a representative of the North Caucasus identity;
- to prepare and hold a series of discussions on the topic “Local Identity” in the territory of Ingushetia with international experts and to form a partner network;
- to establish a working group to make an ethnic map jointly with the Ingushetia government, international and regional project centers, centers of culture, design, architecture and modern art, foundations and representatives of political and business spheres;
- to hold a series of project seminars on establishment of the first national project center of the Republic of Ingushetia;
- to plan, prepare and launch Ingush Biennale of Design and Art “Khi Nana” devoted to national strategies of “small nations”.

If our research and attempt to realize the planned steps will result in formation of a basic concept of “Ingush national design” and become one of priorities of the national cultural strategy, we will consider the work successful. We also hope that the Republic of Ingushetia will become an initiator and active partner in promotion and popularization of the “small nations” topic and discussion on the problems caused by globalization not only in multinational Russia but also around the world. It will also facilitate the development of interdisciplinary and multicultural connections beyond the bounds of the country and the Republic.

The role of sustainable technologies in the design

BOSCO Antonio, CACCIAPUOTI Giuseppe

Department of Architecture and Industrial Design “L. Vanvitelli”- Second University of Naples
Aversa (CE), Italy
antonio.bosco@unina2.it

Abstract

The energy management and the environmental impact of a building is one of the weaknesses of the construction sector, for which there is a growing awareness to identify operational rules to reverse the trend of the ever-increasing power consumption and, at the sometime, to monitor the targets set by the international Conventions.

The bio-architecture is earning consensus on an ever-increasing scale, such as cultural approach to the project in order to solve these problems, including the principles of sustainable development, and especially as a technological approach, also facilitated by the local and national regulations that promote more and more the virtuous buildings in terms of energy balance.

Today designers have access to a wide range of techniques and products to satisfy the needs dictated by standard use of the building organism, bringing attention to a rebalancing between the incoming and out coming energy flow. The target is to minimize power consumption by exploiting the available technologies and, at the same time, to maximize the energy produced by renewable sources.

In the technological design process, the designer must know the site and select appropriate solutions, based also on the needs of the user.

The contribution will discuss the technologies offered by the market that best meet the energy performance requirements, a minimum environmental impact and a maximum integrability in the Mediterranean area.

Keywords: sustainable technologies, bioclimatic architecture, Mediterranean area, building envelope systems.

1. introduction ¹

The persistent economic crisis, which manifests itself most clearly in countries bordering the Mediterranean basin, it is a valid reason to reaffirm the need to pursue behaviors aimed at providing a rational use of energy resources, favoring the use of renewable energy sources (RES) rather than those destined, over time, to run out.

The economic and environmental benefits of this approach are now recognized but not always the action of governments and public and private institutions is aligned to a virtuous energy conduct. In fact, although for decades it has been affirming a diffuse environmental conscience, concrete measures implemented in the Mediterranean countries, and particularly in Italy, continue to maintain a substantial detachment from the legal provisions.

There are economic and cultural factors that still hinder the affirmation of alternative models and innovative of energy production and use, and this is even more evident in the construction industry.

In our sector, the conscious energy achievements, although rising, are somewhat isolated and disorganized and, ultimately, the projects fail to give a widespread assortment of bioclimatic and sustainable building.

In Italy, at least two factors which are closely interlinked, influence the diffusion of energy-conscious design, the first relates to the objective difficulty of applying the principles of sustainability and energy saving to the extensive existing assets, while the second is related to the relatively low production of a new building that is

¹ In this work, a collaboration between the two authors, Antonio Bosco is engaged in paragraphs 1 and 2, and Giuseppe Cacciapuoti in paragraphs 3 and 4.

smaller compared to the activity related to the restoration and renovation of historical heritage, or at least consolidated.

The construction industry, although aware of these difficulties, and therefore careful in proposing solutions and oriented products to the recovery and upgrading the energy efficiency can't be by itself a driving factor in affirming the principles of modern sustainable design.

New products and technologies are widely accepted and considered by the designers, but especially in small and medium-sized operations, are often opposed by operators linked to the old ways of building.

Designers must take on the task of educating builders and sensitize the users compared to the benefits and opportunities offered by the new available technologies, indicating with clarity and precision the economic and environmental benefits determined in the medium and long term, by the use of products often more expensive than the ordinary ones.

Professionals and scientists of building technology must take another responsibility, to better identify the needs of well-being related to the particular climate of our peninsula (Mediterranean climate) and, therefore, the resulting specificity design necessary to satisfy them optimally.

For too many years, the climatically careful project has been related, even in Italy, to principles and solutions created in very different climate areas from the Mediterranean, often more attentive to the conduct in winter conditions, outlining in fact, a partial solution to the question of internal environmental well-being of our regions.

Actually the variability and complexity of the phenomena associated with the Mediterranean climate have placed the need to outline approaches and solutions specific to that environment that take into account both the need for winter and summer, without neglecting the specific requirements of the interim periods that characterize the temperate climate.

For these reasons the bioclimatic design needs to address, in the Mediterranean area, problems more complex than those posed by extreme hot and cold climates. The external conditions variability forces the designer to define the correct calibration of the technical and structural measures to be taken to ensure the appropriate level of humidity and thermal inside wellbeing.

In our regions the choice of solar energy systems, both active and passive, can't be separated in any way from the valuation of the local conditions of exposure and orientation, but these should be evaluated together with the absolute necessity of attention to the contextual conditions. In fact, both in the new project and in the already existing interventions, we can't ignore the importance of landscape and environmental values that, under no circumstances, can be contradicted.

For this reason, the adoption of new materials and latest technologies must be continually confronted with the values and must induce the designer to define sustainable approaches in terms of landscape. This approach should be valid both in the context of interventions operating at an architectural scale and in those that involve changes to the urban or regional micro-scale.

Changes in architectural profiles of the buildings and the modification of optical and tactile quality of the surface buildings of the adoption of solar technologies, must be calibrated with respect of the quality of the environment you are going to enter, offering solutions that take into account the current type-morphological balances existing.

2. The role of sustainable technologies in the design

The huge amount of energy derived from fossil fuels, combined with technological progress has made possible the great work done so far, through the use of innovative materials and equipment. In the past the architecture has been gathering the products of progress, progressively losing sight of the problem of the relationship with the environment, focusing almost exclusively on the possibilities offered by technology systems and realization of construction.

Since the Seventies, with the development of environmental ideas, the first real pollution problems, and the evidence of the problem of energy supply linked to the availability of fossil fuels, it was necessary to verify whether this condition concealed complications.

One of the effects of these new impulses is a new focus on the nature of the architectural project and on the limited availability of resources.

At the center of the design strategy there is a simple and effective idea: using natural resources in a much more productive and profitable and better way for both humans and the environment. The aim is to reduce the global energy consumption, increased by 45% since 1980, of a percentage, of 70% of 2030.

Today more than the half of the energy consumption is associated with industrial activities and functioning of buildings; it becomes necessary, for this reason, to adopt sustainable energy strategies able to meet the ever-increasing consumption.

The main objective of these strategies must be the respect of the environment accessible through the adoption of new design solutions, the optimization of construction techniques and the implementation of systems of new generation plants, which should make possible the drastically reduction the use of nonrenewable energy resources.

A building consumes energy throughout its life cycle, from the retrieval of raw materials for the production of building materials, up to the time of its disposal.

The most critical step coincides with the life of the building, in fact, considering a horizon of 50 years of use, it is noted that heating, summer cooling, lighting and hot water production affect, for over 90 %, on the total energy consumption of its entire life cycle.

Energy efficiency is the quickest, cheapest and cleanest way to reduce energy consumption and to achieve the level of GHG emissions required to satisfy the objectives of the Kyoto Protocol.

Savings can be achieved either by changing the process so that are secured less waste or using technologies that transform energy from one form to another more efficiently.

Sustainable architecture is a cultural approach to the project that indicates a systemic view of the report "function-man-nature" and proposed buildings capable of limiting the impact on the environment.

According to this approach a good design must consist the following factors:

- control of energy use to identify potential savings and dysfunctions, particularly in restructuring and recovery;
- installation of equipment and low-power systems;
- installation of equipment for the production of energy from renewable sources;
- optimize the use in the long term through improved the insulation of the building (roof insulation and ventilation, walls, windows, etc. ..);
- continuous monitoring of energy savings through a continued commitment to supervision and maintenance.

The designer must be aware of the multi-disciplinary nature of these problems, especially in interventions on the existing building, involving different skills that pertain to architectural design, to environmental and land, to history, to restoration and energetics, without forgetting the importance of economic and environmental impact assessments.

Special attention must be given to the effect of the environmental and functional project arising from the adoption of innovative technologies in the field of plant engineering and construction, by use of new materials.

The progressive affirmation of the principles of eco-compatibility requires a deep review of the conventional building process in synergy with the progress of technological innovation.

The reduction of energy consumption and environmental compatibility are essential parameters in dealing any process of transformation of the territory.

Also, if you think that most of existing buildings in Europe has more than 20 years, we understand that the rehabilitation of this heritage can provide relevant insights for finding design solutions "energy-aware", coming to assumption an energy saving up to 30%, resulting in a lowering of the operating costs of the building organisms.

Following these reasonings it can be said that the creation of a professional profile of scientific-technological content and managerial-management for the integration of innovative technologies in construction allow for a strengthening of the skills needed for the project and ensure, for the future, a highest quality level of the entire building system.

3. Energy strategies for building envelope

Designing an energy efficient building requires two aspect, that are analyzed separately but are held together by a strong link:

- the building envelope, which is a set of elements that enclose the heated rooms;
- plants, which convert the energy.

The desire for low energy consumption buildings is increasing by both construers and buyers. Marketers and advertisers mostly offers false properties, masking them with only solar energy panels. Which in reality, they produce more energy than what is actually required for the property and used by the owner. But, due to incorrect design choices, the problem of decreasing energy demand stays unsolved.

The heat demand is for residential space heating and production of hot water, while electricity demand is mainly used for lighting and power supply systems.

While maintaining the same levels of comfort you can drastically reduce the energy exchanges through efficient measures to make the buildings envelope.

Other interventions concern the replacement of utilities thermal systems with renewable sources such as solar thermal or use of heat pumps and condensing boilers or other more efficient equipment, or for the illumination measures that direct towards better technology for lighting (lamps high efficiency).

Are of particular interest, the actions relating to air conditioning, insulation and lighting of the interior, which give immediate returns through the application of existing technology.

It is generally thought that isolation during colder season the importance of insulation system superiors those of warmer seasons but in reality they both possess the same importance.

The reduction of energy consumption involves the design choices and the energy needs in both winter and summer has to be taken into account.

During the winter, the energy balance of the building must take into account the losses and gains in terms of free energy contributions, although in the Mediterranean The question must be considered carefully in order to avoid counterproduction in the summer which is the season with more demand of energy and higher energy consumption.

You should also carefully consider the contributions due to radiation on opaque walls and window areas and, at the same time.

An efficient energy comes from using relevant technologies for the building envelope. Today, designers have a wide range of products and techniques at their disposal to meet these needs. Considering the lost energy, about 80% of the heat or cold passes through the walls, roof and floors. The remaining parts of the dispersion is due to uncontrolled air currents generated by poor sealing of doors and windows.

3.1 Roofing

The roofing are the critical element of the housing: in summer, during the hottest hours, are the areas most exposed to the sun, almost perpendicular to it.

For this reason they must be designed with particular attention to the problem.

For pitched roofs, it is very effective adoption of the ventilated roof that, in the Mediterranean area, produces the greatest benefits in hot weather when the problem is to minimize heat gains, avoid overheating and optimize the circulation of fresh air.

In warm climates, therefore, the effectiveness of summer thermal performance can be achieved through the adoption of ventilated roofs or the design of the stratigraphy of roofing to high thermal inertia.

Ventilated roof provide the roofing seconded by insulating layer, creating a cavity that allows a uniform flow of air to circulate from the gutter up to the top; the cavity, carefully studied, ensures the ventilation of the roof and the micro ventilation of the undermantle.

The resulting chimney effect promotes the dispelling humidity, across the top of the roof and then the healthiness of the mantle, reducing maintenance costs.

The ventilation increases and enhances the features of the insulating layer, expelling heat from the top. Monitoring carried out, show that the only ventilation reduces the temperature in the spaces below of 8-10 ° C.

The stratigraphy with high thermal inertia, are able to accumulate heat for several hours before it is transmitted to the interior, and attenuated phase-shifted in time.

A massive design solution is given by the green roofs and the roof gardens. In this type of roofing, the insulation and the hygrometric comfort vary by stratigraphy adopted.

Green roof is a passive cooling system to reduce the thermal load.

In summer, the green roof protects the building from direct solar radiation, and the overall performance is better than winter, in fact, the substrate in any condition of thermal humidity provides significant benefits to the internal environment, functioning both as thermal insulation, which as a heat extractor, or as a combination of the two possibilities.

The surface temperature of the layer of vegetation assumes a value equal to that of the air temperature, while below, the various components have a temperature gradually lower.

In addition to the function of sealing, noise attenuation and thermal insulation, green roof solution also offers aesthetic advantages, and a fundamental ecological contribution, because it increases the availability of green in urban areas and reduces the "urban heat island" .

3.2 Outer walls

Against overheating in summer of the building due to the excess of direct solar energy that crosses the outer walls, you must use the walls with high thermal inertia or ventilated; adequate shielding to impede the penetration of sunlight and the glare in summer and, finally, design strategies which facilitate natural ventilation.

You can, for example, to fill performance gaps, using screening elements usually present in buildings (balconies, porches, window sills) or additional accessories such as climbing plants, green walls and brise-soleil able to increase the insulating characteristics and selective of the walls.

In addition, through a proper study of orientation, solar and shading paths, you can increase the performance efficiency of facade systems both opaque and transparent.

The vertical closures transparent, glass is a material that has significant potential for use but at the same time, significant critical issues.

For the purpose of thermal control shall be assessed the level of insulation of the glazing system, its ability to counteract the heat transfer by conduction, convection and radiation from the higher temperature to the lower one, in reference to the thermal transmittance (U_g).

The transmittance of the simple plate glass, is greater than 5 W/m²K, but can be reduced, up to values less than 1 W/m²K, using the following technical solutions:

- double glazing: double or triple layers of glass separated by an air cavity. Double glazing counteracts the transfer of heat by conduction and convection. The performance improves with the

increase of the thickness of the interspace, which can vary from 4 to 20 mm, and replacing the air with noble gases such as Argon and Krypton;

- low-emissivity surface coatings: on the surface of the inner pane of the double glazing, are placed film-forming metal layers (such as silver or tin oxide), improving by 50% its insulation characteristics, effective in opposing the transfer of heat by radiation (in the specific case, the dispersion of the radiative component of the heat produced by the internal heating);
- solar control: the solar control glass is a product with high technological content designed to allow the passage of sunlight through a window, operating at the same time the reflection on the outside of most of the solar heat. In this way, the interior spaces are bright and much cooler than normal glass;
- low-emissivity surface coatings and / or spectral selectivity. On the surface of the outer slab or on its opposite face are placed thin metal layers or dielectric, effective in select visible radiation and rejecting most of the infrared radiation, counteracting the heat transfer by radiation, in the specific case the thermal load due to the solar radiation;
- photochromic glasses in dynamic performance (transparency varies, due to the particular chemical composition of the glass, from bright to dark, depending on the variation of the external light intensity).

The most effective solutions to be adopted will depend on factors such as exposure and orientation, which guide the designer's choices depending on the local conditions and performance levels to be achieved.

With regard to the specific requirements that the vertical opaque borders must satisfy, there are various options of isolation, both related to the technical solutions to be adopted that related to the different materials available.

Use technologies for energy control applicable to opaque closures allows us to:

- reduce heat dispersion produced by the internal heating sources;
- isolate, damping, phase shift, protect from summer heat outside;
- to prevent uncontrolled surface and interstitial condensation;
- Insulate from noise.

The insulation requirement is satisfied with both and creating mono-layer walls, in great depth, and realizing stratigraphy that providing specifically insulating materials, ie components with very low thermal conductivity.

The use of multi-layered walls helps compared to the massive walls, to more easily achieve very low U-values; but this solution does not guarantee protection from overheating in the summer as effectively as structures with high thermal inertia.

A very effective technique, and performance, that of constructive simplicity, especially in the building renewal, is the thermal coating. It is possible, in adopting this solution, to consider intervention techniques that differ in the position and the way in which the insulating layer is applied: inside, outside or in the cavity of the wall. Each of these possibilities implies the adoption of different materials and application methods that determine both advantages and disadvantages.

The internal insulation allows you to get the most primary energy savings because there are no constraints on the size of the thickness of the insulating elements, except those from the greater or lesser reduction of living spaces.

In this type of solution, the biggest drawback is related to the failure correction of thermal bridging and the danger of condensation, which may necessitate the use of a waterproofing membrane.

This system excludes from heating the mass of the perimeter walls, speeding up the achievement of the comfort temperature.

The second method of intervention (intended to walls with cavity) is represented by the possibility to fill the cavity using insulating materials such as clay, vermiculite, granulated cork, cellulose fiber or glass wool.

Alternatively, you can use expansive foam or polyurethane urea.

The advantages of this technique are the cheapness and simplicity, since these materials can be inserted in the cavity from the inside by small openings in the walls.

Also in this case it is not possible to eliminate any thermal bridging.

In general, this solution allows to achieve a long duration of operation and the drastic reduction of the economic burden maintenance.

The external coat system involves the application of a heat insulating layer, consisting of panels of appropriate thickness, and an external layer for protection and mechanical strength.

In historic buildings a strong contraindication to adopt this system is the loss of the projections and thresholds on the front.

The ventilated wall is a constructive dry solution, that it provides designers a solution for the fulfill the requirements for thermal and acoustic insulation and protection of the building against the combined action of rain and wind.

Installation of the system, both for new buildings and for renovations of buildings, gives considerable advantages in terms of durability and energy efficiency of the wall, especially in the case of high buildings detached or heavily exposed.

This system determines an cavity air between the wall and coating creating a "chimney effect" that triggers a natural ventilation that removes heat and humidity for a high living comfort.

The ventilated walls can reduce, in hot weather, the heat load on the building due to partial reflection of solar radiation by the coating, to the ventilated air gap and to application of the insulation, resulting in a significant reduction of costs conditioning.

Conversely, in the winter season, ventilated walls retain heat with savings in terms of heating.

A variant of ventilated walls are the green walls (or vertical gardens), these offer a natural protection by noise pollution and smog in addition to energy savings.

Green walls can be made in large panels or modules that can be assembled, which integrate with the characteristics of the front and ensure the functionality of windows and doors.

It is evident the limit of the applicability of the last two technological systems on buildings of historical and artistic value.

4. Plant efficiency

For the plant engineering solutions we must consider that the energy efficiency of thermal plant is linked to the individual components and then to the production system (boiler), distribution, emission and regulation system and control.

4.1 Radiant panels

Heating environments, by radiant panels, seats underfloor takes place by radiation through a flow of hot air, which is propagated from the bottom upwards, generated by a heat source placed in the floor screed.

To generate this flow is necessary to create two areas in the same living that they have different temperature.

Specifically, with floor heating (zone A) we create a temperature difference compared to the roof (zone B), which generates an upward movement of hot air and a downward motion of cold air. Initially the volume of cold air is greater respects the hot air, and then the heat exchange will be faster and with less expenditure of energy.

The continuous application of radiating force will gradually increase the volume of the hot zone, because the downward flow of cold air meet increasing resistance and the system will tend At a point of maximum efficiency that can be maintained with a minimum energy.

In systems with underfloor heating the particular location of the radiant panels and the transfer of heat by radiation generates a temperature stratification that is closer to the ideal situation of thermal comfort.

The heat distribution is uniform in all the spaces, as opposed to a traditional system, where near heat sources are concentrated high temperatures.

With traditional systems of heating the floor is cold to touch; contrary, the radiant floor has a warm and pleasant temperature that can be maintained in a uniform and constant throughout the period in which the system is in operation.

The use of heating in the floor leading to energy savings of about 35% compared to conventional systems, the heating screed uses fluid at low temperatures (30 ° - 35 ° C) with an operating temperature of the surface of 22/24 °, allowing operating economy and energy savings.

4.2 Self-energy

Of great interest is the self-produced energy from renewable sources to meet the energy needs that requires the management of the building.

In recent years the production from sources such as solar, microeolic, and geothermal power has increased significantly, both for the convenience of the exploitation of these technological opportunities, facilitated also by government incentives, and for the growth of public awareness on environment problems.

A building system with valid energy strategies, with high plant efficiency and supported by self-generated electricity, is at the base of the zero impact buildings.

For this important technological resource, we will stop to analyze, in a critical manner, the necessary attention connected to how use and application in value places.

The Mediterranean countries, and particularly Italy, they have a landscape heritage of great value and use of technologies for the production of energy from renewable sources may submit a critical element with respect to the alteration of the places.

Their landscape impact can depending on the type, extent and location of the facilities.

The modification of the places that can result from the adoption of these systems must first be assessed by means a careful analysis of connotative character of the landscape in which it operates.

This means, for example, recognize the presence of spots and scenic routes, the significant visual reporting between the place of intervention and the context and the changes made to them following completion of the intervention.

In general, the location in the historical centers, such as proximity to scenic routes, viewpoints and sensitive visual, it is critical especially in hilly areas where it is prevalent the "top view".

It is also very delicate the interference with areas of high naturalistic value or subject to restrictions of protection, and placement in agrarian landscapes with historical and traditional value.

The main impacts on the landscape of power plants from renewable sources can be traced back to the visual intrusion due to the chromatic character of the collectors, their shape and reflective surface that, in general, are in contrast with the morphological, material and color character and cause the loss of the existing value of the architecture on which you operate.

Any operation that modifies the configuration of a site must be configured as landscape design ie starting from a careful consideration of the relationship that the system is to establish the context.

Layout, design, materials and colors, work and accommodation of the areas must be the result of an organic project that respects the existing structures and give added value.

Just for the negative impact on the landscape that the use of such technologies can have in some urban or rural areas, we must use caution on the project, using the best and most viable solutions that the market offers us, bearing in mind also the critical of using of some techniques in certain contexts and, if necessary, to give up any benefits, however bridging the shortcomings with other methods that involve the renunciation of them.

It should be noted, in conclusion, that the interventions in the field of plant must be directed to the rationalization of their use on the basis of user needs that change during the day and seasons and depending on the conditions of use of the living and job environment.

In this sense, the new technological frontier is directed to energy efficiency of the plant based on automation (building automation). This sector relates to the ability to manage devices that consume energy in order to optimize the performance, in terms of "how to use".

The most significant technological initiatives included those for the management of "stand by" electrical appliances, the timed management of those thermal plants, and the automatic control of lighting systems directly related to the presence of humans in the environment to illuminate.

Earthen houses in the Draa Valley

Paola RAFFA

Dipartimento di Architettura e Territorio, Università degli Studi *Mediterranea* di Reggio Calabria, Reggio Calabria, Italy.

paola.raffa@unirc.it

Abstract

Travel literature takes us in Draa Valley, in the South of Morocco, through fascinating and mysterious tales. The Oued Draa starts from Tizgui Falls, on Anti-Atlas, to the Atlantic Ocean.

Between Agdz and Zagora are grouped a variety of rural settlements. People of this valley are called imazighen, the noble, the free-born, they are Berbers who have not succumbed to any dominance.

Follow travelers in their tales and descriptions brought us to draw a detailed map of the Draa Valley.

Arab travelers, Roman historians, French artists, popular magazines or accredited tourist guides all have a common denominator. The geography of these places is drawn by water. Water combines a landscape made of a few elements: the water, the oasis, the architecture. These elements are repeated in their uniqueness, in their essence. They had the ability to accommodate many human groups. The environment, the building material, the technique are mixed and repeated, for centuries, in the same way and without change.

The building of the architecture, as well as the building of the oasis, is the result of actions marked by time, specific, experimented. Few innovations, only the verification of consolidated events. Kasbah, tighremt, agadir, ksar are the mark of a landscape constructed by invoking the saying: "can is able to resist the time for the time that it can resist". Surveyed and drawing architecture and landscape of the Draa Valley means safeguarding an ecosystem in a poor state of survival.

Keywords: Earthen Houses, Architecture, Survey, Cultural Heritage,

1. Earthen Architectures: form and character

Ruin is the term that Western culture attaches to the material heritage in degradation.

Ruin is a work that inhabits a landscape and it establishes a series of relationships that are modified in relation to its degradation and to the dynamics asset of place itself.

In the Draa Valley in southern Morocco a series of works in ruins are part of a landscape completely built by man. The tape, fluid and sinuous of the palm grove, which marks the course of the river, is the work of skilled and scrupulous agricultural activities.

Urban settlements, ksour, are the work of communities socially developed. This is not spontaneous architecture. But the result of high cultural background.

Architectural grammar and vocabulary of ksour highlight the origins and influences of ancient Mediterranean civilizations, with clear influences of Islam and Middle East features.

"Le ksour marocaines ne sont jamais des amoncellements confus de maison. Il se composent par grandes masses, par constructions puissantes et vastes bastions et leurs murs restent très élevés"

[1]. Ksour are villages built in clay. This kind of architecture can not resist at the time.

It is sensitive to the time and man.

Its dissolves under the rain and for lack of constant maintenance.

Ksour are urban settlements that are repeated in the landscape as unique settlement pattern.

They are placed at regular distances and create a network easily recognizable in the region.

The distance is that of the pertinence of the fields, in turn governed by the irrigation systems. They are cities whose shape is defined by a drawing and whose functions follow urban layout.

“Le ksar avec son artère axiale coupée à angle droit de voies secondaires, ses impasses semblaient aux derbs des villes musulmanes, n’est donc pas, par sa forme, une agglomération rurale” [2].

Ksour are enclosures marked by high perimeter wall with corner towers.

A main access gate, a space of connection between the semi-exterior and interior; a large public square, the market and assemblies places; Mosque and annexes; the shopping area; the shops of artisans. These spaces are all located near the front door.

The road structure is minimal, a main axis starts from the gate and one or two transverse axes which distribute districts. The streets are narrow and covered to ensure climate protection. In this subdivision the houses are arranged next to each other simply juxtaposed.

The rule of proximity fulfills the requirement of the occupation of the smallest possible space. The neighborhoods are so distinctly separated from each other and arranged in ethnic hierarchies: neighborhood of Jews, nobles, slaves, etc.; and each one occupies a privileged position according to the mosque, to the gate, or near the gate that connect to the fields of grove palm.

The house in the ksar is still a unique type that repeats itself. The courtyard type.

It finds its origins in an ancient past of Mediterranean influences. The courtyard house in its becoming ruined shows the microcosm of synergies between the elements which generated it. Inside the abandoned villages, "perspective view" and "isometric view", full scale, describe the form and the function of architecture. Fragments resistant to time show up as sculptures, as unique objects, still able to communicate their being architecture.

The image of the "ruin" refers to the character of the architecture. To the essence of its construction. To the function of the work that one time was necessary for a family to live there, for a community to express their social values. And now, in its becoming ruin, the house, denounces its “value” which belongs to all. In the ruins emerge characters of architecture. Its concrete form, the technique of building, the structures. The link with the origins, the place, the language of the building.

Fig. 1: Ksour of the Draa Valley. Google Earth view.

The relationship between architecture and construction is strictly linked to the site. This connection is given by two prevalent conditions: the shortage of building materials and climatic conditions.

The construction of a house, a tighremt or a ksar is the result of the small availability of the building material. Earth, water, palm trunks.

The relationship between architecture and construction is a formal and space relationship. The physical and structural characteristics of building materials influence the size of the space and consequently its shape. Palm trunks determine the length of the floors; pisè determine the size of the walls and the height of house floors. In the earthen house exist correspondence between the characters of the form and the characters of building.

"The elements of the construction are converted in elements of the architectural language" [3].

The core of the courtyard, the rooms that are arranged around, the open spaces of the terrace. These three components create the space. The spaces of the house are not longer visible. The syntax of forms is conjugated from the "ruin", from what remains.

From what that time retains and the man has not yet taken away. At the time resists the most solid structure. The columns of the courtyard and the walls of the upper floors. These are built with adobe, brick clay and vegetable fibers.

The use of brick allows for the creation of decoration. These are still visible in the courtyard and on the walls of the terraces. Geometric friezes that alternate horizontal appeals; the columns of the courtyard are often lightened to cut corners and recesses in the trabeation or arches. The technique of pisè is used for the construction of the walls of the ground floor. The mixture of wet earth compacted and assembled for horizontal bands overlapped is the first to be leached, and then the first subject to collapse. The wood used in the construction of the floors is immediately taken away and used in new construction.

After the survey, just the drawing returns the shape of the house. The composition of the space. The relationship between open spaces and built-up areas. The drawing returns the character of the architecture.

Fig. 2: Ksour of the Draa Valley. External walls and towers.

The inherent relationship between the inside and exterior of the house.

The type of house, the courtyard house, which is repeated within the ksar, defines spaces whose main matrix is to be found in the geometric shape of the square.

The houses grow in height around a central courtyard.

The section connects the spaces between them. Explains how the space of the courtyard connects vertically all the other spaces of the house, through the passage of light.

On the lower floors the light is soft, slow to arrive. The rooms are well sheltered from the sun and heat. It is the ideal place to preserve food and to shelter animals.

On the upper floors, two or three, the light gradually materializes the space. There are places for food preparation, the living room and bedrooms. At the top, the terrace, the main place of the house. The space becomes polyvalent. It is useful to all living functions.

The link between the court and the terrace sets up the character of the house.

Spaces connected and organized according to the same formal unity closely linked to the function rural dwelling. The house of a ksar disclaims the character of their function in relation to the ground and the sky. The lower levels are linked to the street, the palm grove, the work; those higher ones dedicated to the functions of living.

"It is more correct to speak of tradition rather than history because tradition is inherent in the concept of the principle of continuity, not as an ideological choice but a necessity". (A. Monestiroli)

Fig. 3: Ksour Ait Iassa.

Survey and draw the earthen architecture of the Draa Valley means doing those simple act of knowledge useful to give value to the tangible heritage of a community.
 It means to build documents of knowledge and checking of the status of cultural heritage.
 It means to describe the identity of places in modification. Document a process of harmony between history, technology and reality; return images that can give recognition to places depleted and consolidate the expression of communities that are struggling to survive.
 It means rebuilding the palimpsest of a territory through the existing documentation into a archive in the open sky.
 The systematic study of earthen architectures in the Draa Valley allows you to bring order and recognizable places; it allows you to have knowledge of the quantity and quality of tangible heritage, to identify actions useful to the protection and enhancement.
 Survey and representation are used as tools able to re-establish a connection between site and architecture, between new places and new communities.

Nisida, the memory of a myth

Claudia CENNAMO, Ornella ZERLENGA

Department of Architecture and Industrial Design, Second University of Naples, Aversa, Italy.
ornella.zerlenga@unina2.it

Abstract

The island of Nisida is made up of a cluster of yellow tuff of volcanic origin, covered by a layer of inconsistent gray tuff mixed with pozzolan. This stratification originates underground cavities that, as for the city of Naples, cause the well-known heterogeneity of the subsurface. The presence of factories on the surface, often positioned in correspondence or in the vicinity of such irregularities, causes microcracks in the tuff, which tend to deteriorate over time, both for reasons related to *flegreo bradyseism*, both for propagation of cracking strengths phenomena.

The island of Nisida is home to the juvenile Criminal Institute, housed in a building from the thirties of the last century, below which old Bourbon volumes are preserved, recently under excavation conducted by the current prison administration. To date, the morphology of these areas is not yet defined in terms of space, nor there is a clear functional relationship with the ancient Bourbon Laundry located along the ridge overlooking Porto Paone.

The research in place includes two integrated phases. The first consists in an architectural and environmental relief operation, of the buildings interested by the recent excavation, and of the possible paths that marked the old infrastructural network of the island. The second consists in an assessment of the mechanical characteristics of the material constituent the isle and the artefacts, with the aim to determinate the staticity and integrity of the same, and of the load-bearing capacity as foundation rocks. The general objective of the research is the architectural and environmental safeguard of the island, and the assessment of the stability about the slope and the foundations of the buildings, including the Penitentiary Institute and the factories of the Bourbon period.

Keywords: Nisida, architectural and environmental survey, structural identification, texture wall.

1. The architectural and environmental survey (Ornella Zerlenga)

The island of Nisida is neither directly visible from Naples nor the geographical environment of Mergellina. In fact, from this vantage point, the well-known landscape of Naples ends on the foothills to the west of Capo Posillipo and, when the air is clear, is enriched by the views of the Sorrento peninsula and the island of Capri in the background. In order to see Nisida, it is necessary to go over the hill of Posillipo and go to the viewpoint of Parco del Virgiliano or to the final stretch of Via Manzoni. These viewpoints proudly, and unexpectedly, put the island on display making it possible to appreciate the full spatial configuration of its north-east side. However, there is a substantial difference between these two observation points. In fact, from the viewpoint of Parco del Virgiliano the perception of the island is more foreshortened and the view of the bridge that connects the island of Nisida to the mainland is partial, not allowing (as in Via Manzoni) to fully comprehend the connection with the beach of Coroglio. In addition, from Parco del Virgiliano the front view of the large ILVA steel plant is obstructed and, therefore the image of Nisida is captured in its original environmental context, an enchanting natural landscape of rare beauty, which includes the bight of Baia, the headlands of Capo Miseno and Monte di Procida and the islands of Procida and Ischia (Fig. 1).

However, this magical image of natural harmony (as seen from Posillipo) misleads and obscures the historical and current reality of the island of Nisida. If seen from the beach of Coroglio (i.e. from Bagnoli), Nisida is an island that 'is not there'. In fact, despite there being a bridge (built around the

1930s), access to the island is prevented by virtue of its intended uses. The island, therefore, is in fact 'isolated' from the context of the city since both access to it is denied as well as any form of visual inspection. Therefore, if on the one hand, the prohibition of access to the island has allowed for the preservation of the natural environment that still characterizes the island, on the other knowledge of the places and existing architecture remains the privilege of a selected few.

Fig. 1 – Nisida by Google Earth and Parco del Virgiliano and Via Manzoni (ph. by Ornella Zerlenga); Nisida without and with ILVA in Bagnoli and with Tom & Jerry (by Hanna e Barbera, *Neapolitan mouse*, 1954); Nisida by Pozzuoli (ph. by Ornella Zerlenga) and Camaldoli's Hill (ph. by Angelo Granieri).

Nisida has an ancient history [12]. Firstly, geo-morphological, being the island the result of an ancient eruptive cycle of Campi Flegrei: the current bay of Porto Paone was created by the violent action of the sea on the south-west taper of the original volcano [16]. In addition, due to the effects of the extreme excursions of bradyseism (characterising the largest Flegrean area) that connects it to the mainland until the Augustan period (mid-first century A.D.), or shortly after, when it detached becoming an island. The ridge of Chiuppino, in front of Nisida, facing the beach of Coroglio, was in fact a tunnel that made it possible to get to Nisida from the mainland [22, 27]. Its small size seems to be the reason for its name, since a topographic analysis shows how it derives from the Neapolitan dialect and, in particular, from the vernacular nickname of 'Nesis' (which in turn derives from the Greek) 'islet'. In addition, over the centuries, the island's link to the myth of the Campi Flegrei has meant that the small Nisida has played a significant role in Neapolitan iconography [7, 18, 26].

Mythology links Nisida to the adventures of Odysseus and, in particular, to his meeting with Polyphemus and the myth of the earth inhabited by Cyclops i.e. the area of Campi Flegrei. Thus, Porto Paone seems to correspond to the natural harbour where Ulysses landed with his ships before reaching the cave of Polyphemus, perhaps recognizable in the nearby Grotto of Seiano in Capo

Posillipo. However, there was volcanic activity in Greek times and it is also true that the island of Nisida was rather sporadically frequented.

In Roman times, the island's history is mainly linked to the figure of Brutus, who apparently had a summer residence here in the first century B.C. and where he met with Cicero; indirectly, the island is linked to the conspiracy led by Brutus and Cassius against Caesar. There are no traces of the villa but the discovery of 'opus reticulatum' near the prison tower (located at the top of the island) suggests that the villa stood in the highest and most panoramic point of the island so as to avoid smelling the air currents coming from the stagnant waters of nearby Bagnoli that, until the reclamation of the early nineteenth century, was a veritable swamp.

Fig. 2 – Nisida by Conte di Monterey (1635. Archivo General de Simancas. Mapas, Planos y Dibujos). Remains of the historic defensive tower; Bourbon laundry; Porto Paone; Juvenile Detention Centre (ph. by Ciro Scognamiglio).

The discovery, however, of some pylons heading toward Capo Posillipo and Bagnoli suggest that there was a Roman port on the beachfront of Bagnoli and that the villa of Brutus could be reached along a road that differs very little from today's, located along the northern side of the island. In addition, due to its size and strategic location on the island, it is conceivable that this Roman port could have served as a shelter for merchant ships and surveillance.

In the fourth century A.D., the island of Nisida was granted to the Neapolitan Church, consequently either an important monastery was built on the island or more buildings constructed to form a monastic centre. The sources that document the existence and location of the monastery are very scarce and once again it seems that the monastery stood in the highest part of the island, near the current round tower, now annexed to the courtyard of the Juvenile Detention Centre. Some ideas believe that the monastery was identical to the current courtyard of the Centre, whose square shape and the presence of arches (now walled) recall a type of cloistered courtyard (Fig. 2). However, this part of the building seems to be dated between the fourteenth and fifteenth centuries, with it therefore being a subsequent structure. In this medieval period, reports of the island are scarce and it is therefore conceivable to think that the island was a sought-after destination, as attested by the literary sources of Boccaccio as well as those relating to the queen, Giovanna. The construction of a cylindrical watchtower located at the top of the island can be attributed to the Angevin period and therefore conceivable as the primary system of the subsequent 15th century cylindrical sea tower [13]. According to documentary sources, at the beginning of the sixteenth century, Nisida was still property of the archbishop of Naples, who in 1518 granted the lease to Jacopo Carafa, while in 1544, sources report it as belonging to Pietro de Orsanques who, in turn, sold it in 1554 to Giovanni Piccolomini, Duke of Amalfi. With Piccolomini, the island was modernized and beautified, becoming a sought-after and elegant meeting place for nobles and artists, local and foreign, as highlighted by the quote by the famous writer Cervantes in Book II of his "La Galatea" and who in all probability went there. In addition, the importance of Nisida is also demonstrated by being included in almost all the most important maps of the time, even those in large scale that due to its size should not have been included. It is believed that it was Piccolomini who either began work on the sixteenth-century tower or transformed the former into a noble residence,

retaining its defensive function and maritime control. At the beginning of the seventeenth century, Nisida was bought by Vincenzo Macedonio, Marquis of Roggiano who continued the beautification of the island.

The other 'history' of Nisida, or the one that sees it as a place of segregation – that even today defines it – seems to have started in Roman times when Augustus confined his sister Giulia here. However, it was at the end of the sixteenth century that a merchant quarantine station was built on the ridge of Chiuppino. In 1593, the city of Naples bought the island of Nisida and exploiting the close position but at the same time isolated, built a quarantine station to store merchandise from places suspected of having the plague. The hospital was only built between 1626 and 1628 by engineer Alessandro Ciminiello and master builder G.B. Ferraro as a result of the epidemic in Naples in 1619 and later the plague in Messina in 1624. As a result, both the port as well as the hospital were subjected to repeated interventions. In 1766, work was started on the port of Nisida and, with the French decade (1806-1815), Gioacchino Murat decreed that the island should be connected to the islet of Chiuppino and the building of a maritime quarantine station for the hospitalization of infectious Neapolitan patients. In 1815, the State Property Office took possession of the island. With the return of the Bourbons, the island of Nisida was at the centre of a lively debate on the construction of a new port and hospital, whose work (begun in 1855) were very weary and consisted of the link between Nisida and the islet of Chiuppino as well as in the realization of the east pier and the lighthouse [9, 17, 23]. Simultaneously, in this period, the ancient tower on the top of the island was transformed into a penal washroom, while the main part of the building called 'Il Palazzotto' was transformed into the prison laundry (hence the name 'Bourbon Laundry'), near which a small chapel and the 'Convict's Graveyard' was built. During the Bourbon period, both criminals and political prisoners were locked up in this prison, including Michele Pironti and Carlo Poerio. In addition, the prison was visited by writers such as Alexandre Dumas, Matilde Serao and Jessie White Mario. After the Unification of Italy, the prison housed only ordinary prisoners and had about 1,100 inmates in about 70 dormitories. Croce, who visited the prison and published the results in an issue of 'Napoli nobilissima', described the penitentiary building as cylindrical in shape with three floors where the ground floor was occupied by laboratories and the rest by prison cells [14-15]. In 1901, after visiting Nisida, Victor Bérard wrote: «the whole island is nothing more than a prison» [8].

In fact, the island was destined to be permanently divorced from the city and especially the realisation of the ILVA steelworks on the vast plain of Bagnoli in front of the island finally severed any possibility of the development of spa-bathing tourism in the area, for which Nisida certainly would have been a cornerstone. Therefore, additional uses were allocated to the island (such as military), which helped to strengthen the island's isolation from the city. At the same time, in 1935, the old prison was abolished, with two-floors of the original penal tower being demolished and seven halls built to house and school the juvenile detainees on a farm. The new buildings (unlike the theatre and gym) are similar with a central staircase (which serves two floors) and the washrooms placed in a curved projecting block. The same was also done for the connection to the mainland between the island of ex-islet of Chiuppino and the beach of Coroglio. On 25 June 1935, the old quarantine station was demolished and the tuff promontory of Chiuppino cut off to realize the road that joined with the road to Coroglio that leads to the top of the island.

During the last years of World War II, Nisida was used as a military logistics centre for the allied forces, and by the end of the war, it resumed its role as the 'isolated' island due to the strengthening of the industrial vocation of the Bagnoli area with founding of the Italsider plant, which finally closes the spa-bathing tourism that had characterized – albeit timidly – the coast from the 1920s to 1950s of the last century [20]. In 1948, the juvenile detention centre was transformed into a 'House for Juvenile Re-education' and in 1971 an 'Institute of male Rehabilitation for observation and treatment'. The last decades have seen the entire area affected by large-scale projects and ideas that celebrate various uses of the island in relation to the city: a marine park, a tourist centre, a youth city, etc. All hypotheses that have remained on paper, leaving Nisida the island that 'is not there', with forbidden access and which is still debate how to return it to the collective heritage while respecting its natural and historical identity [19, 21].

In this sense, the surveys of the architecture on the island built in different historical periods are significant. The disciplines of surveying and representation of the built and natural environment have constituted an opportunity for the knowledge and documentation of reality, contributing their findings to the formulation of proposals aimed at the enhancement of what is present. In the case of Nisida, the relevant documentation assumes a greater significance as well as a valuable point of departure for any proposals for valorisation, it allows to 'give a face' to architecture that would otherwise remain unknown to most. Thus, the memorandum of understanding for cultural activities and research signed in March 2014 between the Department of Architecture and Industrial Design 'Luigi Vanvitelli' of the Second University of Naples and the Department of Juvenile Justice of the Ministry of Justice has the aim of studying and analysing the material sources for environmental protection and proposes a scientific survey of some buildings that have recently been brought to light and that may answer some

questions. The survey campaign (launched in March 2014) carried out as part of the Laboratory of Final Synthesis in 'Survey and representation of architecture and the environment' under the scientific coordination of the author, the correlation of Claudia Cennamo for the structural aspects and the scientific advice of Vito Cardone, noted scholar on the history of the island [10, 12].

Thus, in this survey campaign, the surveys already carried out during the 1990s by Felice Costagliola and Lucia Trapanese are particularly relevant and constitute material of significant value and unprecedented use of social as they allow to know more about the form and structure of the housing that characterizes the island [28]. The surveys in question describe most of the religious and civil architecture on the island. Drawn to a scale of one to one hundred, through the design of plan, section and elevation and, in some buildings, including through the use of graphical representations suggestive of a three-dimensional perception (specifically, axonometric), these drawings represent the planimetric configuration and elevation of the buildings located on the island of Nisida, such as the church of the Immaculate Conception, some buildings of the Juvenile Detention Centre, the remains of the historic defensive tower, the Bourbon laundry (for which exploded isometrics were also performed in order to highlight the areas used for the hydraulic lifts), residential halls with a theatre and gym. Analysis of these graphs allows to: read the dimensional and formal characteristics of the buildings surveyed, to retrace the traces of ancient environments, even by comparison with archive documentary sources, to compare between their forms and types such as, for example, residential halls, built around the 1930s located along the ridge that divides the island into two sides (one facing the mainland, the other towards the sea).

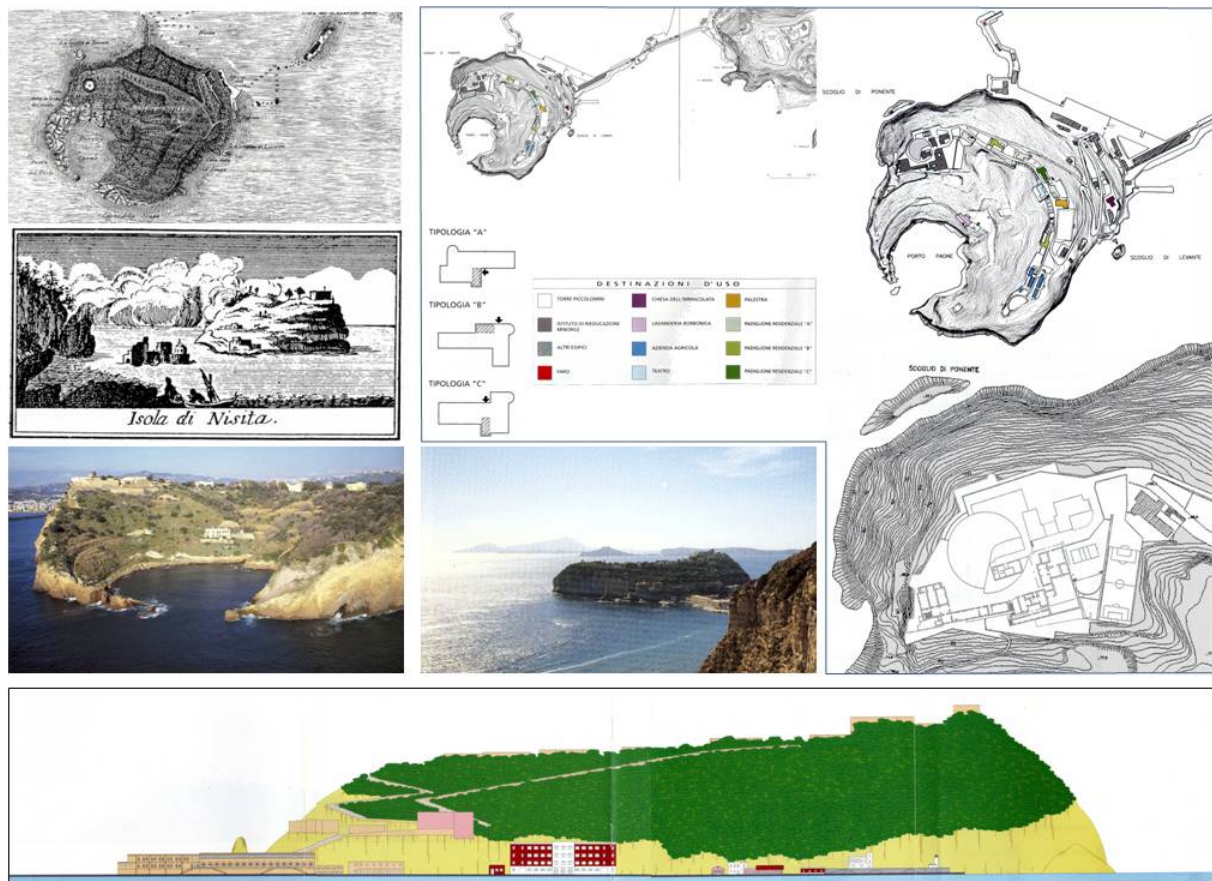

Fig. 3 – Nisida by Giovanni Carafa Duca di Noja (1775); with some buildings (church, Juvenile Detention Centre, defensive tower, Bourbon laundry, residential halls with a theatre and gym); Nisida: Porto Paone, and by Parco del Virgiliano (ph. by Mimmo Iodice); by Coroglio (drawing by Letteria Spuria).

Upon completion of the morphological surveys of the architecture on the island, an environmental survey was also carried out (Fig. 3). This is the elaboration of the two aspects of the island: one, longitudinal scale 1:2.500, carried out by observing Nisida from Bagnoli; the other, front, with the inclusion of the architectures that characterize this side of the water-front and document the coastline along the stretch from the building currently used as a headquarters of the Guardia di Finanza up to the lighthouse (scale 1:1.000). The graphs, drawn up in 2001 by Letteria Spuria under the scientific coordination of the author, allow to read the environmental relationship that links the island of Nisida

across the bridge to the hill of Coroglio, the altimetric collocation of the architectures, the presence of vegetation and the steep tufa walls [11], the chromatic impact of the water-front towards Coroglio [28]. At the same time, the graphs evoke and emphasize the secular environmental relationship that links the island to the Campi Flegrei (Fig. 4), proposing a spatial configuration when looking at the island from east to west i.e. from the coast of Pozzuoli [24-25]. Thus, emphasising the environmental (and historic) link that connects the island of Nisida to Campi Flegrei and, more generally, to the west of Naples cannot consolidate the idea, and hope, that the future Nisida, that today is the island that “is not there”, could find a new social dimension that cannot provide for a national and collective use of the island in a more general proposal for the reorganization of the western area of Naples in the aftermath of the dismantling of the ILVA steel plant [translated by Sacha Berardo].

Fig. 4 – From Nisida: Bagnoli with Italsider and Camaldoli's Hill; Parco del Virgiliano; Villa Pausilypon; Penisola Sorrentina, Capri, Ischia and Monte di Procida (ph. by Ornella Zerlenga).

1. Structural identification and first dating of the artifacts basing on the observation of the texture wall (Claudia Cennamo)

The interpretation of the ‘masonry’ through a precise structural model and the development of a readable mathematical model, able to take into account any mechanical characteristic, is a complex problem, since, including under the term masonry all that vast range of materials that show, between the main features, predominantly inelastic character, the study becomes very onerous. In fact, due to the texture of the material that presents itself somewhat differentiated depending on the mode of construction, or on the type of brick used, or also because the individual structural elements are less unwieldiness of the beams, pillars and floors in steel or reinforced concrete by the contemporary structures, the studies about masonry structures are controversial, and the mathematical model able to represent them is not uniquely determined, but it is still the subject of careful study and always new elaborations. Really, to arrange a model that includes all or at least most of the masonry types and to define the laws that govern all mechanisms, is very difficult: so far there is no general theory so as to

adapt to the multitude of special cases which have come over the years by the observation of the masonry structures behavior.

On the other hand, since the historical monuments testify, with their millenary presence, the validity of the construction methods of the past and the strength of the masonry (if 'workmanlike' built or 'well built'), which is threatened mostly by catastrophic events -mainly earthquakes and bombings-, there is a clear need, before tackling the project of restoration of a masonry building, to acquire as far as possible, the scientific and technological elements on which its original manufacturer based the project, some of which are part of the constructive 'modus' commonly in use, although modified today in accordance with a more rigorous logic.

The decay of the artifacts found in Nisida, deserves a particular attention, because it is caused primarily by the lack of maintenance, as well as by the exposure to the sea, by the continuous bradyseism in the Phlegraean area, together with the poor knowledge of the construction material, that came from quarries on the island, and it isn't the classic Neapolitan yellow or gray tuff, but it has primary mechanical characteristics (Fig. 5).

Fig. 5 – Nisida, actual state of an ancient tuff wall along the path to the sea (ph. by Claudia Cennamo).

Studying about the evolution of construction techniques is crucial not only for the value of historical evidence, but especially to reconstruct the "intuition" about one particular masonry structure that motivated the architects of the period, to translate it into modern scientific terms, and finally to evaluate the more suitable mode of action for ancient buildings of particular significance; a problem that requires the use of appropriate techniques which allow to avoid the alteration of the static characteristics and the mechanical properties through which the artifact was originally conceived.

So, in this logic, through a brief historical comparison of the various component elements of the Nisida structures and some of the main techniques of calculation, it is possible to come into a first knowledge of the masonry buildings on the island and of their structural performance, with the aim to be able to design an intervention that allows both a possible functional recovery, both a preservation of the structures over time.

Therefore, it is helpful to go back very briefly on the steps that have marked the evolution of masonry construction, signaling, albeit briefly, the most representative typologies of the past.

One of the more ancient known types of masonry is that of the Cyclopean walls, which enclose the ancient Mycenae and supporting the embankment on which was placed the temple of Apollo at Delphi: these are large irregular blocks with surfaces accurately machined, matched between them without any binder, which Vitruvius called *silex* («ubi sunt saxa quadrata, sive silex, seu caementum aut coctus later sive crudus, his erit utendum») [6; I, V].

The resistance, that in these dry walls was entrusted only to the friction and to the weight of the blocks, could be improved, then, by the use of the mortar which, in addition to facilitating the implementation of the stones, spreads the stresses with greater uniformity, increasing, when correctly used, the overall strength of the wall structure.

The stone walls with mortar have different typologies in relation to the way in which the stone was used, in a stage of processing more or less refined and accurate.

In order to achieve a better stability and a more uniform transmission of loads, sometimes courses of coarsely cut stones with rows of squared stones were positioned, or brick and stone cutters were

alternated. In any case, for the parts subject to greater stresses, such as corner posts or shoulders of walls, the more resistant stones to compression were selected and used.

These constructive features were not essential in the walls formed by the only squared freestones, because the same shape of the blocks guaranteed the horizontality and the regularity of the rows, which together with the vertical staggered of the joints, ensured a more effective strength and resistance to the whole structure.

The Italian historical sites, such as those of the whole of Europe, have a long tradition. Deriving from ancient plants, often of Roman, have undergone medieval restructuring and transformations in the Renaissance and during the Counter-Reformation, taking on a bourgeois aspect in nineteenth century. The common technology is masonry, but the difference between the way of building in the old times and today is clearly placed in the foundation 'cultured' of modern society that is taught in universities and spread with the means of the entrepreneurial market, against the spread 'popular' of the building typology in the past.

In fact, given the difficulty of transport, the first problem that arose for the manufacturer, to build a masonry structure, was the choice of the type of stone to be taken, which was primarily limited to those materials that can be found on the premises or in the immediate vicinity: therefore the structural safety and all the final appearance of the historic center were influenced by local stone and also the spread of a particular typology had rather limited diffusion pathways, mainly entrusted at the ability of the individual who was the promoter, to pass it. Cases of transport of material from distant places are included only for the construction of monumental buildings of particular value: such shipments were made generally by sea, e.g. the buildings of Piazza dei Miracoli in Pisa, made with stones from far Sardinia.

Once identified, the available materials were used for different elements of the construction, in relation to their qualities of resistance to crushing, of duration, of resistance to atmospheric agents, to their specific weight, to their workability. The form in which the stone had to be processed to be used, will be defined in a second time.

Giuffrè distinguishes the two schematic strands of masonry technique, which have been mentioned previously: the popular tradition; the classical (or cultural) tradition [4].

At the popular tradition can be attributed those walls that were said *formacei* from a definition of Plinio il Vecchio [5], built with clay strongly pressed between formworks.

In addition, the *lateres* can be included, which are unfired clay bricks dried in the sun, mentioned by Vitruvius [6; II, III] and often used by the Greeks, Romans and to this day in many parts of the world.

Finally the *macera* can be considered belonging to the popular tradition, that is masonry consisting of rough stones side by side without binder, as we can still see in the Italian countryside: the *macera* marks the boundaries and acts as a wall to a shelter, or as a support to a terrace.

The classical tradition may be, however, schematically represented by the squared stone masonry, i.e. the *isodomic* and *pseudoisodomic* masonry that Vitruvius attributes to the Greeks, whose next expression was the *opus quadratum* in Roman times.

So, gradually in the time, the masonry typology passes to a first embodiment consisting in perfectly squared blocks; the *opus quadratum* is in fact made up of two rows of stones: the *orthostates*, namely rectangular blocks placed with the longer side in the direction of the wall, and *diatones*, with their greater length placed perpendicular to the wall.

Unlike of masonry cataloged among those of popular tradition, the *opus quadratum* is courses or horizontal rows: the vertical joints are staggered and follows studied rhythms alternating between orthostatic and diatones. The construction of such walls obeys, therefore, to strict geometric rules, both with regard to each element that composes them, both with regard their position. As will be seen below, even the mechanical model of reference can not be the same for both the typologies.

Turning now to the binder, as another component of the masonry building, its interposing between the stone elements with great accuracy and regularity, and especially the no exceeding as quantity, are critical factors for the good performance of the structure; the experimentation has shown that the limit load borne by a masonry panel, is inversely proportional to the thickness of the mortar joints. It is also deduced, always experimentally, that for an optimization of the behavior of the masonry, the mortar should be present with a volume fraction on the masonry variable between about 10% and 30-35%.

However, the mortar used in ancient buildings had low resistance; this means that the degree of safety of these structures requires a careful evaluation, since the only physical integrity of the constituent elements is not enough to assume a satisfactory resistance of the whole.

On the other hand, from some experiments carried out on brick masonry, the inopportunity of the use of mortars with high resistance is carried out, because beyond a certain limit, the increase in resistance of the binder does not correspond to an equal increase in the overall strength of the masonry; instead, it is found that the optimal behavior is obtained with mortar whose compressive strength is between 50 and 100 kg/cm², with bricks of characteristic strength of 150 kg/cm². This suggests, therefore, that, even if the resistance of the masonry is influenced by the characteristics of

the individual component materials, for a more realistic safety criterion it is necessary refer to the behavior of the whole artifact.

The note 'pozzolana', used in Phlegraean area, or 'cocciopesto', used to waterproof the Piscina Mirabilis in Bacoli, are high-strength mortars whose presence is in fact almost unchanged over time; nevertheless, to argue that the global stability of certain structures is due only to the binders, is a paradox. Rather, it depends on the same Architecture, understood as weight, shape, cut, blocks placement, and symmetry of the plant, regularity of the elevation, proper sizing of solids compared to empty, clamping between the vertical walls, proper sizing of the roofs, etc etc.

2.1 The mechanical model

As already mentioned, the organization of the masonry texture that is found in the ancient buildings is very different from what is currently adopted in masonry buildings, and it is extremely variable from case to case; this involves many difficulties when attempting to establish computational models for ancient masonry structures [4].

In other words, if for a masonry made by regular and squared blocks, the finite element method (FEM) can be easily applied, for a chaotic masonry [5] it does not provide adequate results, and the more inherent method appears the macro-elements one, which allows a global vision [6] of the whole structure.

The extreme variety of textures does not allow, therefore, the formulation of a single model of calculation, but allows, on the other hand, the setting of a pattern of behavior quite flexible, which, even if it can not reflect every possible aspect characteristic of the material, can be however adapted, with appropriate diversification, to the numerous schemes according to which the 'masonry' material is catalogued.

This is mainly the model called traction not reagent (TNR): in fact, as it is known, from the experimental tests we can note that both the tuff materials, both the lava stones in general (that represent the large part of the 'walls' on our territory), have an excellent resistance to compression and a virtually zero resistance to traction; so the behavior of the material can be generalized neglecting the tensile strength, which is assumed irrelevant with respect to the global behavior of the structure. In general, in fact, the structure is actually designed trying to do work the material only under compression, in an attempt to prevent the occurrence of tensile stresses that could produce brittle fractures.

The TNR model is preferably used for walls in which the randomness of the directions of the joints and the irregular shape of the segments do not result in preferential directions of detachment (eg. walls built according to the 'popular tradition'): in that case the material can be assumed as traction not reagent in all directions; instead, in the walls formed by the superposition of regular rows of square blocks (such as eg. for walls constructed according to the 'classical tradition'), it is possible to identify preferential directions of fracture, in consequence of the sliding phenomena along the horizontal joints: so the inability to transmit tensile stresses are reduced only into the directions of the joints, and does not involve other directions. If then the joints are sufficiently staggered from each other, assuming that there is no breakage of the individual stone elements and that the lesion occurs along the links, the action of the sliding is combined with the friction force between the ashlar, giving rise to a certain tensile strength in the horizontal direction.

The traction not reagent model is one of the most used for the study of the 'masonry material', but it is not the only one. In fact the rigid-plastic model, the elasto-plastic model (it is assumed that the masonry, after a short phase in elastic behavior, enters into the plastic phase, that is, eg., the situation where is located steel when it exceeds the yield strength, now unable to pay back the energy used to deform, and unable to return in the original configuration) may be admitted; the elastic-brittle material, which retains a moderate resistance to tensile stresses, but, with the opening of the fractures, loses its property to transmit tensile stresses along the fractured direction, may be also taken as a model; instead, there is the argument about mortars, as already mentioned: the mortar (sand, water and cement or lime) is a binder and, therefore, at least in the case where it is not dry and dehydrated, provides to the individual blocks greater cohesion and to the masonry even a modest elasticity, to be taken into account in the initial phase of the characteristic curve of the material. It is necessary, finally, to consider the friction between the blocks, whose major or minor contribution can transform the model that is being developed (e.g., a column composed of individual blocks with a very high coefficient of friction may be, ironically, assimilated to a monolithic block).

When the choice of model to be used to locate the material is been made, it is possible to pass to the actual structural model, that is the structure that is being analyzed as a whole: in fact, the 'workmanlike' is considered, i.e. optimal proportion reports between the individual structural elements, good clamping between the various wall panels of a building, and a whole series of features from graphics, based on the geometry of the bodies, that were used by the designers of the past, which did not have the scientific knowledge available to the contemporary culture. And since these simple rules,

sometimes intuitive and ever empirical, still defy the passing of the centuries, some scientists yet put the 'workmanlike' in high rank in the scale of values for the global static security.
In conclusion, starting from these few but essential parameters of knowledge, it will be certain possible, in future study developments, produce an initial dating of the structural elements present on the island of Nisida.

THE TIE RODS IN HISTORICAL HANDBOOKS

Luigi Mollo,¹

⁽¹⁾ Department of Civil Engineering, Design, Building and Environment, Second University of Naples, Aversa, Italy

Abstract

The paper aims to describe synthetically the result of an research in historical handbooks on application of chains in the strengthening of masonry buildings. This study is seemed necessary because the actual trend in strengthening of building contemplates application of tie rods. The reference to the building tradition is seemed necessary because in the second half of 20th century the study on chains was neglected..

Keywords: building technologies, tie rods

1. Introduction

Tie rods have been largely employed since ancient times till the first half of the 20th century. During this century steel concrete became the largest employed material both for new buildings and for restoration and structural consolidation. It allowed innovative operations of consolidation, far from any reference to building tradition. Nevertheless, in the last years, the large use of reinforced concrete (for riveted joints, injections, insertions of cases in the wall skeleton) proved to be dangerous both for the scarce durability of the material and for the irreversibility of the interventions that, in some cases, determined destruction of the monument. At the end of the 20th century these serious failures of reinforced concrete determined a renewed attention toward the traditional techniques of consolidation. In particular tie rods again have been employed for seismic upgrading and consolidation.

Today they are considered one of the better solutions for seismic upgrading of monumental buildings as also the Ministry recommends: "The traditional technique of inserting of metal anchors and tie rods is considered, in general way, the most effective provision for seismic upgrading in relation with the impact on building, so its use is required to be adopted as a rule". Tectonics, which is traditionally concerned with the mechanics of solid bodies that are stressed by dynamic and static forces, is able to work out a mathematical seismic check of the project in case of building made of reinforced concrete and steel. The simplifying hypothesis of homogeneity and congruence of the resistant material might be assumed for those buildings. However, it could be not effective and congruent when this simplifying scheme concerns building. Its elementary components and structure are considered neither homogenous nor elastic. The quality of the material, its performance and conservation state highly influence its behaviour under seismic conditions so that it is hardly possible to make good predictions. Operators working in the field of seismic prevention, however, have become more sensible to the problem since the last years so that they recommend as necessary a quality enquire on the real condition of the building. The diagnosis shall not only express mathematical values. However, in order to provide relevant interventions especially for the preservation of the original static building typology, the diagnosis shall take into account logic considerations in relation to the resistance of each component and to the reliability of the whole building.

Fig.1: Anchor of wooden beam made up by iron bar fixed on beam. (C. Formenti, La pratica del fabbricare, Milano 1893, parte prima, pag.184)

Therefore, it seemed necessary to study the traditional solutions adopted in the past according to the

technical literature published till the beginning of 20th century. They are highly innovative for the way

Fig.2: Tie rod applied during the building to strengthen a vault (C. Formenti, *La pratica del fabbricare*, Milano 1893, parte prima, pag.177)

they conceive the consolidation and the construction of new buildings.

1.2 Tie rods in technical handbooks

The first historical document about the use of metal tie - bars dates back to roman times. It confirms that this technique has been largely employed since past times. Besides authors' documents of that period, an interesting evidence of the employment of anchors in roman times can still be admired in the archaeological site in Pompei. A large number of anchors join connecting angles and crossing walls of the houses in "Soprastanti" alley. These interventions might be due to the damages determined by the earthquake that upset the area about 10 years before the eruption of 79 A. C. During the classical period chains and their anchorages were made of iron, wood or bronze. In the past as still nowadays the use of chains were functional to the elimination of seismic stress on walls in the presence of flying structures such as arches, vaults and trusses but also to provide the building with a

Fig. 3: Same different anchor and connection devices (C. Formenti, *La pratica del fabbricare*, Milano 1893, parte prima, pag. 118)

better steady condition especially in seismic areas. Leonardo gave a significant example. He

suggested that a better steady condition might be achieved keeping the walls firmly together.

Fig. 4: The anchor made up by a large plate and iron bar reticulate. The tie-bar fixed with a two big bolt (Residential building in Aversa)

Referring to a widespread building tradition he wrote: “each beam shall be passed through the walls and be secured there with sufficient chains, since beams have often been dislodged, ruining walls and floors in an earthquake; where they were secured with chains, they have kept the walls firmly together and the walls in turn have secured the floors”[1]. Besides Leon Battista Alberti and other writers of that period, Leonardo referred to the current building technique, which consisted in the use of floor beams to join the walls and firmly anchoring the beams to the walls. Wood chains were still widespread at that time as it also results from the hoop of Santa Maria del Fiore dome in Florence. It was made of chestnut and iron beams which were set in round arches. Moreover, the use of this material was widespread because it was easy to work, cheap and easily available. Iron was employed when wood was inadequate. The first documented applications in medieval times were linked to the building tradition of gothic cathedrals. Among the most famous applications those in the Saint Chapel in Paris by Pierre de Montereau (12th century), the Cathedral in Strasburg (14th century), the Carcassone Cathedral (12th century – 14th century), and the Narbonne Cathedral (14th -15th century) are worth of mention. Iron and wood have both been employed for some centuries. In 19th century iron chains substituted almost totally wood chains. Between 17th and 18th century thanks to Gallileo’s studies a new structural trend was born. Scientists were concerned with important studies about the applications of tie - bars and hoops and with the improvement of building stability. On the 15th September 1606 Bernardo Buontalenti drew an application of hewn stones with a metallic structure – he probably thought to set chains in stone arches such as the building system adopted by Vasari in the “Uffizi”.

The use of doubly reinforced stones was adopted in florential buildings just at the beginning of the 19th century whereas this system was already widespread in France since the second half of 17th century. It was Giuseppe Martelli, who came back from a short scholar visit at Polytechnique in Paris, who first adopted metallic beams in the Royal Lodge on the Grass (1821-30), projected by Luigi de Cambray Digny to reinforce the epistylum made of sand stones. In the 19th century numerous books dealt with this method. Since the second half of 19th century many Italian theoretic manuals have provided technicians of that period with specific information about tie – bar scaling and with a very useful project.

Among the most known manuals the following ones are worth of mention since they are innovative and complete examples. Besides the most usual applications of tie bars in roofing trusses of big loft buildings, A. R. Emy in the "Treaty on the Art of Carpentry" [2] supplies a scheme with all the most used iron systems of the current carpentry. The analysis of this scheme underlines that several technical solutions were adopted for the iron-wood –and iron-iron attachment. Besides the allowable tensile stress for each square centimeter in the "Manual of Practical Mechanics" [3], A. Morin calculates the admeasurements of an iron chain section, provided that the tensile stress is known.

Fig. 5: The anchor made up by an eyelet realized in extremity of the beam or tie-bar and by a little pile. It fixed the little pile into the eyelet and it secured with a wedge. (Residential building in Aversa)

Also the "Elementary Practical Guidelines about the Art of Building Civil Factories"[4] by A. Cantalupi provides typologies and some calculation examples of iron chains to be used instead of wood chains for roofing trusses. "In the Art of Building" [5] G. Curioni wrote about the chain scaling: "Chains or crowns made of iron shall be used to ensure the stability of the arch, when piers of the needed size cannot be built for any reason. They allow to join firmly both side of the arch and to hinder its deviation. Crowns are made of one piece or many pieces; in general they are placed horizontally. This system is mostly effective, if crowns are placed in the arches close under the joining point, where the failure on the sides generally occurs. (...). Anyway, iron crowns are better than that made of wood; the size of the transversal section should be 0,015 per 0,025. They occupy very little space inside the walls, where they are placed. If two or three pieces of the crowns gather together in one place, they

should be joined to a vertical sliding bar, fixed to the wall. This system allows to obtain resisting cases, which are firmly secured in the wall and able to hinder horizontal thrusts”.

Fig. 6: Reinforced walls. Lascasses method (F. Masciari Genovese Trattato di Costruzioni antisismiche, Milano 1915 pag. 266)

After a short outline about technologies of iron production for chains and about their warm working methods in the “Economy of building” [6], A. Sacchi gave examples of several iron applications in the course of the centuries. He underlined that during the ancient times iron was first used for making anchors and cramps of different size and shapes. Then the author dealt with tie rods, which were usually employed to join the walls and to hinder the tensile stress of the arches and vaults. He also gave an example of innovative iron application in a doubly reinforced beam. G. A. Breymann suggested

several solutions, which were adopted during past times, to join freestones of the walls. These structures were made of iron and classified as anchors, cramps and dovetails. In the “General Treaty about Civil Buildings” [7], the author quoted the technique already described by Leonardo. In order to link two walls firmly together so that they cannot shift each other, he suggested to use a beam equipped with an iron crown at the top and a screw eye at the end, where a sliding bar shall be set in. The description of the mixed floor made of H-beams, which are blocked by sliding bars in the walls, and of a secondary roof frame made of wood rafters, is also worth of mention. The quick widespread of iron floors was also quoted by prof. P. Boubée, in the “Elementary Theoretic and Pratical Treaty of Metallic Buildings” [8].

He described the technique to join floor beams together with tie rods, aimed at ensuring stability, keeping bars-track constant and stiffen the whole. Also C. Formenti underlined the use of horizontal tie rods. He also suggested that “the use of tie rods and of horizontal iron chains to be fixed and blocked at their end by vertical bars makes the lateral thrusts on pillars and on the walls coming from the arcades in two opposite directions contrast and hinder each other. They are called either sliding bars or bolts. The stretched chains prevent piers from opening as a consequence of the tensile stress of the arch. Each floor of the factory building shall be supplied with a latticework of tie –bars, attached to the main walls, at the height of the arch springer, that is, at the point where the thrust is stronger”. [9] The building tables of the manual showed how to make iron chains with the old method of forging iron. Flat bars were pinched and beaten at the extremities to make a screw eye where the sliding bar was set in. The chain was stretched by iron shims, which were inserted in the screw eye against the sliding bar and pinched to guarantee seal. Tie bars could also be made by a more modern method, that is, threading round bars at the top with a dado for fixing. In that case, a screw coupling along the tie - bar stretched the chain. The substitution of the screw eye with the bolted connection allowed the consequent introduction of anchor plate. The plate was almost always thin to allow lime plastering. Moreover, Formenti's manual outlined all the new technologies in the field of chain junctions and sliding bars that technicians of the iron industry had at their disposal. In addition, very interesting executive tables describe the laying mode of the chains for different types of arches. While Formenti underlined the role of chains in hindering thrusts by the arches, A. Lenti's concern was “on the role of chains in keeping the different parts of the walls together and preventing it from breaking” [10]. After that a terrible earthquake upset Calabria in 1905, a decree law updated the rules of 1887. New technical rules were required in the field of aseismic buildings. The article 14 stated to place on each floor iron chains horizontally at about one meter below the top of the walls in longitudinal and transversal direction and along the perimetral and dividing walls. The chains are to be hardly stretched and supplied at their end with a sliding bar and an anchor beam to be placed against a metallic slab. The end of each tie rod is required to be part of the chain and not soldered or added. Since the new code has been adopted, many authors and treaties concerned aseismic buildings and suggested how the regulations could be improved. In order to make the anchorage system more effective, M. Baratta [11] suggested to link the sliding bar of the ground floor with the one under the roof into one rugged iron sliding bar, to be set at the joining point of the chains with the wall. Moreover, he suggested the use of large plates or metal latticework in order to distribute thrusts on a larger surface and to get thrusts contrasting each other. In addition, he found necessary to butter iron with protective minimum before using, in order to avoid the chain rusting, degradation and the consequent wall breaking. In the “Treaty on aseismic buildings” F. Masciari Genoese describes different building solutions which were adopted and patented in the entire world to front seismic events. Here The Lescasse's method is also worth of mention. This method was patented in California in 1868, published by the eng. Lescasses nel 1877 and used by himself in China and Japan. However, it is still unknown if this method encountered success. Nevertheless, it is interesting because it concerns tie rods use for reinforced concrete walls and somehow reminds the structural idea by Bernardo Buontalenti or the recent experiments on reinforced concrete walls. Lescasse thought that building walls could be ideally divided into vertical slices or into a sort of pillars through the vertical lines of the opening. Each pillar should build just one indeformable block and at the end all these pillars should be all joined together in an invariable way. He suggested a system of pillars strengthened by vertical and horizontal iron tie rods, to be set in the walls and to be firmly linked together in the three orthogonal directions of the building: height, width and length. Vertical tie rods made of rod-iron ensure the monolithic structure of the pillars whereas horizontal pillars made of flat bars make one block. The effects of thermal dilatation, due to temperature variation, could also be prevented by a system of compensation, obtained by placing wood keys in the junction points.” [12].

Abstract

The perception of reality depends on ambient conditions and one's own personal physical and mental state. New problems arise when we use modeling to provide "remote" visits to monumental environments and viewing of artworks.

Current technological tools already allow us to distinguish between viewing an artwork reproduction and viewing an immersive virtually reconstructed image of the same artwork (virtual reality). Other issues involve the possibilities provided by modern technologies to manipulate the images, including three-dimensional images. Of course, we cannot ignore the inherent risk that any variation may falsify the communication.

Therefore we need to experiment at length in order to establish the limits of these variations. Within the framework of a valuable interdisciplinary dialogue, the experiments which have been carried out in recent months on important sculptural works and monumental environments all focus on these problematic issues. The goal of the experiments was to scientifically analyze how the brain reacted when a person looked at artworks or architectural environments and then assess how these reactions influenced the communication of documentation and survey.

This paper focuses primarily on the statue of Moses by Michelangelo in the Basilica of St. Peter in Chains in Rome. We believe that this experiment can lead to interesting developments in digital communication; in any case, it will be exciting to consider the reliability of the communication and the possibility to vary the perception of an object.

Keywords: Virtual reality, 3D modeling, brain activity, Michelangelo's Moses

1. Introduction

It is a well-known fact that the perception of reality - and, therefore, any artwork - depends on, ambient conditions (lighting, clear air, etc.) and one's own personal physical and mental state (feelings, training / cultural interest, etc.). The relationship between the viewer and the artwork also depends on many other factors; when figurative images are involved, people will react differently when they look at a small work of art (as Arnolfini Portrait by Jan van Eyck) or a large painting; likewise in the architectural field, the reaction of a visitor to the Sacro Speco in Subiaco will be different to the one he has when visiting St. Peter's. Extensive scientific bibliography exists about these problems.

Fig. 1: The interior of the Basilica of St. Peter in Chains in Rome.

In this time when, thanks to technological developments and its fallout on communication tools, we rely more and more widespread use of modeling and its manipulation to provide “remote” visits to monumental environments and the viewing of artworks, perceptual aspects are proposing new problems, including, first and foremost, the need to recreate the most realistic and favorable conditions in which to enjoy the cultural heritage.

For this purpose the current technological tools already allows us to distinguish between viewing the reproduction of an artwork (perhaps created using a laser scanner, but not to size) and viewing an immersive virtually reconstructed image of the same artwork (virtual reality).

The latter image recreates the true size of the artwork, making it possible to view the object as if one were actually in front of the real thing. Other issues involve the remarkable possibilities provided by modern technologies to manipulate the images, including three-dimensional images. For example, if ambient light conditions influence the way a visitor reacts when he looks at a marble statue, then when we propose an immersive virtual reality model of the statue we can modify the ambient light and the light and shade features of the model to improve the visitor's perception of its characteristics.

Of course, we cannot ignore the inherent risk that any variation may falsify the communication and, as a result, induce an incorrect or ineffective “remote fruition”.

Therefore we need to experiment at length in order to establish the limits of these variations.

2. Direct observation and immersive reality

Within the framework of a valuable interdisciplinary dialogue, the experiments which have been carried out in recent months on important sculptural works and monumental environments all focus on these problematic issues. The goal of the experiments is to scientifically analyze how the brain react when a person look at artworks or architectural environments and then assess how these reactions influence the communication of documentation and survey activities.

Particularly the experiment aims to evaluate the perceptual differences that exist between the vision of a real object and the vision of a reconstructed object through 3D modeling.

The goal of the research can be summarized as follows:

- 1 – to record brain activity during the direct observation of an architectural or sculptural episode, possibly in different lighting conditions;
- 2 – to virtually reconstruct as closely as possible the architectural environment or the sculptural work and prepare it for an immersive experience of reality;
- 3 - to record the brain activity of the same observer in the field of immersive reality, by varying artificially lighting conditions and contrast of the environment or of the virtual object so that it can stimulate different reactions of the observer;
- 4 - assess the reactions recorded in step 1 and in step 3 for any observing conditions which better are suited to a situation of “well-being”.

Among the steps of program briefly mentioned before, the first three are obviously kind of preparatory and easily achievable.

Fig. 2: The three observation points of Michelangelo's Moses. The first, on the left, were in front of the statue, roughly three meters away. The second, in the middle, to one side of the statue, in the right nave, about four meters away. The last one, on the right, again in front of the statue, but roughly ten meters away.

The fourth requires that testing be extended to a lot of subjects, environments and sculptural work, with different characteristics (considering that the brain reactions vary according to the decorations, type of surface finishing, lighting conditions, etc.).

The results should help to identify the specific criteria to be met in virtual models, especially for the purpose of preventing that they falsifies the intentions of the artist-author, by intervening in order to make communication more acceptable to the observer.

3. The observation of Michelangelo's Moses

Among the experiments planned the first focuses on Michelangelo's Moses in the Basilica of St. Peter in Chains in Rome (Fig.1).

A group of ten adults (of different cultural interests) was invited to look at Michelangelo's Moses from three different viewpoints and with two different light conditions: natural and artificial light.

The observation points (Fig.2) were in front of the statue (one time roughly three meters away and then roughly ten meters away), and next to one side of the statue (in the right nave, about four meters away). The cerebral activity of all the adults was recorded while they looked at the statue and each adult looked at the statue from each of the three positions, with different lighting conditions (a total of six experimental conditions) for the same length of time (one minute for each observation performed).

Brain activity was recorded by a mobile electroencephalographic devices (EEG) provided by *BrainSigns*, a spin-off by Rome Sapienza University. We choose the indicator defined in specialized international literature as Approach/Withdrawal [1] to assess the cerebral activity in each experimental condition. Using this indicator we can objectively assess how much the individual in the experiment appreciates the object when subjected to this kind of sensorial stimulation (in this case the statue of Moses).

The same ten adults were then subsequently invited to look at a three-dimensional reconstruction of Moses statue in an immersive virtual reality structure, with the same experimental lighting conditions and from the same spot they stood in previously in the Basilica.

The structure used for virtual reality is the CAVE system at IRCCS Fondazione Santa Lucia (Fig.3).

It consists in three back-projected active stereo screens (3 walls) and a front-projected screen on the floor that surround the subject. Left- and right-eye images are alternately displayed at 60Hz each and synchronized by Nvidia stereo glasses. The head position and orientation are tracked at ~120 Hz by means of Intersense IS 900 tracking device.

As special feature of the CAVE system, the four images are seamlessly joined together so that subjects do not see the physical edges of the adjacent walls. Hence, the active stereo projection is perceived as a continuous virtual world.

This allows to reach a high level of realism so that the subject feels himself as physically immersed and present in the virtual environment.

The measurements in the CAVE system are generally divided into two sessions. The first part of data recording is performed in a guided navigation mode in which subjects allow to experience a whole selected architectural environment by standing in the middle of the CAVE. This part of the experiment permit the subjects to familiarize with the virtual scenario and the related neurophysiological and behavioral measurements. In the second session, subjects are directly exposed to both original and modified specific architectonical elements.

Also in the CAVE we proceeded to record the cerebral activity of ten subjects for all the experimental conditions employed.

Fig. 3: Three picture of the CAVE system at IRCCS Fondazione Santa Lucia.

For the experiment it was built a small digital model of the architectural environment of the Basilica of St. Peter in Chains, as well as the model of Moses sculpture. In both cases use was made of both the electronic scanning (realized through Scanner Leica C10) and the processing and three-dimensional modeling programs (Cyclone, Autocad, Rhinoceros, 3DStudioMax) [2].

During the second phase of the experiment in immersive reality, it was decided to change - according to preset parameters - both ambient light conditions than those of luminance contrast on the surface of Moses (Fig.4), in order to record the brain reactions of the observer in various situations.

4. Why this experiment?

To understand whether the point of observations plays a role in the cerebral and emotional fruition of architectural artifacts and sculptures it was decided to analyze the cerebral reactions of a group of subjects during an observation of the Michelangelo's Moses sculpture in the ancient church of St Peter in Chains in Rome. It presents the interesting feature that the Moses's face has the orientation not toward the observer, but rather tilted toward the right side of him/her.

Thus, in the Moses sculpture the observers are not pointing on the Moses's face. If Moses was a paint, there will be no other available information. However, since it is a sculpture it is then possible to collect the different cerebral and emotional reactions to its observation from different points of views. Thus, it has been decided to collect both neurometric and emotional responses of the observers

during the contemplation of the sculpture from different points of views that are significant for the gathering of different details related to the sculpture.

This experiment provided neuroelectrical evidences of the activity of the prefrontal cortical areas in occurrence of the evaluation of a succession of aesthetic stimuli. By collecting the emotional and cortical responses during the observation of a real sculpture we observed such dissociations of the cerebral signals linked to the different modalities of fruition of the same sculpture.

We believe that these observations could be used in a future to generate specialized paths across the museums to induce different emotions and perception of sculptures and artworks in the general public. This will be made possible by the possibility to collect reliable measurements of brain and heart activity not only in the neurophysiology laboratories but rather in a challenging environment such as museums, art gallery, churches and archeological sites [3].

Fig. 4: Two pictures of Michelangelo's Moses with different light conditions and luminance contrast

5. Conclusions

From the current research will undoubtedly lead to interesting consequences for the digital communications; will be interesting to consider the aspects that, regarding the possibility of changing the perception of the models, however, relate to the reliability of the communication.

With regard to the experiment, in line with the general objectives of the research, it has allowed us to describe in an objective appreciation of the brain of individuals in the experimental view modes of Moses statue, by viewing the real monumental complex and the immersive virtual reality, with proper evaluation of the different reactions to the environmental and perceptive changes.

Deferring the delineation of the first general conclusions to the completion of all trials provided, it is possible, even now, to anticipate one of the main problems that the research suggests. Of course, in the process of fruition of cultural heritage, many variations will be fit for use; will be necessary to discern which of them can be practiced and within what limits. It is also expected that some changes are useful and / or appropriate, from time to time, in relation to education, interests, purposes of the observer. It is necessary, in each case, to consider that no communication is "neutral".

For this reason, since it is, however, affects the viewer, it is absolutely necessary that in every case it strictly reflects the content of the artwork to which it relates and does not betray the author's intentions. This aspect will again need the competence of the "communicator subject".

From Pompei to Çanakkale: the Officiamuseumed project proceeds his way

Claudio GAMBARDILLA

Architecture and Industrial Design Department, Seconda Università degli Studi di Napoli, Aversa, Italia
claudio.gambardella@unina2.it

Abstract

In 2013 SUN realized the "Summer School in designing of company museums systems in euromediterranean area" with Okan Üniversitesi of Istanbul and Fachhochschule Köln. This is an IP (LLP ERASMUS) approved, flying colors, by Indire National Agency of the Italian University Ministry. During the Turkish week, the Teachers College were assigned the task of designing a museum in Çanakkale (TR) for German, Turkish and Italian students. Çanakkale is known for its traditional pottery and it is the nearest major town to the ancient town of Troy. For these significant features Çanakkale has been chosen to be the center of turkish museum system for design and applied arts. So this new museum can be homologous to the one under construction in Pompei. Subsequently, three of the sub-themes of the School (Bridge Museum over Çanakkale Cayi; Factory Museum over Çanakkale Cayi near the old abandoned factories; Underground Square Museum, near the terminal ferry) were assigned to Interior Architecture's students of SUN for their final exam and degree thesis. The full paper will be analyzed using three fundamental aspects: 1) How the School has been an important first step to bring the project of the museum system of design and applied arts outside Italian borders and what could be the future of Officiamuseumed; 2) what are the potential interconnections between development of Design in Turkish area and architectural plan of museum; 3) which method was adopted to plan and launch while using little working groups and study models.

Keywords: Officiamuseumed, Company museums, Summer School, Pompei, Çanakkale

1. Introduction

In any research project, there is always a "mythical" element, sometimes hidden, which illuminates and guides. OFFICIAMUSEUM and OFFICIAMUSEUMED [1] are scientific projects with clear repercussions in the Concrete sphere, they are therefore *ideas-forces*, to quote the French philosopher Alfred Fouillée, capable of generating actions and influence on so many aspects of reality overcoming the various obstacles they encounter in their being realized; and these ideas are opposed forces, on the one hand, regulations and procedures – the bureaucracy –, and, on the other, the human psychological weaknesses with which it must deal. However, these two projects would be deprived of a soul if they were not driven by a "mythical" element, essential to deal with the real friction; from an ideal that want to "incarnate" with an attitude, in some ways, heroic. It is worth highlighting in the first project the idea of wanting to make the relationship between museums and entrepreneurs in the regions of Southern Italy organic, i.e. between the storage places and those of producing to build a design nostrum [2]. Before to that, however, there is the idea of wanting to get out of an atavistic southern precariousness of our world that makes it so unstable and poor. And, perhaps, even before that, I would propose the anxiety of redemption, the wanting to stay in the South knowing how to compete with the North, the desire to preserve an ancient originality, rooted in modernity. All this is reflected in the second project, with an airiness proportional to its geographical size, the Mediterranean. Here, the ideal is to think of a meta-world dominated by an old beauty, artisan, "a

beauty of here”, as one of our women, that may be transferred into a modern framework of Design, that nurtures a durable construction. There is more though. OFFICIAMUSEUMED brings with it an ancestral and poignant attraction towards the East that pervades our world. An east that Maffesoli called “mythical” because it does not necessarily coincide with what lies to the east of us, which is found only in the most established forms of art, but also in the most basic tourist consumerism towards distant destinations, both East and West. An attraction rooted in Western Culture as well as the spirit of our time. Without doubt, there is a downside and it is called Orientalism, an idea that is not completely innocent, «[...] an idea created by the West to subjugate the other [...]»[3], as revealed by Edward W. Said [4] in his essay *Orientalism. Western Conceptions of the Orient* (1978). However, according to me, it is worth saving the need to go to the other without saying that it cannot be interpreted solely in terms of anxiety of Western hegemonic power, which also led to colonialism and imperialism [5]. In other words, the desire of the other and the other which is the basis of love should be saved. Without much rhetorical emphasis the Bilateral Agreement signed with Turkish universities and the subsequent “Summer School in designing of company museum systems in euro-mediterranean area” (2013) were healthy concrete tools, scientific and administrative, who have held the profound need to meet each other.

Fig. 1: Çanakkale (picture by <http://looklex.com/e.o/canakkale.htm>)

2. Çanakkale and the Summer School

Turkey was therefore the first country in which to try to “export” the Officiamuseum model, or, more precisely, starting with its international version, Mediterranean. In 2013, the Seconda Università degli Studi di Napoli (SUN) realized the “Summer School” project with Okan Üniversitesi of Istanbul and Fachhochschule Köln. This is an IP (LLP ERASMUS) approved, by the Indire National Agency of the Italian Ministry of Universities. The Summer School had a double meaning. It was an important and compelling educational experience, carried out within the Erasmus program as well as the first concrete initiative to create a local museum of design and applied arts system outside of Italy. The management was long and complex. We had started to talk with our Turkish colleagues from Okan in 2012. In the edition of that year of the International Forum Le Vie dei Mercanti, with my colleagues Ayse Ozbil Torun and Jochen Siegemund from Cologne, we presented a full paper to define the scientific basis of the project Officiamuseumed in Turkey and verify the feasibility of the project. The conference was followed by a trip to Istanbul in September of the same year, to propose and discuss in detail with the Dean of the Faculty of Engineering and Architecture of Okan, Prof. Nejat Tuncay Ramazan and Prof. Dr. Harun Batırbaygil, Head of the Department of Architecture, the project of the Summer School. From that moment on, an intense and daily work started, consisting mainly of e-mails between the various parties involved. It was the Batırbaygil colleague, responsible for the two weeks of the school, the Turkish one, to propose Çanakkale as a possible centre of the museum system in Turkey. Çanakkale is a sea town on the southern (Asian) coast of the Dardanelles in Anatolia: it has a seaport and a river - Çanakkale çay – that passes through it. Çanakkale later became known for its

pottery, hence the name the Çanak Kalesi “pot fortress”. Moreover Çanakkale is one of the most well-known historical cities, housing many world famous sites and ruins of antiquity like Troia, Assos, Apollon Smintheion, Alexandria Troas and Neandria etc., and is the land of many events that take place in antique mythology of the region. For example, the Judgement of Paris took place at Mount Ida which is now locally called as “Kaz Dağı”. It was one of the major events that led up to the Trojan war. In addition, there are 20th Century warfare heritage from Gallipoli war of the WWI, in addition to Ottoman relics and artisan works of the region. For example, Çanakkale ceramics of the 17 - 18th century are famous for their original forms and design. It was one of the major events that led up to the Trojan war. For these significant features Çanakkale was chosen to be the centre of the Turkish museum system for design and applied arts. Thus this new museum can be homologous to the one under construction in Pompeii.

The long bus trip with students and professors of the School, from Istanbul to Çanakkale, revealed an unseen part of Turkey to me. I started to understand how this country is neither a so-called developing country, third world, backward, nor a country whose *genius loci* is devoured by capitalism as in China. Turkey is at the centre of opposing forces that do not seem to annihilate the identity; they have not wiped out the memory, but try to take it into “modernity”; they have not canceled the rural and still largely archaic landscape, but conserve it, for example, not only a site like Troy, but also its wider context. Pompeii, on the contrary, has been lost forever, from the 1960s onwards, even the surrounding area because of the disastrous building policy as well as the culpable failure to enhance the value of the cultural heritage. At the same time, in Turkey, there is a thriving ceramics industry that is in strong expansion in the global market and well supported by an intelligent and extensive promotion through international exhibitions. The Summer School was aimed at students in their final year of Architecture, at the the German Fachhochschule Köln, Okan Üniversitesi in Turkey and Italian Degree Courses in Architecture - Interior Design and Autonomy , in Italian and English, of the SUN. In addition to the theme, the participating student groups were asked to carry out their designs in four conceptual places of the City of their choice. The places were as follows: 1. A floating museum on the harbour, 2. a bridge museum over “Sarıçay”- river bisecting the city; 3. A museum intertwined with old structures stretching beside Sarıçay, and 4. An underground museum at Central Square in front of the harbour. The project work was carried out in mixed groups and continued in the Italian week in Campania. It was, therefore, an activity which, on the one hand, should take into account the Turkish OFFICIAMUSEUMED museum, considering all the strategic aspects related to the creation of a museum of companies: the relationship with the city, the target visitor, the bond with other historical museums and production activities in Turkey, craft and industrial; on the other hand, being an architectural project, it was necessary to take into account all the relevant aspects: the relationship with the urban context and/or landscape; the relationship with the contemporary; the structural setting of the project; the project construction.

2_BRIDGE MUSEUM

3_UNDERGROUND SQUARE MUSEUM

Fig. 2, 3, 4: Çanakkale: the locations of three sub-themes

3. The Museum of Çanakkale : designing with 3D models

The Summer School was an amazing teaching and human experience. It highlighted the different settings in the teaching of design, which for Italian students is not only through seminars and workshops, but also lectures. This is not because the professors in this country are tied to a method that has now been exceeded in the rest of the world, but because design is an expression of a culture open to humanistic thinking. A sign is, therefore, rooted in a deep plane where memory and innovation, art and philosophy, sociology and anthropology meet.

In just two weeks of work, the first in Turkey and the second in Campania, the fourteen students of the Summer School produced interesting, but not quite mature, results. This experience of the School was proposed to students of Interior Architecture at the SUN. Thus, three of the sub-themes of the School (Bridge Museum over Çanakkale Cayi; Factory Museum over Çanakkale Cayi near the old abandoned factories; Underground Square Museum near the ferry terminal) were assigned to students for their final exam and degree thesis. Of the four sub-themes assigned during the Summer School by the professors, the three “stably” linked to a physical place were chosen, excluding the fourth – that of the floating museum – due to it being closer to Design.

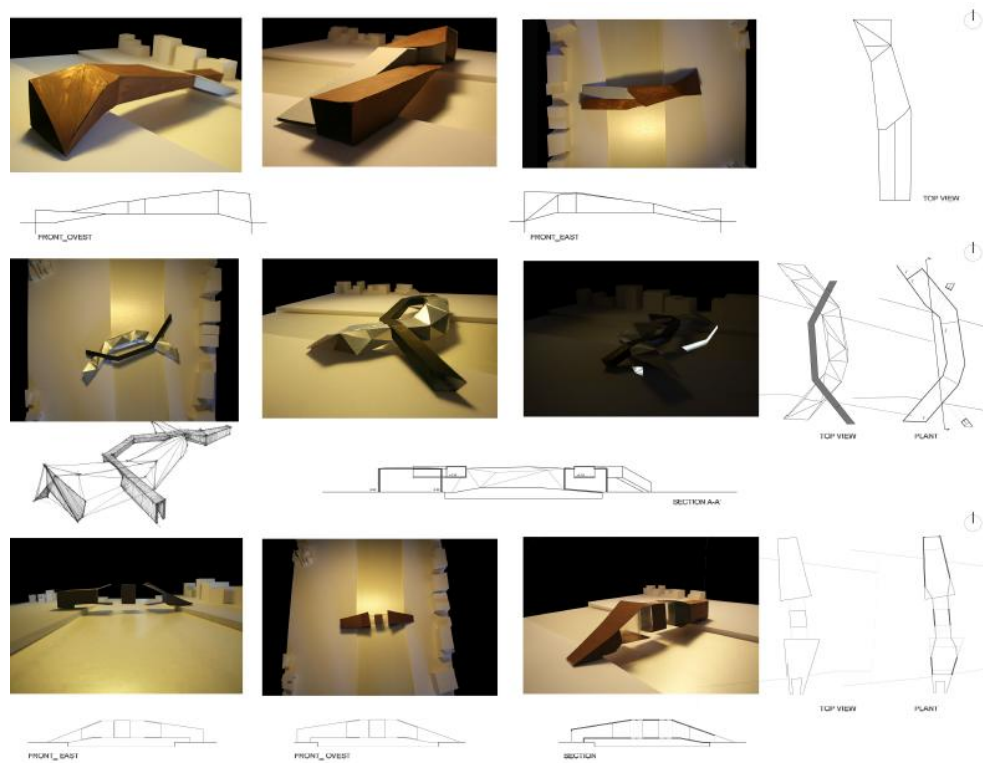

Fig. 5: The Bridge Museum. Study models by M. Contestabile, D. Fimmanò, L. Gnerre

Two of these sub-themes were considered near the mouth of the Çanakkale Cayi, the river that runs through the town and then into the sea after passing a series of pedestrian bridges and viaducts. The Bridge Museum, closer to the mouth, is a bridge between two different realities, a poor and unapproachable neighbourhood, due to it being infamous – but with an ancient fifteenth century fortress, Kale-i Sultaniye, also unapproachable because a military area – and a residential neighbourhood, with private and public green areas. On this side, along the river bank, families, young people, friends meet in a lush grove, the Osnabruck Parki, drinking tea at all hours, as often happens in Turkey; on the other bank, it is possible to see the stalls of an area that when there is no market is completely desolate. The two areas that the Bridge Museum could connect are so different from each other, with the idea of the bridge being an intervention that can heal the deep contradictions of this place. Nevertheless, metaphorically, the bridge is also the construction that connects not only two different areas of the city, but also two different worlds, Craft and Design. The relationship between Craft and Design – that De Fusco and Alison founded on a third kind studied in Italy in 1991, called “artidesign” – are the pillars upon which the entire framework of OFFICIAMUSEUM and OFFICIAMUSEUMED are based. The sub-theme of Factory Museum was identified in an area close to the previous one and separated from the latter by means of one of the two bridges that defines the boundaries. The title of this sub-theme comes from the presence of a group of old abandoned factories in the area, with a car park directly overlooking the river. In this second case, the intervention is declined both through a new building as well as through the reuse of existing ones. The Underground Square Museum is conceived under another crowded square, in front of the Maritime Station where it is possible to take a ferry to the largest island of Turkey, Gökceada, in the Aegean Sea and close to the Greek islands of Lemnos and Samothrace as well as Kilitbahir, where there is another fortress similar to that of Çanakkale built by Fatih Sultan Mehmet in 1463 to control the Dardanelles. Istanbul can be reached from Kilitbahir by car and bus. The square is located at the

confluence of major and busy roads. Two, for everthing, the Cumhuriyet bulvari – which comes from inside the city, running almost parallel to the river – and the pedestrian promenade Kayserili Ahmet Paşa Caddesi, a continuum of cafés and restaurants. The sub-theme of the Underground Square Museum was also recently studied in a tesi [6].

Through these three sub-themes, the students had to articulate a complete project, starting from the casing up to the preparation of the museum. A museum that falls under the category of general Company Museum [7], a far cry from that of the general museum because it aims at the promotion of trade-marks ; in particular, as already mentioned for the Temporary Museum of Pompei or the Casa Enzo Ferrari [8], the museum in Çanakkale is set up as a museum of firms in a country, Turkey, connected to its numerous museums of ceramics, glass, metals spread throughout the country.

The complex and multidimensional representation of the landscape on the Volturno River between Capua and Castel Volturno

Abstract

The Volturno River – one of the main waterways of Southern Italy due to both its length and water flow – was the forced crossroad to many who, coming from the sea, wanted to reach the Port of Casilinum (today known as Capua). The reference territory for the analysis concerns the fluvial axis between Capua and Castel Volturno, which also includes the towns of Santa Maria La Fossa, Grazzanise and Cancellor Amone. The multi-disciplinary investigation, and the photographic report, focus on a landscape analysis related to the history, traditions, agricultural production as well as archaeological, natural, and cultural assets of the area. Furthermore, elements of degradation were considered, such as landfills and illegal constructions that have contributed, over the years, to undermining this part of the Ager Campanus defined the “Garden of Europe” by 18th century travellers. Nevertheless, the landscapes of the Volturno remain beautiful and can become a resource, not only aesthetic, but also for the area’s economic development, for example, through the creation of cultural and tourist routes. Thematic maps were developed by analyzing the historic, rural, flooded, urban and contemporary landscapes. From the analysis comes out the project for the establishment of a network between the fluvial axis and the cultural and landscape heritage of Campania, including the six World Heritage properties of the region [Caserta, Naples, Pompeii, Amalfi, Cilento, and Benevento (Italy Langobardorum)] as well as the emblematic places of the region: Mt. Vesuvius, the islands of Capri, Ischia and Procida as well as the Phlegraean Fields.

Keywords: representation, landscape, cultural heritage, territorial governance, cultural identity

1. Methodology

The research was developed within the “Aesthetic of Landscape”, Department of Architecture and Industrial Design at the Second University of Naples (professor Jolanda Capriglione – architect Alessandro Ciambrone), with the participation of 10 students,* in the academic year 2013 – 2014. The cognitive method, intended as a preparatory phase for each project proposed by the research, is related to multi-dimensional [1] and multi-disciplinary principles [2]. This allows to investigate from the territorial-landscape scale to the architectural art craft, regardless of the date the object of study, the anthropic and natural phenomena intended as complex and in progress realities through a process of discretization and measurement that allows to study each element of the entire research object [3]. This process makes it possible to know the intangible heritage, which is an integral part of the historical and cultural heritage of the area. It is in the discovery of the identity matrix of the places as well as enhancing the human capital of the territories, which the traces capable of stimulating actions for the protection and enhancement of heritage are sought. These are intended as parts of collective projects, coordinated and concerted, among the involved institutions – at different territorial scales – as Public entities, Universities, Research centres and local communities, represented by the principal actors of the associated and business sectors [4].

The main objective of this research is the propose a knowledge platform for a subsequent phase of a project that can envisage a landscape regeneration of the river axes from Capua to the sea. This axis had an historical importance. The axis represents the link between the Mediterranean and ancient Capua, the most important cities of southern Italy in Roman times. In the design phase, in addition to the enhancement of the river axis, the proposals hypothesize the inclusion of the city of Capua in the World Heritage List as well as Castel Volturno in the Man and Biospheres network, along with the mouth of the Volturno, the Oasis of Variconi and the area of the lakes.

2. The historic landscapes

The analysis of the landscapes starts in the east and continue towards the sea. Capua is a city set in a bend of the Volturno River, founded in the middle of the eleventh century by the Lombard Count Landone I. It stands surrounded by walls, on the banks of the Volturno in the place of Casilinum, the ancient port, and takes its name from the ancient city of Capua, which occupied the area of actual city of Santa Maria Capua Vetere. The new Capua soon became a major economic and military centre.

The outstanding urban testimony and the surviving monuments make Capua the real capital of the Lombard art. The strategic role played by the city in this period is documented by the many monuments still well preserved and not influenced by the Carolingians, and also by a large part of the original layout of the urban plan developed at the side of the ancient Appian street. Further west, the City of Santa Maria La Fossa is located in the area known as the "Mazzoni". The area was famous in the past for the cultivation of roses. The town was built around the year one thousand as a hamlet of the town of Capua and reached its maximum development in the Lombard period. The city centre is located just 4 km from the Royal site of Carditello, built by the Bourbons [5]. Continuing towards the sea, there is the City of Grazzanise, which is the main centre of the Volturno plain, and is about 14 km from Capua. Grazzanise, Asylum of Graces. This according to historical sources is the name given by the ancient Romans to the modern city centre. This ancient origin is found constantly in the life of the City, which takes its name from the three figures of Greek mythology, daughters of Zeus, the "Three

Graces": Eufrosina, Talia and Aglaia. They are depicted on the emblem of the City's banner and the main roads of the City are also named after them. Further to the west, there are the cities of Cancellò and Arnone. The first documents date back to 1114 AD, when the town of Arnone is mentioned in a document of the monastery of Sant'Angelo in Formis. After belonging to Capua, in 1200 it passed into the hands of a few noble families, such as Filangieri, the Estendarda and Cantelmo and ended up among the domains of the archbishops of Capua. The municipality extends on either side of the two banks of the Volturno, where there are the two hamlets of Cancellò and Arnone. Buffalo breeding and the production of buffalo mozzarella are very important here. On the mouth of the Volturno River, Castel Volturno owes its name to the "Castle", and the Volturno River. Located at the end of the Campanian plain in the last offshoot of the Mazzoni, it was first inhabited by Opici, then by the Etruscans, who built the city of the Volturno, and subsequently by Osci. It carried out the function of emporium, market of the goods produced by the entire lower basin of the Volturno and was an obliged crossroads for those who wanted to head inland from the sea and reach the port Casilinum on the Volturno, and from there the ancient city of Capua [6].

The historic landscape. Design by Maura Coppola

3. The rural landscapes

The landscape of the province of Caserta, in the centuries-long succession of historical events and up to World War II, has been not only the expression of a rural culture but it has also focused on innovative agricultural processes through a conscious attitude of man towards this extraordinary natural heritage. Over the last decades, it has passed, in a short time, from agricultural to industrial use, denaturalizing the natural vocation of the territory. This has involved a meaningful variation in the models of life and fruition of the area. The province of Caserta has been defined an "immense Mediterranean garden" by the travellers of the XVIII century and Terra Laboris, due to its characterization linked to the agricultural production and extraordinary fertility of soils. The rural landscape in the eighteenth century, is strongly marked by extraordinary hydraulic engineering works: the Regi Lagni, a massive irrigation canal that runs through the hinterland to the sea; and the aqueduct of Vanvitelli, declared World Heritage property in 1997 along with the Royal Palace, the royal gardens and the industrial city of San Leucio characterized by its production of silk [7].

The landscape of the Caserta province, characterized by buffalo pastures and “bufalare” on the coastal stretch, is also strongly marked inland by particular crops, like those of the ancient “viti maritate” (married vineyards) for which many scholars believe appropriate to ask for special request for protection by UNESCO. Among the finest wine production, it is worth noting the “Falerno del Massico”, wine of excellence for the ancient Romans, and the “Asprino d'Aversa”, of Norman origin together with Galluccio and Casavecchia, all DOC (Certified Origin). Other worldwide famous products are the extra virgin olive of the “Terre Aurunche”, “annurca” apples, cherries, Vairano hazelnuts and the “percoca aversana” along with the famous buffalo mozzarella.

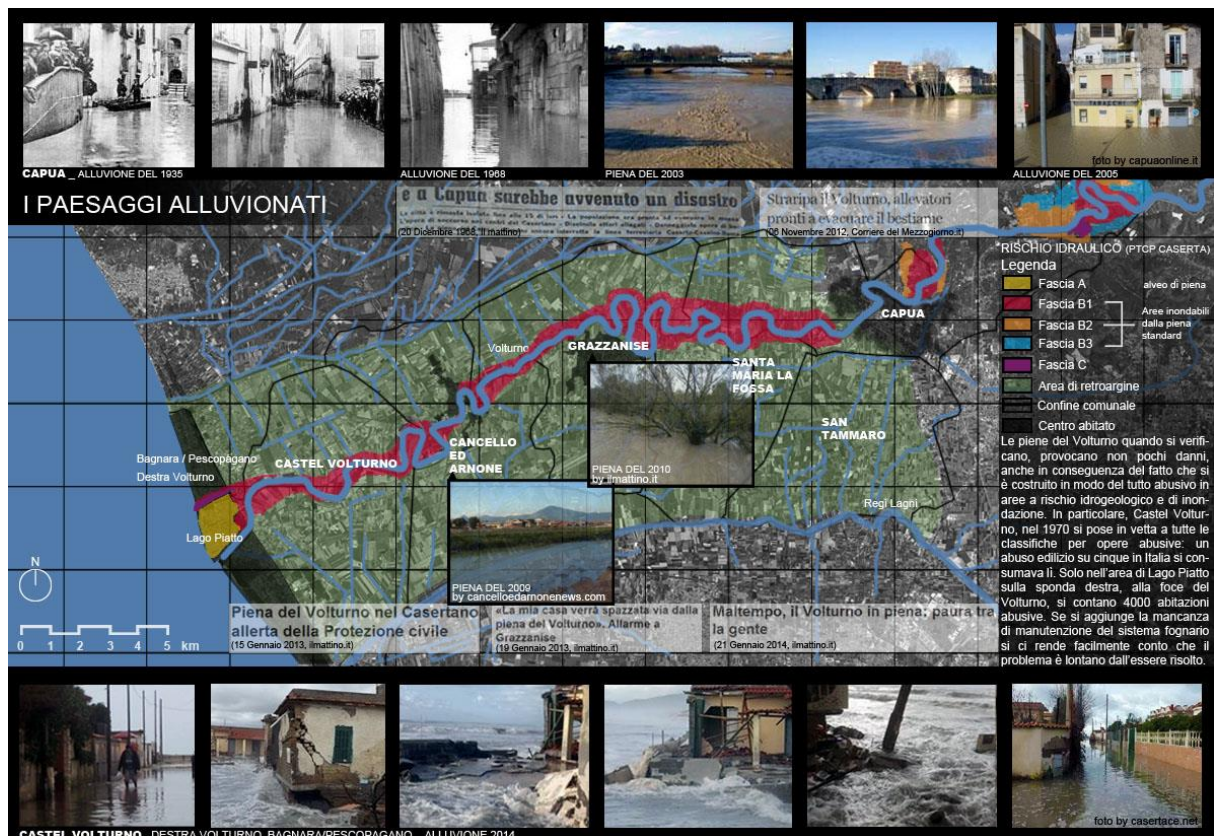

The rural landscape. Design by Giovanna Nichilò

4. The river and flooded landscapes

Five bridges characterize the landscape between Capua and Castel Volturno. At Capua, the Roman bridge, ruined several times, was restored to its original state by Federico II, who built the two towers, of which today only a part can be seen today. Destroyed during the Second World War, it was rebuilt as it appears today. The new bridge, always in Capua, is in a poor state of maintenance. The bridge of Grazzanise is called “United Bridge of Italy” since the unification of Italy took place on the Volturno River with the bloody final battle between the Bourbon army and the forces of Garibaldi. Highway “7 quarter Domitiana” is a variant of the Appian Way [8]. It starts from Formia and crosses all the Domitian – Flegra coast, ending in Pozzuoli, where it connects to the Naples ring road. Near Castel Volturno, the road crosses the Volturno river. Finally, towards the sea, the new bridge at the mouth of the Volturno was built in 1954 near the I century A.D. Domitian bridge of which remains only a hint in the arc of red brick in the medieval castle. The area around the river is at hydro-geologist risk. The floods of the Volturno, when they occur, cause a great deal of damage, due to the fact that a lot of constructions are illegal and located in areas of hydrogeological and flood risk. Particularly, Castel Volturno, in 1970 was first all the classifications for unauthorized works: one abuse out of five in Italy was erected in this City [9]. Only in the “Lago Piatto” district on the right bank, at the mouth of the Volturno, there are 4,000 illegal constructions. In the area of study there were numerous floods, especially after the Second World War, as a result of the many illegal houses.

5. The urban contemporary landscapes and the landscapes of beauty

Exceptional historic architectures, rural villages, and in some cases, poor housing, characterize the five urban centres under study. Capua (surface of 30 km², 18,853 inhabitants) is a town rich in historic buildings of architectural and artistic importance, characterized by ancient gates and interior courtyards (or cloisters). This type of construction has been, over the past 60 years, re-used in the areas of expansion of the city, which are composed mainly of one floor and multi-family buildings, as in the neighbourhoods of Madonna delle Grazie, Risorgimento and in the Fuori Porta Roma.

The three municipalities of Santa Maria La Fossa (area 29.5 km², 2,722 inhabitants), Grazzanise (surface of 47 km², 7,085 inhabitants) and Cancellor Arnone (surface of 49 km², 5,290 inhabitants) are characterized, in most cases, by simple constructions, such as linear buildings of two or maximum three floors, with an entrance and courtyard. These are the most commonly used building types, due to being functional and suited to the needs of the population, mainly related to agriculture and livestock working activities.

Castel Volturno (surface of 72 km², 24,183 inhabitants), outside of the historic centre, hosts buildings of two or three floors, constructed over the last 40 years. Since the 1970s, many constructions, nearly all abusive, have been built near/on the river banks. This uncontrolled urban development differs substantially between the simultaneous constructions of Castel Volturno and Capua, which was not subject, except in rare cases, to a spread of illegal urban development. Castel Volturno is now considered one of the places in Italy where the predominant degradation faced by some of these residential areas is most evident, with a lack of public services and commercial activities [10].

6. The enhancement of the river axis river, and development plans for Capua and Castel Volturno

The exceptional historical, landscape, artistic, architectural and intangible heritage of the river axis between Castel Volturno and Capua was not put into a network system and generates very limited contributions in terms of cultural, social, and economic development for local communities. A network between the heritage of this area, the cultural districts within the province of Caserta and at the regional level should be created.

gives Capua the real role of the Lombard art capital. It also has an extraordinary historical and artistic heritage consisting of 59 religious, 109 civilian, 29 soldier and 89 archaeological architectures [13]. This heritage can be part of a cultural network, within the cultural district of the province of Caserta and the fluvial axis, including the landscape heritage of Castel Volturno. In the coastal town, for example, a Man and Biosphere in the area that includes the Oasis Variconi, protected by the international Ramsar Convention, the lakes' districts, which was set up by private entrepreneurs, the Mediterranean Eco-park, and the mouth of the Volturno river could be established. The realization of the river port might enhance the activity of fishing, which for centuries has characterized this area and connect, as in the ancient and glorious past, Capua to the sea [14].

The reading of the tangible signs of the territory and its paradigms altered, the latter understood as elements of the places of persistence and life but also of action and reaction, allow the drafting of a multicriteria-elements of representation, where the sides of reason and reality territorial come together in a unique identifying mark representative communicative element complex as what he wants to be in the contemporary world "territory." Tangible presence of the sign territorial, is its connotation within its historical path that marks the places in need in the prospects of development planning, systematic analysis of existing structures optimization of the combination of essential explicate between place and space. The reading of these elements, the schematic ordered them, the return also altered, allows the appearance territorial revitalization, the latter in the firmness of pre-existing dialogues with the attitude to the future planning in a direct and vectorized. Intensity with which density and spatial knowledge in the places, the point of application as a characteristic element of the study context, understood as a form of value and meaning of meaning assigned to read, and understood how to sign proposition, almost obligatory direction of development, calling and waiting. Not neglecting then through a conscious approach to its analysis of the problematic Successive cultures in places, their actions and reactions of the territory. The territory, the vast area known, understood then in his new reading, with force as a stimulus for investigation and clarification through the preparation of true signs and control with those achievable programming. So in the end all presented epidermically the relationship of the sign to the man actor-spectator; single subject, the internal space volume multi-dimensional reality and meta- reality of investigation and design. The fact, therefore, requires a reflection of multi-track score, and on the meaning of the territorial reality, therefore, a strong view on the meaning of the signs, visible and invisible, and the role that those who now competes for quality cultures and scientific interests is in charge of dialogue and to intervene operating on the tissue, ensuring, conservation, protection, reason-region, organic growth.

Keywords: places, identity, systematic, territory, reason-region.

The reading of the tangible signs of the territory and its altered paradigms, the latter understood as elements of the persistence and life places but also of action and reaction, allow for the drawing up of a multi-criteria representation elements, where the aspects of reason and territorial reality come together in a unique identifying mark representative communicative of the overall element as what the "territory" wants to be in the contemporary world. The tangible presence of the territorial sign is its connotation within its historical path that marks the places in need in the planning prospects of development, systematic analysis of existing structures, optimization of the essential combination

between place and space. The reading of these elements, their schematic ordering, their restitution, also altered, allows for a revitalization of the territorial appearance, the latter in the firmness of the pre-existing dialogues with the approach to a direct and vectorised future planning. With intensity which density and spatial knowledge in the places, the point of application as a characteristic element of the contextual study, understood as ascribed value and attributing it meaning and seen as a sign of proposition, almost an obligatory direction of development, vocation and expected. Not therefore neglecting through a conscious approach, the relative issues of the analysis of successive cultures in places, their actions and relative reactions of the territory. The territory, the vast known area, understood as its new reading, with force as a stimulus for investigation and clarification through the preparation of true signs and control with those that can be achieved through planning. Finally, all presented epidermically to the relationship of the sign to the man actor-spectator; single subject, in multi-dimensional spaces, reality and meta-reality, of investigation and design. This, therefore, requires a reflection on the sign and the multi-level traces of the territorial reality, therefore, a strong consideration of the meaning of the signs, visible and invisible, as well as the role that those who now compete for quality cultures and scientific interests is open to dialogue and to intervene operating on the tissue, ensuring, conservation, protection, reason-region, organic growth.(Fig.1) From the experience of perceptual and emotional places, then proceeding in the construction of a new “vision of the city”, assuming a kind of “resemanticization” of its places that seemed crucial. Excursions, walks... are famous “tactics” that have returned throughout the twentieth century a particular history of the city: they told us the trivial city of Dada, of the unconscious and dreaming of the Surrealists, of the playful and nomadic city of the situationists. All visions of particular facets captured through a simple action, a walk - understood as “aesthetic practice” (practice from that experience has almost reached the status of an autonomous discipline) - act capable of giving an idea of the city “in which the spaces of being are the islands in the great sea formed by the space of going”. All the ideas of the city in which to walk while not representing a real “building”, implies a “transformation” through a new attribution of meaning. From those experiences we have learned that “wandering” in one place and the changing perceptions that are received represent a form of transformation that does not leave marks, but still culturally change the meaning of places and space. Thus, a walk is at the same time, a perceptive and creative act that takes shape through a “route”.

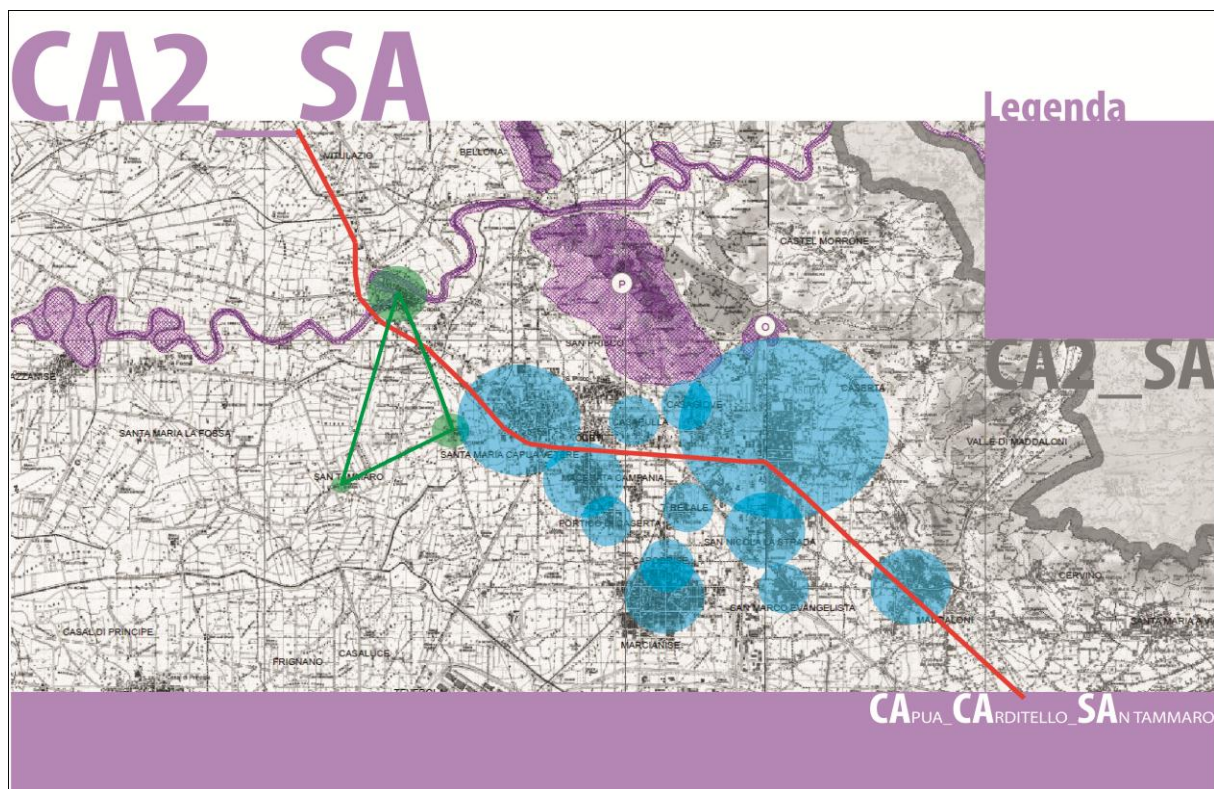

Fig. 1: Territorial analysis; the validity of the signs as a result of visual.

A heavy term, the meaning of which embodies, at the same time, the idea of the physical act of crossing (the path as the action of walking) , the idea of the trajectory, that is the line along which crosses the space (path as an itinerary), and the idea of the story of the space traversed (path as a narrative structure). These aspects of the route and the "story" - and the representation that underlies them both - are the most interesting because, through these two dimensions, the "walk" tends, on the one hand, to produce "maps" of the territory and, secondly, to attribute to it the symbolic and aesthetic values whose representation is manifested in specific visual artifacts from a strong communicative impact. The idea of the route and itinerary as the narrative is evidently connected to the complex action of the possible mapping of the territory. This is from the earliest maps of nomadic cultures, which constitute an interesting outcome in terms of representation, the slow and steady action of appropriation of the land by those peoples who first posed the problem of "inhabiting the earth by covering it". However, the idea of the "map" contains in itself the most diverse narrative outcomes, which in various ways have been developed over time. (Fig. 2) It is worth mentioning, due to the particular fortune that similar issues have gained in the contemporary debate, the meaning it assumes in influential meta-graphs of the situationists or the psycho-geographical maps drawn by Guy Debord of Paris in the 1950s. These are maps where places of the city, completely out of context, appear as the land of passion, while the city itself is conceived as a "psychic landscape built with holes, in which whole parts are forgotten or deliberately suppressed, to build in the endless empty in possible cities". It is therefore driven by an experience that wants to narrate the territory, also proposing walking as an aesthetic practice, capable of describing and modifying areas of the city whose nature often goes even interpreted and filled with "meaning", rather than by "objects". Elsewhere, however, it is intended to interpret the idea of the "map" restoring all its meaning of "guide to the exploration of places", but enriching the key of the reading through an approach that has intertwined the results with those relating to the contemporary debate around the meaning of more complex "geographies of communication". However, wandering cannot always do without "map", that is not always possible without the absolute acquisition of news and information on places. It is on this issue that the building and transfer of information, interesting food for thought emerge from the experience and computer graphics that the particular field of visual communication that is interested in the representation of the "information" in graphical form. A whole industry, infographics is interested in the information for city maps, information systems, signage systems all fall into this horizon of communication that often, in the contemporary scenario proposes artifacts not quite conventional, capable of transforming the collection of information into an experiential action that involves the user in a dialectic relationship and makes the acquisition - and sometimes the building - the information at the same time simple, useful, enjoyable. Often the same city is interpreted as a "sheet" upon which to plot directions and routes, a city as a fabric (and therefore once again as a text) to write possible stories through the images of the new frontier of signage systems. Intuitive, dynamic, environmental, the signs today are using the city as a support, and working towards the redefinition of visual landscapes, giving new meaning to the experience of places. The multiple actions proposed by the project in the urban and social fabric of the city, return, however, an idea of multiplicity that cannot find consistent representation in individual communicative artifacts. Interpreted as "viral actions", that could trigger a chain reaction in the identity statute transactions of the city, the project activities have ended up merging once again in possible "vision of the city", each of which lives and strengthens its position in the light of the others, above, below.... The events that can potentially invade the city are linked to a number of paths of culture and art and food, greenery and energy. They can often simultaneously give the idea of a pulsating city, full of vivid events: concerts, performances, exhibitions, events, while in the greenhouses of art, spread all over the territory, showing the world the spectacle of nature. The information on such a jumble of activities and initiatives finds with difficulty their own representation in the forced two-dimensional map of the complex redefinition of its objectives and or a tourist guide. Eduard Tufte has good reason to define the practice of escaping flatland as a prerequisite to any infographics action. It is precisely to overcome the two-dimensionality that the project has focused, designing artifacts able to contain in a single object - in a sense "convertible" - separately, but simultaneously, useful indications for the use of all the areas of interest. Unconventional maps in which paths should be intuitive rather than identified, because only suggested as suggestions of a possible thematic itinerary that is designed by the reader. Appearing on the map, colour codes and sign elements that are a true correspondence in a system of dynamic and environmental signage invades the streets and physically marking the city

used as a sheet upon which to write, draw, set out directional systems. Even the temporal dimension has its own representation: nocturnal maps reported night places and events visible through special

Fig. 2: Views of changes in metrics, analysis of the graphic references.

inks, using the same technique with which environmental signaling take shape in the dark, defining scenarios of unpublished night landscapes. On the whole, the project is declined as an experimental model of communication, exportable to other experiences and other territories, and to take an approach that seems to convincingly interpret instances that arise in the contemporary debate: the life of a city and the story of its heritage are at the bases of the life of the relationship that it is able, over time, to weave with its users; it is the story of the characteristics of this relationship and the ways in which it can interpret different levels of intense forms of communication and dialogue; and of this dialogue, the “dynamic maps of identity”, there seems to be an interesting support. Once again, the cultural horizon imposes reflecting on the communication strategies and actions, searching among those that are best able to interpret the emotional dimension that the experience of tradition and culture can give. However, these interesting interpretations are likely to remain purely theoretical, if it is not possible to convey to the community the idea that cultural heritage can concretely represent “a piece of its everyday life”; if it is not possible to convey the belief that that heritage is “accessible” – in the sense that Rifkin gives to the term - namely, that it is really part of a “possible experience” . (Fig.3) The theme is to be related to the widespread opinion that the new economies of experience supplant those of knowledge and in the short term the “learning society” will have to deal with and confront the relentless “emotional society”.

Fig. 3: Views of changes in metrics, meaning the little face in the spectrum bitonal

All the values that often seem to be far away from the communication processes, but can find their own expressive figure, as stated by Perniola in “a way of doing based on memory and imagination that does not flee the world, but moves it.

Fig. 4: Views of changes in metrics, meaning the geographic visual displays such as picture communication

The power of making and sizing are and will serve as a boost for the new landscape of the contemporary world; the final idea (Fig. 4) of this contribution is that it is possible to draw from our past energy to invent our future, our observation of the signs of territoriality and drive a scientific project towards a sign - a sign of memory and imagination.

Staircases as a representative space of architecture

Ornella ZERLENGA

Department of Architecture and Industrial Design, Second University of Naples, Aversa, Italy.
ornella.zerlenga@unina2.it

Abstract

Due to its important architectural function, the staircase of a project is as old as the architecture itself, with there being significant examples throughout history, from those of the Palace of Knossos in Crete and Persepolis in Iran as well as in the works of Francesco di Giorgio Martini, Leonardo da Vinci and Bramante. However, it is in the Baroque period that we experience forms that restore the staircase of a project as a space-time configuration representative of the architecture, along with not only the monumental but also imaginative dimension as demonstrated by some European models introduced by Johann Balthasar Neumann in Germany or Mansart in France. In Italy, however, there is a particular design period of the staircase as a representative area of the architecture in Naples, with the work of Ferdinando Sanfelice being a masterful example. Specifically, the staircases of Ferdinando Sanfelice in Naples will be studied, highlighting the geometric-configuration arrays of his two main models i.e. the "gullwing" and the cantilever, which earned the architect the nickname of "Ferdina lievato sotto" (Ferdinando get out from below). The unusual and bold formal configuration of his staircases, whether they were "neck" structures or, especially, "overhang" or "in flight", had such an echo to the point that their lightweight appearance gave rise to legitimate doubts about their solidity and resistance.

Keywords: Neapolitan historic buildings, Ferdinando Sanfelice, staircases, architectural survey.

1. The staircases of the historic buildings of Naples

Open eighteenth-century Neapolitan staircases originate from the 1400s and are architectural organisms characterized by peculiar space-perception relations. This complex architectural reality manifests itself through a dynamic journey of flights of steps covered with vaults and a changing perception of views, with light and shadow created by perforated walls. These holed fronts are an added value to design capable of triggering a space-perceptual continuity between the courtyard (interior space), where there is a staircase and the road (external space) from which the staircase takes you through the archway of the entrance. In this sense, while in pursuit of its main architectural function (the vertical connection between the different floors of a building), the open Neapolitan staircase is, at the same time, a reservoir of space representative of several factors which are produced in it and manifest themselves. This condition finds reason in the distress of the roads with the consequent inability to grasp from each road the unique design of each façade. Therefore, in the expressive requalification programme of the residence, the portal and the staircase assume the task of attractor as if a piece of scenery where the portal is the proscenium and the staircase the backdrop. In residential Neapolitan architecture, it is worth noting the widespread existence of an entrance that consists of a portal, entrance hall, courtyard and staircase. The portal draws the attention of the passerby as a attractor element due to its shape, size, material, decoration as well as function (to allow the passage from an internal to an external space) that antiquity has given a symbolic meaning. Functionally, the portal is an opening that allows for the passage from one environment to another. Symbolically, the function hails back to the arc of triumph, monumental building of the Roman period

designed to celebrate a victory, arranged along the streets where the triumphal processions were carried out and under which the leader marched with the spoils of war, treasure and slaves [13]. In historical Neapolitan buildings, the portal is the first link in a continuous spatial sequence marking the transition from a public space (the street) to a private one (the building). Whether it is a noble or lesser building, the portal is a symbolic means of representation that, by virtue of size, shape, material and decorations invades the street attracting the attention of the passerby. In close connection with the road, the plastic-figurative spatiality of the portal and the light-shadow-light pattern (which connotes the sequence street-entrance-courtyard) attract the passerby who, having passed the entrance hall, looks into the intimate space, the courtyard, an open reservoir of space where in most Neapolitan buildings there is the “open staircase”, often located in the front position with regard to access in order to visually seduce the passerby (when passing by on the street), thanks to the strength of an ever-changing spatial dynamism generated on the performance of the buttresses and a multiplicity of vaulted structures, typologically different and variously articulated. In some cases, behind the staircase, there is the garden, and the set is transformed into a multidimensional perceptual context in which the portal is the intermediary (Fig. 1), with a masterful example being the eighteenth-century “gullwing” staircase in Palazzo Sanfelice by the architect Ferdinando Sanfelice, located in the Sanità neighbourhood in Naples.

Fig. 1: The access systems of a residential architecture: portal, entrance hall, courtyard, staircase, garden.

2. The Sanfelician “gullwing” model: the extroverted staircase

Among all the open staircases of eighteenth century Naples, without a doubt the most impressive are the work of Ferdinando Sanfelice (or his collaborators), unconventional architect due to both language and structural design. For Sanfelice, the model of the “open staircase” is a bold disseminator capable of reworking the linguistic and structural elements using an ingenious and free invention: the back wall of the courtyard (opposite the road and hiding the body of the staircase) is interpreted as an improvised and piece of scenery to burrow into, with the prime task of manifesting to the outside the complex system of flights of steps. In this sense, Ferdinando San Felice moved away from frivolous and superficial decorations to experiment with bold and unprecedented formal solutions capable of being implanted on unusual planimetric configurations, pillars, arches, vaults and flights of steps with a unparalleled structural fluency. In this unified architectural composition, the real protagonist of the cognitive experience is the visual-perceptual dynamic use of space and light, with the latter being generated by the ever-changing play of solids and voids.

In the 1720's, Sanfelice designed in Via Arena in Sanità his family home, consisting of two buildings assembled on the street with a single façade with two identical portals, straight broken profile with molding and embossed. The staircases, with a different spatial layout, each facing a courtyard with a different shape. In particular, one of the two staircases (number 6), taking up and reinterpreting the tradition of the monumental double staircase, introduces in the panorama of the building an unusual theatrical model called by recent historiography “hawk wing” or “gullwing” [6] (Figs. 2-B, 3-B).

The staircase occupies the entire width of the transverse façade of the courtyard opposite the entrance and is made up by a body that is the same height as the building. The structural system includes sixteen pillars whose planimetric rhythm is regulated by a double bilateral symmetry and in which there are different flights of stairs, landings and wells, and upon which the whole system of vaults and arches rests, including the horizontal flights and rampant. Both sides of this staircase, of considerable size (the one facing the entrance as well as the one facing the back), are completely perforated and projecting outside the pillared structure through the use of pilasters. In addition, on the facade facing the entrance, a parallel system of moldings, taking higher up the levels of the landings of the side elevations, shows the outside the altimetric development of the landings and lines of the slopes of the flights of steps and, therefore, connotes the design the perspective with an original use of the sloping lines and the subsequent allusion to movement.

Specifically, the spatial configuration to “wings of seagulls” comes from the peculiar planimetric design of the staircase. This, in fact, refers to the double monumental staircase with four flights of stairs that

wrap around an empty space sharing a central flight. In this diagram, the edge of the staircase is set along the transverse direction, thus confirming the architectural layout called a double monumental staircase, and at the same time, giving the central bay on the ground floor, free and not committed to any flight (see, for example, the staircase in Weissenstein Castle in Pommersfelden by Johann Dientzenhofer, 1711-18; the Daun-Kinsky Palace, 1713 by J. L. Hildebrandt) (Fig. 2-A). This solution allows to connect the front courtyard with the free space behind to be used as a garden. At the same time, by virtue of the existence of a completely perforated body of the staircase, this solution allows the passerby to see through entrance, beyond the body of the staircase and into the garden at the rear.

This model – with or without a garden – was widely replicated in a Naples that had fallen in love with spectacular Baroque scenery, with the staircases of the Spagnuolo (Via dei Vergini, 19), Fernandez (Via San Giuseppe dei Nudi, 25) and Trabucco (Vico San Liborio, 1) being outstanding examples albeit with more or less relevant differences.

In 1738 Ferdinando Sanfelice was responsible for realising a noble residence in Via Vergini, known as Palazzo dello Spagnolo, re-proposing the “gullwing” staircase with some slight variations, which make the perspective on the courtyard even more “ethereal”. While the main supporting structure still consisted of sixteen pillars, the floor plan of the double staircase, as in Palazzo Sanfelice, and the main body of the staircase, the diaphragm between the two courtyards (one of which was to be used as a garden), the perspective onto the entrance is reduced even further since the wall system is reduced to the pillars upon which the arches and vaults rest. In addition, the wing shaped marcapiano – that gave continuity to Palazzo Sanfelice, with three horizontal, broken strips – is discontinuous, thus enhancing the verticality of the side and central spans. Finally, the last level of the perspective, instead of ending with a view of the pillars and rear loggia – presents an additional floor pierced by arches with the same line. The building also has a rich array of stuccos, subsequently realised by Aniello Prezioso based on drawings by Francesco Attanasio (Figs. 2 - C, 3 -C).

The staircases of the noble residences Fernandez and Trabucco were based on the “gullwing” model and built by students from the Sanfelician school. If compared, the fronts of the courtyard of the two staircases seem to arise at the antipodes, almost as if hybrids of the previous Sanfelician solutions. Unlike the original models, these two staircases do not have a garden behind them, with the only façade perforated being the entrance. The scenic backdrop of Palazzo Fernandez refers more to Palazzo Sanfelice since it has both a front pierced with arches (a low arch) and windows (instead of only the reduction of the pillars), as well as the molded strip that, however, has a lesser inclination since the layout of the staircase is different. In fact, in accordance to the model of the double monumental staircase, there are only three flight of steps that wrap themselves around at right angles to the corresponding wells in Palazzo Fernandez; the fourth flight (the one that touches the front of the courtyard) is absent and replaced by a few steps. Therefore, the horizontal strips that create the prospect appear less pronounced and almost horizontal (Figs. 2-D, 3-D).

Built by Nicola Tagliacozzi Canale, the staircase of Palazzo Trabucco serves five floors (unlike the previous one which only four) and looks out onto a courtyard whose transverse dimension is much smaller than the others. This accentuates the effect of vertical thrust of the perspective that, even in this case, is enhanced by the reduction of the front wall to the sole of the pillars with arches and the absence of a continuous molded strip. Consequently, there is a dynamism in the perspective that is created by alternating the height of the vertical bands corresponding to the central and side spans, which is further accentuated by the remaining ones that, qualified by a reduced passage, leave space for the rampant openings, perceived as if slots (Figs. 2-E, 3-E).

Overall, the open Sanfelician “gullwing” staircase innovates with imagination and boldness the design of the residential staircase, making it the central place of the representative space of architecture. The objectives of Sanfelice such as the scenic and, at the same time, structural wonder give a new type of body to the staircase that make the multiple perceptions as well as contrasts of light the main elements of an original design. The reinterpretation of the double monumental staircase and its spatial reconfiguration in multiple vertical levels (made possible thanks to a daring experimentation of walls, pillars, arches and vaults) results in a new space of the journey; the perceptual experience is dynamic and full of multiple views presented by both visual continuous visual crossings that along with the “holes” of the arches and wells allows the gaze to go in all directions as well as the change of the tonal value of the light. In this architecture of visibility and multiple experiences, the prevailing feeling is one of being in an “explosive”, “centrifugal” space, where anything can and must remain immobile.

Fig. 3: B-Palazzo Sanfelice; C-Palazzo dello Spagnuolo; D-Palazzo Fernandez; .E-Palazzo Trabucco.

3 . The Sanfelician “cantilevered” model: the introverted staircase

As previously mentioned, in the 1720s Ferdinando Sanfelice realised his family home in Via Arena in the Sanità, consisting of two buildings (with independent entrances) and two courtyards (separate and different shapes) overlooked by two different staircases, the “gullwing” (previously described, n. 6) and the “twin-scroll” (n. 2). It is well-known that the spatial configuration of a “spiral” staircase arises from a planimetric circular or oval shape where the steps dwindle in size towards the center or the inside, however, leaning on a central pivot (called “core” or “column”). The solution designed (and realised) by Sanfelice is “double” in the sense that there two separate staircases that run parallel but in opposite directions and are accessed by a single straight flight located in the middle (Figs. 4 -E , 5 -E). The typological reference is, therefore, the double staircase where the central ramp is lower and bisects into two right-angled sides as well as the double spiral staircase in the castle of Graz in Austria and dated 1499 where, unlike the one built by Sanfelice, the flights are initially separate and then come together in a share landing. Sanfelice’s solution was to follow the one rectilinear flight with the two spiral flights in a median position, serving two distinct and symmetrical entrances with respect to the central axis of the planimetric configuration. Overall, this staircase is full of the intense “introverted” spatiality, internal and confined. In fact, while going up the steps, it is gradually revealed, with surprise, stopping at to the small overlook, that is over the courtyard, and then leading to the first and only floor. In addition, the presence of only two light sources (the aforementioned small one and a single open window overlooking the rear perimeter wall) contribute to the gradual unfolding of the reservoir of space particularly in light of the significant tonal variation of the natural light that is appreciated during the climb.

Sanfelice designed a further two “introverted” staircases in Naples which, just as with the twin-scroll of Palazzo Sanfelice, are characterized by the analogous design of an attractive and intense internal space that is not manifested by anything outside: these are in the noble residences of Palmarice (Piazzetta Teodoro Monticelli) and Bartolomeo di Majo (Descent Sanità, 68). The design of both of these staircases revisit the “ring” where the steps, clamped to the side walls, leave a central space known as a “well”. In this case , the steps are “cantilevered” and the staircase is statically self-supporting in the sense that it does not possess load bearing elements apart from the connection of the steps to the exterior walls. This type of staircase can also be developed on a square plan, variously polygonal, as well as circular or oval plane: in the latter, there are noteworthy examples of “cartouche” staircases by Jacopo Barozzi, known as Il Vignola, in the Palazzo Farnese in Caprarola as well as oval staircases by Andrea Palladio, including the one built in the Academy of Venice and, in 1786, Goethe said to be “the most beautiful spiral staircase in the world [so that] we do not grow weary of climbing and going down it”. Thus, the staircases of the noble residences Palmarice and Bartolomeo di Majo are cantilevered stairs which represent further remarkable examples of the unprecedented structural imagination of Ferdinando Sanfelice.

The staircase of Palazzo Palmarice can be accessed through a small Sanfelician style portal (mixtilinear molding wrapped with studs and diamond point located in the left corner of the courtyard (Fig. 2-B, 2 -B). The staircase develops planimetrically along an octagon, or a square rotated 45° and with the vertices blunted. This allows to set the flights along the directions of the diagonals as well as obtain triangular landings and a central square shaft, which is also rotated 45° with respect to the portal. This is not insignificant, when considering, in relation to the direction of the front of the perspective that “hides” the scale, that they are not parallel, but rather, create an unusual perceivable dynamism from both the entrance on the ground floor as well as the openings at the different levels and from which the staircase is illuminated. The intrados of the flights is solved with Roman vaults while the landings are covered with spindles. The spatial configuration of the staircase of Palazzo Palmarice has a basic geometric layout but the result is spectacular, not only due to the dynamism that the solution of the rotation to 45 degrees generates, but due to the contribution of the natural light that, penetrating through the arches opening onto the courtyard (including the top floor, one oval eye), is the other variable and constant component of the spatial design by Sanfelice.

In 1726 Ferdinando Sanfelice renovated Palazzo Bartolomeo di Majo, creating another unique cantilevered staircase (Figs. 4-A, 5-A). In this case, the spatial body is a rhombus with convex sides towards the inside of the well and rounded vertices. Even in this case, the four flights are arranged along the diagonal directions of the rhombus to the convex sides and, consequently, the planimetric shape of the well is to concentric with that of the reservoir wall so that, looking at it, the planimetric plane of the Palazzo Bartholomew di Majo staircase (also in this case, the flights are covered by barrel vaults and the landings with spindles) seems to be the topological stretching of the Palazzo Palmarice staircase along one of its axes. Looking at it from below, the Palazzo Bartolomeo di Majo staircase seems to stretch upward like an elastic material, almost unfolding like a ribbon and this feeling is supported by the absence of moldings on the external walls joining the arches that support the flights. Bernardo De Dominici, biographer of Sanfelice, commented on this staircase with great admiration: «It is the most capricious staircase in Naples, bringing wonder to how so a great staircase can be in the air, with only one part being connected» [1].

The description of the design of the open staircase by Ferdinando Sanfelice for Palazzo Capuano-Lauriano in Vico Pellegrino (Figs. 4-C, 5-C) is worth mentioning. Planimetrically, the staircase relates to the double staircase model, while introducing a variant. In fact, the lateral flights, from which it has access, do not have a rectilinear development but are arranged at a right angle along the adjacent sides of a square rotated 45° with respect to the courtyard, while the flight is arranged along the median axis. This allows to jut part of the staircase onto the courtyard and to model the perspective spatially. Thus, the three sides of the masonry walls, which extend towards the hallway, open up a series of arches (on the central front) as well as a series of oblong octagonal windows on the front sloping sides. As with the “gullwing” staircase, also in this case, the line of slope of the flights is declared to the outside by virtue of the presence of a molding that follows the movement of the facade and which contributes to reinforcing the dynamic effect of the design of the perspective. However, unlike the “gullwing” model, the flights ramps but not unload onto pillars but rather onto masonry walls that reduce the transparency effect of the staircase.

The open staircase of Palazzo Mastellone also seems to be inspired by Sanfelice, located in Piazza Carità and renovated in 1732 by Nicol Tagliacozzi Canale, architect of the adjacent Palazzo Trabucco (Figs. 4-D, 5 -D). The spatial layout of this staircase has several elements that connect it to the work of Sanfelice, such as the theme of the double staircase and the projection onto the courtyard, although in this case, the part that juts out into the hallway is only the flight of steps that leads to the ground floor, modelled according to a curvilinear connection. Specifically, the theme of the double staircase and the projection onto the courtyard make it similar to the double spiral staircase of Palazzo Sanfelice as well as the perspective of Palazzo Lauriano-Capuano.

4. Architectural surveys as an investigative tool

The graphical and configurational analysis of the similarities and differences of the Sanfelician staircase (and those built based on it) have been the subject of study by a research team led by the writer and includes Giuseppe Celiento, Vincenzo Cirillo, Raffaele Federico, Valeria Marzocchella and Salvatore Volpicelli. The diagrams compare – for the first time and to the same scale of representation – the staircases designed by Sanfelice in Naples and highlight the spatial qualities that have made them well-known (Figs. 2, 4). These issues have been dealt with in an architectural survey campaign of several staircases in Naples, where the spatial layout refers to the Sanfelician models discussed here, and where, specifically, the research work was supported by the recent archive studies carried out by Alfonso Gambardella, one of the most important scholars of the works of Ferdinando Sanfelice. The staircases, studied under the scientific coordination of the author, have been analysed by the entire research team as well as individually by each member of the group (Fig. 6). They are located in Via Nilo, 30 (Palazzo D’Afflitto, Vincenzo Cirillo), Salita Capodimonte, 10 (Palazzo Santoro, Raffaele Federico), Via Duomo, 220 (Palazzo Persico, Giuseppe Celiento), Via Salvatore Rosa 98 and 103 (Palazzo Maciocco, respectively Salvatore Volpicelli and Valeria Marzocchella).

The architectural survey campaign of the staircases was carried out by Pasquale Argenziano (the laser scanner survey), Antonio Grillo (3D prototypes) and Assunta D’Urzo, Gino Spera, Igor Todisco, Antonio Trimarchi (the photographic documentation).

Specifically, in the early Sixties of the last century, the staircases in Palazzo Maciocco and Palazzo D’Afflitto were surveyed by Michele Capobianco as part of a teaching laboratory and published - together with the findings of most of the Sanfelician staircases examined here – in three issues of the journal “L’architettura. Cronache e storia” [4, 554-557; 5, 694-697]. The surveys and photographs attached contribute to the data making it possible to carry out a comparison with the significant changes that subsequently occurred. The staircase of Palazzo Santoro was previously studied and then surveyed by the author in 1992 as part of the educational field survey coordinated by Rosa Penta [10, 11]. The architectural survey carried out on these five staircases - whose formal and spatial characteristics from a geometric-configurative point of view refer to the Sanfelician models analyzed here - give a new and innovative contribution due to both the type of comparative study of the similarities and differences as well as the instrumental innovation introduced during the survey campaign that allowed to exploit even more the formal and metric data. Moreover, by virtue of modern modeling vector digital systems, it was possible to see new and unusual views of the staircases, thus confirming the prominent role of representative space of the architecture of the residence.

The architectural survey and analysis of the staircases is currently in press (translated by Sacha Anthony Berardo).

Abstract

This study is concerned with two moments of analysis and one of design on different and historically dense urban areas, which are undergoing rapid, uncoordinated and not characterizing changes. The dominion of Capua is the scenery and the rule of these areas. This study has compared a long section of back of old rural houses in front of the campaign, on the sidelines of a centuria (Casagiove) and the secondary fronts of some ancient buildings that form a large empty square near a major urban hinge (Santa Maria Capua Vetere). The first-in order to reflect on the fate of tuffaceous skylines that have drawn the prospects and the boundaries of the villages built into the fields for hundreds of years- takes its cue from the areas of study of a doctoral research of the first 90 years, focused on the order that there is a need to give to the things built in urban areas of small and medium size. The second refers to the work of some students of a laboratory of architectural design on the quality of the space strongly characterized by the introversion and its centrality misinterpreted. In binding to the two sites chosen, is finally described, as an example of the method used to interface properly old and new buildings in respect of both analyzes, the project nearing completion of a parish complex on the a small ground of outskirts in Caserta near the agricultural area of the Atellano (Marcianise).

Keywords: Territory, City, Limits, Modifications.

Fig. 1: Territorial framework

1. Reading

The work intends to return to the issues of modification of the inhabited space and, as in the previous study presented at the meeting of Capri (2013), attempts an example of reading of the events that relate to the architecture, in order to assess them. The goal is to add a small piece to the research on the transformation of urban morphology, where they have tried to note down how and what has been built in cities and in their suburbs for the past 30 years; a short period of time characterized by the irrepressible race toward every possible form of residual expansion. These reflections are absolutely necessary, now that the various levels of planning are available almost everywhere and there is a need to give a final functional and formal structure to the territories. Hereunder we will be carefully watching three different episodes. The territory on which a few kilometers north of the Gulf of Naples triangulate, is the dominion of Capua and its polycentric University. The choice derives from the connection that it seemed to be between them according to a brief reasoning. The first two, unresolved but emblematic, respectively in the outskirts of the town of Casagiove and in the urban center of Santa Maria Capua Vetere. The third, a work in progress in the large agricultural municipality of Marcianise, for the problems addressed, shape and arrangements, serves to recall both the previous episodes.

Fig. 2: Case studies

2. Casagiove_XL

In 1992 was completed the drafting of the first doctoral thesis in architectural of the school of Naples, who had read the strength of planning of the centuries that was still alive in the territory of Capua. [1] The paginated and the experience were closed by the idea of design of a small new piece of city, a project to highlight the position of the modules surveyors. Via Luigi Castiello, street of the centuriation, was chosen as the setting because it was the only isolated and densely built road able to express an independent urban quality. It, into his rectum flat route from the south to the mountains Tifatini, today supports a settlement that continues to expand itself westward and a single row of courtyard houses without windows on the the countryside, from the opposite side. Many changes of the urban form have occurred on via Castiello in the twenty-two years thereafter and here we could certainly give a critical testimony of these without fear to be going off topic, however, we preferred to shift the focus and go further the scene of the strong transformations planned and still in progress (the one rearranged in the doctoral project), attracted by the tuffaceous skyline that constitutes the poetic back of the houses built to the east of the road. It is one of many skylines that are in the plain on the margin between the edification and the countryside, but also one of the few to still be almost intact; this and other similar ones tend to be slowly absorbed or replaced by amorphous and unprincipled buildings; just look around to be able to annotate a rich casuistry of variants. It's just the absence of the plaster who has made so dry and suggestive, in its apparent incompleteness, the tuffaceous back of the towns and villages of the area of Caserta. How much testimonial value should be recognized? Which type of formal-morphological energy can be express by these places? How much capacity for change do they have? Since it is clear and visible what awaits them in the future, if we don't preserve their image or

don't program the modification, we must try to assume three realistic ways to address the problem: 1) If they were considered worthy tracks the history of places, the first could be that of the full conservative protection of what remains.

Fig. 3: collage on the right with the study area via Castiello and on the left the image of doctoral research.

Fig. 4: Skyline of the project of doctoral research.

Obviously in the points where the typical tuffaceous continuity had already been interrupted by demolitions, for the avoidance of false history, it should be sewed up with the signs and the lexicon of our time. 2) Alternately to the inevitable replacements of buildings and to the spurious forms that appear everywhere, a more realistic way to intervene could be to use these walls as a simple fund of support for other buildings with a single overlooking. The buildable volume should be distributed with a single planning action, so as to obtain an artifact (or many connected and functionally different artifacts) similar to what exists for the size and visual impact, but especially bearer of an contemporary image. 3) The third, finally an hybrid, sum of the first two with the Additions of a road, a driveway or any other kind of usable space interposed between the skyline and the new *double face* buildings, which are constructed according to a parcelling of urban architecture of new generation.

3. S.Maria Capua Vetere_M

In 2008 in Aversa, the students of a workshop of the architectural design of the third year, conducted a study on some interesting landlocked areas, lateral to an axis of ancient Capua (now Corso Garibaldi of S. Maria Capua Vetere), to check how they could have become useful to the city if reformulated in their spatial and functions. Among those spaces that have been analyzed and designed, we are interested in recall the only one on which faced only rears of buildings and walls of gardens. Exactly the opposite of the previous example, as much for planimetric "collocation" (the others, resembling the walls of a fortified city - this, an unspoken centrality in the dense built of a nineteenth century city), as for planimetric "design" (the other, a long extrovert strip - this, a square introvert enclosure). They have in common only the fact that, today, they're both a "front-back " who has unexpressed potentialities. We start from the important fact that the area was a garden long before it became a public parking lot for about a hundred cars. If we add that the axis corresponds to the maximum hinge of Capua in his

Etruscan phase, it becomes quite clear that it is misunderstood and under-utilized compared to the centrality that it expresses; similar spatialities deserve to have forms and spaces of high quality in order to obtain a satisfactory and full participation of the citizens. Even in the second episode as in the previous, we try to speculate the possible ways to address the problem: 1) The amending act is certainly the simplest; it focuses on philological recovery of its ancient vegetable nature like urban garden, enriched on the margin or inside by small equipments and bio-compatible functions. 2) Another is the one which provides small covering artifacts on the walls of the gardens and on the fronts of blind houses which surround the square, allocating the pavilions obtained from the edification on the perimeter's edge and the new centrality, to the spaces for an excellent and thematic handicraft, or similar functions. 3) The third way, like the first, could start from the redevelopment of the walls and the building, without significant changes or important additions, but this time allowing the objectuality of the architecture to express itself more, convertible with an extreme gesture in a only central building, transparent as the crystal of the pyramid of Pei at the Louvre or open as the lodge of the Market of the Pig in Florence. [2]

4. Marcianise_S

In 2007, following an architectural competition was designed, for the populous district of San Giuliano di Marcianise, a parish complex that included the church and the classrooms for catechism. [3] Although not being a spatial dimension as the first example, or an urban one as the second, the small soil to be built is very similar to the others for the correspondence with the centuries and for its square shape. Since it borders for two sides with other properties who have tuffaceous blind fronts, here is the most important of the affinities and, perhaps, a solution to be taken as an example. What would have happened if the neighbors had decided the demolition or change the profile? What should have been done to avoid this risk for the quality of space? In the project have been built on the border with the already existing ones, the classrooms, the ramps and the porches. The danger, at least here, have been averted.

Abstract

Over the last thirty years, the theories on the evolution of the species and natural inheritance of genes have been sources of inspiration for the research of new techniques of stochastic optimization. "Complexity theory" focuses on the interdisciplinary study of its systems. In its evolution, the study of complex adaptive systems and the emergent phenomena associated with them are of fundamental importance.

Complexity is the property that a modelable system has to show behaviour not all pre-settable (or necessary), although potentially anticipated (or possible) to an intentional observer of this system.

The landscape as a complex system is a topic that has not been explored in sufficient detail.

The purpose of this work is the study of the landscape as a complex adaptive system and its possible scenarios.

Keywords: Landscape, Complex adaptive system

1. Introduction

A great deal of effort involved in the design of fuzzy logic-based applications are expended in the Complexity is the property a modelable system that has to show the behaviour that are not all pre-settable (or necessary), although potentially anticipated (or possible) by an intentional observer of this system.

The complexity of a system can be attributed to:

1. the structure of the system, determined by the number and variability of its components as well as between the local nonlinear relationships that are established;
2. the system's behaviour over time and in relation to its reference, which together determine the ability to make transitions between different regimes, or states of the system;
3. the emergent properties of the system over time. The dynamics of a complex system, its behaviour, is also the lead of the interaction of the three points above.

2. Definition of complexity

There are situations that are decisional situations. In this case, it is more natural to deal with - *Computational complexity (Logical depth)* introduced in computer science is defined as the minimum time it takes for a computer to solve a problem. It is a definition closely related to the field of action and a measure that is evidently dependent on the implicit context in the definition, in relation to variables such as the power of the computer used or the characteristics of the calculation software installed. Unlike this setting, computational complexity in the subsequent definition of scholars trying to proceed to a formal explanation of the context, through the indication, within the definition of "conditions" of the *neutrality* of the measurement, as in the case of the complexity of grain.

- The *complexity of the grain* of a system is the length of the shorter message able to describe, at a distance and at a given level of resolution (graininess), a system, provided that the two parties are able to speak the same language and have a comparable level of knowledge and understanding. This definition formalizes the context specifying the conditions that affect the measurement, which include not only the level of knowledge expressed by the parties involved in the message - the more knowledge is different among these, the longer the necessary description of the same message is -

but also the level of "granularity" chosen. The increase of grain, as in the photo, can be compared to an increase of the resolution that the system also determines the increase in the level of complexity or length of the message.

Evidently, this formula is not generally applicable, given that the level of complexity (the length of the message) is significantly affected by the prospect of observation chosen and the different level of knowledge expressed between the two parts of the message.

The notion of complexity or algorithmic computing: the *Algorithmic Information Complexity (AIC)*, associated with the work of Kolmogorov in 1965 and Chaitin in 1974, has its roots in the theory of computation and complexity measure in terms of the simplest algorithm that describes a particular task or phenomenon, given that in the absence of compressible regularity, the simplest algorithm coincides with the description of the same phenomenon. In this case, no reference is directly made to the length of the message, but the length of the computer program capable of printing a string of bits (binary digits 0, 1) by a computer. Compared to the complexity of grain, algorithmic complexity introduces new sources of arbitrariness, not only related to software or hardware, but also to the codification program used. The level of compression, however, is not absolute, but depends on the individual's ability to find a theorem that could allow for further compression. This form of complexity in conclusion does not capture regularity as the lack of regularity of a system.

- In the context of the theory of complex adaptive systems (CAS), Gell-Mann in 1995 suggests a complexity measure that defines "effective" and that, with reference to an adaptive system observes and builds a schema, the length of this scheme. In this case, the observer complete definition does not capture the complexity of the system, just as its regularity. The result is that the actual complexity of a system is maximum when the algorithmic complexity is neither too large nor too small.

- Close to the actual definition of complexity, there is complexity as proposed by Casti in 1986, according to which complexity is the latent properties of a system and which is manifested in the moment of interaction between the observing system (S) and the observed system (O). This type detects the relational nature of the measure; unlike the other, however, it admits that the interaction between the two systems is not bidirectional and unidirectional, admits that the observed object carries some form of influence on the observing system. In the moment of interaction, there are two forms of complexity, design complexity, referring to S, and control complexity, referring to O, to emphasize a role, not a passive object (system) observed on the observing system. It is worth noting that each system is assigned a certain level of complexity, in turn the result of the characteristics of its components. According to Casti, the situation of better interaction between the two systems occurs when both show a similar level of complexity. This implies that the tension to a higher level of complexity as part of a system may be desirable considered by an observant, as a source of further variety in the understanding of the observed reality. Another consequence is that the possibility to manage complexity, by the observing system, passes for the creation of the faithful models of both systems and not only of the observed system. Identification and management complexity are therefore the result of a process of interaction between the two systems. Chaste proposes measuring complexity by the number of non-equivalent descriptions that S can provide for O, where description refers to some form of interaction that S can have with O. A new class of non-equivalent descriptions emerges whenever the system through a bifurcation or creates a new organizational level in its hierarchy.

- LMC complexity was proposed in 1995 by López-Ruiz, Mancini and Calbet as a statistical measure of complexity. It is the product of two quantities: entropy (as formulated by Shannon) and a quantity called imbalance. The latter is a function that reflects the difference of a given probability distribution from a uniform distribution. This product decreases in the two extremes, order and disorder, and therefore can be considered a measure of the complexity, positioned in an intermediate regime between the previous two

- Another definition of complexity stems from biology and artificial intelligence studies and is interested in understanding how relational complexity and density variability of the interaction that takes shape between the agents involved.

All of the above complexity can be considered as partial representations of the same reality, however, they can be used in a complementary manner. In fact, if the first four describe the complexity of the information that circulates in the appearance of content between agents of a system, the fifth and sixth will miss the side represented by the structure of the interaction between agents as shaped by information flows between them. Information content and structure of the interaction may partially describe the complexity that characterizes many systems, such as the enterprise system. For example, assuming that in an enterprise system complexity is in the first instance an expression of the number of individuals, technologies, procedures, and their interdependencies that, for various reasons, come into play in the recruitment, expansion, exploitation of a certain resource or expertise. In this context, a new source of complexity is related to the use and production of resources in the context of highly complex technological systems and humans, as they occur in conditions of high causal ambiguity to the outside observer.

3. Approaches and roots of complexity

The first approaches to complexity were founded with studies of first-order cybernetics in 1942, during the Second World War. The organization goes back to New York for one of the ten conferences sponsored by the Josiah Macy Foundation, which brought together scholars from many disciplines, committed to deepening the problems of self-regulation in the animal and the machine. The cybernetic movement is enshrined as an interdisciplinary movement with the publication of the Wiener fundamental, one of its leading exponents, published in 1948, immediately after the war. Cybernetics focuses on the study of the mechanisms of control and communication present in human and mechanical systems. The term "Cybernetics" comes from the Greek word *Kybernetes*, meaning steersman. Plato in "The Republic" uses it to describe the element of caution inherent in the art of "governing". In English the word governor is used in two senses, the first in reference to the person who takes decisions in the public interest and the second in relation to the mechanism of a self-regulating valve of a steam engine, which keeps the engine at a constant speed under varying load conditions.

In essence, the base of a control behavior of the type exemplified by the governor of the steam engine is a feedback loop (negative feedback), through which the output of a system is connected to its entry in such a way that the changes in output compared to a standard established or planned for accordingly have a stabilizing compensatory behavior that tends to bring the system's output to this rule. The same mechanism works in different types of systems, even those biological (homeostatic mechanism) and would be the basis of phenomena such as homothermy. In the social sciences the identification of these mechanisms has led to theorizing the purposive behavior of a system - limiting the role of the interaction linear cause-and-effect - according to which the stability, which is its purpose, is regulated by a negative feedback mechanism. In Cybernetics and in particular in that of the second order, that for reasons of space will deal simultaneously with that of first order, although it is next, are deepened also circuits to positive feedback. With them are systems that amplify the oscillations, causing the machine or system to be divergent or have disruptive behavior.

The contribution of Cybernetics in the study of complex systems is evident; many of the concepts acquired have merged in the maturing body of theoretical complexity. On the other hand, organization theory, political science, cultural anthropology and social psychology for many years have analyzed the social groups as complex communication networks are characterized by a multiplicity of feedback loops. With Cybernetics, there is a structural-functionalist approach, mediated by the behavioural. In essence, the method requires that the observer arrives primarily to modeling the structural and functional organization of the object analysed, and then proceed to the study of the possible states that the organization may take in response to various stimuli in the entry system (social systems are typically open).

In 1954, Von Bertalanffy founded the Society for General Systems Research (SGSR) whose purpose was to encourage the development of theoretical systems, applicable to more than a traditional sector of science. A consequence of the existence of the general properties of the systems according to the author consists in the appearance of structural similarities or isomorphisms in different fields. The isomorphism is therefore much more than a mere analogy. How are such systems defined? And what system is it? They are defined as a complex of interacting elements, which presupposes the existence of n elements n different relationships between the elements and an observer can assess the relationships between the elements. The systems upon which it focuses the author, being a biologist, are open ones. Biology has quite recently understood open systems;

In open systems, living does not occur only a production of entropy due to irreversible processes, but also as a decrease in entropy, and the consequent possibility that the latter reaches negative values. Thus, living systems, maintaining themselves in a steady state, can avoid increases in entropy, and may even develop towards states of increased order and organization. The relationship between order and self-organization, has already been dealt with by Cybernetics, through the concept of order from noise Foerster, and is studied in greater detail not only by Von Bertalanffy, but also by other scholars, such as Lovelock, Maturana and Varela and Ilya Prigogine. For all self-organization, there is the spontaneous emergence of new structures and new forms of behaviour in open systems far from equilibrium, characterized by internal feedback loops and described mathematically by nonlinear equations. In the wake of this concept, in 1967, in a speech on the occasion of a Nobel Symposium in Stockholm, Prigogine, the Russian chemist, provides the first definition of self-organizing structured systems presenting his theory of dissipative structures. The term emphasizes the close association between the paradoxical existence of structure and order on the one hand, and loss and wastage on the other, a phenomenon that occurs due to the presence of mechanisms for feedback from amplification (positive feedback). Prigogine argues that if in the past (Cybernetics) were associated with situations such as a destructive feedback system, dissipative structures then become new sources of order and complexity.

The problem is, however, to identify the relative weight of individual events in a given time, since the system may have a different sensitivity compared to the same stress, both in relation to different combinations of events stressing. Probably the dissipative structures of Prigogine cannot answer all of these questions, however, they can profitably enlighten us about the behaviour of the system over time, when due to the mechanisms mentioned above reaches, a limit of stability, called the bifurcation point, i.e. a radical and unexpected change of the trajectory of the system in the space between the phases. The bifurcation describes a divergent evolutionary path of a system in graphical form. The single line of the fork is a first linear section of the path which then branches, or forks, in correspondence to a certain critical value of some parameter. At this point, the system loses its previous adaptation and must choose between the two paths.

Depending on the case, this may be the time in which the system jumps to a new state of heightened organization, developing a new and more elaborate.

The concept of bifurcation opens the door to the analysis of the historical dimension of the system. Because of bifurcations, complex systems have unpredictable behavior and irreversible. Unpredictable because in a bifurcation point we can not predict which branch will be followed by the system, you can know the possible states that may take, but you can not predict with certainty which of these will actually be taken in a well-defined period of time. Irreversible because the choice of a branch rather than another is an event that could not produce, but having that product determines the subsequent evolution of the system, making it irreversible and bringing out new interactions between agents ordered and coherent system.

All this takes the name of path dependency, namely the inability to abandon a certain path once undertaken: the state of a system at a certain point t_k brings with it the memory, the living, the path since there peculiar path, but, in turn, it was in t_k affects the future evolutionary trajectories.

Irreversibility and unpredictability characterize, therefore, the behavioural model of the system, so that, by Prigogine onwards, it is not uncommon to find allusions to the science of complexity as emergent behavior of complex systems in non-equilibrium conditions.

Just at the Santa Fe these efforts and enthusiasm of these result in the birth of a new unified science: the science of complexity.

There are many disciplines involved ; copious research of the Santa Fe: all, however, revolve around concepts such as: emergency, non-linearity, self-organization, adaptation, coevolution, experience, learning, multiple equilibria, the edge of chaos

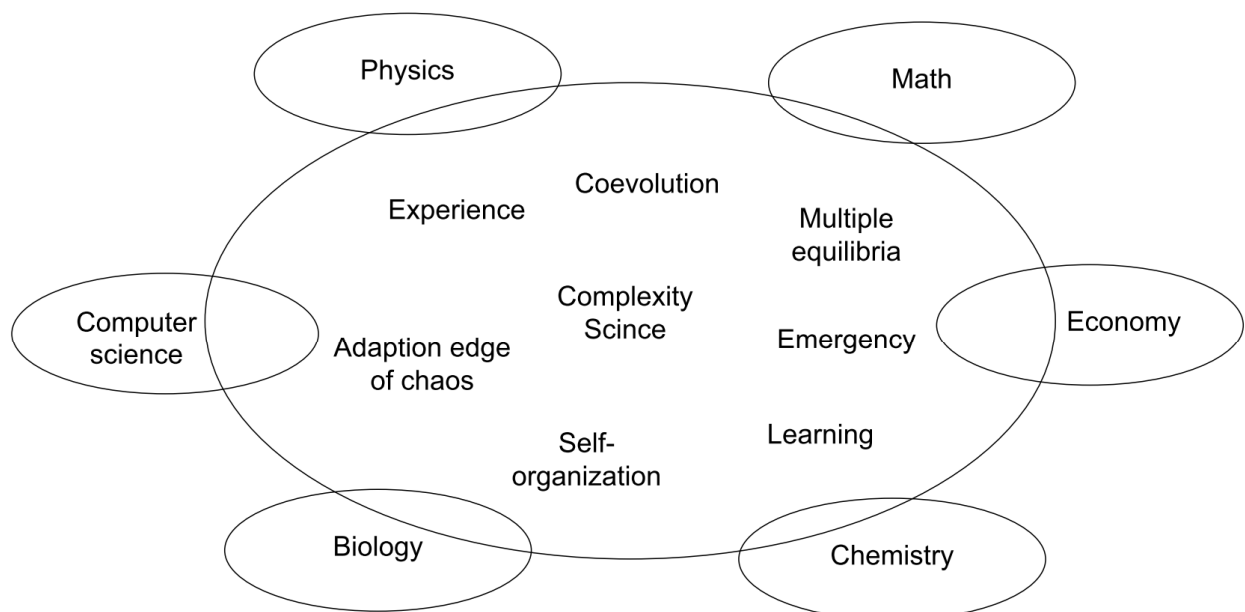

Fig. 1: The research themes of the Santa Fe Institute

If you want to trace a common unit of analysis, this could be construed as being in a complex system, an expression with which they denote any phenomenon that emerges from the interaction of the elements of which it is composed.

The complexity arises because many elements interact simultaneously and are self-organized locally (i.e. from the bottom) ; complexity is therefore in the organization of the elements of the system, or rather in their self-organization; it is the system that selects, who opts for one of the countless combinations in which its members can interact; it is the system that chooses one of the possible models of orderly and consistent interaction, without any intervention of any outside agent in the selection. With the process of self-organization, collective properties emerge, or rather systemic, i.e. properties attributable to the system as a whole, but not owned by any member, by any element individually considered: it is global properties, i.e. non-existent quality and non-deductible logically prior to the formation of the system, and empirically ascertainable only after its formation:

for example, the property of liquidity, which emerges from the interaction of individual molecules of water, but that is not owned by any single molecule.

Emergent phenomena are considered to be associated with the nervous system, the mind, the life associated with any biological system, the so-called " environmental balance " associated ecosystems, and phenomena such as social organization, culture, the economy associated with social systems. At each level, new emergent structures are created and engage in new emerging behavior and one of the main challenges of researchers at Santa Fe is to find the fundamental laws of the emergence.

It is an approach to science and to " do science " bottom-up, which focuses on how the interaction between agents forms ordered structures and patterns of behaviour and consistent. The complexity, in other words, is emerging as a science, a science that deals with phenomena - natural or social - emerging, namely:

- Associated with the operation of a complex system that evolves over time ;
- Generated from the bottom up, that is exclusively due to the local interactions between the system components ;
- Unpredictable, the trend of which is expressible i.e. by means of non-linear equations ;
- Irreducible, that is, independent of the existence and properties of the individual components of the system.

Self-organization, emergence, collective behaviour. How to react and adapt to their environment emergent phenomena? To which part of the environment fit? How does the environment on the system? What structures underlying the adaptation? What are the mechanisms of adaptation? As part of the experience of interacting with the environment " holds " the whole system? What are the limits, obstacles, the system encountered in adapting to the environment? How can they be compared to the different processes of adaptation and assumptions about their dynamics?

John Holland is - one of the world's first PhDs in computer science - to "inject" in the program of the Santa Fe to study the adaptation of complex systems. For Holland, the self-organizing complex systems not only denote mostly non-linear behaviour, but they are adaptive in that they do not just passively respond to events, but shall endeavor to proactively take the best of any situation. The complex adaptive systems (complex adaptive systems, CAS, for example, brains, immune systems, ecologies, cells, developing embryos, cultural organizations, economic and social) seem to be united by some basic properties summarized in the table below.

The complex adaptive system:
It 'an open system
Each agent co-evolves, that is constantly trying to adapt to all the other
Self-organizes spontaneously
It consists of a network of agents operating in parallel
It has positive and negative feedback
It is engaged in a continuous cycle of learning, review and classification of experiences
Its agents have the ability to make assumptions about the future
It is always far from equilibrium
Its evolution is path dependent

In the figure 2 i show a visual, organizational map of complex systems broken into six sub-groups.

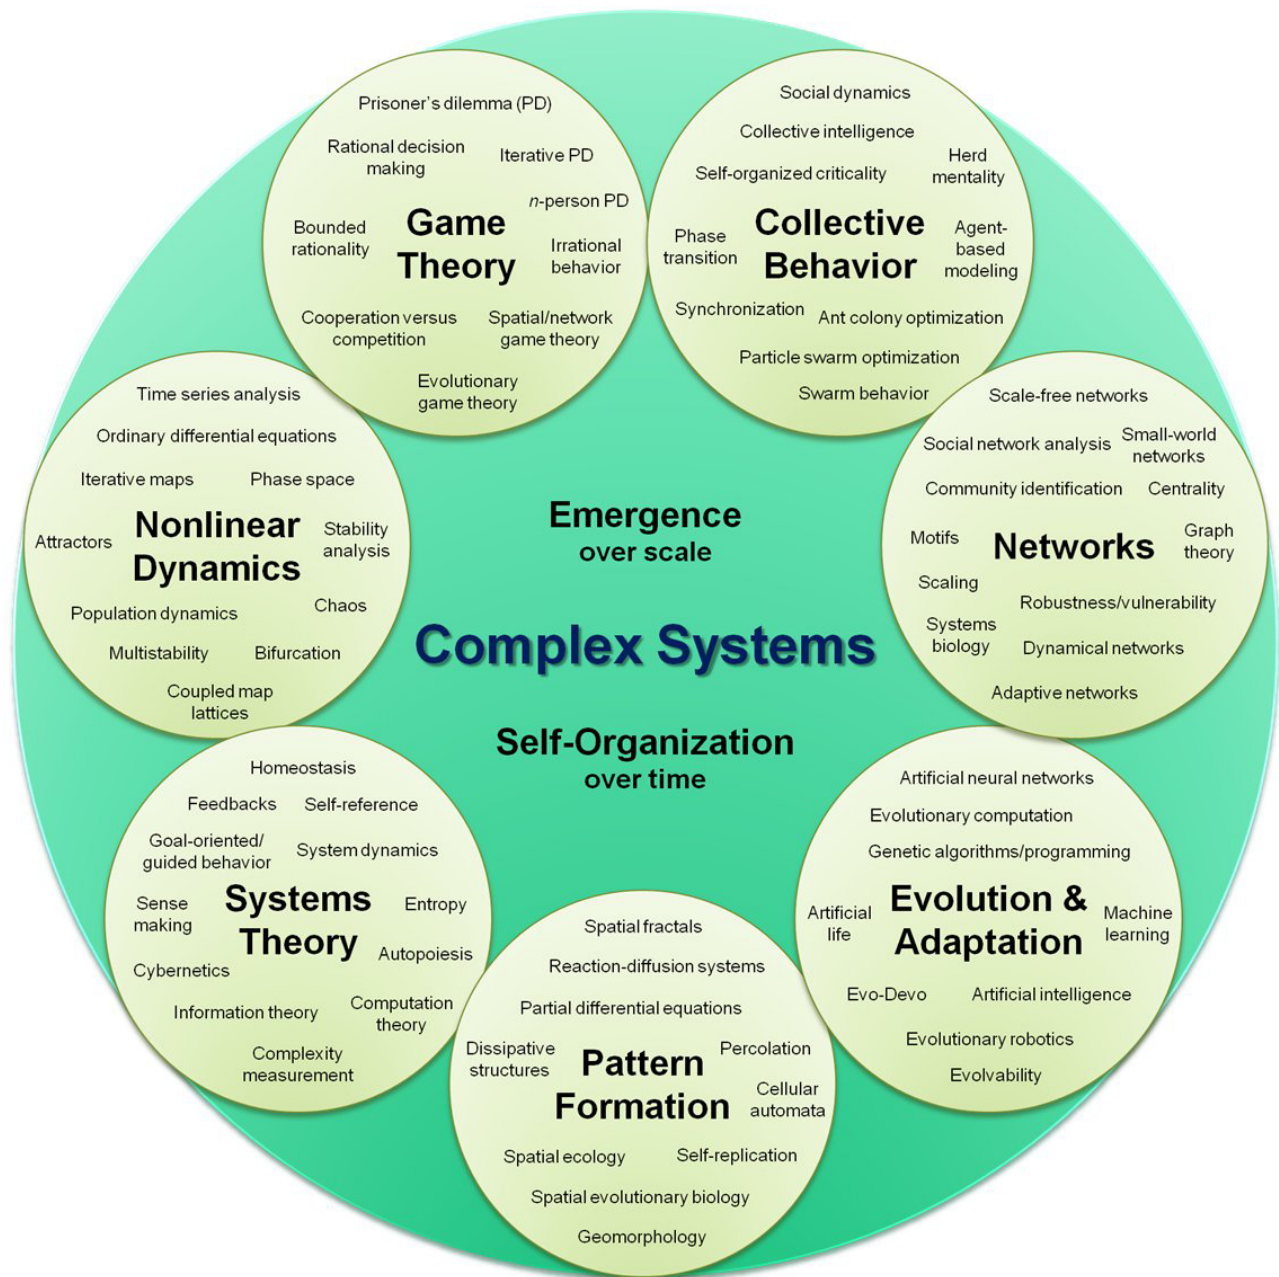

Fig. 2: The complex systems

4. Landscape as a complex adaptive system

In physics, a complex system is a system in which the individual parts are affected by local interactions, short- range, which cause changes in the overall structure.

According to Casti (1994) are considered complex systems not those representable through equations in more unknowns, but those that have a non-linear " trend ", according to Simon (1996), a complex system is formed by a multiplicity of parts which have between them numerous interrelationships (Simon 1996)

The characteristics of complex systems are:

- 1) Many components more or less complex: in the more complex systems, subsystems (i.e. components) are themselves high complexity ; components can be "hardware" (molecules, physical processors, cells, individuals) or "software" processing units (virtual) ;
- 2) Interactions between components: components interact by passing information (in the form of energy, matter, or digital information); the amount of connections and the presence of substructures and recursive feedback loops (so-called "rings") increase the complexity of the system, but the information that the components are exchanged may not be too many (otherwise the system becomes chaotic) nor too little (the system will " crystallize ");
- 3) Absence of " pyramid " hierarchy: if there is a single component, which alone governs the behaviour of all, the system cannot be complex; its description is, in fact, can easily be reduced to that of the subsystem - leader; different is the case of complex systems " hologram ", in which each

component has information about the system as a whole (for example, each cell contains all the genetic information of the organism to which it belongs).

These are supplemented by a fourth defining characteristic of complex adaptive systems:

4) adaptive interaction with the environment: the system is much more complex, as there are many factors that affect its adaptation to the environment (which must take into account the model): incidence of random factors, learning, interaction with the ' observer of the system, and so on. ; while the system evolves, its subsystems co- evolve by developing strategies for co-adaptation (symbiosis, cooperation, communication, etc..).

The problem of the complexity of the landscape is evident in the light of the gap between theory and practice, a sign of incommensurability between theoretical dimension and operational disciplines such as planning and design.

As defined by Ulrich Beck planning is a professionalization " not - very - successful " because of the weak connection between the theoretical and practical dimension.

The definitions of landscape fail to take into account the diversity of practices and outcomes, not all predictable, nor of their mutual interactions, therefore, that are non- profits; thus it is necessary to establish a closer relationship between theory and practice.

The first hints of complexity theory within planning were found in the 1960s and later the theory of systems defined planning as an ongoing process aimed at controlling and monitoring of complex urban systems was introduced.

The landscape can be considered a complex system not only because it means different things to different people and it means different things at different scales, but mainly because the analysis of the rules and internal logic of each system where the landscape is composed not enough to understand the results, and therefore, are crucial interactions.

It is no coincidence that one of the reasons for the appeal to the broad strategic planning consists in giving coherence to the multiple objectives of the public by establishing an order of priority between the same goals and hypothesizing, checking the veracity, the possible interaction between them.

The landscape is a complex adaptive system because it affects a number of factors that follow rules, different logics, and the interaction that give rise to "other " rules, and adapting to unexpected outcomes, subject to fitness, to the new conditions.

Therefore, apply the complexity of the planning is relevant when you consider the possibility of the unexpected and the landscape as a plurality of objects and subjects, that is, if you consider all the possible outcomes that can arise in complex systems and the natural evolutionary adaptation of the landscape.

In conclusion, the concept of planning, namely the management and evolution of the landscape itself, should not be that of an illusory total control, as the ability to imagine possible futures and adapt to change unexpectedly trying to limit the non-desired outcomes.

Abstract

The international cooperation for development has been working during decades to reduce the inequalities between the persons and the peoples of the world. Within these inequalities those who take place between women and men have to be placed in the first position, provided that women concentrate the 70 % of the world poverty, a fact which we name a feminizing of the poverty. The architectural heritage possesses an important potential as generator of development in the communities where it is located at. This is why the interventions in this heritage must be used in the projects of international cooperation to reduce the inequalities and then to promote the gender equality. But in many cases a great difficulty exists in showing how an intervention in the heritage promotes the development and how it can help to reduce the inequalities between women and men. This brings sometimes to question the convenience of the rehabilitation of heritage facing other one type of projects (education, health, infrastructures...). With the purpose of being able to demonstrate that an intervention in the architectural heritage is capable of generating development and therefore to reduce the inequalities between women and men it is necessary to establish a series of indicators that are capable of measuring the results of these projects of cooperation. In this paper a series of indicators that allows evaluating how the rehabilitation and management of the architectural heritage promotes the gender equality.

Keywords: Development, cooperation, architectural heritage, gender approach, indicators

1. Introduction

According to UNESCO [1], 100.000 persons in the world die every day of hunger. The majority of them are children; in fact, every 5 minutes a 10-year-old child dies as a consequence of a deficient nutrition. This is due to the fact that more than one billion people live nowadays below the threshold of the extreme poverty (less than 1 dollar per day), without access to drinkable water, without a worthy housing and without access to sanitary basic services. It is therefore evident that inequalities between the persons who live the planet exist. But if we were indicating in a map where these inequalities take place, we might observe that they are not distributed the same way in all the countries, and this is why we can affirm that not only inequalities between the persons exist, but also between the peoples of the world.

Other important information related to these inequalities would be that not only they take place of unequal way between the different countries, but also that inside the same geographical zone the poverty always accents in the women. From more than one billion persons who live below the

threshold of the extreme poverty, 70 % are women [2] despite the fact that in the world there are 57 more millions of men than of women. Women live longer but in worse conditions than men. In the case of women, beyond the level of extreme poverty major work in the house, worse conditions of work, major difficulty of access to the education and to medical effective treatments, etc. make the situation worse for them. According to data of 2010 [3], women spend more than twice the time than men do to the domestic tasks. Then, considering the paid work and the non-remunerated one, it can be stated that women work more hours than men. Women continue earning less for the same work. Only 13 of the 500 principal companies worldwide have a woman in the position of general director, and this number does not improve in the public sector, where only 14 women in the whole world hold the presidency or the leadership of the state. Two third parts of the illiterate world population are women, and 54 % of the school absenteeism takes place between the girls. Only a fourth part of the top investigators in the whole world are women. The main reason of death in women worldwide continues being the cardiovascular problems provided that the pharmaceutical companies and the medical researches base their experiments mostly on males. These are the reasons why talking about the poverty feminization is becoming more and more popular [4].

International cooperation for development can be defined as the work that from public and private organisms have been carried out since the middle of the last century to reduce these inequalities [5]. Though in the beginning this cooperation was centered on a purely economic growth, exporting the formula that had worked in the enriched countries where the economic progress had carried the later social well-being, recently it has evolved into a more human aspect of the development once it has been verified that this social well-being was not reached. This is why nowadays we speak about human and sustainable development, which is focused on promoting the growth of the human being in all its aspects: beyond the material well-being a more satisfactory and valuable existence of the human beings has to be considered. At the same time, the growing has to be sustainable in time and not only kept for the period of time that the cooperation lasts, continuing once that the projects of help have finished.

Within this wider context of the concept of development the architectural heritage can play a fundamental role. San Nicolas [6] affirms that the real heritage relies on the system of ideas, on the philosophy that it inspires and supports the objects materiality and the constructions. On the basis of this definition we can assign to the architectural heritage three values: social, scientific and economic. The first one provided that it serves to identify ourselves before third persons as a group. Secondly, it is capable of promoting the knowledge, both cultural and historical. Finally and thanks to the so called cultural tourism, it is capable of generating economic growth. It will be the exercise of these three values what will allow us to generate the desired human and sustainable development by means of the intervention in the architectural heritage.

2. How architectural heritage can be integrated in the projects of cooperation

If in its wider sense heritage is the set of goods inherited from the past, consequently the architectural heritage can be defined as the set of built-up goods, of any nature, to which every society attributes or in which every company recognizes a cultural value. But this is a dynamic definition, since the cultural values are changeable; this implies that the concept itself of architectural heritage is under permanent construction and that the objects that integrate this heritage form an opened set, capable of modification and, especially, of new incorporations.

Traditionally the idea of architectural heritage has been assimilated to the idea of "monument" by his historical and artistic values and, in short, worth being preserved by its usefulness or potential of use. Nowadays the concept has been extended including other properties and buildings till now not considered. As an example we can mention the popular - traditional architecture and the buildings related to handcrafted or even industrial activities in disuse. Also in another aspect, not less important, there is the architectural heritage conceived as a part of the whole, that is to say, the architectural sets which are urban centers of historical character, monumental sets, urban plots, gardens, etc.

Heritage in general and therefore the architectural heritage are in itself a treasure of incalculable value that gives coherence to the idiosyncrasy of the peoples and at the same time it is the reference to the interpretation of the history. This is due to the fact that the heritage concentrates three types of values, as previously said. The first value, the social one, makes heritage useful to identify ourselves before third persons, gives internal cohesion and representation of a group. The second one is a scientific value, for its potential to generate historical and cultural knowledge. The last one of the values, the economic one, is the one that nowadays turns out to be more evident provided that the heritage is

turning into one of the most important engines of the economic local and regional growth by means of the tourism.

These three values given to the architectural heritage are those that need to be exercised to generate development from them. First as an important factor of economic development; it is well known that the strengthening of cultural industries or the heritage conservation by means of the cooperation are elements that can improve the living conditions of a community, even more today thanks to the cultural tourism, a new element that the cultural cooperation has to bear in mind.

Despite this, the economic factors are not, or they shouldn't be, the only ones that the cultural cooperation bears in mind; this might redound to a vision of the architectural heritage exclusively as an end, not as a way. If we recognize the instrumental paper of the culture in the development of the societies, then culture cannot be limited to being a factor of economic progress; it has to be reaffirmed also as form of preservation of values and traditions, access to the knowledge and increasing of the capacity of intervention of the persons in the cultural community life. The question is, definitively, that the intervention in the architectural heritage operates as a factor of empowerment of the recipient society.

We can say that with the intervention in the architectural heritage the objective is to contribute to the improvement of the living conditions of the persons, for which the actions go beyond the mere physical intervention, promoting and facilitating the socio-economic structures for a sustainable utilization of this heritage put in value. This way, the general aim is complemented with the transverse aims to promote the equality between men and women, to respect the environment, to contribute to the democratic governability and to promote the human rights and the respect to the cultural diversity. Therefore the value enhancement of heritage involves cultural, economic and social aspects; that in addition complement each other with the institutional strengthening, the valuation and social appropriation, and the formation.

3. The gender approach in projects of cooperation

As defined by the OXFAM organization in 1997 the word sex refers to the description of the biological difference between women and men. The concept "gender" designates what in every society is assumed to be characteristic of each of the sexes, referring to the social construction of the fact of being woman and man, to the interrelationship between both and the different relations of power / subordination in which these interrelationships appear.

The System Sex - Gender historically has generated a situation that discriminates the women so much in the public sphere since in the private one, in economic, political, social and cultural aspects and that, historically, has located the intervention of the men in the productive area and that of the women, in the reproductive one.

The gender equality supposes the full and universal right of men and women to the possession of the citizenship, so much in the political area as in social and civil. The way of obtaining the gender equality is the so-called gender equity, understood as the justice in the treatment to women and men according to their respective needs. The aim underneath does not mean that women and men have to turn in equal, but their rights, responsibilities and opportunities should not be determined by the biological differences. It is important to clarify that it is not the same differences than inequality. Precisely with the gender equity we are raising the introduction of differential treatments that could help us to correct inequalities, which will allow men and women to enjoy the equality in terms of rights, benefits, obligations and opportunities.

According to the Program of United Nations for the Development (PUND), a series of conditions have to be given to enhance the gender mainstreaming:

- Political Will that turns into an institutional commitment related to the strategy, in which sufficient human and financial resources are destined.
- Not to disregard the specific actions directed women in favor of the aim to obtain the equality of kind.
- To agree and to unify between all the implied actors what, when, since, by whom and for whom of the strategy.
- To elaborate and to spread suitable tools of analysis and planning, as well as to promote the formation and the knowledge around the institutional mechanisms, information and research, which help to identify gender inequalities to be able to advance.

Another term that is necessary to stand out is that empowerment of women, understood as the self-affirmation of the capacities of the women for their participation, in conditions of equality, in the processes of decisions taking and in the access to the power. Through empowerment, women access to the information, knowledge, social networks, financial resources and processes of decision taking.

4. How to measure the contribution of an intervention in architectural heritage in the reduction of feminine poverty

Apart from the objective of a project of cooperation for development, there are some aspects or values that have to be considered to obtain a transformation beyond the purpose of the project. These values, called transverse lines, are three: respect and consolidation of the human rights, governance and reinforcement of the social fabric; promotion of the sustainability; and gender approach.

The planning of our actions has to bear these aspects in mind and, not only this, but also it has to be given as an example. In this sense, the activities developed in the framework of the project, the used methodologies, etc. have to be coherent with these values, whichever is the object of our project, even if it is an intervention in the architectural heritage.

To verify the measure in which our project is contributing to the gender equality, including activities and actions that contemplate this aspect, it will be necessary to establish a system of follow-up and evaluation. According to the Development Cooperation Directorate (DCD-DAC) of the OECD, the evaluation is the systematic and objective appraisal of a project, program or politics in process or concluded, of its design, putting in practice and results, as well as of his relevancy, efficiency, impact and viability for the development. An evaluation will have to provide credible and useful information, which allows incorporating the educations learned in the process of decisions-taking of beneficiaries and donors. The evaluation also refers to the process of determining the value or the significance of an activity, politics or program.

It is therefore, the analysis of the results and effects of a project, during it or once its execution has finished, used in order to learn from the experience. In this sense, it is necessary that the evaluation is seen as a useful tool and not as a load, thinking that it is going to be of great help for us to take decisions as for example:

- To continue or to end the project.
- To improve the procedures.
- To add or to eliminate technologies.
- To establish other projects in similar realities

Given the importance of the evaluation, it shouldn't be confused with other activities or phases of the cycle of the project, to avoid the mistake of thinking that other actions cover already the expectations and aims of the evaluation. It would be easy to think that the follow-up or the audits constitute already an evaluation. But it is not like that, we distinguish in the evaluation other activities such as:

- A research: though similar methodologies are in use, the end is not the same.
- The follow-up: as before mentioned, the evaluation is a punctual action though it can be realized in a constant way along project, whereas the follow-up is a continued action. The aim of the follow-up is, on the one hand, to bring the control of the execution and, of one other hand, to be able to take decisions that allow to re-lead the execution. The evaluation, on the other hand, will be carried out in different stages of the project, not only during the execution, and the aim it is to learn and to be able to take decisions that allow the reorientation of the processes. The evaluation will use the reports of follow-up to analyze and to evaluate the execution.
- An audit: it is centered on the accounts and uses the budget as document
- An opinion: the evaluation is more than an opinion; we could say that it is a well-taken opinion, which is based on an exhaustive and objective work.

Therefore, to measure the contribution of the intervention in heritage to the gender approach, the evaluation has to be realized in every phase of the project, from his identification up to his effects and when time has passed from his conclusion. To evaluate every aspect of the project (from the inputs up to the specific aim, going through its logic of intervention, evolution and formulation) indicators have to be used by his respective check sources.

It is thus how in every phase of the project of cooperation specific indicators will have to be established to assure that the gender approach is contemplated. This way in the phase of analysis the existing situation will be identified with the intention of creating a vision of the desired situation and of selecting the strategies that will be applied to obtain it [7]. It will turn out indispensable to contemplate the current situation of women, their specific problematic and the wanted situation for this group with the purpose to give response to their needs and interests. Then it will turn out indispensable to establish exclusive meetings with the women of the community in order that they could explain their problems without the submission of the males who in general should recover the organizational tasks and of control in the settlements. Also it will be vital for the success of the program to identify women's associations of local area that they could collaborate with the project and use as link of union with the feminine population

In the phase of design, when the idea of the project constructed in the previous stage takes shape and turns into a plan orientated to his execution, the information obtained in the previous phase regarding the situation and expectations of the women there will have to be contemplated particularly. Taking into consideration the necessary and sufficient conditions to obtain the aims (what we name a vertical logic), we will have to decide what we try to obtain, the hypotheses and important interests that could escape to the project and to be capital for the success of the project regarding the gender approach. As we will see later, this will be the most important part for the success of the project and thus for the achievement of the aims regarding gender. Then, it turns out indispensable not only to identify the effects of the project to be measured, but also the necessary resources identifying the indicators and the pertinent check sources.

It will be in the phase of programming where the activities to realize to reach the aims raised in the project of cooperation will be identified, to plan them in time and to assign them budget. It will turn out therefore necessary to design, to plan and budget activities to guarantee the success of the project regarding gender. These will have to be based on two aspects, in one hand in increasing sensitivity of the masculine population regarding equality and on the other hand the strengthening or empowerment of the women in favor of his rights, benefits, obligations and opportunities.

As previously said, the most important phase in the evaluation of a project of cooperation will be the measure of its effects in the way that much in short than in the long term. A project formulated in a correct way won't be useful if it does not generate a measurable change in the society, which has been called "wanted situation". To be able to measure these changes or to evaluate the results of the project, indicators must be established that allow us to measure periodically the changes provoked as an effect of the project.

From the works developed by Revert and Carrascosa [8] with the purpose of measuring the contribution of an intervention in the architectural heritage to reduce the inequalities that take place in the so called feminizing of the poverty, we can establish the following indicators:

- To measure the number of activities generated around the patrimonial rehabilitated good that promote the values gender equality
- To measure the number of women who are employed at activities linked to the rehabilitated heritage
- To measure the number of women who direct activities linked to the rehabilitated heritage
- To measure the free time got by women as a consequence of activities generated or services facilitated by the patrimonial rehabilitated good that liberate them of domestic work
- To measure the career and/or professional training received by women in activities realized around the rehabilitated heritage

5. Conclusions

Facing the problem of the poverty and the urgency of action in certain regions (epidemics, hunger, wars ...), it might be understood that to deal with the architectural heritage in projects of cooperation is slightly opportune. It is necessary to emphasize that we're not speaking of putting the heritage as the subject of the cooperation for development, but, on the contrary, that heritage has to turn into the resource that will have the purpose to contribute to the human and sustainable development.

Facing the problem of the feminization of the poverty, it is evident that any project of cooperation must contemplate the gender approach. If the rehabilitation of heritage is the strategy to obtain the aim of the project, how can we know if this intervention is promoting the equality of women and men? It turns out indispensable therefore to establish a tool capable of measuring the contribution of an intervention in the architectural heritage in the gender equality. Not only to demonstrate the attainment of the aims of the project, but even more to notice in front of other options or types of interventions, the viability of the rehabilitation of the heritage and his relevancy to generate development and to reduce the inequalities between women and men.

This is the reason why with the present paper the need to define a list of indicators that relate heritage, development and equality is emphasized. These indicators will allow to demonstrate the repercussion and the dimension of the valorization of the architectural heritage and the potential of management as a generator of development and equality in the communities of the impoverished countries.

Route 66: analysis of a famed cultural corridor in the United States and implications for heritage tourism

David Listokin

Center for Urban Policy Research, Edward J. Bloustein School of Planning & Public Policy, Rutgers University, New Brunswick, USA
listokin@rci.rutgers.edu

Abstract

The highway Route 66 in the United States is an extremely rich and diverse historic and cultural corridor that attracts significant tourism, including many international travelers. This paper summarizes a study by Rutgers University that analyzed the so called “Mother Road” with a focus on its historic preservation, economic landscape, and heritage tourism. Highlights of the study include: mapping of the Route 66 corridor utilizing Geographic Information Systems (GIS) and using the GIS resource to develop the first-ever census-based profile of who lives along the Mother Road; completion of the first-ever national survey of travelers along Route 66; and analysis of the economic contribution of Route 66. The overall study points to the benefits of heritage tourism (e.g., the “branding” of sites and considerable traveler spending) as well as the challenges of such tourism (e.g., over-commercialism and adverse effects to historic sites).

Keywords: preservation, heritage tourism, economic impact

1. Introduction, History, and Study Framework

Running about 2,400 miles from Chicago, Illinois, to Santa Monica, California (see Figure 1), Route 66 is an American and international icon, myth, carnival, and pilgrimage. Gestated in the booming 1920s, and completed in 1937, during the 1960s and 1970s, Route 66 became less important for highway travel as people flocked to the more efficient ribbons of concrete of the multi-lane interstate highway system which was begun in 1956. The final section of Route 66 was bypassed in 1985.

But transportation engineers do not rule the heart and the siren call of the Mother Road and its special sense of place, personality, and time continues to lure legions of United States and international tourists. To cite just one example, the Route 66 Museum of Clinton, Oklahoma (a community of about 9,000 located approximately 100 miles west of Oklahoma City) attracted about 35,000 visitors in 2009 (almost four times the local population), including about 10,000 international visitors.

The preservation of Route 66 is being abetted by national and state governmental and volunteer associations dedicated to that goal. (See Table 1 for examples of contemporary Route 66 preservation.) Indeed, there is much to preserve and cherish as is evident from the sample of Mother Road sites in Table 2. Despite these efforts to maintain the iconic sites and highway, many preservation challenges still remain as attested to by such actions as the World Monuments Fund (WMF) listing Route 66 on its 2008 World Monument Watch.

This paper summarizes research by Rutgers, The State University of New Jersey [1], which analyzed Route 66 with a focus on its historic preservation, economic landscape, and heritage tourism. The study included such original research as mapping of the Route 66 corridor in GIS form and related census (2000) socio-economic analysis, the completion of the first-ever national survey of travelers along Route 66 (a probe based on 100,000 questionnaires distributed along the highway’s full 2,400

miles with some 4,200 responses), mapping of the Route 66 corridor in GIS form and related census (2000) analysis, survey of 25 Main Street (combined historic preservation and economic development) programs and 33 museums along the Mother Road, completion of 25 in-depth case studies of iconic Route 66 sites (some summarized in Table 2), and implementation of input-output models to quantify the economic contribution of Route 66.

We highlight some of this research below.

2. Who Lives Along The Route? : a reconnaissance GIS-census analysis

While there is much interest in Route 66, the profile of those living along the Route has never been examined – a crucial mission. To quantify this profile, Rutgers University mapped the full 2,400-mile Mother Road in GIS form (the first time this has been done in GIS), and following this, identified the census tracts (1,206 in total) located on or within one mile of Route 66 (termed the “Route 66 Corridor”). Using the most current United States census data available at the time of our analysis (2000), the following are some of the study’s major finding concerning who lives along the Route.

1. About 5.5 million person people live within 1 mile of Route 66 (the Route 66 Corridor), about the same number of people who live in the entire states of Arizona or Minnesota.
2. Compared to the United States as a whole, the Route 66 Corridor has fewer whites (Corridor–68 percent; U.S.–75 percent) and blacks (Corridor–8 percent; U.S.–12 percent) but more American Indians (3 percent versus 1 percent) and “other” and “two races or more” (16 percent versus 8 percent).
3. About a quarter of the people living in the Route 66 Corridor population is Hispanic, identical to the Hispanic representation (25 percent) among the total population of the eight Route 66 states, but is approximately double the Hispanic share (13 percent) of the total United States population as of 2000.
4. There is tremendous demographic diversity within the Route 66 Corridor. For example, about 15 percent of the population in the Route 66 Corridor in Arizona and New Mexico is American Indian (for the entire corridor it is 3 percent), as compared with less than 1 percent in California, Illinois, Kansas, Missouri, and Texas. The New Mexico Route 66 Corridor has the highest percentage of Hispanics (42 percent), followed by California and Texas (both 32 percent), Arizona (25 percent), Illinois (12 percent), and finally Kansas, Missouri and Oklahoma each with less than 10 percent.
5. There are about 2.039 million households in the Route 66 Corridor. Their median income is \$40,760 (close to the national median household income of \$41,994 and similar to the eight Route 66 state household median income of \$40,082).
6. The aggregate income of all the households in the Route 66 Corridor amounts to a significant \$112 billion.
7. There are definite economic challenges confronting the Route 66 Corridor population. About 820,000 persons, slightly more than one-seventh (15 percent) of the population, earned an income under the officially designated poverty level, and almost 200,000 persons, or about 7 percent of the civilian labor force, was unemployed. These poverty and unemployment figures as of 2000 (as is all the data in this section) exceeded the nation’s incidence of poverty (12 percent) and unemployment rate (6 percent) at that time.
8. There are approximately 2.220 million housing units in the Route 66 Corridor. Almost 0.182 million of these (8 percent) are vacant, similar to the vacancy share in both the eight Route 66 states and the entire nation.
9. The above data points to challenges and opportunities for the Mother Road. Challenges include a not-insignificant share of poverty and unemployment, and the difficult task of what to do with almost 200,000 empty housing units. Yet there is much opportunity. The \$112 billion in aggregate household income translates into about \$80 billion of household consumption (e.g., for food, housing, clothing, transportation, and healthcare), and capturing more of those billions on or near the Mother Road would be of great economic benefit. The census analysis

also points to the need to better synthesize celebration of the Mother Road with the history and culture of Hispanics and American Indians, as these two groups comprise not-insignificant shares of the Route 66 Corridor population west of the Mississippi.

The GIS analysis of Route 66 expands our knowledge of this corridor from anecdote to factual profile. It more broadly points to the value of GIS in better understanding a historic and cultural resource.

3. Who Travels Along the Route?: findings from the first comprehensive route 66 traveler survey

Travel is one of the most significant industries in the United States (about \$1.5 trillion nationally and about 8 million jobs). In turn, heritage and cultural tourism is an important and growing component of the total travel industry (at least 20% of total U.S. person trip volume). Thus, it is instructive to examine travelers to Route 66.

In collaboration with the *Route 66 Pulse* (a free periodical newspaper distributed along the 2,400 miles of the Mother Road) and a panel of Route 66 experts in both the public and private sectors, Rutgers has conducted the most extensive survey to date of travelers on Route 66.

Approximately 100,000 surveys were distributed along the entire road (inserted into two issues of the *Route 66 Pulse* and also made available in “kiosks” at 33 popular Mother Road-associated travel destinations suggested by an expert panel) between June 2009 and June 2010 (to cover year round travel behavior). A total of 4,178 surveys were returned.

The four-page intercept survey contained a total of about 30 questions concerning the travelers’ residence and socioeconomic profile, trip expenditure characteristics, and traveler perspectives on Route 66 (e.g. attractions and challenges). The following reports some key survey findings.

3.1 Route 66 Traveler Origins

Route 66 draws visitors from a broad geography and the 4,178 interviews included travelers from all 50 U.S. states and about 40 foreign countries. About 84.7 percent of the 4,160 respondents (with respondent residence data) indicated a current U.S. residence, while 15.3 percent came from abroad. Not surprisingly among the U.S. travelers, residents of the eight states through which the Mother Road passes were heavily represented (i.e. 6 of 10) in the survey. Of the international responses, the most were European and Canadian in origin. (Recall: the questionnaire was English-only, so this may have affected the above-cited international origins.) Of the European-based respondents, the largest number came from the United Kingdom, Germany, the Netherlands and Italy.

We acknowledge again that the English-only questionnaire may have deterred participation by international travelers. In fact, log book entries (visitors voluntarily signing a log book on entering a site or museum and indicating their place of origin) from well-known Route 66 sites often indicate a high share of international visitors, such as 30% at the Ariston Café in Illinois, 33% in the Route 66 museum in Oklahoma and 56% at the Round Barn in Oklahoma.

3.2 Route 66 Traveler Profile

From the survey response, the socioeconomic profile of the Route 66 traveler is:

1. Overwhelmingly (97 percent) white in race.
2. Overwhelmingly (97 percent) *not* Hispanic in ethnicity (recall however, the English-only version of the survey).
3. Overwhelmingly middle-age (median of about 55 years) with a prominent senior contingent (46 percent were 60 years or older) and a younger cohort as well (about one-ninth were 20 to 39 years of age).
4. Typically well educated (about 30 percent have started or finished undergraduate college and an approximately equal share have started/completed graduate work), with some exceptions (about one-eighth have either just attended or graduated high school).

5. Employed in many occupations (about one-fifth are in service, sales, transportation and maintenance), though the most popular occupation category by far (36 percent) is management and professional (the latter management/professional finding comports with the typically more advanced educational attainment noted earlier). Of note is that about four-tenths of the Route 66 travelers are retired.
6. Generally of middle-income (median household income of about \$62,500), though there is a considerable range in household earnings (about 8 percent earn \$25,000 or less annually, while almost one-quarter earn \$100,000 or more per year).
7. Compared to the persons living in the Route 66 Corridor (derived from the 2000 Census and described earlier), the Route 66 traveler (derived from our survey), is: far more likely to be white in race; has a much lower share of Hispanic ethnicity; has more years of schooling; is far more likely to be either retired, or if employed, is working as a professional or manager; and is more affluent from an income standpoint.
8. Comparing the Route 66 traveler to heritage and cultural travelers more broadly (the latter information derived from the Travel Industry Association of America and Rutgers research on other studies) shows many similarities. For instance, both groups are decidedly middle-aged, are well educated, are relatively affluent and are disproportionately either retired or work in professional/managerial occupations.

3.3 Route 66 Trip Characteristics, Traveler Perspectives and Trip Expenditures

1. The bulk of the respondents, 77.5 percent, indicated vacation or leisure to be one of the purposes of their Route 66 trip; 21.0 percent indicated they would visit friends or relatives; while others cited "other" or a combination of objectives.
2. The respondents included both those for whom travel along Route 66 was the primary objective (38.6 percent) as well as those (47.7 percent) viewing Route 66 as one of several objectives or (13.7 percent) as not a guiding objective at all (the latter, an "accidental" Route 66 traveler).
3. The most important Route 66 characteristics cited by the respondents were "historic sites/monuments"; "notable places/landmarks"; and "landscape." Rated just below these three traits, but still important were: "small towns"; "U.S. history"; "National Parks"; "vintage restaurants and motels"; "Gateway to the West"; "car/motorcycle cruising"; and "navigating highways." The least significant characteristics were "bars/nightclubs" and "entertainment/amusement." Not surprisingly given the above, about six-tenths of the respondents had also visited other destinations noted for "Americana."
4. About nine-tenths of respondents indicated a least some data in at least one of eleven questionnaire-specified spending categories (lodging/camping, eating and drinking establishments, other food/snack/beverage, airfare, auto and RV rental, auto repair, other transport, gasoline and oil, admission to museums, other admissions and all other).
5. The spending per trip (Route 66 portion) for all purposes is in the range of \$1,500 to \$2,000. Of that sum, the largest expenses are for lodging, eating/drinking and direct travel-related trip outlays (for airfare, auto/RV rental and gasoline and oil).
6. What is the total spending of all Route 66 travelers, not just the outlays of the respondents to the Rutgers survey? *That educated estimate is conservatively (a lower rather than higher estimate) \$38 million per year.*

4. Economic Findings Viewed From Macro and Micro Perspectives

It is instructive to view economic impact findings from both a broad or macro "lens" as well as a more narrowly focused "micro" lens. Input-output (I-O) analysis personifies a macro lens because it can translate spending in a given place to a broader economic consequence, including multiplier or ripple effects, at a more encompassing geography (e.g., to the extra-local state and national levels).

The Rutgers study specifies the total economic effects of Route 66-related spending through a state-of-the-art I-O model developed by Rutgers University, termed the Preservation Economic Impact Model (PEIM), and it quantifies the following from the Route 66-related spending:

1. **Jobs:** employment, both part- and full-time, by place of work, estimated using the typical job characteristics of each industry;
2. **Income:** “earned” or labor income, specifically wages, salaries, and proprietors’ income;
3. **Wealth:** value added—the subnational equivalent of gross domestic product (GDP);
4. **Output:** the value of shipments, which is reported in the Economic Census;
5. **Taxes:** federal, state, and local tax revenues generated by the activity; and
6. **In-State Wealth:** wealth less federal taxes.

This study applies the PEIM to the different components of Route 66 spending. *Annual* direct economic effects from Route 66 spending include, at a minimum, \$38 million in tourism spending, \$67 million in Main Street (local efforts to combine historic preservation and downtown economic development) spending, and \$27 million in Route 66-connected museum spending—for a total of \$132 million. Further, the one cumulative long-term Route 66 spending program that was examined by Rutgers, the Main Street-related activity occurring in Route 66-located communities, had produced \$923 million in direct economic effects (adjusted for inflation) over the life of the Main Street initiative.

The results in the Summary of Economic Activity and Benefits on Route 66 show that the *Mother Road nurtures the economic pocket book of jobs, income, and wealth as well as the heart!* When multiplier effects are taken into account from the \$132 million annual Route 66 investment, the total annual impacts to the *nation* (United States) include a net economic gain of 2,401 jobs, \$90 million in income, \$262 million in overall output, \$127 million in Gross Domestic Product (GDP), and \$37 million in tax revenues.

Meanwhile, with regard to the \$923 million in cumulative effects from the aggregate Main Street investment on Route 66, that investment contributed 15,606 jobs to the *national* economy, as well as \$1.817 billion in industrial output, \$908 million in gross domestic product, \$687 million in earned income, and \$276 million in taxes.

While the I-O model-indicated economic effects are not very large compared to the huge overall United States economy, the Route 66 economic contribution is *relatively and contextually* very important. Compared to new construction and such stimulus favorites as investing in highways, *historic preservation—such as historic rehabilitation of Route 66 properties—is a reasonably comparable, if not superior, economic pump-primer.*

Another consideration of what comprises a “good investment” is the relative comparison of historic preservation investment versus investment in such sectors of the economy as manufacturing, data processing and finance. On this basis, historic preservation, such as that occurring on Route 66, typically has economic advantages. *Preservation generally has more economic stimulus “bang for the buck”* (in this case, per \$1 million of investment), especially concerning job creation.

Turning from a macro lens view of the economic significance of Route 66 spending as personified by the input-output results described above, to a micro lens perspective, what does Route 66 spending mean in the immediate community in which it takes place? *It is on this contextual local level that Route 66 economic activities have their greatest impact. As documented time and time again in the 25 case studies conducted by Rutgers (Table 2), in many smaller communities along Route 66, tourism related to the Mother Road is one of the most significant, if not the only “economic game in town.”* The restored Route 66-themed motel, restaurant, and gift shop may not have a high-dollar business volume (especially relative to the much larger regional and state economies), yet they anchor the downtown in many small communities and change the perceived image of a place from a dowager town abandoned by the interstate to a community with a Route 66-linked past and future.

5. The Broader Lessons From Route 66

The analysis employed by Rutgers in analyzing Route 66 (GIS, traveler survey and economic impact models) can and have been used in considering other heritage and cultural resources. More broadly,

to the extent that our investigation more generally speaks to the larger subject of heritage tourism, we infer both exciting possibilities mingled with challenges.

1. The potential visitor draw of heritage travel is powerful. In time after time, the Route 66 sites, often located in challenging locations (e.g., require circuitous drives and do not have direct air access) drew large numbers of travelers and the lion's share of these travelers came from afar (including not a small share of international visitors).
2. Linked to the above observation, is the powerful economic activity and benefit (especially measured contextually) flowing from large influxes of heritage travelers (let alone the place-making enhancement of a community sought out in this fashion).
3. While these observations have a positive spin, there is a challenge of cultural management. The flipside of many visitors is wear and tear on the places visited and the host community. A local "authentic" cultural place bearing the imprint a founder's vision or a donor's largesse may have long term staying issues as these individuals exit the stage. There is also a thin line between fresh authenticity and repetition of a successful model.

Table 2: Sample of Route 66 Iconic Sites

<i>Case Study and Location</i>	<i>Description</i>
Palms Grill Atlanta, IL	History of iconic downtown restaurant (name inspired by the founder's fascination with Los Angeles, California), built in 1934, that was restored with period details in the late 2000s and once again serves as a local café and anchor for the downtown.
Pontiac Murals Pontiac, IL	Including a famous Route 66 shield mural on the back of the Route 66 Museum in Pontiac, this town has embraced a mural program to spur tourism and enhance its economic fortunes. The total of about 20 murals (on individuals/subjects ranging from Abraham Lincoln to a famous local candy store—"Palace of Sweets") attracts about 20,000 annually.
Shea's Gas Station Springfield, IL	A time capsule of an early (oldest portion from the 1920s) local neighborhood filling station (encompassing Marathon and Philips 66 components), with thousands of period-correct oil-company-related memorabilia (signs, pumps, and marketing materials). Facility was operated for decades by proprietor William Shea; he converted it to a family-run museum in 1995.
The Mother Road Festival Springfield, IL	This festival is a three-day event that has been held each September since 2001. With nearly 80,000 visitors and 1,000 classic cars on display, it is one of the biggest car shows in the mid-western United States. The event combines classic car culture, Route 66, and the historic downtown (Springfield) Main Street themes.
Round Barn Arcadia, OK	Built in 1898, collapsed in 1988, a retired carpenter (Luke Robinson), an intrepid "Over the Hill Gang" (senior 60s group) and other local volunteers help restore (in 1992) the most powerful reminder of Arcadia's frontier roots and one of the most recognizable historic sites (an authentic round barn with a 60-foot diameter) in Oklahoma and along Route 66.
Route 66 Museum Clinton, OK	Originally opened in 1968 as the Museum of the Western Trails, this institution reoriented to a focus on Route 66 from 1995 onward. One of the nation's largest (10,000 square feet of exhibit space) museums on the Mother Road, the history of Route 66 is conveyed decade-by-decade (over six decades) starting in the 1920s.
Rock Café Stroud, OK	History of the Rock Café (opened in 1939, incorporating stones excavated from original Route 66 construction), with a focus on operation by its current owner, Dawn Welch. Details rebuilding of restaurant after 2008 fire and current significant national/international visitor patronage.
Conoco Station Shamrock, TX	History of the 1936 architecturally unique (Art Deco 100 foot tower) Conoco gas station (and U-Drop Inn), and its changing fortunes (prospered for decades, closed 1997, and restored/reopened in early 2000s as a museum).
Blue Swallow Motel Tucumcari, NM	History and continued operation of a historic (built 1939) and iconic motor court-style motel with a world-famous blue-lit neon sign. The motel is perhaps the oldest vintage motor court still in operation on Route 66.
Cool Springs Kingman, AZ	History of the Cool Springs Camp (opened 1926), its prosperous early decades and family-run operation, demise (destroyed by fire in 1966 and blown up in a movie shoot in 1991), and recent (mid-2000s) rebirth as a snack and gift shop.
La Posada Hotel Winslow, AZ	Connected to famous personalities (Fred Harvey—the mastermind behind the "Harvey Houses"—and noted architect, Mary Elizabeth Jane Coulter), this historic jewel of a hotel, which opened in 1930, described as the "finest small hostel in the southwest" closed in 1957, but was recently (late 1990s) reopened and brought back to its original splendor.

Abstract

A phenomenon of great interest is the "modern" Pompeii, which was city founded ex novo in the early twentieth century. This phenomenon was driven by social and human motivations related to a territorial plant that has a characteristic vocation of different entities, measurement, communication and historical relationship. Three are the receptive poles that can be abstracted through the versatile richness to capitalize and to put in a network with the territorial system considered in its macro area of interest: The ancient Pompeii, that the archaeological, the religious and the productive Pompeii. Translatable poles into stream axes and paths where one can transcribe a mutation by a process of gathering fragments of history, of paths and of representation of the scenarios derived from the city announced. The city as a structured reality - and the sum of the individual fragments that form itself. This consists of a 'text' which, as a whole, can be written, read and interpreted as a complex system of signs, drawings, and messages all posts inside of a semiotic perspective; or in a more general 'aesthetics of reception and perception', which can be understood as the "reverb messages on social behavior and cultural behavior, on projects and subsequent production to their appearance." Today, as in the historicity, a renewed attention to the relationship that is established between the city and the community of its users, which in turn play the role of privileged recipients of the aesthetic message that the city produces, but also that of the undisputed architects and protagonists of its continue invention.

Keywords: Pompei, modern, signs, complex system.

1. The city of Pompei "urban": historical references

author: Pasquale VAIANO

The city of Pompei "monument", hibernated by the eruption in 79 d.C., and contained in the archeological boundaries, clashes with the city of Pompei "urban", risen around the Sanctuary since 1875 and known all over the world for its devotion to the Madonna del Rosario. The founder of the nineteenth-century city, the lawyer Bartolo Longo, was entirely aware about the enormous responsibility that the new urban structure must had to the ancient centre, an organism devoid of vitality but preserver of the extraordinary artistic, architectural and urban statements. In fact, what today appears like a building fabric devoid of quality, resulting of an expensive guided by property speculation since the end of the Second World War, conceals interesting architectural fragments and urban reasoning. To Longo is attributed the adjective of "urban planner" because of his refined accuracy used for the rational and knowledgeable planning of the new city. The first stone laid was a spiritual stone; the lawyer, husband of the countess De Fusco, worried about the spread of the faith all over the Valle, to prevent the legends linked to Pompei, the city of the ruins, considered as a profane place and as the "land of false Gods". In 1873 Longo organized the first celebration for the Madonna del Rosario and after a while began the magnificent construction, starting from the structural and architectural recycling of the ancient Salvatore's chapel[2].

Fig. 1: Valle di Pompei, topographic map, IGM, cart. 80/cat. 9618, 1906.

Endowed with great entrepreneurial attitude and with the help of the Bishop of Nola, Longo advertised «a competition of a coin per month, to build a catholic temple devoted to God on the land of the false People», that allowed him to raise economic energies indispensable to build the Sanctuary. The cultural model taken as example was Lourdes, the most important religious center in the Europe, after the apparitions of the Virgin Mary in Massabielle's cave. The 8th of May 1876, at 11 am, the works for the construction of the Sanctuary began, a few meters from the north of SS. Salvatore's chapel. The project of the shape of the building was edited by Antonio Cua, professor in the Neapolitan university, while the architect Giovanni Rispoli dealt with the realization of the façade with the atrium and with the "cupola maiolicata a losanghe" using black and white colors[1]. Thanks to this collaboration, arose a perfect harmony between Rispoli and Longo, so that he put the planning of a great part of the buildings destined to the new city, into the hands of the technical, who became the architect of the Valle of Pompei. Longo, in 1891, describing the "rising city" New Pompei, affirmed that the disposition of public and charitable buildings which arose around the Sanctuary wasn't casual but it was respectful of Giovanni Rispoli's parameters of rationality and adornment [4].

The crossroads of the ancient vectors of the traffic direction of the Regia Via delle Calabrie and of the street which link Castellammare to Nola, became the centerpiece of the new settling system, establishing a criteria of orthogonal urban redevelopment, popular in the second half of the nineteenth century.

The primordial nucleus arose in 1884 with the building of the Collettorio Postale, the Scuola Tipografica and the first wooden railroad station. Similarly, the expansion of the built-up area happened through the use of house cell iterated until the assembly of a unique village destined to the workers of the New Pompei. Bartolo Longo's vision, in fact, doesn't seem extempore or utopian; on the contrary his vision appears in agreement to the proposals of the new urban and productive settlements elaborated in that period in other cities. Some documents show the relationships of the lawyer with the industrialist Alessandro Rossi – inventor of the Nuova Schio – who instituted a village connected to the wool factories of his own property, to give an appropriate residence to his workers [5].

Fig. 2: Giovanni Rispoli, perspective view of the workers houses.

The Neapolitan architect Giovanni Rispoli, who knew about the European phenomenon of the workers – village, projected a district of workers – houses, applying well advanced constructive criterions, getting inspiration from the village destined to the workers in Berlino e Vienna.

The allotment of the workers district, measured nearly 1760 square meters, divided in five similar buildings, measured nearly 18x14 meters, to form a chessboard. One of these buildings was in the center of the block, while the other four were at the rectangle's vertexes, so that the perimetral buildings were opened on the public streets while the central building was opened on the spaces external to the houses. In this way, four courtyards were formed. Rispoli projected the neighborhood using a rectangular shape, producing combinations and proportions similar to a square, determinate by a system of parallel and orthogonal axis which established not only the neighborhood's constitution but also the public spaces of the streets and the square. The rectangular shape close to the square of the workers – village, organized as hinge around the free central space of the square, would have defined the square of the last one. At the same way, the geometric shape connotative the individual worker – land would have defined the interior design and, consequently, the external one of the courtyard. The whole worker-village was the expression of a unitary project, which established symbolic and functional connections with the other buildings of the New Pompei.

Due to economic and financial difficulties, in 1888 was realized only one block with its own square instead of the realization of more workers' blocks [3].

The volume's articulation, the geometric purity of the structure, the simplified architectonic language of the facades ease the building's stateliness, harmoniously integrating it to the surrounding landscape.

2. Flux of wealth

author: Rossella BICCO

A new challenge for “modern” Pompei is to redefine a production model of value through the application of new projects, prompts, or models that are effective and sustainable and transform promoters, agents and protagonists, into methods of social innovation, that generate the basis for the creation of wealth and value, not necessarily or exclusively economic.

Today an identity cannot be considered as individual or stand alone, but seen in its macro area. The success of any choice is connected to the support services and to the infrastructure both social and material that surround them as do the interactions of the agents referred to previously. Integrating the point of view of the stakeholder is necessary to the development of an effective strategy, far from the utilitarian approach or of greenwashing techniques.

If the final target of the territorial authority is to create value, the process must be sustainable and long lasting in that they include and satisfy the various stakeholders, that bring functional resources to the long term project. This means that the procedures have to valorize and consolidate the collaboration and insure its sustainability. This is not limited to the sharing of the created value but the creation of the shared value. The theme of shared value was formalized in 2010 by Michael Porter and Mark Kramer, influential researchers of business management, and shown for the first time in the 2011 issue of the Harvard Business Review. The basis of the new concept is that all of the territorial agents have to work to converge the territorial interests to meet those of the individual agents: to create economic value that at the same time creates territorial and social wealth also. A new point of view regards the valorization of the know how available in the territory that has not been exploited. To identify and make available each ones added value, each ones know how, the infrastructure, the management systems using a reticular and multi directional logic: business – university - territory.

Pompei is an international and national centre of excellence included in the UNESCO classification since 1997, its touristic pole generates a flux of tourism that is second only to the capital. The tourist sector is without a doubt the territorial sector with the most potential. At the moment it is hardly exploited and the primary indicator of this is the length of the stay of the visitors of the cathedral and the archeological site. The analysis of the visitor flux and the regeneration of the flux helps us study and understand how to positively channel the cultural process that takes place with the visitors who come thanks to the riches of such a well known territory.

“il viaggiatore, che vuole in poche ore visitare il Santuario, innalzato in onore della Vergine del Rosario su questo pezzo di cielo lanciato in terra, come chiamarono i poeti la zona perivesuviana, si presenti alla stazione di Napoli e chiedi un biglietto di andata e ritorno per Valle di Pompei, che è la stazione che segue immediatamente a quella di Pompei [...] tutta quella grandezza pagana finì. Quella grandezza non oltrepassava la tomba, e nulla sapeva dei futuri destini dell'umana specie. [...] silenzio diciotto volte secolare grava sopra di essi! Non sono passati che cinque minuti, ed il fischio della locomotiva lo scuote e lo avverte che ha lasciato la stazione della Pompei che è morta, e si appressa alla stazione della Pompei che risorge”.

As said by Bartolo Longo in his essay about the dualistic aspect of a religious city, “reborn” with a covered city.

A wider but less articulated analysis of the territory quickly brings to our attention the many agricultural greenhouses in the area, in fact both agriculture and horticulture are strong characteristics of Pompei, especially those of small businesses. Therefore it becomes necessary and indispensable to revitalize and add value to this sector as our target and definite programmed interventions we can re organize and elevate the awareness of the visitors and transform even the proposed production into a unique wealth. Not only a religious tourism or archaeological but a well informed tourist that will be brought to read the city as a part of the whole territory in which it relates.

3. Pompeii between the Future, Tracks, Identification and Legend

“Le città come i sogni sono costruite di desideri e di paure.”

Italo Calvino, “Le città invisibili” 1972

author: Ludovico MASCIA

The “Urban dimension” in its entirety refers to a definition that can be conceived and redesigned as a complex organism of elements and signifiers collocated within a generalized reconfiguration linked to a new and impromptu concept of “aesthetics of reception”. Thus, we try to relate the city as a vector and the community of its users representative of a modular value that is indispensable. (Fig.5) The latter in turn play the role of privileged recipients of the aesthetic, generative, communicative message, that the macro-territorial system of the city structure produces.

Fig. 5: The district of Pompeii. Areas of territorial influence.

The users of this space, in addition to being undisputed architects of this change and inventive reading thanks to the correct practice of receiving, listening, modifying, transmitting and using, propose a new method of observation and translation to the city in a direction that favours communication between the text and reader. The status of the aesthetic restitution is determined by the attitudes of relocation and redefinition of urban spaces, that at the end of the cyclic process are configured as construction actions of the image, which in turn is identificative of the city, not only as a non-active reception of its own becoming.(fig. 6) It is the urban dimension not only as an “object” but conceived as integral skills and reading. Thus, a reading of the “vision of the city”, that contemporary Pompeii now provides the different users of its community is carried out as well as an analysis of the real possibility that this vision has to be configured into an identity. Few places in the world have a such a strong and widespread image as Pompeii, but very few places in the world are suffering, like Pompeii, a well-structured and deep-rooted lack of identity linked to the idea of the city. Crushed between the evocative power of the myth of antiquity and the irrepressible strength of the spiritual “Marian pilgrimage”, the city struggles to compete with its “own” identity. There is a feeling that it is difficult to define one.

Fig.8:The district of Pompeii. Relations with the graphic visual coast marine.

Luncy, there is a definition of “representability of places” that is the “quality that gives a physical object a high probability of evoking a vigorous image in every observer”. Looking at the city of Pompeii from this particular point of view, it is possible to draw some other consideration useful in identifying possible visual design strategies. Pompeii is characterized by a large number of highly connotative “signs” that give it, apparently, from a physical-environmental and symbolic point of view, a heightened visibility and recognition: the profile of Vesuvius upon which the ruins of the archaeological site stand; the “limits” (ancient, but also recent) that define the “physical break” of the excavation area from the rest of the urban fabric; the bell tower of the shrine, which is a key visual reference not only for the city but for all the neighboring towns; the rhythmic sound of the call to prayer that fills the space itself and marks the time so surreally, especially when seen in relation to the adjacent and promiscuous commerce of sacred and profane images that characterizes the High Street of the city and that among souvenirs, the greenhouses that occupy a considerable area of the town and that accompany it, clearly characterizing the path of those visual approaches to the city by highway or railway, ... powerful signs, if read in their individuality and when analyzed by point of view of their “meaning” and their “identity”. (Fig. 8) However, for the purposes of the definition of “figuration” of the urban image, reading them from a “structural” point of view is less convincing and that from that particular point of view that investigates the ability of individual signs to be shown in the “system” and therefore able to trigger spatial relationships to establish a strong and clear reference to visual and emotional orientation to the users. Proposing several research ideas and project, aimed at the analysis of the perception that the city itself and the construction of possible narrative paths that can promote a reading in an alternative way to the strong bond that binds Pompeii to its stereotype, knowing how to reach the elaboration of project proposals that, in terms of communication strategies, projects, visual identity, experimentation with new languages and detection of unusual scenarios, propose measures that can aim with a new aspect, the potential notes as well as more unusual ones highlighted by trails in the sense previously identified. An exercise of transcription within a new universe of meaning that the city has in terms of image and imagery and all that the imagination of the new scenarios is able to “set up” to help overcome the clichés of Pompeii that characterize the collective judgment, but also to return to the city to itself, giving a sense to areas of neglect, guilty of careless neglect or deterioration. (Fig. 9) The intent is to think of new communication plans, visual identity plans that try to represent the idea of multiplicity and the presence of distinct aspects of identity and the different elements of interest.

Fig. 9:The district of Pompeii. Historicized view of the relatively subdivision in areas of compensation.

The identity of the territory is in some way identified with the architectural and environmental heritage and the whole geographical area is enclosed, as if in a kind of “visual synecdoche”, in some of its qualifying, exciting, evocative elements. It is believed in the contribution of spatial analysis to return to such a layered city logotypical identification, semantic attitude, wanting to leverage the communication of abstract values linked to the idea of “effusive” liveliness and power, a cultural and natural heritage that does not want to only be secure, but that purports to spread and expand as a shared value, vital and creative potential for the entire territory.

ARCHIPELAGO CITY: AN INHABITED DESERT?

Silvana SEGAPELI

Researcher, GERPHAU Laboratoire Philosophie Architecture Urbain, Ecole Nationale Supérieure d'architecture de Paris La Villette, Paris, France

Mail address: silvana.segapeli@st-etienne.archi.fr

Abstract

How to determine the identity of an archipelago city? Before the existence of the atlas there were 'isolari' (insulaires) where the entire planet seemed like a collection of fragments of sizes and shapes as varied as possible.

In contemporary times, the transition from a fabric of blocks to a more jumbled "urban substance", which variously compacted composes and breaks down above all the margins of the city into fragments and pieces of land, marks in today's settlement framework of the periphery the loss of threads, rules and orders and opens the peri-urban territory up to new configurations.

As a counterpoint, the absence of real city systems and interconnected community spaces in these archipelagos make an urgent need for a new paradigm of investigation, which may make up for the separation between territory and built environment.

The purpose of this study is to advance understanding on the management of this "geography of the indescribable", in Boeri's lexicon, namely that entire part of the metropolis that needs to be represented according to new spatial orders. Although many are calling for a new charter for the contemporary metropolis and the centre-periphery dichotomy is considered an obsolete way of observing urban phenomena, the real dialogue between historical city and periphery, the former dense, homogenous and continuous, afflicted by excess, accumulation and a glut of signs and meanings and the latter torn and disconnected, without history and identity, is still an open issue.

A case study on french *tissu pavillonnaire* (in the city of Saint-Chamond) will provide a more deep comprehension of the archipelago city phenomenon.

Keywords: Public space, suburb, sprawl, close reading, wake density

1. From Urban Dissolution to Human Desert

How to determine the identity of an archipelago city? Before the existence of the atlas there were 'isolari' (insulaires) where the entire planet seemed like a collection of fragments of sizes and shapes as varied as possible.

In contemporary times, the transition from a fabric of blocks to a more jumbled "urban substance", which variously compacted composes and breaks down above all the margins of the city into fragments and pieces of land, marks in today's settlement framework of the periphery the loss of threads, rules and orders and opens the peri-urban territory up to new configurations.

The break up of the city, a pre-eminent theme in studies on the quality of the contemporary urban fabric, goes hand in hand with this reflection on an extremely widespread housing *milieu* in the West. *Pavillonnaire* in French, residential suburb in English, this term designates a settlement framework that is structured on an elementary housing cell, the *pavillon* or detached house, a monad incorporated in the fairly regular weave of a parcelling-out of the land, indifferent to the surrounding connective urban tissue. Fencing, separating walls, gates, barriers and high hedge rows are the spatial correlatives of this housing principle based on seclusion.

The reduction in the quality and quantity of human exchanges, along with the spread of the molecular enclave, has altered the meaning of the urban space and reduced the reasons to walk among it, to frequent it and to use it.

The desert as an image of a sterile and monochrome reality, associated in the title of this study to the notion of city archipelago, represents the critical point of the living dimension of this kind of *milieu*, connoted by a meagre human presence (in the streets as well as in the contact spaces) and a lack of activities.

It is the loss of sociality as the primary axis of urbanity that this metaphor seeks to convey. The very idea of desert is drawn on here to define the impossibility or too powerful inertia for transformation, in the sense of dissipating the possibilities of transforming structures grounded in the repetition of typological motifs and the introversion of spatial motifs.

"There is deep-seated and invisible *anticity*, which does not challenge the cities we live in, but rather erodes them from within. Without making grand gestures, moving pervasively within the mechanisms of reproduction of contemporary urban space; it undoes the connections, wears down the nodes, compromises its very working. The *anticity* that is most worrying today does not arise from marginalisation and revolt, but from the fragmentation and dissipation of the vital energies flowing through every ambient of city life. It is not born out of the extreme exacerbation of community living conditions, but from the triumph of mediocrity and banal repetition in the space of a few housing models: the one-family home in the centre of a lot, the warehouse, the terraced house, the apartment block, the shopping centre. A sequence of solitary and grouped buildings without any clear logic, without any relationship of need." [1]

Stefano Boeri, taking up once again the theme of the scattered city in *Anticittà* [2], incisively represents the attributes of a city system that evolves by fragmenting itself. In his urban allegory, the malaise of a "liquid society"[3] (Bauman 2000) is expressed in the stigma of an epidemic that corrupts the systems of connections from within and alters the urban synapses.

Fig. 1: Dan Graham, "Row Houses" 1966

1.2 After Sprawl. Public spaces in liquid cities

As in Dan Graham's famous images on the uniformity of American suburbs [4], the solitude of the buildings described here bears the watermark of the unsolved dilemma of a lack of spaces of relation as the connoting feature of the city-archipelago. If the public square and the block can no longer perform the role of matrixes in the city space, then the absence of an articulation of open spaces and

of contact, in their capacity as public places, is the glaring manifestation of a further mechanism of social disintegration.

The idea of a ground project [5] (Vigano 2010) as the place and occasion for mediating between the players in the decision making process of *vivre ensemble* can also be seen as an action of building a sagacious juxtaposition of different systems of use and multiple spatial practices.

The role of community spaces, in reformulating a collective dimension of housing, would be determining in renewing the housing fabric, as is recognised by studies on the sociology of visual communication[6]. It has long been shown how both the human and city landscape are interdependent, and just how strong are the repercussions of socio-cultural transformations in urban planning.

If already in the 1950s Siegfried Giedion highlighted the need to humanise the new city settlements, those based on repeating the prototype of the “family cell”, a re-education towards collective life then seems even more necessary today.

In a passage of his *Architecture et vie collective*, Giedion illustrates the rift between thought and sensibility as the hallmark of the planning culture of the age “(...) *le droit à l'éducation de la vie émotionnelle des masses n'existe pas, ou bien il est considéré comme accessoire et abandonné aux spéculateurs et aux agitateurs sous prétexte qu'il s'agit là de propagande politique.*” [7] The right to an education of emotional and sentimental life corresponds to a need for cultural and social emancipation. An urban project that does not address its actions towards the community involved in the transformations, more so than towards the transformations themselves, is unthinkable. The link with the land, according to Augustin Berque, takes place through the oikumene. The oikumene is the true human dwelling.

In Paolo Amaldi's perspective, it is in the deviation between designed project, namely planned, and lived space, that the unease of our age is established: “(...) *cette opposition entre espace vécu et espace dessiné est aussi une façon de nommer et de pointer du doigt les instruments modernes de planification qui se sont largement développés dans l'après-guerre, lesquels tendent à gérer et organiser le territoire en plan, en neutralisant la dimension temporelle et le vécu quotidien.*” [8]

2 Exploring the archipelago/ Traversing the frontiers. A case study

Situated on the metropolitan axis connecting Lyon to Saint-Etienne, the city of Saint-Chamond is a polycentric conurbation of about 35.000 inhabitants. Over the last few decades, it has suffered the consequences of a general break-up of the city model based on the establishment of industrial zones on the city margins.

Saint-Chamond is a city *"en attente"* awaiting reconversion, environmental clean-up and renewal. Its urban fabric, bearing the traces of a recent industrial past, opens out in *"friches"* or brownlands that are frayed along diverging lines as far as the Pilat regional natural park. Almost a century ago, Frank Lloyd Wright in his *"The Disappearing City"* talked of the forces tearing the city apart in terms of emancipating energies. *"The lovers of space"* could start off again, in this urbanity hallmarked by the interpolation of the tropes of the city with those of the country, precisely with these *"(...)"* forces exercising pressure on the city."^[9]

The multitude of frontiers opening up like fault lines between the city archipelago that have become so widespread in the last century throughout the southern part of the city and the large territorial systems made up by the vast Pilat regional natural park, by the disused industrial zones on the Gier river and by the rail network, amplify the natural friction between resistant and ephemeral structures, between strong and weak appurtenance.

Today on these fringes, together with the system of broad scars of disuse, there is an archipelago of *"family capsules"*, detached villas, marked by sporadic connecting points between urban life and nature. This molecular system has introverted the idea of open habitable space and established a lifestyle based on estrangement with respect to the collective city space and on individual movement by car.

The individualist model of *"maison en milieu d'ilot"* (house in the middle of the lot) seems little sustainable today; architects, researchers and town planners are all hastening to redefine the settlement rules of this urban fabric urged on by the twofold need of physically and visually reconnecting up with the large natural park and intensifying, albeit ineffectually, the density of the lots.

The challenge begun by the municipality to reinforce the settlement framework with a weak densification, through the directives of the latest PLU ^[10] (2013) and adoption of a BIMBY (*build in my backyard*) program ^[11], encounters a series of dilemmas acting on different scales. These range from the difficulty of guaranteeing a landscape coherence to the disordered periurban archipelago, to the dialogue to be restored with the traces of the past, from the torn mesh of detached housing that has become denser on the ridges or along roadways, to the large *maisons de maître* (mansions/country

house) with their big abandoned gardens and endless enclosure walls, today largely perceived as “*un devoir de mémoire*” (duty of remembrance).

What kind of intervention might favour a process of regeneration of urban fabric? What are the devices to implement and to promote a process of sustainable densification? To favour the tactics of adaptation rather than the huge overblown strategic plans, to support and stimulate processes of self-organization and self-regulation, to consider public space as the device to reactivate spatial practices, at the same time redefining the notion of ‘residential area’ – all these could be the lines of an eco-sustainable procedure.

In the periurban archipelago without any order or hierarchy, the idea of public space deserves reworking; in other words, a different positioning in the framework of urban devices that preside over transformations. The public space as an open, relational configuration, encouraging the activation of networks and exchanges, as a vehicle for flexibility, evolutionary adaptation, active metamorphosis, would seem to be the most coherent answer in this scenario.

There are many examples in the contemporary planning panorama. The concept of Deep Planning by Vab Berkel & Bos is an eminent departure point for planning theories based on adaptability to the environment and self-organisation. The principle they postulated of ‘continuous difference’ opens up the world of architecture to the concept of mutation following self-regulating processes. While James Wines is once again proposing the ecological paradigm of the 90s, formulating an interpretation of architecture as a system of ‘passages’, MVRDV through their projects (as Data Town, Private KM3-3D, etc.) are putting forward an idea of the city based on a new alliance (that of Ilya Prigogine) between nature and technology, according to principles of self-sustaining architecture. Flexibility, lightness, mobility, ecosystem is their paradigm.

2.2 The living suburbs: how to represent the transformation

\\ Atelier S7/D1 « *Dynamiques architecturales et urbaines* » 2013/2014

“*Le projet de l’espace public comme enjeux d’une densification douce*”

Ecole Nationale Supérieure d’Architecture de Saint-Etienne. Directrice de l’atelier: Silvana Segapeli Partenaires associés à l’atelier: Arnaud Carré, DDT-Loire, Cédric Boussuge, CEREMA Centre-Est

“We do not have to be afraid of the change, but rather try to understand its principle: the imagination produces the present, and mutually, the present product the imagination. As we shall see it, the change shows itself by the interaction repeated by the imagination and the present.” *Moo Do Chul Hahk*, Hwang Kee

This Laboratory, in partnership with local actors *Direction départementale des territoires/DDT-Loire* (sustainable territorial development) and *Centre d’études et d’expertise sur les risques, l’environnement, la mobilité et l’aménagement/CEREMA-Direction Territoriale Centre-Est* (The Centre of Technical Studies and Equipment), has enabled students in the workshop on architectonic and city design of the Master “*Materialités Contemporaines, Art, Paysage*”, to (re)interpret the notion of urban plan and (re)define interdependent connections between public space and architecture, urban fabric and nature.

The planning process workshop began with a phase of exploring the territory, called “*Pratiques exploratoires de l’espace*”. Understanding the terms *transurbanza* [12], (walking/knowning), *erranza* (city roaming), walkabout, drift, city walk, has led to defining a set of protocols to observe the city archipelago and has formed the basis of a collective and cooperative work. The sensitive reading of this *milieu* presented the challenge of a subjective, emotional representation of the real situation. Cartography as a system of visibility, one of the possible systems, somewhere between icon and diagram, was the theme leading to a work of accumulating material, of comparing different viewpoints, of different receptive regimens. Reading the human landscape in order to represent both the visible as much as the indecipherable, the latency as much as the transformation, has steered the entire first series of reflections.

In his long artistic career, Bill Viola has cut a very precise groove in the field of representing transformation. His videos delicately reveal the mystery of time as an accumulation of passages, in which there is a mutation, an evolutionary condition in each precise moment. In the desert of Chott-el-Djerid, with an extremely sensitive 800 millimetre telephoto lens, the transformations of a drop of water depict a desert of multiple colours as never seen before.

Breaking with the dictatorship of the zenith-view paradigm of the system of interpreting the city, closing up the distance between object and observer and starting off again from the body as the foundation of both reception and understanding, appeared from the start as the main criteria of the sensitive approach.

Fig. 2: Saint-Chamond and the Natural Parc of Pilat (image: Silvana Segapeli)

The walk as aesthetic practice is a way of rediscovering the role of the body in the space, from one *milieu* to another. A reading of the unstable spaces through the series of traces, evocative signs and invisible thresholds has allowed identifying ‘ambiances’ of a different matrix.

Learning to observe, to listen to sensations and emotions, integrate individual codes with the shared codes of representation, to be aware of the statute of the observer as an individual but also part of the observed surroundings, extend the perceptive process by multiplying the observation points and extracting the object from the automatism of perception (Shklovsky 1917) these are, in brief, the motives leading to the compiling of sensitive living maps.

BIMBY (Build In My Back yard) : shifting to an alternative approach of urban sprawl, is a project supported by French National Research Agency, headed by David Miet (CETE Paris Region) and Benoit Le Foll (CETE of Normandy and Center Regions). Challenge : Single-family homes to gain ground while curbing urban sprawl

It would appear that the urban sprawl phenomenon has come up short on both the city planning and political fronts. Suburban area development has often been considered the root of all evil, conjuring up increased grid and energy spending, considerable, commute- driven pollution, and damage to biodiversity and farmland. Unable to resist the phenomenon pandemic any longer, France seems to have joined the movement : Out of 34 million housing properties, over half (19 million) are single-family residences, and 160,000 pop up each year. What will it take to change how we view this growing trend that has taken root over the past few decades, and put a positive spin back on this type of construction, which continues to rank among those preferred in over 80% of French households ? Such is the goal set forth by research-action program Build In My Back Yard (BIMBY).

Abstract

This paper presents a first technical-scientific step on the multitemporary airborne surveying activities (2012-2013) for the discretization of the cannabis' cultivation in natural, off and inaccessible environment. These activities were conducted by a university-military team of the Department of Architecture and Industrial Design "L. Vanvitelli" of the Second University of Naples (SUN) and of Gruppo Esplorazione Aeromarittima (GEA-GdIF) of Guardia di Finanza. After verifying the scientific procedures planned, and experiencing the technical and operational protocol at the air task in Albanian territory (2012), the attention has been given to multi-temporal reading, and the intersection of the data acquired - through the platform sensors, specially configured - and stored in a geodatabase. The integrated interpretation of the data produced a territory's theming, based on the previous experience, the subsequent oriented planning of flights - also with a view to also with a view to resource optimization - and based on the discretization of tree species in relation to geomorphological data in support of the signature spectral.

During the last airborne surveying activity (2013) in Albanian territory, it was also used a high resolution photographic camera added visible information to spectral information (scientific type). The visible information are especially useful for communicating the procedures and the results achieved to the institutional bodies of the Republic of Albania.

The comparative results of the two years of remote sensing led to a greater awareness and understanding of the specific nature of the Albanian territory, and of the techniques and temporal processes of cannabis' cultivation, so to highlight a series of items for study and ex-ante control the phenomenon's evolution.

Keywords: Airborne Remote Sensing, Hyperspectral survey, Thermal survey, GIS, multitemporary analysis.

1. Research methodology (Carmine Gambardella)

The research originated from the fact that any action aimed at the defence and development of natural and man-made environments cannot be separated from an activity of multi-dimensional knowledge-based discretization of the traces that characterize the Territory, understood as heterogeneous "signs" of anthropogenic modification and multiform vegetation presence.

The multi-sensor airborne survey in national and international territory interested synergistically researchers and professors of the Department of Architecture and Industrial Design "L. Vanvitelli" of the Second University of Naples, and the Officers and NCOs of the Aeromarittima Exploration Group (GEA) of Naval Air Operational Command of the Guardia di Finanza. In particular, this operative-scientific partnership has been validated with the Convention for remote sensing activities by airborne

sensors between the Headquarter of the Guardia di Finanza and the Centro Regionale di Competenza BENECON S.C.aR.L., signed on March 21, 2011 and extended on February 25, 2014 .

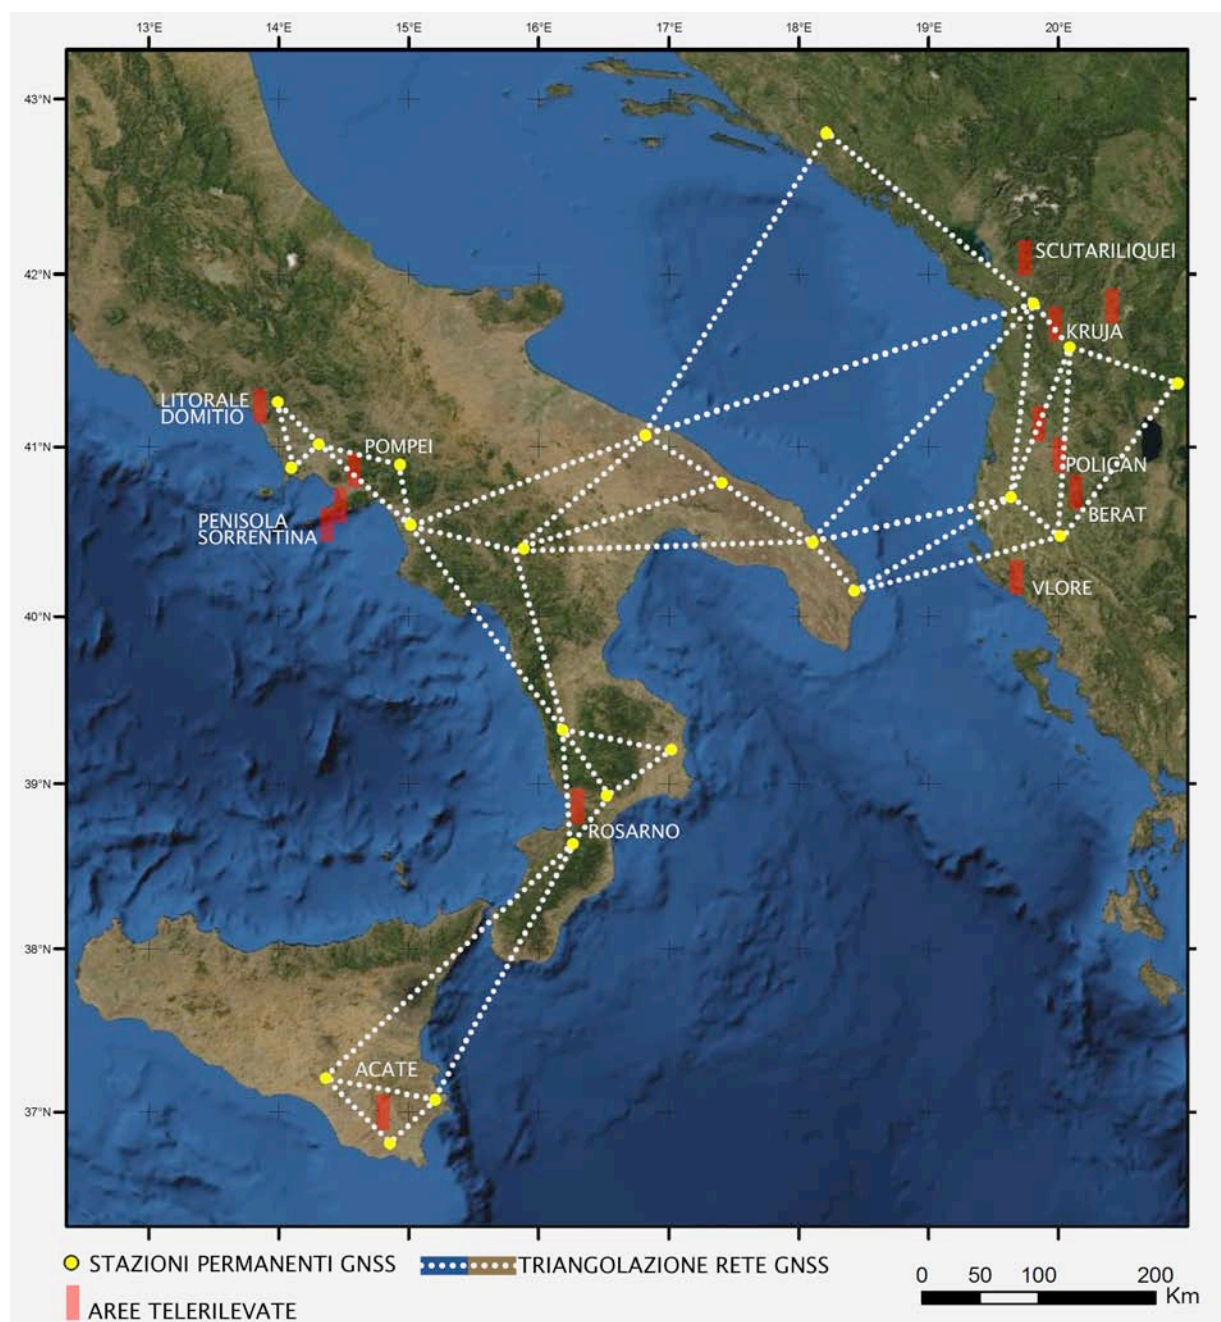

Fig. 1: The multi-sensor airborne survey in national and international territory.

The aerial exploration in Albanian territory, which is the object of these notes, began in June of 2012 as part of "Operating Protocol between The Public Security Department of the Italian Home Office and the Central Department of the National Police of Albania", signed on May 16, 2012 in the city of Tirana. The mission of airborne remote sensing on the Balkan territory continued in June 2013, following the renewal of the Operational Protocol and is currently in progress.

The airborne surveying (2012-2013) in Albanian territory was aimed at the characterization and the discretization of the cannabis' cultivation in natural, off and inaccessible environment. The multi-sensor platform - experimented with different instruments and aeronautical configurations - integrates active and passive sensors, for the airborne remote sensing, that allow for the scanning of geometric and spectral components of the Territory. The LIDAR sensor provides the discrete morphology (cloud of points) of the territory overflow, the aerophotogrammetric camera, the hyperspectral and the

thermal sensors record - each for its own technological declinations - the electromagnetic reflection of the territory in the segment between ultraviolet, visible and infrared thermal.

Fig. 2: Airborne platform sensors.

The “model” resulting from the integration of the acquired data in a single geographic reference system , contains in digital form, the dimension of the visible and invisible, tangible and intangible heritage of the area examined. The syncretic analysis, selective and simultaneous of the data opens up avenues (itinerary) of research in relation to specific discretization expectations. According to this methodology, the spectral analysis of the vegetation from near-infrared to thermal infrared allowed for the discrimination of particular tree species according to the principles of indirect survey.

Those technological professional and scientific synergies, between the University and GEA-GdiF, are outlining an experimental definition of a technical-operational Protocol on multi-dimensional Territory knowledge as an essential instrument for a deeper economic-financial investigation and its relation to the socio-urban fabric to achieve fiscal equity and social justice.

Fig. 3: The technical-operational Protocol.

The operative-scientific partnership by applying the technical-operational Protocol in Albanian territory (2012-2013) has achieved a great results for the mapping and identification of illegal plantations. In particular, at the end of the aerial missions completed in two years (2012 and 2013), the activity of remote sensing was conducted on more than 15% of the area of the country. The hyperspectral survey and high-resolution photographic analysis of vegetation have detected more than 325 hectares of land planted with cannabis.

2. Geographic Information System: a tool for multi-temporal analysis (Nicola Pisacane)

The different steps related to the mission of remote sensing survey for the detection of cannabis crops are supported and recorded through the use of a GIS platform. The possibility offered by these systems to manage all the data produced and collected throughout the mission led to subsequent processing operations useful to police tasks connected with the activities of remote sensing. The integration of data acquired during two missions (years 2012 and 2013) and during the same annual mission through geoprocessing tools for information and maps allows comparison, merging and analysis of complex land data.

The activities previously described through the operating protocol involved the take-over of maps of the national territory of Albania. In particular, the scheduling of airborne missions with hyperspectral sensor were carried out on the LFC-Europe (Low Flying Chart) map. The LFC map is realized to support the aerial operations at low altitudes. The navigation maps are all in the format CDRG (Compressed ARC Digitized Raster Graphics), a raster format for scanned maps published by United State of America - National Geospatial-Intelligence Agency (NGA-USA). This map format has been designed to meet the requirements of digital cartography. Its structure is particularly suited to load-on-demand and allows you to select the coverage that is best adapted to a given display scale. In particular some maps used for this mission are taken from series Italian CDRG produced by CIGA-Italian Air Force, Ministry of Defence in 2012. In particular we use the map 5NINM3134 which cover Italy territory but also other States on Mediterranean sea.

The flight planning, designed in accordance with air navigation standards and produced in close collaboration among the researchers team and the one of Italian Guardia di Finanza, is totally prepared on GIS platform through the identification and representation of flight run lines and the table display of the coordinates of start and end of each run lines and start and stop operation of recording with ITRES CASI 1500 hyperspectral sensor. Multi-temporal analysis, subject of this research, has been possible also thanks to similar flight plans missions in two different annuity and within the same year, in order to carry out a diachronic comparison of the same territories from one year to another, both in the evolution of farming from planting to harvest. When planning air missions, the import within GIS of information about the land orography, through the Albanian territory Digital Elevation Model (DEM) with a resolution of about 30x30 cm, allowed to define not only the average flight altitude but also the average land altitude for each run line, as well as the ground resolution of the digital data acquired and consequently its metrical accuracy necessary for the subsequent operation of identification of the plantations and multi-temporal comparison.

Fig. 4: Vau i Dejes Lake area. GIS: run lines of flight planning and municipality boundary on DEM map.

Fig. 5: Lazarat area. GIS: run lines of flight planning and municipality boundary on DEM map.

Inside GIS system are also imported vector layers with national spatial data. From different sources, in fact, we have acquired information about the hierarchy of the administrative division of the territory (country, district, municipality), as well as roads and waterways. These information are also crucial to identify the areas of interest on which investigate together with the indications of "risk levels" (probable presence of plantations) provided by the Albanian police. The presence of access roads to plantations, as well as waterways to supply irrigation pools may represent a further clue in the search operations.

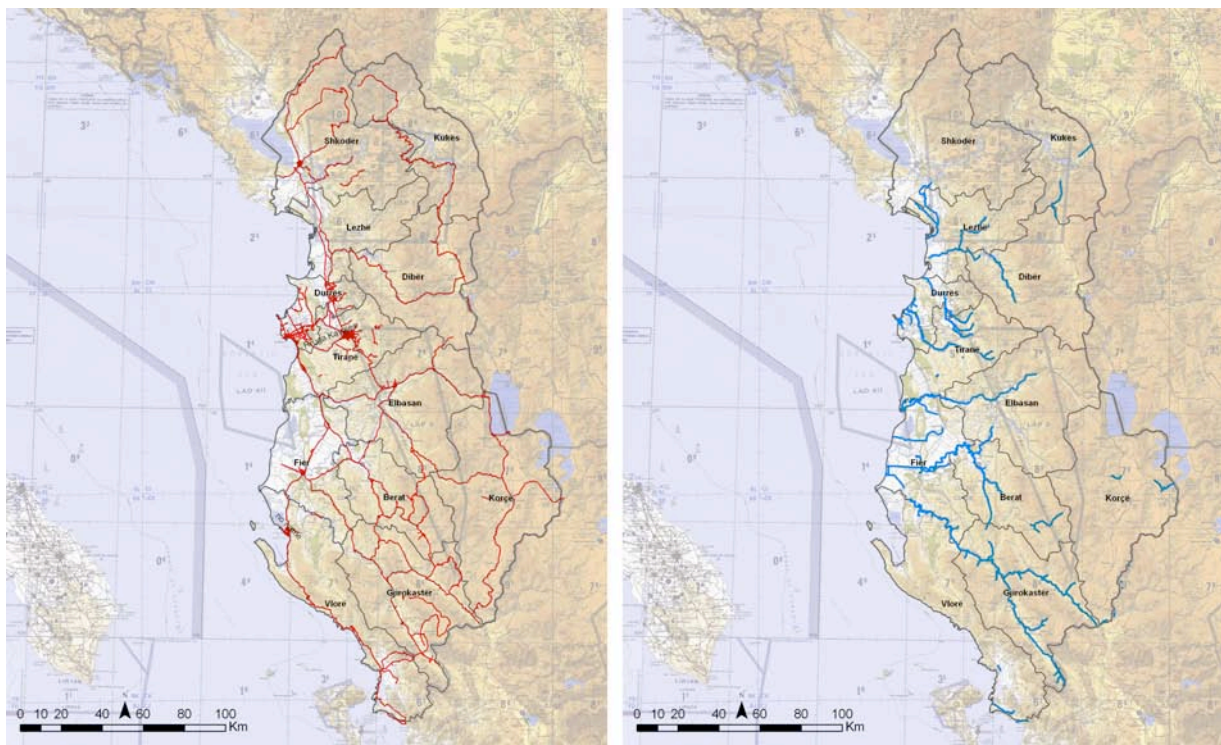

Fig. 6: GIS: road and district boundary layers on aerial navigation map (at left); GIS: waterways and district boundary layers on aerial navigation map (at right).

The flight planning has also been supplemented by further data, such as, for example, weather conditions and their evolution in the short and medium term in order to plan and execute flight activities in full compliance with the operating parameters of ITRES CASI 1500 sensor and high resolution camera to guarantee the best quality of the hyperspectral and photographic data acquired. In addition, all flight plans have been exported from the GIS platform into an interchange formats for tablet device used by the pilots, through dedicated applications, during the flight missions. During these operations are also recorded all mission data and traced the flight patterns with GPS tablet device supplied to the flight crews. Furthermore the platform has been implemented with the data for the thermal environmental factor because high temperatures could interfere with sensors and with the permanence of the crews in thermal stress.

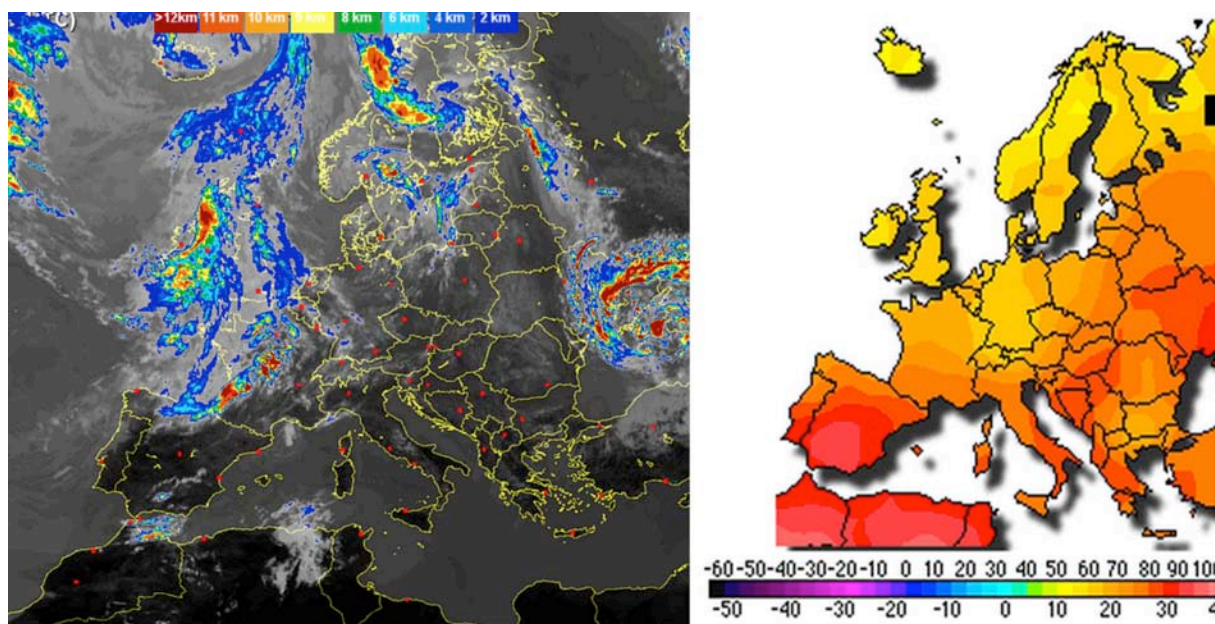

Fig. 7: Weather condition and thermal environmental factors.

Fig. 8: Flight pattern and data mission on tablet device.

During the stage of hyperspectral data acquired processing, after airborne mission, the flown run lines are examined and identified the areas with the possible presence of cannabis plantations. The analysis, carried out through the ENVI software for processing and analyzing hyperspectral image, is aimed at the perimeter of the areas in which the analysis of spectral signature and the comparison with the high resolution photographic image leads to the identification of plantations. In these areas, through software processing, are drawn the Region of Interest (RoI) corresponding to the geometrical georeferenced perimeter of plantation on hyperspectral map. The seamless integration between the different platforms and compatibility of geographic data products has allowed the interchange of data among the management software of the hyperspectral data and GIS platform. The import of the RoI, previously drawn on GIS platform, has allowed all subsequent geographical analysis, as well as the creation of the database associated to the graphical data of the perimeter.

This method has followed two procedures with some little differences of calculations for two different geographical areas: the city of Lazarat and other areas identified in the Albanian country. The very different intensity of cultivation in the two areas has meant that the procedures were not the same, also in order to proceed to the multi-temporal data comparison between two years missions.

For Lazarat municipality, emblematic case of intensive cannabis cultivation, the perimeter has referred to the whole urban area and peripheral one, excluding the few non-cultivated areas, buildings and roads. The perimeter was carried out directly on GIS in which has been mosaicked all run lines of hyperspectral images of the interested area, as well as high resolution photographic and a satellite image from Earth Remote Observation System-B (EROS-B), performed on the same day of aerial survey. At same time we verify the spectral signature of the data acquired with CASI sensor and we cross these information with photographic images. Of this large cultivated area we calculate the extension and for some sample areas calculate the number of plants and the average number of plants per square meter and then estimated the total number of plants and the amount of production.

Fig. 9: Lazarat area. GIS: boundary of cannabis cultivations on hyperspectral map (at left) and on high resolution camera image (at right).

The other part of Albanian country, affected by the same phenomena but not so intensive, has been surveyed and analyzed with a similar process for perimeter, but directly in the hyperspectral data analysis software and subsequently exported in GIS. The analysis of the data, however, has been applied to areas very parceled. In particular, the 2013 year mission has led to the census of 304 plantations with average size of 150 square meters. For these plantations, often localized in areas deliberately concealed, sometimes wooded or with a complex orography, it is identified the centroid of each RoI, calculate the geographic coordinates of these points and prepared a report in which for each plantation, in addition to the above data, is compared the hyperspectral image with high resolution one. In order to facilitate the sharing of geographical location of the plantation were generated placemarks in .kml format, coded with the same standard used for the geographic database, viewable on Google Earth.

Fig. 10: GIS: boundary of Albanian district and centroid of cannabis cultivations on aerial navigation map (at left); placemarks on cannabis cultivations in Google Earth (at right).

3. From the airborne remote sensing to the multitemporal data analysis: the case study of the Vau i Dejes Lake in the Prefecture of Shkodra, Albania. (Alessandra Avella)

The integrated interpretation of information acquired during the airborne missions carried out in the Albanian territory in the years 2012 and 2013, allowed the multitemporal analysis and characterization of the area surveyed. In particular, the testing of multi-temporal analysis (2012-2013) was performed on the territory that comprises the Vau i Dejes Lake in the Prefecture of Shkodra - the subject of these notes - through the application of the technical and operational Protocol for the integration of optical data, hyperspectral and thermal data by airborne multi-sensor platform. The Protocol was validated by the university-military research group during airborne surveying carried out since 2010 in national and international contexts.

In this Protocol, the first activity is the acquisition and systematization of either numerical or rasterized maps, official orthophotos, and three-dimensional models of each geodetic certified reference of the territory, archived in UTM-ED50 coordinates in relation in the time-zone to which it belongs. Most of the mapping products were provided, before the air mission of 2012, by the CIGA (Aeronautical Geotopographic Information Centre) of the Italian Air Force, in order to "structure" the geographical data base upon which to plan airborne surveys, systematize the acquired data, project the homologous information on the corresponding layers, diachronically analyze the recorded data in a cyclic process of targeted analysis and full verification of the information.

The aim of the first step of the research consisted in the acquisition of hyperspectra, thermal and photographic images aimed at the analysis of the Albanian territory in relation to the selection of the areas that are more suitable to the illicit cultivation of cannabis because of the morphology, the orography of the territory, the distance from city centers, the localization in natural inaccessible and unaffordable contexts.

The multi-sensor platform - experimented with different instrument and aeronautical configurations - installed on board the Piaggio P168 of the 'Gruppo Esplorazione Aeromaritima' of the Guardia di Finanza - integrates active and passive sensors for airborne remote sensing that, by the recording of the electromagnetic 'responses' of the natural and built environment, allow the scanning and the return of data necessary for the representation of the territory in the visible range and in the thermal and hyperspectral field.

In 2012, the sensors employed to acquire images and auxiliary position and orientation data were: the CASI-1500 characterized by a CCD of 1500 elements (pixels) for the part of the spectral range VIS-NIR; the TABI-320 for the thermal component; the POS/AV, useful to determine the geospatial position and the attitude of the aircraft, integrates an inertial unit with the GPS data and provides the

position and orientation data offset. The POS calculates in real time the position data (latitude, longitude and altitude) and the external orientation.

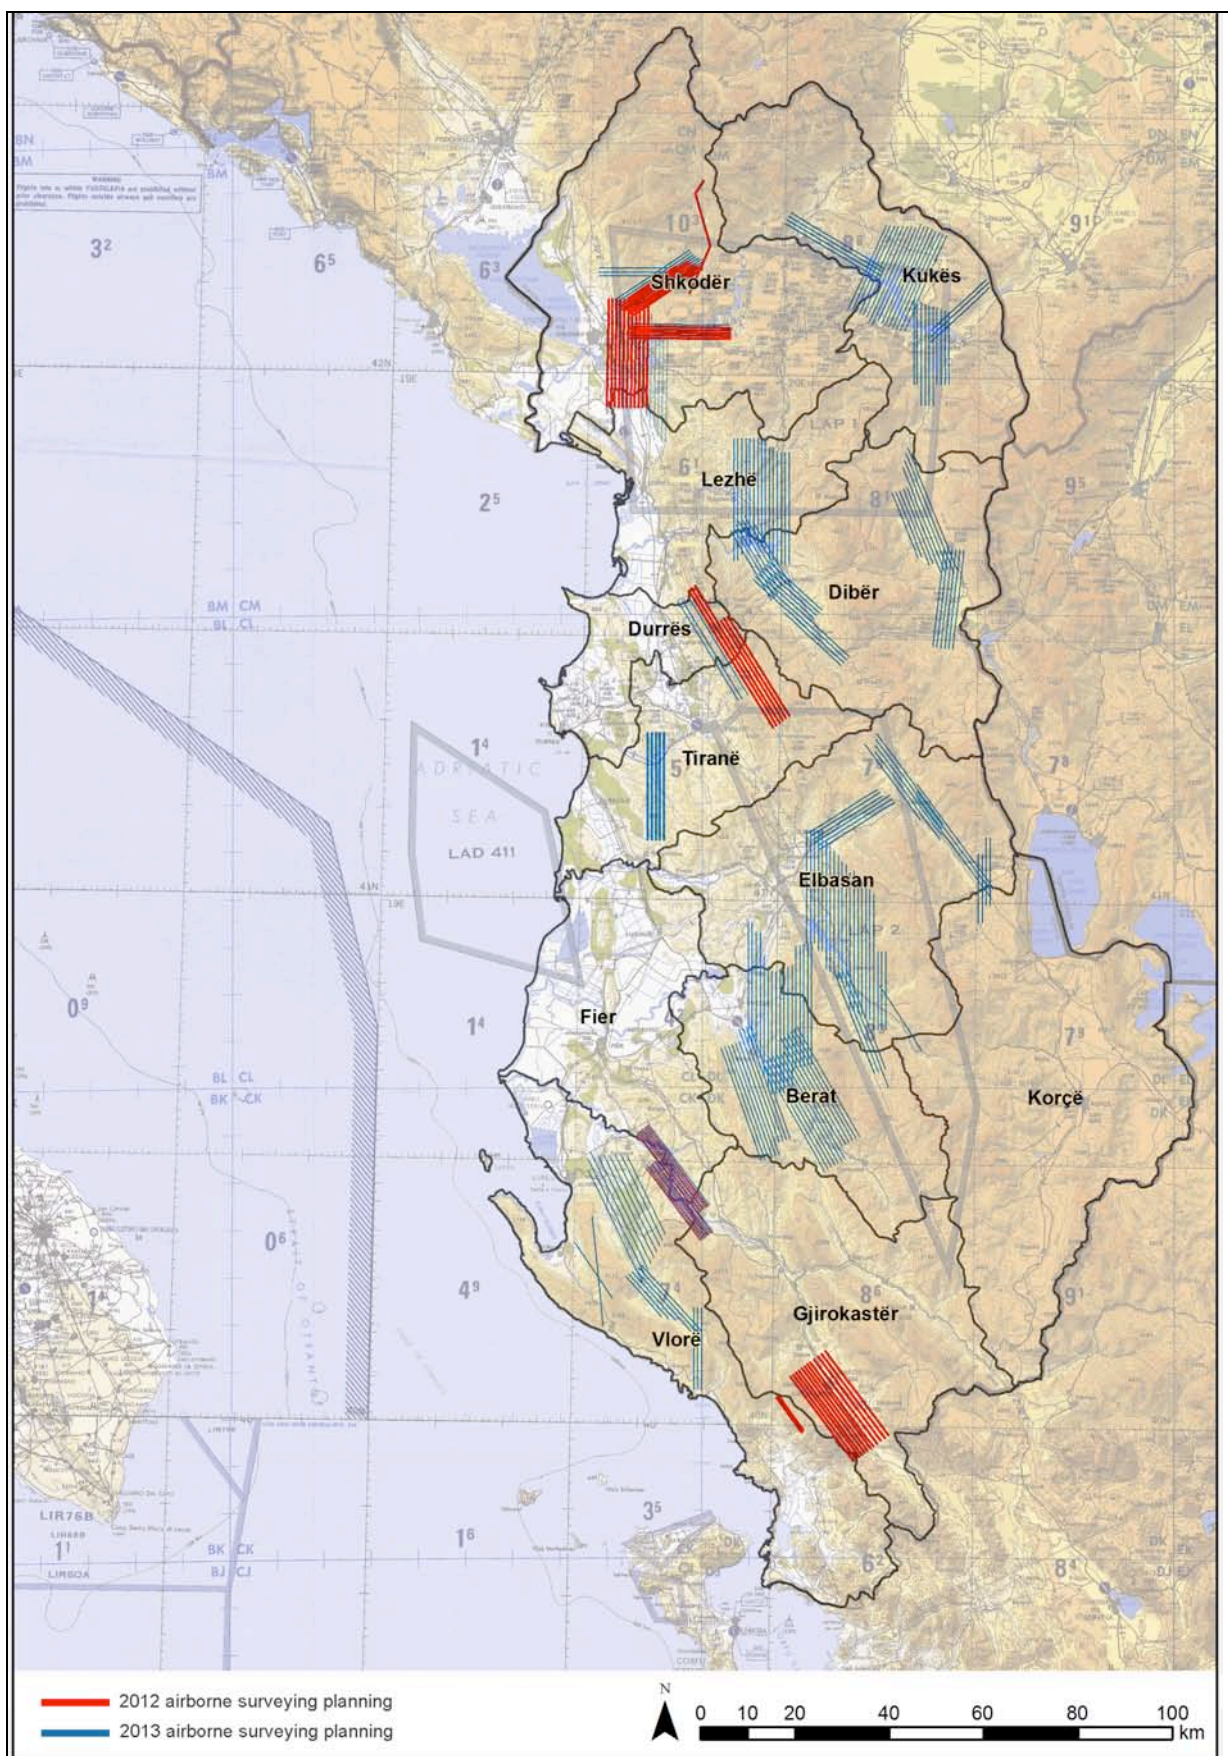

Fig. 11: 2012-2013 airborne surveying planning.

It should be noted that the registration data from the GPS during the flights is an essential prerequisite for the success of the air mission, as well as the efficiency of the aircraft and of the sensors installed on board. In 2013, the multisensor platform has changed: the airborne remote sensing was performed using the same CASI-1500 hyperspectral sensor and adding the PhaseOne iXA sensor that captures orthogonal images to 80Mpx in the 'true color' bands.

The process of geometric calibration of the sensors is performed in order to determine the exact orientation of the sensors in relation to the reference system of the inertial unit that acquires the attitude information of the aircraft during image acquisition. This process precedes the airborne surveying and the following pre-processing data. The airborne remote acquisition campaign was articulated in the following phases: identification of the territory to fly over, definition of the channels and of their spectral ranges of acquisition; planning and execution of the territory scanning; pre-processing of the information acquired; production of thematic maps in relation to possible discretization and the comparative analysis and multi-temporal remote sensing data.

These notes describe the activity of the multitemporal remote sensing (2012-2013) performed in the territory that includes the Vau i Dejes Lake in the Prefecture of Shkodra and in the city of Lazarat. The aerial survey was carried out in both cases by applying the methodological approach of the technical and operational Protocol. The case study of the Vau i Dejes Lake, analyzed in this paragraph, and the city of Lazarat, examined in the following paragraph, have been appropriately selected from the aerial missions planned and performed during these two years over Albanian territory, which was overflowed and surveyed for about 15% of its surface.

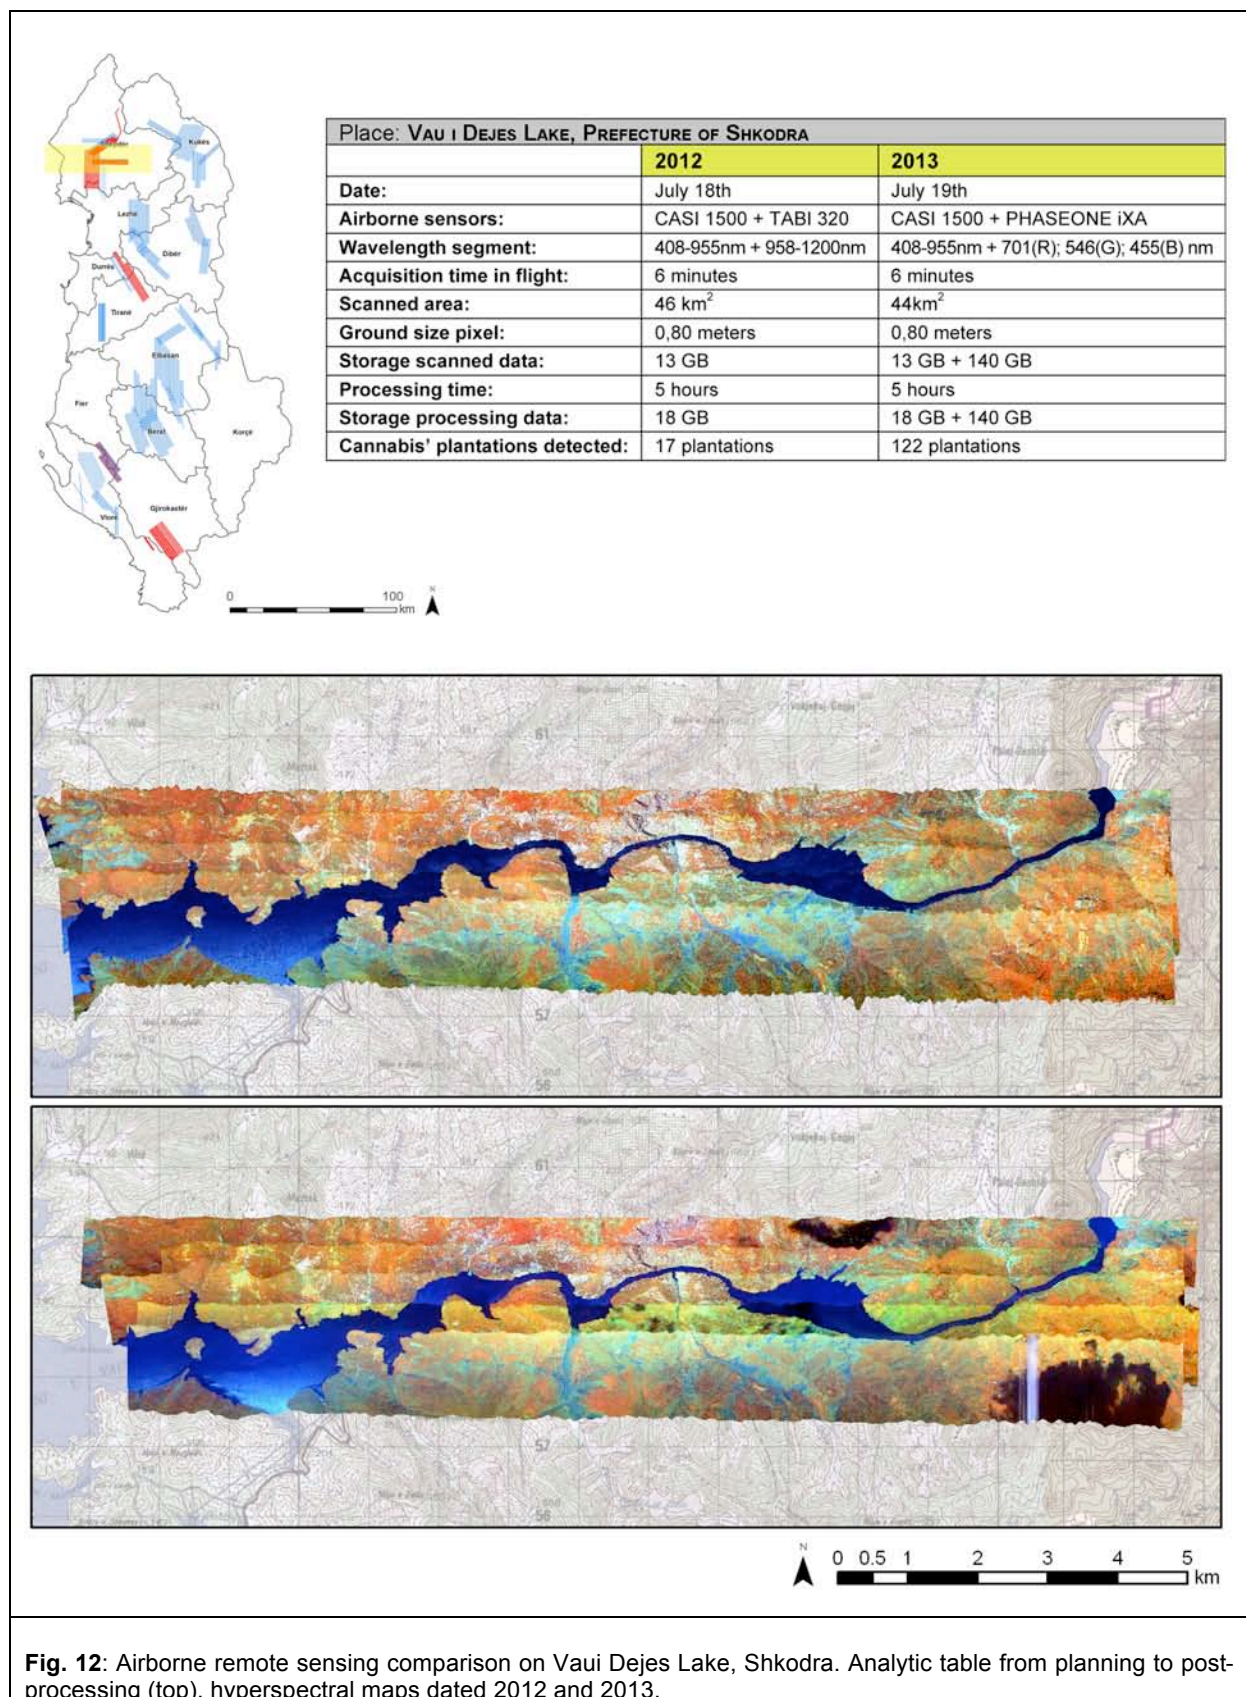

The multitemporal analysis is comparable for the homogeneity of the following circumstances: the date of acquisition (18 July 2012 | 19 July 2013), planning and execution of the flight, configuration of the hyperspectral sensor; all related to the same Protocol. The decision to test the multi-temporal analysis on these portions of the Balkan territory depended on factors linked to the environmental condition: the selected case studies are paradigmatic of the two most prevalent types of illicit cultivation of cannabis plantations: in situations of impervious and inaccessible nature, those located in the Prefecture of Shkodra, in typically urban context, those in the city of Lazarat.

The Vau i Dejës Lake (Prefecture of Shkodra) and the city of Lazarat (Prefecture of Gjirokastra) have different latitude, orography and environmental conditions. The first is located in the northwest Albania, the second in the south of the country. Located at the foot of a mountainous woodland, the Vau i Dejës Lake is situated at the exit of a gorge between the hill of Laç with an elevation of 367 m and Boka with an elevation of 464 m. The hydrographic network is represented by the Vau i Dejës artificial Lake, Drin River and several streams, the most important being the Gomsiqe brook and the Zazlli brook. All these flow from the mountain of Gomsiqe. Therefore, this study area is blooming and inaccessible for the abundant presence of water and the steep hilly orography. In addition, if one adds that the Vau i Dejës Lake was a strategic area because it was the crossing point of ancient roads connecting the east and the west, it is possible to understand why in this territory were detected numerous cannabis' illegal cultivations.

The morphology and the orography of the studied area, which has approximately an extension of 46 km², affect the definition of the navigation files, of the hyperspectral and thermal setting files and of the planning of the flight data acquisition. The hyperspectral setting file is aimed at maximizing the number of spectral bands that can be acquired depending on the conditions imposed by the spatial resolution of the pixel to the ground and the integration time required to detect the radiant energy reflected from the ground. The CASI-1500's configuration was set by a spectrum width 408 and 955nm, which is divided into 13 identical bands. The TABI-320's configuration was set by a spectrum width 958 and 1200nm. TABI-320 was used only in the first aircraft missions (2012). The photographic camera PhaseOne iXA with very high resolution, used according to the configuration set by the specific techniques of the sensor, acquired in the 'true color' bands (701 (R), 546 (G), 455 (B) nm).

In Shkodra territory, the remote sensing mission performed at 120 knots (flight speed) from an altitude of 5400 feet above ground, in order to achieve 0,80 square meter pixels. Note that once the flying altitude is known, this value must be added to the average altitude of the terrain (measured ASL - Above Sea Level) to determine the altitude that the aircraft must fly at (ASL) to achieve the specified resolution. To define the flight mission was necessary to plan the scan 'runline' in order to ensure coverage of the study area, and the resolution on the ground corresponding to a pixel size equivalent to that defined in the configuration set. Specifically, for the remote sensing flight on the studied area of Shkodra, were planned 6 identical runlines, taking into account the configuration settings, the acquisition characteristics of the CASI sensor and the morphology and altitude of the territory. For this reason, sections of the landscape are executed for each scan runline. These have a direction as much as possible parallel to the land orography in such a way that it is possible to evaluate the flight height on each "leg" as far as the land height changes. The orography of the studied area conditions, in inverse proportion, the equidistance parameter of the scan runline: the more the orography is steep, as in the territory of Skutari, the lower is the equidistance between the scan runlines.

The parameters surveying set for the remote sensing flight on the studied territory are described in tabular form in the following graph.

The hyperspectral flight, performed in 18 July 2012 and in 19 July 2013 in the Scutari territory, was planned as shown in the following graphic.

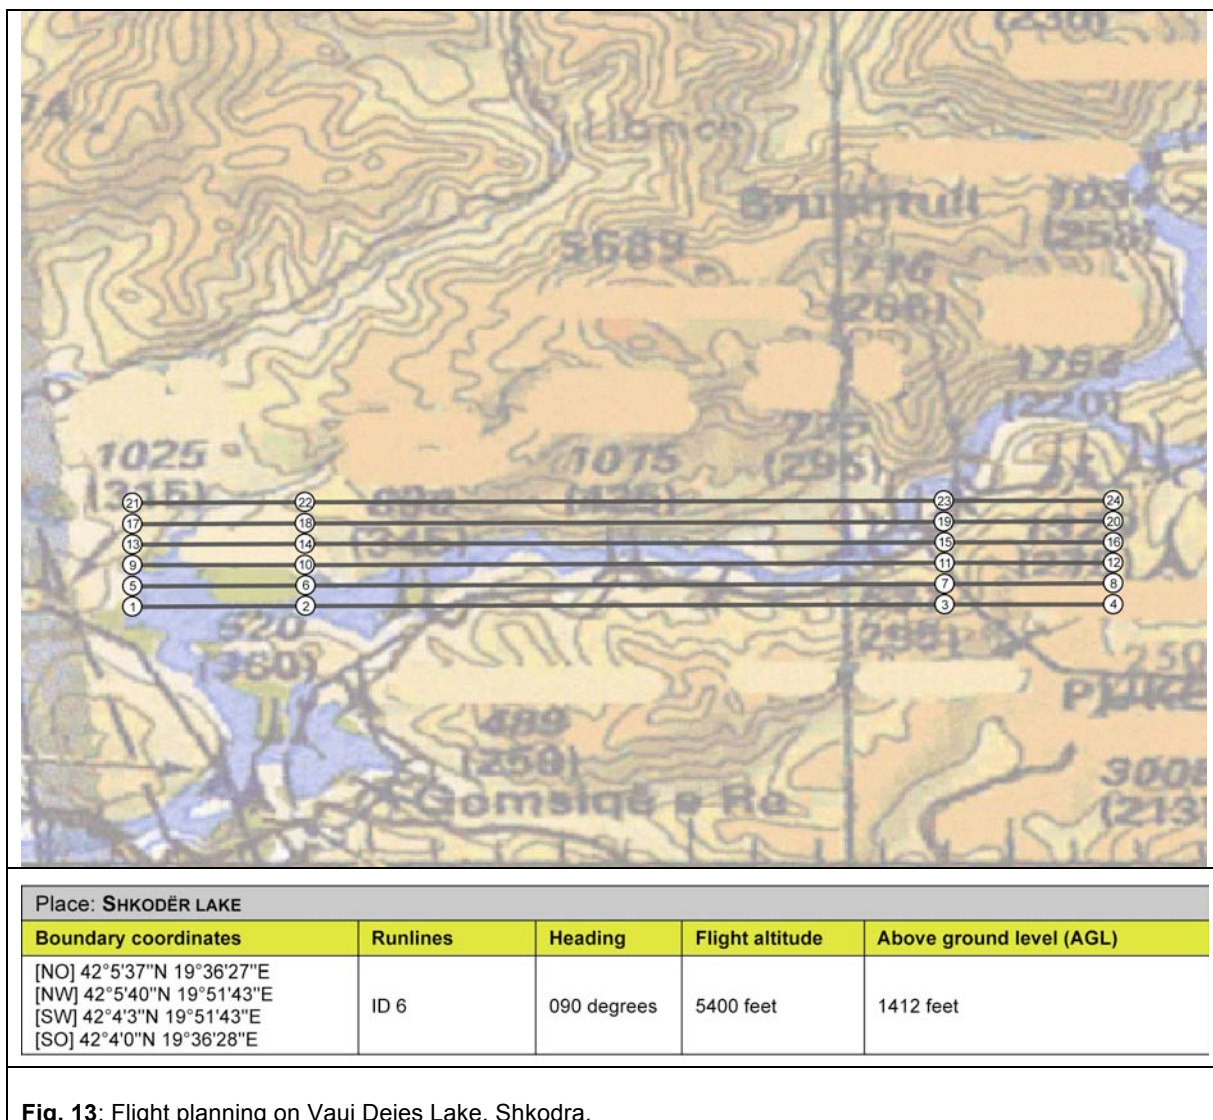

Fig. 13: Flight planning on Vauj Dejes Lake, Shkodra.

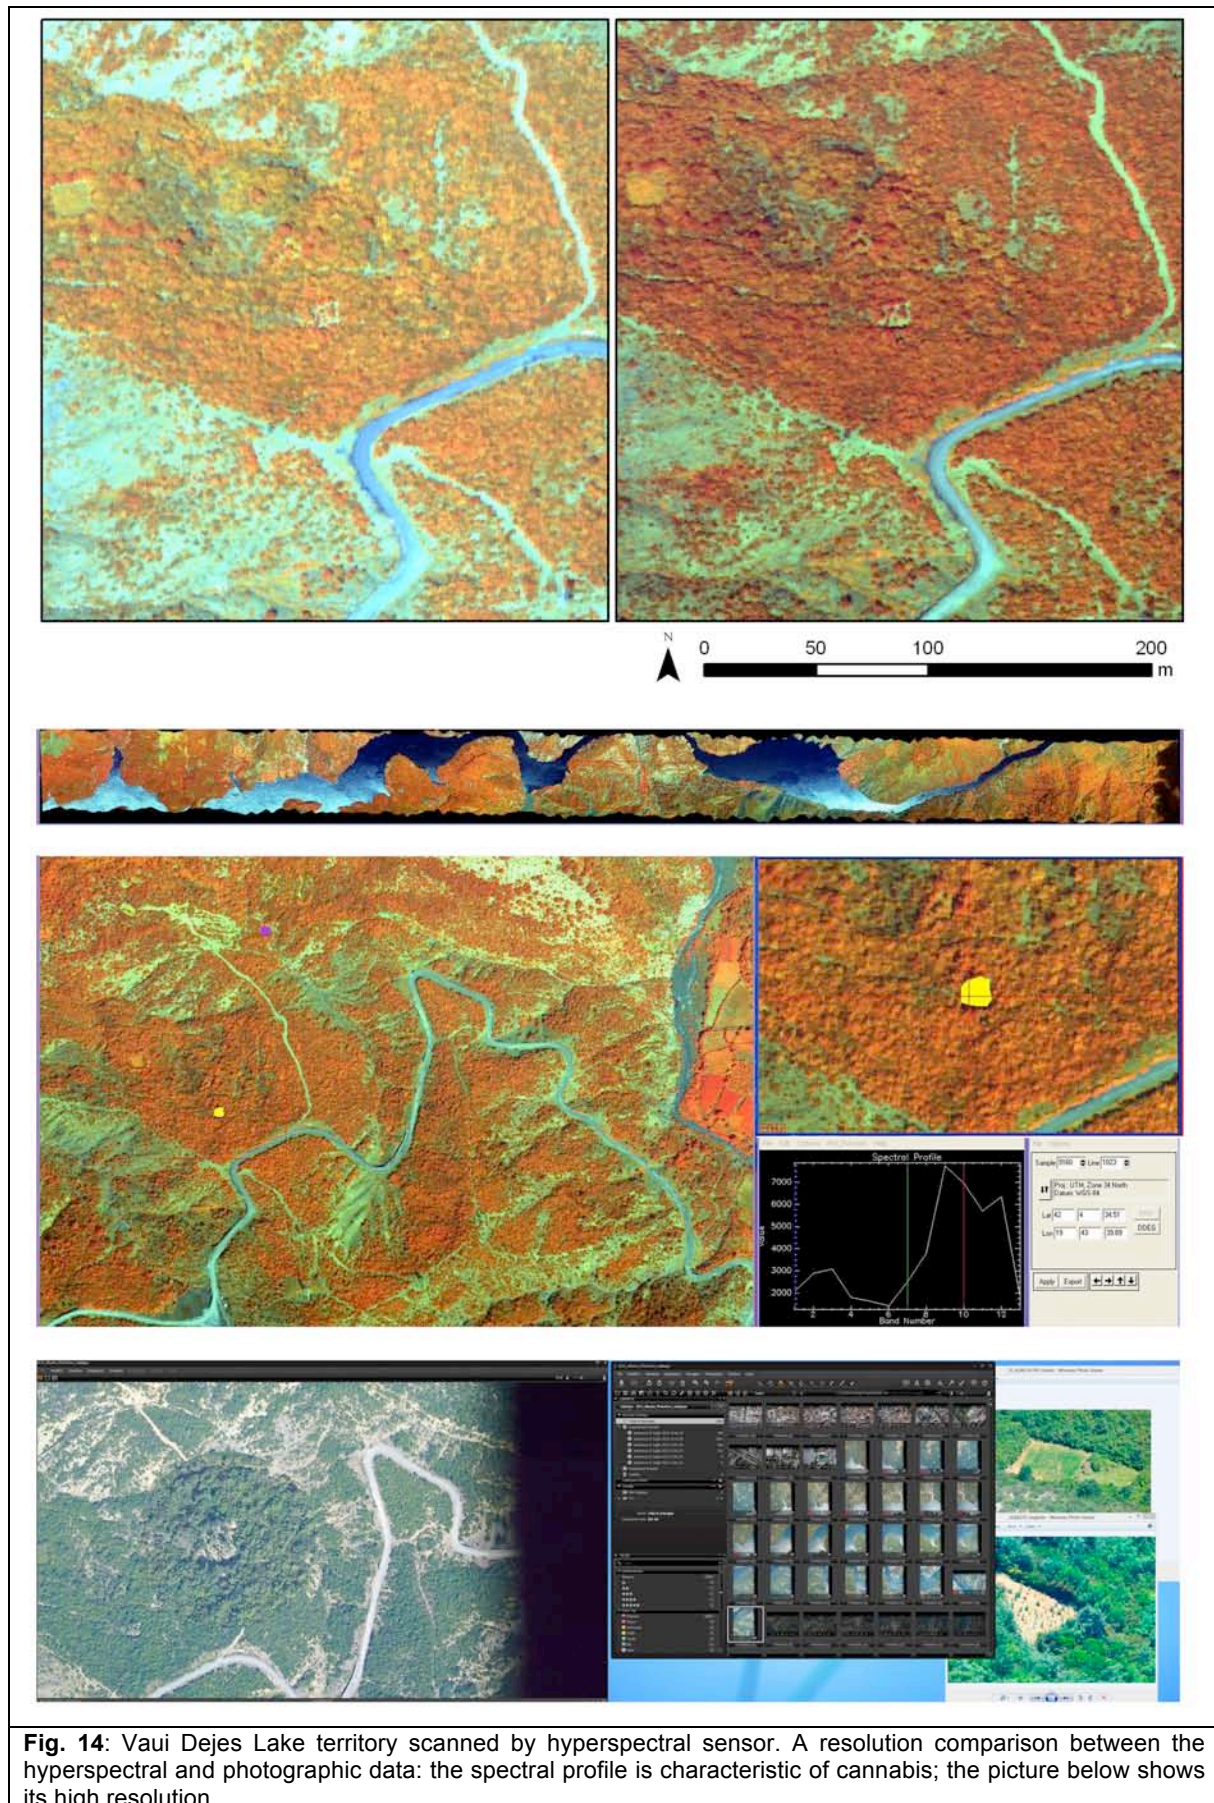

The scanning phase, the storage of the recorded data and the pre-processing of the acquired images follow the input in the on-board computer of the geographical coordinates of the scan runlines and of the spectral configuration. Each flight and acquisition phase is recorded automatically in log files of each sensor. For each scan runline planned, the two pushbroom sensors have returned only a raw file, the photographic camera has taken an ordered series of individual frames to be related to the first during the preliminary stages of processing.

The hyperspectral and thermal images, the photographic images, the aircraft inertial and position data, the GNSS permanent stations data, the DSM or DTM models of the studied territory are appropriately archived and organized for the next phases of pre-processing and image processing through software processes.

The image processing is aimed at the correction of the radiometric and geometric errors and at the geo-referencing of the acquired images through three softwares, distinct and sequential: calculation of aircraft position and attitude every second; radiometric correction of hyperspectral or/and thermal images; geometric correction of the latter. Position and attitude processing runs through the integration of GNSS permanent stations data (static acquisition) with inertial and GNSS on board sensors data (dynamic acquisition). GNSS permanent stations, next to the airport and the area of study, must be functioning and operating in a time period that includes the remote sensing flight. During Albanian mission, we have installed two GPS stations because there were not any GNSS Permanent Stations. The Benecon researchers, in 2012 and 2013 remote sensing mission in Tirana, continuously checked the GPS Base Station provided with a pair of Trimble R5700 antennas/receivers.

The GNSS permanent stations data record the satellite coverage of a wide zone, including the airport and the studied area; the inertial- and the GNSS- on-board-sensor data are a combination between

position and attitude data (roll, pitch, yaw), registered every second during the flight, from takeoff to landing. The integrated processing of all these data reproduces the geo-referenced flight path, so that all thermal and hyperspectral images can be automatically referred to scanned area.

During radiometric correction of CASI images, the raw digitized pixel intensities are converted into units of spectral radiance, thus estimating the true brightness of the target. Conversion of CASI data to units of reflectance requires that ground spectral measurements be collected coincident to the airborne image data. During geometric correction, the image (radiometrically corrected) is aligned to position and attitude data.

Processing result is a multilayer orthophoto paper in which each layer corresponds to a wavelength reflected by the ground objects scanned and recorded by airborne sensors. The classification of various selective layer allows drawing thematic maps, as interpretation of case study.

In 2012 remote-sensing mission, the discretization of the objects present on the ground was performed by the vertical query of the hyperspectral image on each pixel and the analysis of the data recorded in the various pixels, in different ranges of wavelength, characterizing each pixel compared to those next, and by extracting the spectral signature for each of them. The spectral signature is the reflectivity characteristic of each material (natural or artificial), in function of incident radiation wavelength, in comparable environmental conditions. For the discretization of cannabis sativa cultivation, the analysis of scanned data was of inductive type and allowed the identification and mapping of the cultivation of cannabis by extracting the 'spectral signature' characterizing the material, object of this investigation. On each macro-area identified, a combination of variable indices has been applied according to experimental procedures, in order to carry out the classification compared to cannabis 'spectral signature'.

In 2013 remote-sensing mission, after characterizing the 'spectral signature' compatible with that of cannabis, it was possible to compare the spectral data with the photographic image with very high resolution, so as to verify and validate the results of the analysis performed on hyperspectral images with 'visible' information. The photographic images, in fact, allow to recognize the presence of cannabis plantations by other parameters, such as the identification of the morphology characterizing these cultivation. This methodological approach in multitemporal analysis' phase of the acquired data has allowed to obtain the following two results: increase the final data in terms of number of plantations identified; find the illegal cannabis plantations in cases of 'spectral signature' not perfectly recognizable with the cannabis 'spectral signature'. This condition occurred in the Shkodra territory, where the cannabis plantations are frequently hidden by different types of plantations.

4. From the airborne remote sensing to the multitemporal data analysis: the case study of Lazarat in the Prefecture of Gjirokastra, Albania. (Pasquale Argenziano)

These notes explain the technical-scientific protocol through the activities of multi-temporal remote sensing of Lazarat, one of the two paradigmatic cases of two-year study carried out on the Albanian territory.

The village of Lazarat is in the prefecture of Gjirokastrës, in Southern Albania. The town stands between the slopes of Mali i Gjere Mount and Drinos river, a few miles south of the capital, along the main road SH4 "Durrës-Fier-Gjirokastrë", the privileged communication route to Macedonia and then Greece.

The vocation of the villages, located on the eastern slopes of the mountain ridge, is purely agricultural. The inhabitants, devoted to agriculture, benefit from the good exposure of the alluvial Drino-Voiussa valley, and from the mountain slopes, formed by limestone and clay covered, punctuated by various sources. The Mali i Gjere mountain ridge also has numerous narrow valleys that open at right angles to the Drino-Voiussa valley, channeling rainwater, as a further element of lushness of the site. Lazarat is indeed further advantaged by one of these narrow valley opened at SW side.

After localized the study area on digital maps, the flights of the July 8, 2012 and July 22, 2013 were planned according to 10 runlines of parallel scans with a SE-NW direction, aligned with Mali i Gjere mountain ridge, and equidistant variable according to the land orography and the expected resolution of the image. After one year, the airborne multi-sensor platform changed: the first acquisition was performed with hyperspectral and thermal sensors, the second one was made by the same hyperspectral sensor coupled with high-definition camera.

During the first flight mission, the data recorded the electromagnetic reflection of the ground between 408 nm and 1200 nm, considering the spectral continuity of the coupled sensors. While in the second year, the scan covered the wavelength segment between 408 nm and 955 nm, with a optical detailed focus in RGB channels. Therefore, the configuration of the hyperspectral sensor remained unchanged while the thermal sensor or the photographic camera ones acceded to the specificity of places, and to the planned mission. The table below is a schematic summary of the main parameters and the analytical description of the workflow until the post-processing.

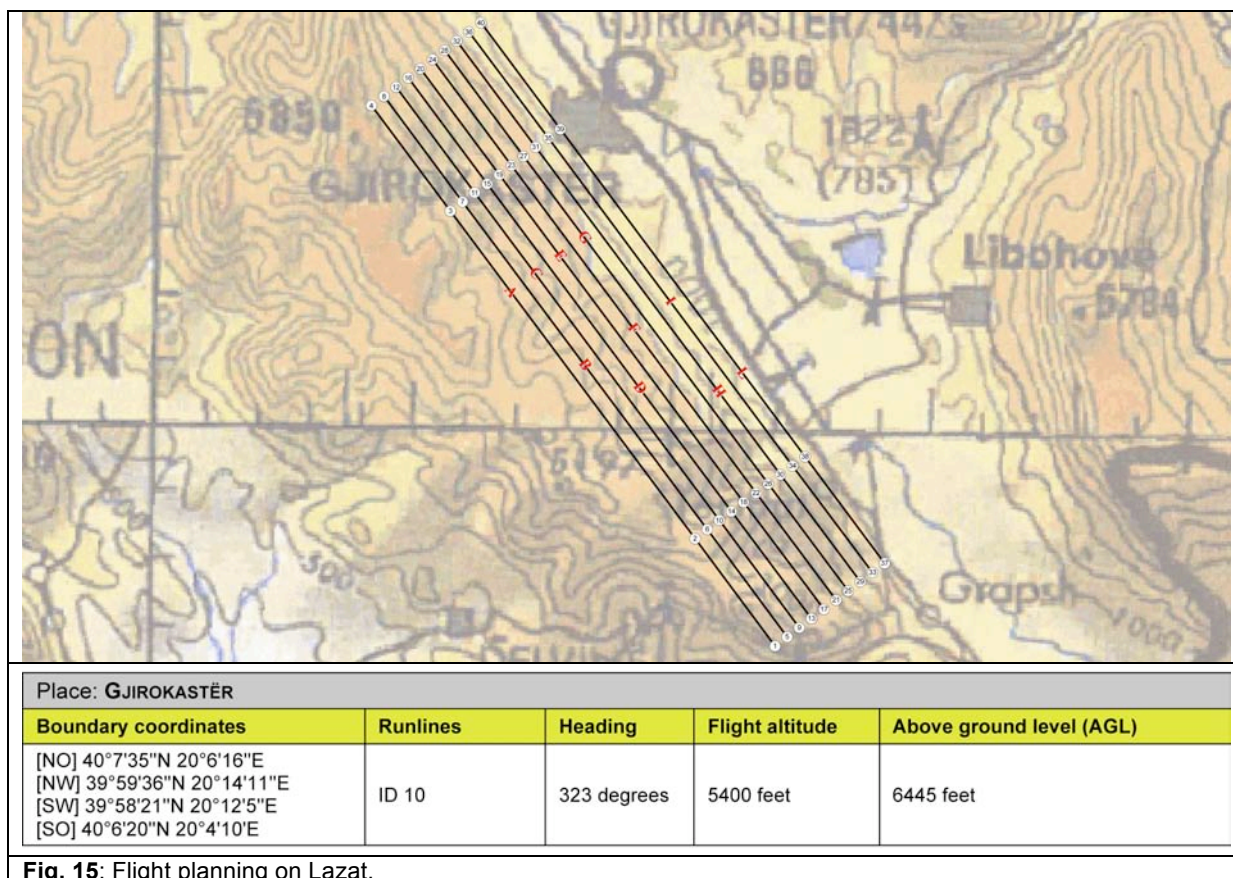

Fig. 15: Flight planning on Lazarat.

The Lazarat's scanning at 2013 was also supported by simultaneous acquisition of multispectral satellite images produced by the EROS-B sensor. This enabled a more thorough reading of the spectral data, as well as a quality control of the geometric data, acquired from the aircraft.

Despite the intrinsic and strategic importance of downloading and storage data, aimed at the result quality, these stages are more often than not valued and treated superficially. Summarizing the range of collected data during the two annual missions, after the aircraft landing, the team proceeded to estimate the qualitative and quantitative data recorded by: two GPS antennas (the first rover on the aircraft, the second fixed as base station), the IMU sensor on board, and the three sensors (hyperspectral, thermal and photographic). For each flight runline, the first two pushbroom sensors produced a single RAW file, while the photographic camera took an ordered series of single frames to be related to the first ones, during the pre-processing.

The management, systematization and data storage - from planning to post-processing - may seem like a purely technical and operational stages. In fact they are three fundamental aspects for the remote sensing project, especially for the multi-temporal one. Therefore, at the beginning quantifying the number, size and type of digital data, expected in each phase of the work, directs definitely the research quality, just as is done by the intrinsic quality of hyperspectral, thermal, photos and geometric data. To complete the analytical framework of the two missions on Lazarat, just think that at least 450 files were managed during the acquisition step, and more than 580 during processing and mapping.

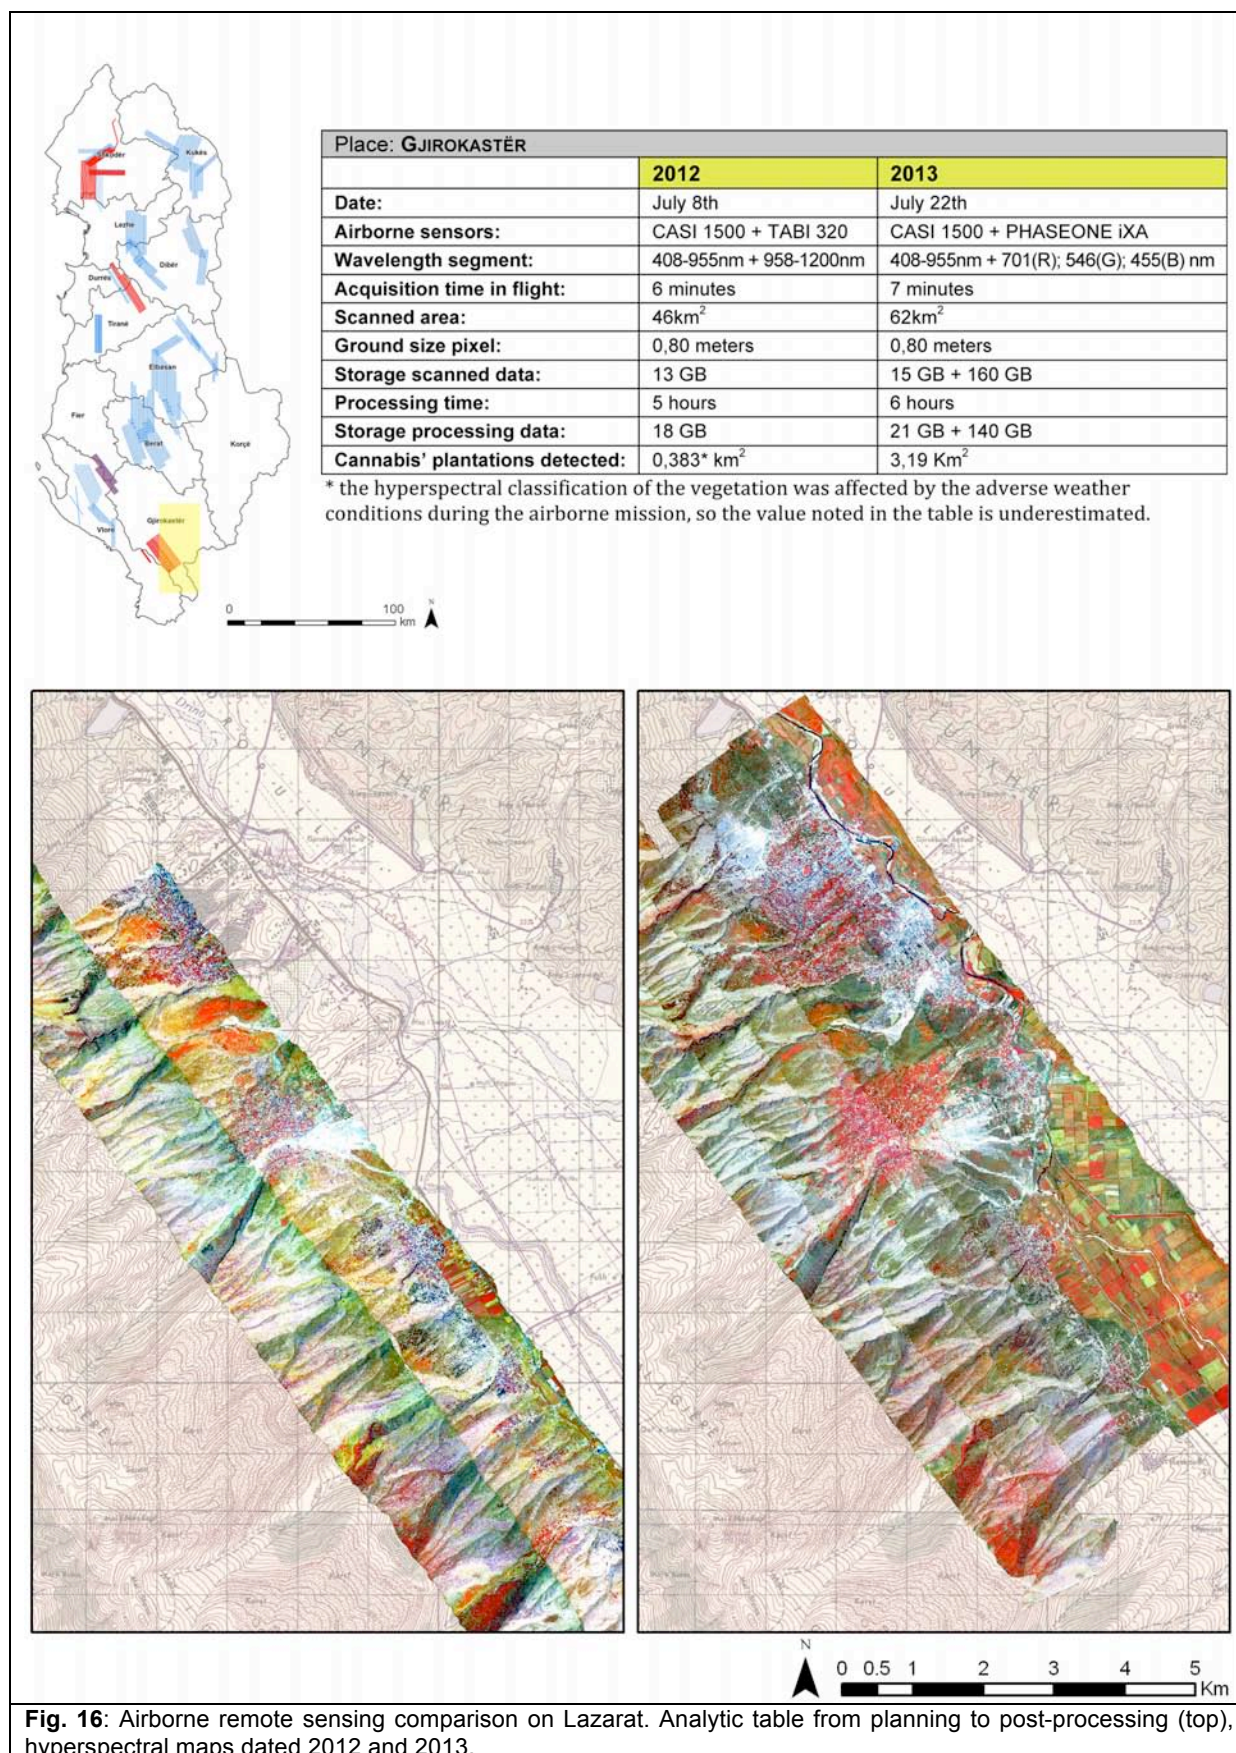

Completed the data processing, the multitemporal analysis of Lazarat is possible thanks to the same chronology and the uniformity of the planning and flight execution, as well as to the sensors configuration. All this because, the team used and checked same technical and operational protocol during both flight missions.

Some news and videos pointed to many cannabis plantations in the urban area of Lazarat. Therefore, the approach to the identification of those plantations was different from that normally used in rugged areas of Albania.

The NDVI classification, crossed with the RedVeg one, allowed the highlighting of green areas in the urbanized area. The classification "Supervised", compared to previously spectral data for cannabis, concluded highlighting the restricted areas cultivated illegally.

While the data on 8 July 2012 were compromised by adverse weather conditions, those of July 22, 2013 gave a clear image of the cultivation of cannabis in Lazarat. In 2013, almost all of the green areas of the city - usually in adherence to the housing - is cultivated by cannabis with ramifications in the northern town hills and along SW narrow valley that descends from the Mali i Gjere mountain. Reasons of confidentiality does not allow a detailed description of the data.

The exceptionality of the data, already detectable during the early processing steps in 2012 (data not perfect and therefore can not be proved with certainty) has been proved by visual recognition of the cannabis foliage, photographed at high resolution with the PhaseOne iXA camera of Guardia di Finanza.

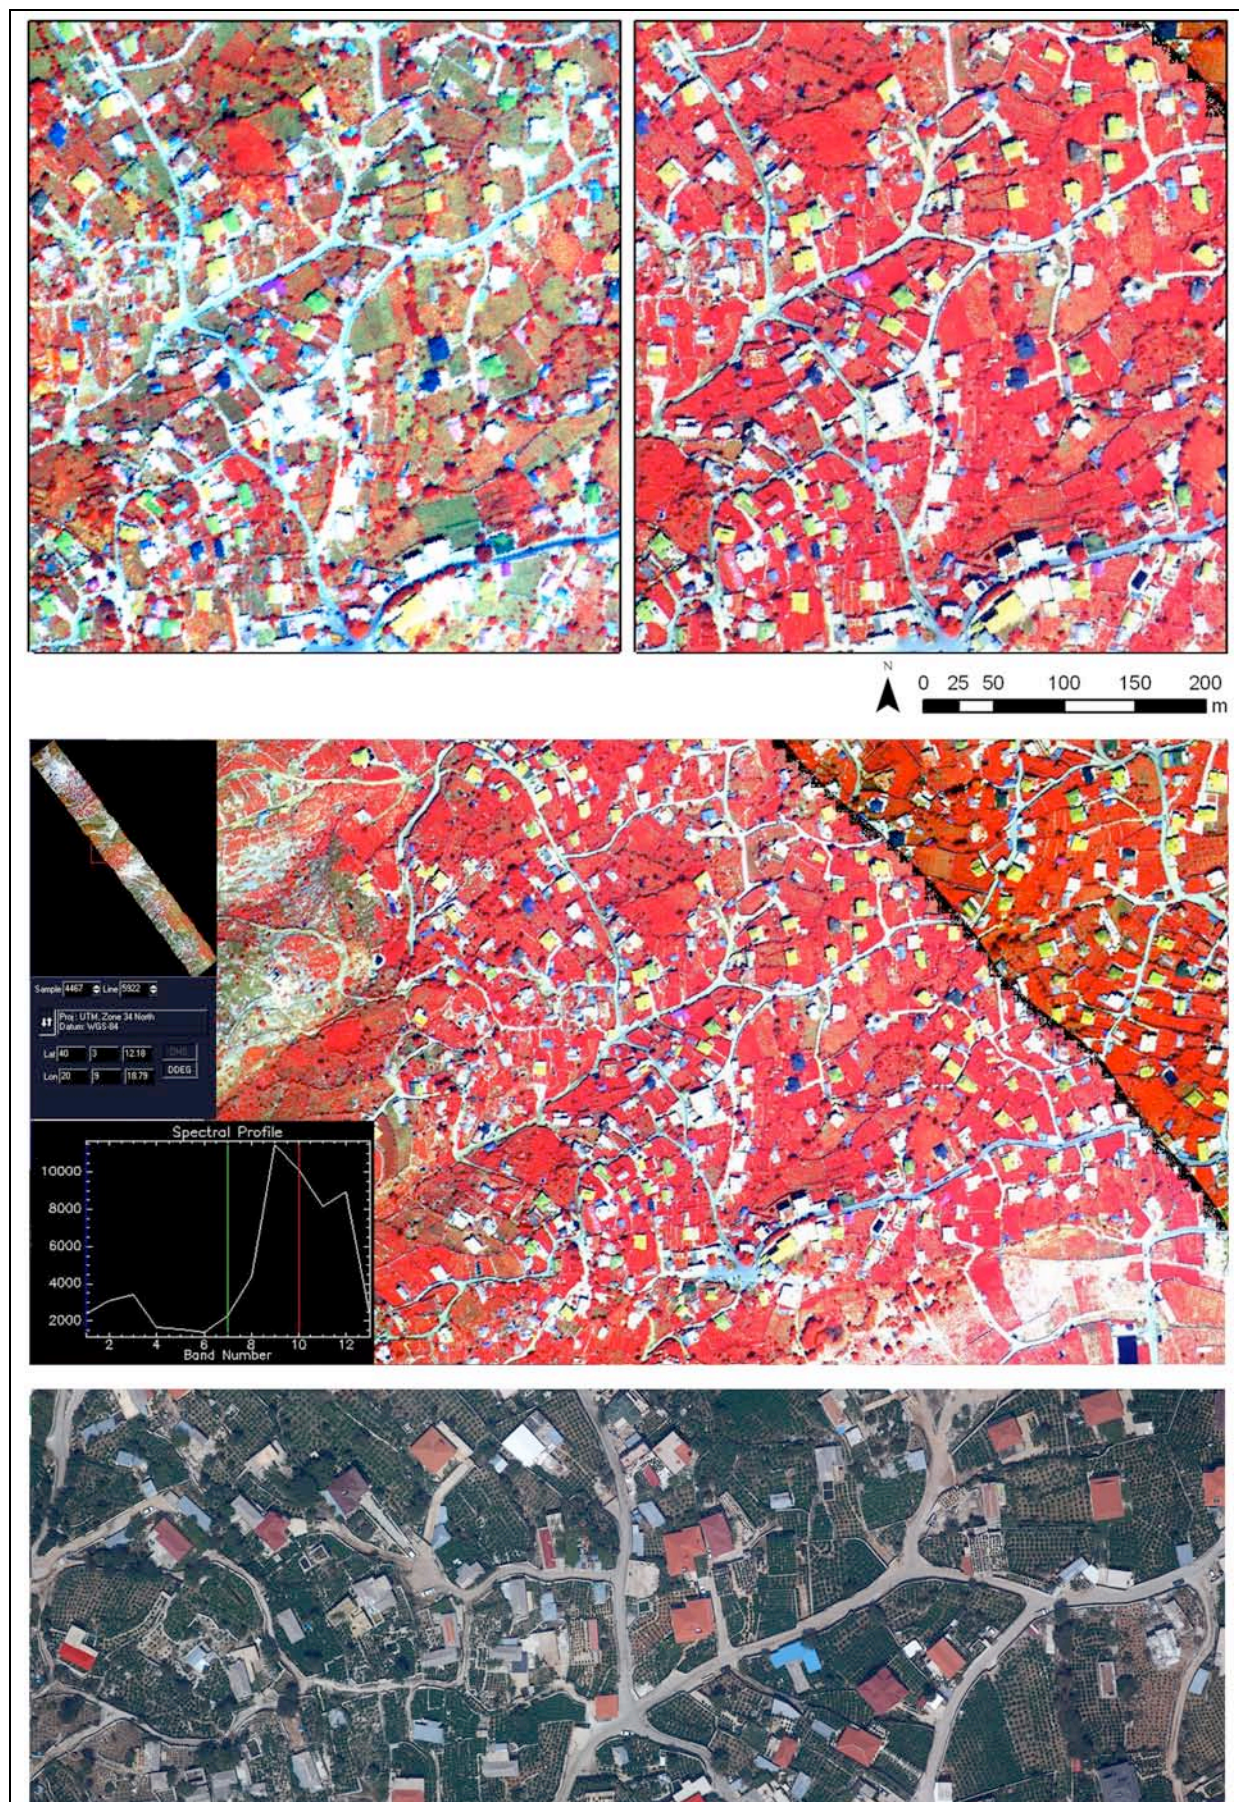

Fig. 17: Lazarat village scanned by hyperspectral sensor. The same urban fabric in 2012 and 2013, by a RedVeg hyperspectral classification (top). A resolution comparison between the hyperspectral and photographic data: the spectral profile is characteristic of cannabis; the picture below shows its high resolution.

Fig. 18: A 3D axonometric projection of hyperspectral, multi-spectral, thermal, and photographic data of Lazat, scanned in 2012 and 2013. The pixel model below is the 30 meters resolution DEM (CIGA).

The hyperspectral data - not always purifiable from the spectral influence of the materials placed at the plants' boundary, falling in the area of 0,8 square meters pixel, projected on the ground - was "visually" proved by the photo-realistic images in high definition. All this proves that the quality and reliability of the remote sensing is directly proportional to both the precise execution of the technical and operational procedures, as the wise integrability of various disciplinary skills, and many research technologies.

The intersection of the Lazarat's multi-temporal hyperspectral, thermal, multi-spectral and photos data, also allowed perimetering of some green areas most interesting and paradigmatic on which to carry out studies for the improvement of the cannabis 'spectral signature', during the plants' evolution. These test areas were also identified in other parts of Albania.

At the conclusion of the two-year investigation into Albanian territory, the village of Lazarat is definitely the paradigmatic case study of the illicit cultivation of cannabis, as it is hardly possible to find such a large and extensive production in the urban context in the world.

Therefore, the study of the city was also prepared a diachronic evolution of the urban fabric and its green areas (not always cultivated cannabis) through a comparative reading of topographical maps and satellite images. The study in progress is not easy, because it's difficult to obtain homogenous topographic data.

Nevertheless, it is possible to anticipate some reflections on the data collected and arranged chronologically the last decade. The urban (located at 400 average meters above sea level) always occurs infrequently, and it is characterised by scattered houses, mostly two levels, in a continuous stretch to urban gardens, readily identifiable in comparison with the boundary barren hills. The satellite image is that of an indented garden city, according to the places orography and marked by irregular and sprawling road network. Until five years ago, this urban fabric was divided into two sectors by seasonal alluvial gravel bed, which reaches the Drino river from the SW narrow valley. In satellite images, it appears as a clear stripe uncultivated, in the middle to a green stain.

At this date the anthropized area (including houses, roads and gardens) is 1 square kilometer. At the beginning of the remote sensing mission, the anthropized area was 2.5 square kilometers: the green fabric had filled the alluvial river bed, and had occupied part of the SW narrow valley. The data reading from the July 22, 2013 highlights that the anthropized area measures about 4 square kilometers, or it is gradually occupying the entire bottom of the SW valley, and is expanding towards the northern side hills, not particularly rugged, reaching the Drino river.

While hyperspectral, thermal, multi-spectral and photographic scanning data on Lazarat shall be addressed to combat the illicit cultivation of cannabis, the diachronic analysis of anthropized fabric of the city and neighboring areas could be a starting point for critical reflections on the evolution of the human peasant culture, before and during the intensive use of cannabis. All aimed at the definition of valid hypothesis, after the complete eradication of cannabis.

5. Geo-intelligence as new frontier for an effective economic and financial police activity, through multitemporal analysis (Stefano Bastoni, Giuseppe Casbarra)

We started our activities of recognition, census and monitoring of the Cannabis plantations on the Albanian territory after the agreement between the Italian Government and the Council of Ministers of Albania signed in Tirana on the 19th July 2007. The main aim of this agreement was the strengthening of the cooperation between these two countries against racket and especially against drug trade.

On May 16th 2012, in Tirana again, was signed an Operational Protocol between the Public Security Department of the Italian Home Office, International Cooperation Police Service and the Central Department of the National Police of Albania.

The big novelty in this Operative Protocol was the introduction of the airplane with airborne remote sensing in order to research and identify cannabis plantations. That was a really effective change both for safety in research operations and for its innovative scientific results.

The international cooperation given by our country, by the Guardia di Finanza aircraft in order to support the Albanian democratic institutions has also another important aim: It wants to stem the drug trafficking starting in Albania and ending in Italy and Europe through our ports and coasts, fostering the economic power and the territory control of the criminal organizations.

For us, Guardia di Finanza, the operative target of this international mission was to locate and focus on the research of the wide, hidden and often unreachable cannabis plantations whose massive production represents a big danger for the European social and economic order.

According to the cooperation agreement the Albanian police has the task of extirpation of the cannabis plantations.

Fig. 19: Airplane Piaggio P168 DP1 of the GEA-GdF in Albanian territory.

The effectiveness of Guardia di Finanza mission has been due to the extraordinary cooperation with the university researchers of the Regional Centre BENECON, established in the Second University of Naples(SUN).

Fig. 20: The instrument's dashboard on board.

The operative-scientific partnership between Guardia di Finanza and the research center Benecon allowed us to create a high resolution thematic geo referred cartography aimed especially to the recognition of the cannabis plantations. So a mixed team of members of Guardia di Finanza and

scientific researchers of Benecon created a temporary lab, in Tirana, where they have planned, organized and processed all the data coming from the devices for remote sensing and from high resolution cameras placed on the airplane Piaggio P166 DP1.

Fig. 21: An high resolution image of Lazat taken by PhaseOne iXA of Guardia di Finanza.

The activity of airborne survey was addressed to those areas of the Albanian territory particularly suitable to illicit plantations of cannabis for their orography. These areas are usually far from big towns and they are hubs of criminal organizations.

According to the 2012 US State Department report, the production and the consumption of cannabis are growing. However, we think that these data are so alarming, because, with our sophisticated equipment, we know now what some years ago was simply unimaginable.

Now here are some useful data to understand the range of the work done:

- With our 25 flight missions, in two months, we have monitored 3,618 square kilometers of the Albanian territory, something like the 12.5 % of the whole national territory;
- We have acquired 675 Gigabyte of hyper-spectral data and 680 Gigabyte of high-resolution images;
- The processing of all these data has given us the possibility to discover and map, with extreme precision, 304 cannabis plantations on 4.5 hectares of land ready to produce 32 tons of product.
- A very meticulous check has given us a clear knowledge of the very special situation of Lazarat, the town that has more than 319 hectares of land cultivated with cannabis. This area produces more than 900 tons of cannabis whose value on the European market is the same as 4.5 euro billions.

Our mode of operation for the recognition and the monitoring of the cannabis plantations is a reason of proud for our Country. Because we succeeded in putting together in a new and synergic way academic and scientific competences with professional and technical competences all supported by a well-advanced technical equipment.

The 'Seconda Università degli Studi di Napoli' had also a very valued collaboration with the Mediterranean Agency for Remote Sensing and Environmental Control (MARSEC) that has increased our knowledge of the territory with its satellite data.

We have, in fact, decided to use optical and hyper-spectral sensors in order to collect data and to produce thematic geo related maps.

In particular our collecting data process on Lazarat has been increased by the digital images supplied by the Eros B satellite that are distributed by MARSEC.

EROS-B is an Israeli satellite launched in 2008 with an orbit at 600 meters of height and an optical resolution of 70 cm on the ground.

The satellite images with those taken by the Guardia di Finanza aircraft, with a resolution of 5 cm, have given us the possibility to know Lazarat territory as never before.

Such big amount of data creates the conditions to control the territory in a better way but also could be useful for its desirable improvement and possible reconversion of the cannabis plantations.

Nowadays the Airborne Remote Sensing represents for Guardia di Finanza the opportunity of widening its operative context. And the work shared with the SUN University underlines the unique value of the advantages coming from a positive collaboration.

We are sure that the geo related cartographic database will open new horizons to an effective economic and financial police activity that goes far beyond the search for drugs.

6. Conclusions

At the end of two years of investigation in Albania, the joint team of university and military researchers gained a good experience in the complex data management from airborne remote sensing, together with good knowledge of places, and practices of cannabis' cultivation. All this aimed at improvement of the expected results. In fact, after one year, the amount of plantations reported and the total size of cultivation increased considerably.

The comparative data reading between 2012 and 2013, however, highlighted the modification and the planting of new areas, especially in northern Albania. While it is to be noted that some areas cultivated in 2012 were uncultivated or burned in 2013, thanks to the intervention of the Albanian Police, following the coordinates provided by the Italian team, at the end of each mission.

The research already planned for 2014 will be devoted to a greater and more detailed multi-temporal scan of the territory, especially in relation to the evolution of the cannabis plant. In this sense, at the end of the second year mission some test areas were chosen to scan cyclicly by hyperspectral, thermal and high-resolution cameras, in order to track the 'spectral signature' of cannabis, depending on the plant growing.

Technological evolution of the survey: a methodological approach to the Mobile Mapping Systems

Lina ABATEGIOVANNI

Department of Architecture and Industrial Design "Luigi Vanvitelli", Second University of Naples,
Aversa, Italy
lina.abategiovanni@unina2.it

Abstract

The proposed work aims to provide a methodological approach to the Mobile Mapping technology.

In the present research is taken into consideration the survey through laser scanner, which makes possible a two-dimensional and three-dimensional modeling of the natural and built with a high density of the defined points.

More specifically, it is studied the origin and evolution of Mobile Mapping systems, paying attention to the different situations in the market place and quoting systems VISAT™, ARAN and IP-S2. This raises also the emphasis on the possible applications in the field of survey, summarizing the vehicle detectors in the road sector, and the use of inertial sensors in the context of land navigation. The goal of the methodological approach outlined below highlights a survey facilitated in terms of accuracy, reliability, flexibility and range of use; a survey which is measured from time to time with the tools and technologies available to propose an integrated solution of the knowledge.

Keywords: Survey; Land Navigation; Mobile Mapping; Laser Scanner.

1. From laser scanner to Mobile Mapping systems: Introduction

The surveying technique using laser scanning is having an increasingly widespread in the field of detection. The evolution of information technologies has led to a rapid development and refinement of techniques for detection of solid objects opening interesting perspectives for applications in various fields.

The laser scanner for detection are able to detect millions of points in a few moments with satisfying accuracies in various application fields. The technique consists of the acquisition of metric data structures and deformed because of a detecting apparatus to laser beams.

The result is a three-dimensional point cloud which reproduces exactly the condition of things of the analyzed object, allowing the subsequent solid modeling.

The laser scanning systems operate in an almost fully automatic, and are able to acquire a remarkable number of points per second at times even in the thousands.

From the initial rapid evolution of instrumentation for three-dimensional detecting, there is now a marked attention to the development, improvement and refinement of the techniques of data processing software.

During the last few years, therefore, the relevant technologies have greatly evolved through the use of the laser scanner that allows a two-dimensional and three-dimensional modeling of the environment with a high density of defined points.

Mobile Mapping Systems (MM), combining the precision navigation and digital photography, it has been developed from studies of pure academic interest to commercial applications for land, aircraft and marine vehicles. The extension of the use of MM is related to the parallel technological development that affect systems of digital cameras and lasers.

The term Mobile Mapping was born to indicate the detection techniques by moving vehicles, in which the data acquired from the onboard sensors are directly georeferenced, that is expressed in the desired reference system, thanks to a system of positioning and orientation installed on the vehicle.

It defines Mobile Mapping System (MMS) any mobile platform equipped with sensors and measurement systems adapted to provide the 3D position and almost continued of the platform simultaneously able to acquire geographic data, without the use of control points on the ground. The scanning sensor, mounted on a motorized base, by recording all the visible architectural points compared to the scanning center, according to an adjustable step by the user. As for a topographic survey operated with total station, this survey system requires connection to a polygonal network, with the difference in the greater number of measured and recorded points.

The techniques and instrumentation to deal with the issues related to MM are deeply evolved thanks to the diffusion of 2D-3D LiDAR systems with high performance. These systems allow scanning of roads and road infrastructure with speed and performance until recently unthinkable. From the point of view of the media the introduction of Google Maps with Street View has made possible that systems of this type would reach even users not in this industry. In the context of mobile robotics, this issue is best known as Simultaneous Localization and Mapping (SLAM), which is currently one of the biggest challenges that build/upgrade 2D and 3D maps of the environment and at the same time use them to locate improving the performance of the process of location based on GPS data.

Examples of MMS can be found in different areas and applications. This requires a high level of hardware and software integration of all processes of measurement. The high integration often reduces the work of post-processing and data are often available in real-time using reliable estimates. The current upward trend of the request for survey via MMS is due to the need to quickly and inexpensively acquire geographic data. The rapid technological development in recent years is allowing this. The costs of kilometric survey of Mobile Mapping System, with equal number of detected characteristics, are generally content, when compared with techniques such as aerial photogrammetry or the classic topographic survey. With the MMS systems it has been integrated two fundamental branches of geomatics, geodesy and photogrammetry/remote sensing.

From a systemic and structural point of view, essential components of a vehicle for the MM are therefore the system of positioning and orientation, the onboard sensors, the synchronization system, coordinated by a management system; auxiliary systems are then the data storage system and power system of devices and computers. The control system must allow the verification during the operations of the state of each system, to control the progress of the survey. In particular, they must be verifiable the quality parameters of the navigation data (GNSS constellation status, and their parameters; the state of RTK solution, if available, the state of the navigation solution Real Time GNSS/INS, if available); similarly, it should be able to check or change the status and the acquisition parameters of the sensors (sampling rates, adjusting the brightness and contrast of parameters or iris for cameras, etc.). Finally, an interface should be provided for storage management, with the possibility of defining new files/projects and monitor the regular data storage, the status of available memory, etc. Usually the vehicle is equipped with two video capture sensors and a GPS receiver. The front camera is oriented along the direction of march and enables you to capture information related to the vertical signage, the cross section and the presence of accesses; the rear camera is oriented orthogonally to the road paving and instead allows the extraction of information about the state of the pavement and the trajectory travelled by the vehicle. The video sequences are performed in order to obtain the synchronous frame acquisition rate of the GPS sensor, which enables the geo-referencing of information extracted from the frame. The method also allows the accurate knowledge of the distance vehicle signage of reference, this allows you to get a new seeding of points coinciding with the horizontal signage, thus making easier the extraction procedure of road geometry. The methodological approach, therefore, can only be based on footage of the roadway by video or photo-cameras installed on the vehicle in motion and treatment of those with photogrammetric techniques, where possible, geo-referenced using GPS/INS for a "direct" photogrammetric restitution. The use of GPS equipment in kinematic mode is particularly suitable for the survey road, in particular, the technique of differential GPS with measurements phase is extremely valuable; using said technique in kinematic mode; it is obtained, in fact, a significant benefit of precision and speed allowing the survey of a sowing of representative points of the trajectory traveled by the vehicle. Although the differential GPS technique based on phase measurement has been used for a long time in kinematic applications, a fully operational however requires the resolution of some issues related to the use of the pair of receivers.

2. Origin and Evolution of Mobile Mapping Systems

The origin of the term Mobile Mapping is linked to detection techniques from moving vehicles in which the acquired data thanks to the sensors on board are georeferred thanks to a system of positioning and orientation.

The ultimate goal of such systems is therefore not necessarily the "mapping", intended as survey mapping purposes, but the determination of the position, and possibly structure, of any sensor (or

thermal photogrammetric cameras, laser scanners, gauges the roughness of the road surface) mounted on the moving vehicle, regardless of the final use of the data acquired by them.

The detectors vehicle in the road sector arise from the research of the civil sector on terrestrial inertial navigation, mainly developed at the University of Calgary (Canada) from the second half of the 80s (and continued in the 90s with the integration of GPS) giving rise to a series of prototypes; also the most significant commercial implementation in the road sector is Canadian, while not lacking in examples of detectors vehicle in the U.S. and Europe, primarily of prototype, built by research institutions of important companies or universities.

While GPS technology is basically free, with handset manufacturers and software processing of data distributed in different countries, that of the inertial sensors is still largely subject to constraints and restrictions to prevent the use for military purposes by some third countries; in particular sensors for high-precision navigation (strategic- grade and navigation-grade) are mainly developed in the U.S. by Honeywell and Litton. When these systems are marketed as components of integrated systems, there is a contractual obligation not to disclose the certificate of calibration of the instrument.

There are also a manufacturer of inertial systems in France, Germany, with products suitable for the use in MM. There are also numerous companies in Europe (UK and Germany in particular) but also Canadian, U.S. and Japanese, which integrate the two sensors producing navigation systems GPS/ INS; In this case the added value of the product is given precisely by the integration in terms of interfacing and synchronization, signal processing, calculation of the position parameters, kinematic and trim with Kalman filter in its various implementations (loosely coupled, tightly coupled, etc.). In particular, the first trials of MMS applications for earth vehicle date back to the early 90s, when the GPS was not fully operational yet. In 1993 there were already MMS land and air supplemented with digital cameras. Since then, improvements to these vehicles are due to technological improvement and miniaturization of GPS receivers, to the development of new methodologies to provide the differential correction GPS and to the use of low- medium cost IMU systems available from the second half of the 90s. In the early 90s they used systems INS (Inertial Navigation System) of navigation-grade class, usually the type strapdown of laser-ring. Their cost was around the \$ 130,000 (1990). With the fast decrease of the cost of the GPS receivers IMU system becomes the most expensive part of the system. At the end of the 90s IMU systems spread at low cost. Since the 2000s it was developed the fiber optic gyro systems reaching accuracies close to the needs of high-precision measurements at relatively low cost (\$ 30,000).

Historically, the first applications were those in the road sector, where the emphasis normally affects a range of about 10-15 m (or greater) straddle on the road and it is carried out at speeds between 30 and 70 km / h. The primary areas of application are the cadastre roads and road maintenance, as well as the importance of elements of infrastructure, networks and urban and suburban services along the roads.

To this day, detection systems that combine navigation and survey, the majority of whom voted for the acquisition of GIS data (such as the Cadastre of roads required by Italian law) or for three-dimensional modeling of the roads and their surroundings, are commonly called Mobile Mapping Systems (MMS). During their development, these vehicles have been identified in the literature with different terms, such as Automatic Vehicle Location and Navigation (AVLN), Intelligent Vehicle, Highway Systems (IVHS), Intelligent Transportation System (ITS) and only recently they are universally recognized as Mobile Mapping Systems. The wide literature concerning the application of MMS to the detection of road information allows us to classify MMS terrestrial systems according to the architecture, processing techniques and the information needs arising from particular type of application.

In all the reality MMS that have been made and available on the market, there are some that have distinguished themselves over time, as true "milestones" in the development of these systems for their technology, or for particular applications in which they were employed.

Among them, three systems deserve special mention, the VISAT™, ARAN and the IP-S2.

The VISAT™ (Video Inertial Satellite), developed by the University of Calgary in Canada, in the late nineties, is probably one of the first MMS systems provided both of a system for positioning (POS) and one of the survey (photogrammetric cameras). Inside the VISAT™, in fact, in addition to a dual-frequency GPS receiver, a high-precision inertial platform and an odometer, there are six to twelve photogrammetric cameras aimed at the creation of geo-referenced panoramic images.

The cameras, enclosed in a protective shell with high quality glass and low distortion, can be installed in different configurations, to provide the visual coverage required depending on the type of application and survey (signs and road markings, traffic lights, fire hydrants, manhole covers, billboards).

The images are recorded at a programmable regular interval, depending on the elapsed time or distance traveled, in order to ensure an longitudinal overlap adequate for photogrammetric purposes. As regards the external orientation of the images, the position and attitude of the central outlet of each camera is georeferenced within the reference system of arrival from the integration GPS/INS, performed both in real time and in post-processing.

A second noteworthy MMS is undoubtedly the ARAN (Automatic Road Analyzer). Developed from the second half of the '80s, the ARAN vehicle is the first example of a modular multi-sensor, especially designed for the analysis of road surfaces, their roughness and degree of degradation. With over ninety copies in circulation (including five in Italy, purchased by Autostrade SpA and Sineco SpA) in approximately twenty countries, to date ARAN is without doubt the most widely used MMS, as well as the most significant achievement in the commercial sector road.

The third performed MMS is the IP-S2 (Integrated Positioning System-2) made by Topcon Positioning Systems. Unlike the two systems presented above, the IP-S2 represents the extreme of the concept of modularity dell'ARAN. It overcomes the challenge of the 3D survey with a high degree of accuracy and speed. Accurate vehicle positions are obtained using three technologies: a dual frequency GNSS receiver, an inertial platform (IMU) and external wheel encoders. These three technologies cooperate to ensure a 3D position of the vehicle with high precision.

The IP-S2 is a modular system, it is possible to add sensors based on the needs of the user. It is incorporated in a high performance geodetic GNSS receiver, able to process GPS and GLONASS signals, in order to obtain the maximum capacity of possible tracking. Furthermore, the IMU's inertial technology detects movement in space and provides information on the acceleration and rotation, at an high frequency. If it's combined with the precision GNSS measurements, the IMU allows the system to calculate the positions even when you get close to obstacles such as buildings or trees, or while going through a tunnel or an overpass, without compromising accuracy.

IP-S2 is also able to obtain information on the speed of the wheel due to external encoders with high precision that can be adapted on a vehicle that has no standard installed ABS or traction control. The aim is to estimate the speed and position of the vehicle, based on the position of the previous note. Finally, the system processes the sensor data and provides real-time results, which is given by the fusion of input data. The file recorded data can also be processed and post-processed and filtered off-line in order to obtain better information on the location and geo- registration of the data provided by the sensors. Specifically, the IP-S2 Compact+ includes up to five LiDAR scanner arranged to cover the roadway and the adjacent buildings up to 30 meters away. IP-S2 HD includes a scanner with sixty-four single laser, for generating a very dense cloud of points, with a flow rate of 100 m. Both systems host a high resolution digital camera that provides a 360° spherical images. All tools have a GNSS receiver, an inertial platform, an odometer, six cameras that can produce hemispherical images with high resolution and three laser profilometers, have been compacted within a single system "stand-alone" adaptable to any vehicle. The system is currently used, as well as applications of Mobile Mapping, also by Google™ within its Street View application. The installation of this system can be made either on the vehicle or on tricycle (called Google Trike™), to reach areas not accessible by car, such as parks, pedestrian areas and college campuses. In Italy, and in general throughout Europe since 2000 some vehicle detectors have spread, mainly of a prototype, made by research organizations of large companies or universities. Generally, it is abouts vehicles, almost always vans, which are equipped with different tools in a semipermanent, usually one or more GNSS receivers integrated to an inertial navigation system (POS), an odometer, a laser scanning system and a recovery, consisting of one or more cameras.

In general, in the current use the MM is now extended to all the systems of the positioning and orientation in movement that have precisely the ability to autonomously georeference the position and alignment of one or more sensors installed on board: from the laser scanning plane, photogrammetry live, etc. More correctly we could speak of sensor orientation through a Position and Orientation Systems or POS; In fact, the goal is not necessarily the mapping (that is the topographic survey), but simply the determination of position and attitude of any sensor, regardless of the way the final of data it has collected.

3. The use of inertial sensors in the field of the land navigation

With the term navigation we indicate the methods and techniques for determining the position and attitude of an object in motion.

An inertial navigation system is an aid that uses a computer and motion sensors to track the position, orientation, and velocity (direction towards and form) of an aircraft without the need of external references. An inertial navigation system includes at least one calculator and a platform or module containing accelerometers, gyroscopes, or other motion-sensing devices. The system is initially provided of its velocity and position from another source (an operator or a GPS satellite receiver), and thereafter computes its updated position and its velocity by integrating information received from the motion sensors. The advantage of this system is that it does not require external references to determine its location, its orientation, or its speed once it has been started. It can detect a change of its geographical position (for example, a shift to the north or to the east), a variation of its velocity (speed, orientation and direction of motion) and a variation of its orientation (rotation around a axis). This is done by measuring the linear and angular accelerations inflicted on the system.

Because external references are not required (after the preparation), the system is immune to false

transmissions and to intentional electronic noise.

The inertial navigation systems were originally developed for the guidance of rockets. They came into use more widely with the advent of spacecraft, guided missiles, and commercial airlines. A famous example of INS system for commercial aircraft was the Delco Carousel system, which provided a partial automation of navigation in the days before the common use of flight management systems. The Carousel allows the pilot to enter a series of reference points, and then to guide the aircraft from one point to another using an inertial navigation system for fixing the position. Some aircraft were equipped with two Carousel systems for safety reasons. The use of inertial sensors in the context of land navigation was subject to a significant increase in the recent past, especially with the continuous development of satellite positioning technologies, such as NRTK (Network Real Time Kinematic) and OTF (On The Fly), as well as the algorithms of integration of different sensors increasingly high performed, both for the real time and post-processing.

Generally, the multi-sensor navigation systems, both land and air, use a Data Acquisition System (DAS) for the synchronization, management and storage of real-time data from sensors on board, and a Positioning and Orientation System (POS), which is responsible for processing (in real time or in post-processing) navigation data.

The navigation sensors normally used are one or more GNSS receivers, an inertial measurement unit IMU (also known as inertial measurement unit) and possibly an odometer (DMI, Distance Measurement Instruments). The integration of these sensors allows the estimation in a fixed reference system, the states of navigation at a high sampling rate, generally equal to or greater than 100 Hz. To define the specifications of a navigation system it needs start from the accuracy requirements of the application where such a system is intended. As soon as we understand the well-know characteristics of intrinsic accuracy, namely those related to its system of reference of the sensors used, it is possible at first glance to obtain an esteem of precision in the final reference system, through the laws of propagation of variance and by numerical simulations.

4. Applications of mobile mapping: methodological approach

The survey of the geometric characteristics of the road infrastructure is very timely and has enabled a number of researchers in the development and field-testing of innovative methods. Applications for land navigation, which this research is about issue are related to the Mobile Mapping systems, namely systems that are fixed on moving vehicles, intended for the production of photogrammetric digital mapping, and for the creation and/or updating of land registers of the streets and local computer systems.

Primary objectives of the application of mobile mapping are to acquire and cataloging some of the information needed to carry out the road asset, such as signs and road markings, signage, cross section, the state of the pavement, geometry axis and side entrances.

In Italy, with the enactment of D.L. April 30, 1992, n. 285, begun a process which, through the publication of rules and decrees, should lead to a more rational organization and management of road infrastructure, including through training and upgrading of a Road Inventory. With D.M. June 1, 2001 was specified the characteristics of the Land register and were prescribed the timing of formation of the same for the different categories of roads. Were then drawn up specifications for the provision of specific data (measured or post-processed) and started its calls by operators of roads, albeit with amendments and interpretations with respect to the original text.

At the moment, besides the motorway sector, where the attention to the problem of maintenance and regular exercise also through the use of vehicle detectors had already formed some time, ANAS and a number of provincial governments have given rise to contracts for the realization of the Land register. Although many municipalities are proceeding in this direction, especially where the management of services is already implemented or relies on geographic information systems.

In road applications is normally always present a shooting system, consisting of one or more cameras, both for documentation and to make measurements with photogrammetric techniques; depending on the profile of the mission are then used other survey instruments (in particular, the scanning laser), or other tools specific to the acquisition of the characteristics of the road surface (such as roughness, cracking, etc.).

From a survey made thanks to mobile mapping systems (Fig. 1; 2; 3) is possible to extract informations on the type and size of the cross section of the infrastructure, the state of degradation of the road surface, the actual path travelled by the vehicle that passes on the infrastructure, the presence of accesses and billboards. From the extracted frames of the posterior chamber is possible to determine at any moment the position of the centerline of the vehicle relative to the road markings, if any, provided that enables you to generate a new seed points called "auxiliary sowing" that best approximates the actual geometry of the infrastructure. In addition to survey for Road Cataster and road maintenance, applications can cover several areas including "City Modeling" (surveys of cities, urban areas or industrial sites and generation of 3D models); surveys of the area with restitution of digital surface models (DSM) and digital terrain model (DTM); pads quarries and plants for calculating

Fig. 2: Extraction of geometric informations about the elements of the road section.

Fig. 3: Example of mobile mapping survey inside the tunnels.

surface and determination of the volumes of storage/excavation; measurements of functional characteristics of road surfaces/airport such as the parameters of longitudinal regularity (IRI) and transverse (rutting), and the values of the surface degradation and macrotexture values. Another area of interest of Mobile Mapping is the bathymetric survey of the river or the coast. Made with profilers or scanner sonar, leaned to the GPS satellite system since the introduction; in some cases, such as the delimitation of the waterways in riverbeds or lagoons or estuaries subject to deposition, the accuracy of the location about the order of the meter is usually sufficient.

5. The GPS technology for MMS

GPS technology as part of the survey by moving vehicles instrumentation is crucial for many aspects. Of all the sensors is the only one that allows a positioning directly in a geocentric reference system and therefore forms the basis of the positioning of the mobile means and sensors for the detection of the magnitudes characterizing the roadway in a broad sense. The accuracies achievable by a GPS system used in kinematic mode are centimetric but this parameter may be variable depending on the instrumentation and the operating mode of the survey adopted. From the literature and from experiments conducted by the various operating units that have studied the problem, the GPS system used in kinematic mode with the aid of a GPS reference station placed at a distance of some tens of kilometers, allows centimetric accuracies provided a good initialization procedure, and provided you do not lose the acquisition of satellites. Such conditions in practice are not warrantable for the obscuration by obstacles of a significant number of satellites in the course of the motion. Currently, those who work in this area are equipped with integrated IMU/GPS which require the use of two GPS receivers. The integration of GPS/INS requires that the navigation system decides in every moment what sensors you can get the most accurate information from, or it mixes together the data from the various sensors to search for the optimal solution. The most commonly used method for the search of the optimal solution provides for the introduction of a filter, which can be generically defined as "a set of equations that combine informations from different sensors in order to provide an optimal estimation of the position of the vehicle". The GPS system provides absolute data, necessary to contain the error - time employee of INS. Between two absolute readings the filter estimates the new position using inertial sensors and odometry (prediction phase); when it reaches an absolute measure, the filter estimates the new state of the vehicle determined by applying a weight function between the prediction and the measured value (being updated). A filter widely used in the GPS/INS systems is the Kalman filter. The manner in which the data are being integrated GPS/INS are essentially two, known as loosely coupled and tightly coupled integration. In the first GPS data they are processed in order to obtain the information of position and speed, and this information to be integrated in the filter with data from IMU. In the second mode, the filter combines directly the raw data of the GPS with the IMU. The tightly coupled mode has the advantage of being able to also use the GPS data coming from less than four satellites to improve the determination of the position. The INS-GPS integration is essential and used, with different technologies, virtually all MMS. As regards the system of positioning and orientation, as said the combination GPS/INS is today the most efficient system (in terms of productivity, reliability and accuracy) that technology can offer; there are also important differences in the ways in which it carries out the integration between the two systems GPS and INS and equally important are the hardware features, especially for the INS, with regard to system performance. Rather than lean on the GPS, you can use other systems (for example, have been used and are still used for navigation apparatus for radiolocation by ground stations or satellite). In practice, however, the GPS, or equivalent system, is now indispensable for the advantages in terms of coverage and precision. The classical methodology could solve the problem about georeference only with a block of partially overlapping pictures and a sufficient number of control points on the ground. There are also vehicles for MM who rely on GPS alone, with systems mono, bi or tri-antenna. In the single antenna systems, the accuracy is very low and does not allow the comparison of the accuracy of Italian standard on the subject: it is in fact possible to determine any parameter set-up, if not by integrating the system with electronic compasses and inclinometers. In systems with two antennas (present, however, even on systems with INS) it is possible to obtain at least azimuth and pitch (the typical arrangement is in fact with antennas spaced along the longitudinal axis); obviously there is an error associated with the angle of roll, the more sensitive the greater is the cross slope of the roadway. The systems with three antennas, positioned at the greatest distance possible always to improve the sensitivity in the determination of the angles, instead allow a complete solution of the orientation (position and attitude). The accuracies obtainable from the refund with vehicle detectors are quite asymmetric: in fact in the longitudinal direction the accuracy decreases rapidly with the distance, because the angle of intersection between ray counterparts is always very small and the ratio between base and remote return varies within rather broad limits (approximately 4 to 15), much greater than those of aerial photogrammetry. The need for angular precision in orientation of the sockets are not as stringent, given the scale frame normally much lower and therefore the lower the ratio of angular error on the frame and the corresponding error on the ground. Even pluriantenna systems based on GPS

only on paper so they are able to meet the required specifications. In any case, to obtain greater precision in the relative positioning of the two or three kinematic antennas sufficient to obtain the values just mentioned, is very important to the ability to process the kinematic data of the GPS antennas in the most efficient possible way, using the constraints of location relative between the antennas. In practice, however, the continuous dependence on the availability of the GPS solution makes these systems not to be proposed for a truly operational use: in most real significant situations the vegetation in fact, over and underpasses, buildings, etc. lead to frequent and complete "loss of lock" with heavy repercussions on the continuity and quality of the GPS solution.

6. Conclusions

Mobile mapping technology is able to meet a wide range of applications thanks to the versatility of the system and the speed of acquisition of information that can achieve high productivity in the field and a consequent lowering of costs. These in fact equal to the information collected, are usually limited when compared with techniques such as aerial photography or classic topographic survey.

It is observed that the appearance of the survey with these detection systems is facilitated in terms of accuracy, reliability, flexibility and range of use.

In fact there are simplifications and savings of time and capital invested very significant and greater productivity of the survey itself; then you have both lower operating costs (fuel, maintenance and depreciation of the vehicle) of the survey, both savings on additional staff necessary for the management and monitoring of the receiver at the known point. These benefits are found both in terms of quality in the way they operate on the territory or rationalization of operations resulting in reduced costs of data acquisition. Moreover, the system is very interesting for its modularity, it can be used several types of laser scanner sensors, inertial platforms and systems to shoot images. Depending on the purpose of the survey and the required quality is therefore possible to use the best of each measurement technique with the right equipment to ensure the best performance and to allow the best result.

Abstract

The study of the shape of the Earth involved philosophers , mathematicians, ' surveyors ' , draftsman who , based on their knowledge and skills, attempted to return with different methods and techniques and on different media , the geographical and spatial information for its three-dimensional and two-dimensional maps of the world from globes to the maps, since ancient times. During the twentieth century , with the progress of aeronautics - military and civilian - the study of the geometry of the Earth and its cartographic representation had significant developments related to aerial surveys and the emerging technique of photogrammetry from architecture (land) was strategically used in the recording of photorealistic large portions of the territory. Technological advances and the political and cultural events always influenced the evolution of the representation of the Earth. In some areas of study and analysis of the natural and built , the reading of the information contained in the maps can be the basis for knowledge both punctual that general of the land . Modern technology , with the development of sophisticated digital atlases and web offers the chance to read the evolutionary processes and the urban transformation of the territory and stands as an indispensable instrument of knowledge, research and forecasting changes and transformations .

Keywords: Remote sensing, Cartography, Territory.

1. Reading the Territory

The cartographic representation of a territory originates from direct experience, from a relief or a combination of different elements, suitably adapted, are shaped in a scaled image.

The representation of the shape of the Earth took on different forms depending on the various scholars that you are passionate about it: by philosophers to mathematicians, surveyors and draftsman.

The maps edited by geographers and travelers, useful to pass the armies and goods, contributed to the knowledge and the government of the territories measured and represented.

The maps, in fact, take on different forms and meanings depending on the requirements that must be fulfilled: those nautical policies, from topographic to thematic map.

Probably, the cartography originated with the beginning of human history; with the evolution of civilization, man had the need to represent the earth in order to facilitate its displacement for both economic and military purposes.

In the history, then, the passion for the representation of the land led scholars to produce globes and maps. The production of paper, in fact, guarantees the possession through the description and reflects the social and the productive capacity of a particular historical

moment. The paper is a reflection of the culture that produced it, and it reflects the values of a particular period.

During the twentieth century, with the progress of aeronautics - military and civilian - the study of the geometry of the Earth and its cartographic representation had significant developments related to aerial surveys and the emerging technique of photogrammetry from architecture (land) was strategically used in the recording of photorealistic large portions of the territory.

In the nineteenth century the majority of European states, aware of the need for reliable maps and updated to serve not only the needs but also those of a military character of technological and social development of their countries, began to draw up appropriate bodies responsible for implementing to work on the structuring of geometric and cartographic survey of the areas of relevance. Italy, because of the particular historical events, only after 1870 formulated a unified mapping project. The "I.G.M." began a long journey in the service of Italy, promoting the development of scientific and technological progress. The great cartographic institutions started to create maps using more advanced systems.

The development of electronic computers, electronic measurement of distances by means of laser beams and light, and the use of computers in the design of the cards, together with the increasingly sophisticated software have enabled a rapid evolution

Fig. 1: An example of "IGM" image

The system now widely used for the production of topographic maps is photogrammetric survey, for which we make use of an aircraft flying in a straight line, at constant altitude and speed, and runs at intervals of a predetermined time, a series of photographs on a portion of territory by acquiring spatial data from different angles. The pictures are taken in succession in order to have an overlap between frames. In this way, the whole territory under investigation is covered by image overlap. With the ability to superimpose contiguous images you are able to see what is taken up in three dimensions. The ability to see in 3D allows to have, in addition, a whole series of information in more compared to the vision in 2D. It is thus able to identify forest species, flood zones and areas such as moving landslides.

A real revolution was determined from satellites ERTS (Earth Resource Satellites Technology), supplied equipment for remote sensing, sensitive portions of the electromagnetic spectrum invisible to the human eye.

The type, the quality and the coloring of the images depend acquisition techniques and by the choice of wavelength capable of bring out a specific phenomenon.

The information is transmitted to the ground stations where appropriate, using very sophisticated programs are decoded and converted into readable images. In this, so you will get the documents that allow cartographic processing of high accuracy for almost inaccessible areas.

Above our heads spinning a large number of satellites that orbits and regular every day detect a portion of territory of variable amplitude.

2. The map: a "snapshot" of reality

There are several reasons that prompted and necessitated the translation into signs of the territory and of the individual elements that make it up: the cartography; is both a small and symbolic representation of the reality that a set of signs ordered and relevant to a space man-made, systematized according to a syntax and grammar graphics.

It represents a "snapshot", a picture of the result of natural and anthropogenic agent of that until that time the portion of the Earth represented but assumes, also, the double value of future scenario of that particular place.

The changes of an area were the subject of graphics editors; the great informatic revolution outlined new areas and geographies paving the way for new methods of representation like dynamic maps, animated and interactive.

Increasingly sophisticated and technology have produced cybermappe where the image changes as the world changes the measurement of distances and relationships between the parts of the world.

The approach on the part of man is come to change and has expanded with the development of technology and some key events in history.

Man has always tried to devise simple and reliable system for determining the location of the place where he was on the earth's surface and tried to imagine and realize the direction in which it was moving.

The GNSS system was the most efficient response to this need of man, it defines the global positioning system based on satellite constellations. At present GNSS systems affecting Italy and Europe. GPS (United States), GLONASS (Russia), and Galileo (European Community). The GPS was originally designed as a system for the defense and then, initially, largely protected against external interference.

In 2002, however, it was decided to eliminate the Selective Availability or to the limitations and restrictions for safety reasons, so it is now possible to determine the absolute position with submeter accuracy.

The cartography became a tool designed to act as a support to a type of information disseminated and accessible to all.

The Internet has made outstanding contributions in the development of the discipline for which the geographic information is available to everyone.

The mapping language has changed and it is intelligible to more and more spectacular images. The symbols, in fact, can be read by a more careful eye and preparation; reading an image, result of remote sensing, is instead clear and immediate eye not expert.(Fig.2)

The great development of the cartographic distribution is related to the growth of the Internet as a means of communication, and in it the phenomenon of the world seen from above has become increasingly important over the years: just think of the great diffusion of digital atlases. (Google Earth, Google Maps, Bing, EarthView).

Fig. 2: An example of orthoimage of the province of "Caserta" (2011).

3. Conclusions

In the research , the remote sensing images have assumed a central role in knowledge both puntual that the general of the land.

Modern technology , with the development of increasingly sophisticated digital atlases and web offers the chance to read the evolutionary processes and the urban transformation of the territory and stands as an indispensable instrument of knowledge, research and forecasting changes and transformations .

The research aims to consider the oldest maps as a starting point for the study of a specific area .

A valid path to knowledge lays the foundation temporal analysis of aerial photos , thematic cartography by up to online images of modern digital atlases .

Such a type of integrated analysis , in fact, can afford to rebuild the historical -temporal evolution of an area under study.

The applications of modern technology of remote sensing are considered essential as a method of study, research and forecasting processes of land transformation .

It is essential the ability to interpret the data according to subjective basic interpretive skills in reading complex tracks and signs inherent in the territorial system .

Regeneration of Carditello

Gilda EMANUELE

Architecture and Industrial Design Department Luigi Vanvitelli SUN Second University Naples, PhD student, Aversa, Italy
gilda.emanuele@gmail.com

Abstract

The Real Estate of Carditello, located in the municipality of San Tammaro in Caserta Province, is a part of the Bourbon Sites acquired by the Crown in the reign of Charles of Bourbon and Ferdinand IV. These sites were typically farmhouses, rich vegetation, pastures and game, suitable for leisure activities, such as hunting.

The Real Estate of Carditello, called Real Delight, was intended by Charles of Bourbon for hunting place and breeding of horses (1716-1788) and accommodate in the architectural complex, designed by Francesco Collecini, a student of Vanvitelli, the royal family to return from hunting. Later it was transformed by Ferdinand IV of Bourbon in a model farm for the cultivation of grain and livestock of special breeds of horses and cattle. The entire estate in the intentions of Ferdinand IV was to serve as a prime example of its adherence to the policy farm.

The project of restoration and renovation of the architectural complex is compatible with the original function, briefly described, and in particular it recovers the historical productive vocation of the Estate.

Carditello

Carditello

The Real Estate Carditello, located in the municipality of San Tammaro in Caserta Province, is part of the Sites Bourbon acquired by the Crown in the reign of Charles of Bourbon and then Ferdinand IV. These sites were generally old country, rich in vegetation, pastures and game, suitable for leisure activities, such as hunting. Among these, the Casino Royal Carditello called Real Delight, which was designed by Charles of Bourbon in place for hunting and breeding of horses (1716-1788) and to welcome in the architectural complex, designed by Francesco Collecini, a student of Vanvitelli, the royal family to return from hunting. It was later transformed by Ferdinand IV of Bourbon in a model farm for the cultivation of grain and the breeding of quality breeds of horses and cattle. The entire estate of Ferdinand IV in the intention was to serve as a prime example of its accession to agricultural policy. [1]

The activity detection with integrated digital platform plurisensore Mobile Mapping the route of the track perimeter of the Palace of Carditello, action is preparatory to the project activity within the programming of the Plan Management.

In this direction the first phase and the phases that follow the Management Plan of the UNESCO site in question are aimed at opening up new perspectives which must include other resources that are not yet included, such as the Palace of Carditello and its territorial scope, and that can not be excluded or marginalized. [2]

The second session involved the instrumental side roads the Palace of Carditello according to the route of the SP229 Carditello.

The processing of the data thus acquired has returned a single digital model integrated georeferenced (permanent reference station of the Laboratory ARS Benecon in Frignano) and full scale (1:1) of the

perimeter roads of the Palace of Carditello, which are intelligible model geometric 'point cloud' model and the photo of the building facades and street scenes traveled.

The project of restoration and renovation of the architectural complex of the Estate of Carditello .

The project of restoration and renovation of the architectural complex of the estate is compatible with the original function of the complex, briefly described , and in particular recovers the historical vocation of farm productive character of the palace built by Ferdinand IV of Bourbon.

The restoration project has focused in particular parts of the roof of the complex that retrieves the lines wrap around the old roof with the introduction of strips of wood to restore the original appearance of volume ; was also introduced the theme of the botanical garden with glass panels covered with photovoltaic film to change cromatica.

In particular, the new functions, the two-storey main building was entrusted to a representative function and exhibition halls used by the adaptation of temporary exhibitions on the ground floor and conference rooms and banquet on the first floor, respecting the historical function of these spaces designed to accommodate th

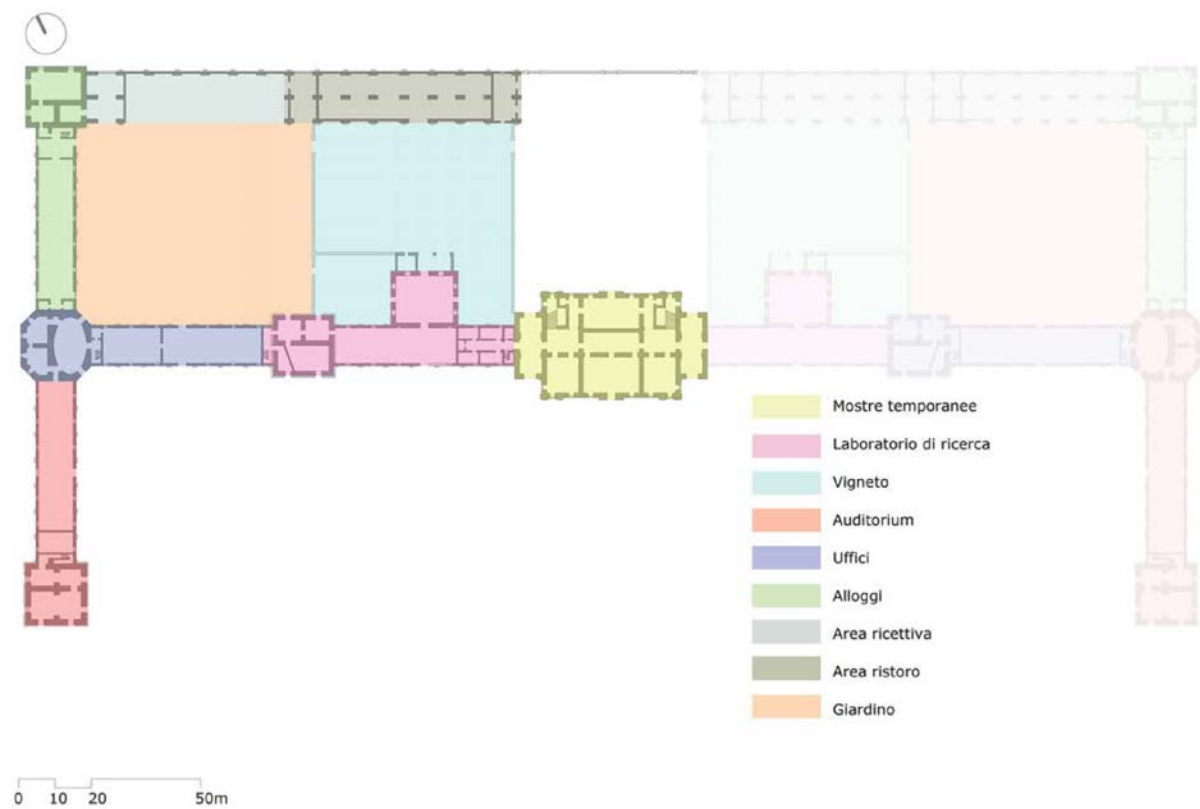

e royal family and halls for receptions held back from hunting.

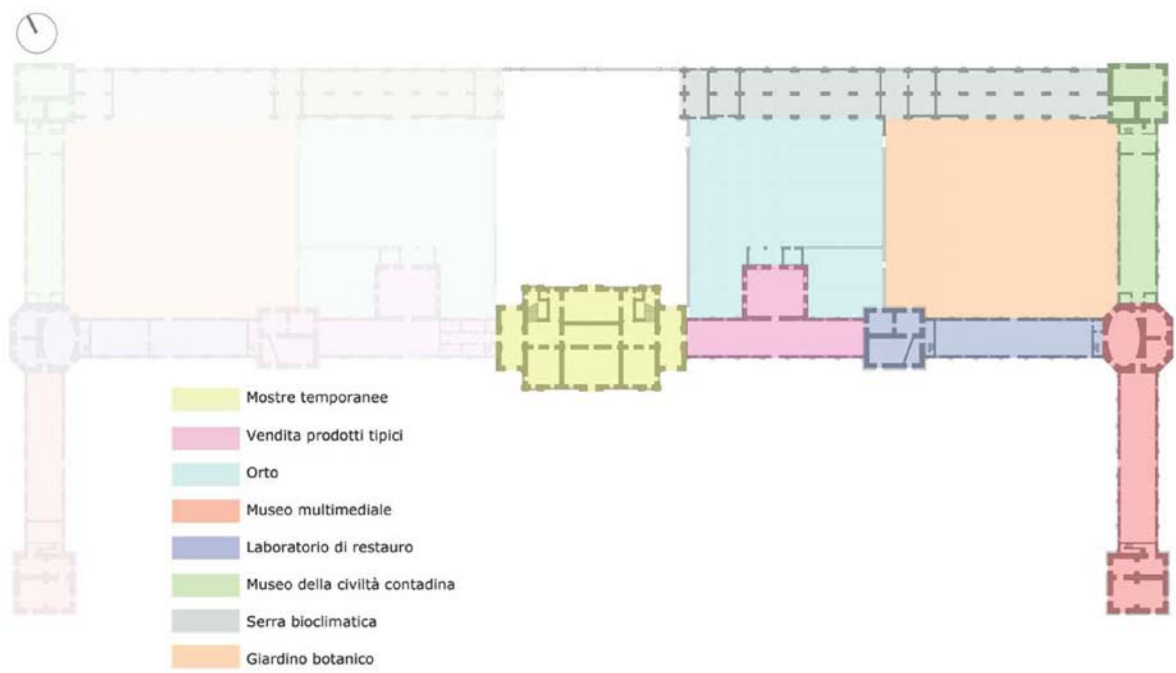

In the left arm were included research labs and offices; in the right arm restoration laboratories and rooms for the display of local products. The northern area has been devoted to the garden, the vineyard and the bioclimatic greenhouse closely related to the exhibition halls of the products. In the east wing of the complex was placed rural museum and the museum multimedia .

In the west wing directly related to the representation of the auditorium was placed on a structured auditorium with light steel structures. The part of the building at the northwest was instead given way to a small guesthouse with temporary housing for researchers engaged in research activities in the complex.

Recovery Plan and Redevelopment of an area in "Salice" (Foggia)

Gianluca CIOFFI

Architecture and Industrial Design Department Luigi Vanvitelli SUN Second University Naples,
Lecturer, Aversa, Italy
gianlucacioffi@hotmail.it

Abstract

The project is inspired from the idea of studying an urban settlement model, which gives order to the impulsive will of urbanizing a piece of territory in the Foggia's country, an extra-urban area named 'Salice'.

For years, this area has been victim of an abusive colonization, where private citizens have autonomously subdivided portions of the extra-urban territory. So, they substitute for municipal competent authorities, for the urban development planning and for the arrangement of a few project areas for residences and not, breaking the provisions and the planning instruments in force.

The reshape of this portion of territory in Foggia provides a particular attention to the paths, which are studied for allowing to delimit the area, as well as to design a straight park scheme, used as a green public area and, at the same time, as a connection between different points of the area.

In this way, the project aims to repair the impulsive primitive urbanization, fitting the area out with first and necessary instruments for starting the project of a new complex urbanization of the area [1].

Salice

Setting 1

1 The settlement is located near the SS16 towards the south- east of the town of Foggia. l'intervento circumcamminamento an O-ring that goes around the areas perimetrare recovered.

The project is based on the need to provide minimum elements of usability of the area , such as: adaptation road (1711 sq m) , sidewalks (503 square meters) , PV street lighting (for both road and pedestrian lighting) , planters, trees , various items of street furniture (benches and wastepaper baskets) and the island green space dedicated to the collection of waste .

In the space in front prospettante road is on an area of 125 square meters dedicated to parking with the availability of n . 10 stalls for cars.

Along the dedicated to parking is on the pitch also dedicated to ecological island (collection of waste) of about 35 square meters, this is designed as a green space where the containers are allocated for the collection.

The adjustment involves the insertion road on the edge of zanelle and grids for the collection of water and stone beads for beading edge road and allow a small difference in height elevation .

The green is expected according to a double register , before a line is formed by low hedges (approximately 165 m) which will signal further limit road , located behind the cordon of stone. Then there is a second line , the higher , which encloses the inner area under redevelopment. The row of trees (2 trees every 10 m) is designed with essences of strawberry tree (*Arbutus unedo*) , which allow an efficient shading during the hottest months , so as to regulate , in a natural way , the microclimate .

The lighting is designed with lampposts double armor so as to allow an effective illumination of the roadway is that of the pedestrian . The lighting system is designed without the provision of sub-systems or network being photovoltaics.

Widening the road: 1711 sqm
Parking: 125 sqm
Sidewalk: 503 sqm
Green bounding: 165 sqm
Green with Trees: 72 sq.m No. 165 _ 2 trees every 10ml
Cord: 419 ml _ 83.8 sqm
Bumps: 751.64 ml _ 225.49 sq.m.
Grids: No. 75 _ 1 grid per 10 ml
Ecological island: 35 sqm
PV street: n. 39

Setting 2

The project presents difficulties of insertion as the area appears to be consistently populated with buildings all the way to the road boundaries , creating some difficulty to intervene.

The project involves the upgrading of existing roads (1239.66 sq m) , sidewalks (614 square meters) injection of 248 square meters of parking split between the front main road (no. 12 stalls) and a small part (# 4 stalls) in the space behind .

Along the main road is also located on the island of 35 square meters ecological placed in a position to facilitate the collection of separated waste .

The adjustment involves the insertion road on the edge of zanelle and grids for the collection of water and stone beads for beading edge road and allow a small difference in height elevation .

The green is expected according to a double register , before a line is formed by low hedges (200 sqm) which will signal further limit road , located behind the cordon of stone. Then there is a second line , the higher , which encloses the inner area under redevelopment. The row of trees (2 trees every 10 m) is designed with essences of strawberry tree (*Arbutus unedo*) , which allow an efficient shading during the hottest months , so as to regulate , in a natural way , the microclimate .

The lighting is designed with lampposts double armor so as to allow an effective illumination of the roadway is that of the pedestrian . The lighting system is designed without the provision of sub-systems or network being photovoltaics.

In the southern area , in a more secluded than the rest of the intervention has been inserted a room for the testing of an urban vegetable garden of 310 square meters.

Widening the road: 1239.66 sqm
Sidewalk: 614 sqm
Parking: 16 200 sqm (248 sqm area occupied)
Green bounding: 204 sqm
Green with trees: 165 sq.m. No. 72 _ 2 trees every 10ml
Cord: 512 ml _ 102.4 sq.m.
Bumps: 1303 ml _ 391 sqm
Grids: No. 124 _ 1 grid per 10 ml
Ecological island 35sqm
Urban garden 310 sqm
PV street: n. 59

Setting 3

The intervention in its geometry looks quite tidy with a regular and a perimeter road system , in essence, already outlined.

The project involves the upgrading of existing roads (1634 square meters) , the insertion of 812.5 square meters of parking spaces divided between the front of the main road (no. 17 stalls) and another portion is arranged parallel to the avenues of penetration (no. 48 stalls) .

The pavements (1400 square meters) and the one-way cycle track (1750 sq m) with a width of 1.50 m walk and simultaneous ring around an area behind the most densely built up and configuring a kind of ideal circuit around it . The two paths are separated by a central strip of low hedge interspersed with elements of street furniture such as the wastebaskets .

Along the main road is also located on the island of 170 square ecological placed in a position to facilitate the collection of separated waste .

The adjustment involves the insertion road on the edge of zanelle and grids for the collection of water and stone beads for beading edge road and allow a small difference in height elevation .

The green is expected according to a triple register , before a line is formed by low hedges (hedges low total 936 sqm) which will signal further limit road , located close to the cord of stone, followed by a second line too low and formed by hedges to separate the bike lane from the pedestrian . Then there is a third line , the higher , which encloses the inner area under redevelopment. The row of trees (2 trees every 10 m) is designed with essences of strawberry tree (*Arbutus unedo*), which allow an efficient shading during the hottest months , so as to regulate , in a natural way , the microclimate . The lighting is designed with lampposts double armor so as to allow an effective illumination of the roadway is that of the pedestrian . The lighting system is designed without the provision of sub-systems or network being photovoltaics.

Widening the road: 1634 sqm

Parking: No. 65 _ 812.5 sq.m.

Green trees with interstitial (parking lot): No. 12 _36 square meters of greenery

Sidewalk: 1404 sqm

Cycle track: 1755 sqm

Green bounding: 936 sqm

Green with Trees: 468 sqm No. 234 _ 2 trees every 10ml

Masts green belt: No. 272

Cord: ml 1170 _ 234 sqm

Bumps: 3203 ml _ 961 sqm

Grids: n ° 320 _ 1 grid per 10 ml

Ecological island: 171 square meters

PV street: n. 114

Setting 4

The intervention in its geometry looks pretty neat with a smooth perimeter for the most part to the west, while more irregular and discrepancies with respect to the road system to the east .

The project involves the upgrading of existing roads (470 square meters) , the inclusion of 68 square meters of parking inserted parallel to one of the roads extended (No. 6 stalls) .

The pavements (888 square meters) and the one-way cycle track (1343 sq m) with a width of 1.50 m walk and simultaneous annular area around the rear (west) setting up a kind of ideal circuit around it . The two paths are separated by a central strip of low hedge interspersed with elements of street furniture such as the wastebaskets .

Along other roads or sidewalks are provided only as in the most irregular to the east there is only one row of trees to act as a border area confiscated.

Along the main road is also located on the island of ecological 171 square meters located in a position such as to facilitate the collection of separated waste .

The adjustment involves the insertion road on the edge of zanelle and grids for the collection of water and stone beads for beading edge road and allow a small difference in height elevation .

The green is expected according to a triple register , before a line is formed by low hedges (hedges low total 806 sqm) which will signal further limit road , located close to the cord of stone, followed by a second line too low and formed by hedges to separate the bike lane from the pedestrian . Then there is a third line , the higher , which encloses the inner area under redevelopment. The row of trees (2 trees every 10 m) is designed with essences of strawberry tree (*Arbutus unedo*), which allow an efficient shading during the hottest months , so as to regulate , in a natural way , the microclimate .

The lighting is designed with lampposts double armor so as to allow an effective illumination of the roadway is that of the pedestrian . The lighting system is designed without the provision of sub-systems or network being photovoltaics.

Widening the road: 470 sqm

Parking 68 sqm

Sidewalk: 888 sqm

Cycle track: 1343 sqm

Green bounding: 806 sqm

Green with trees: 404 sqm No. 202 _ 2 trees every 10ml

Cord: 785 ml

Bumps: 1008 ml

Grids: No. 101 _ 1 grid per 10 ml

Ecological island 171 sqm

Range with trees: 446 ml _ 1338 _ No. 89 sqm 2 alberi_ trees every 10ml

PV street: n. 31

Setting 5

The intervention in its geometry looks pretty neat, triangular-shaped , with a perimeter of regular and a major axis of penetration which is adjusted to the point limit of the buffer zone due to the constraint of inedificabilità Plan Tratturi , in fact and in its under this occasion it was decided to bring in the presence of traces of Tratturo and make it usable by supplementing it, sidewalk and bike path then continues along the perimeter of the area. The project is also designed for a possible subsequent extension of the intervention mirroring the same type on the other side does not object , at present, of intervention.

The pavements (3183 square meters) and the one-way cycle track (4022 sq m) with a width of 1.50 m walk and simultaneous ring around the entire perimeter , including the band falling in the restricted area . The two paths are separated by a central strip of low hedge interspersed with elements of street furniture such as the wastebaskets . Along the way are then designed items such as plaques or signs such as to explain the role and history of the cattle tracks .

The project involves the upgrading of existing roads (406 square meters) and the inclusion of 950 square meters of parking inserted parallel to the axis of the spine extended (no. 77 stalls) . Also along the axis of the plug, and aligned to the parking is inserted the ecological island of 41 square meters for the collection of separated waste .

The adjustment involves the insertion road on the edge of zanelle and grids for the collection of water and stone beads for beading edge road and allow a small difference in height elevation .

The green is expected according to a triple register , a first line is formed by low hedges (total low hedges 2966 sqm) that mark further limit road , placed close to the bead of stone , followed by a second line which is also low and formed by hedges to separate the bike lane from the pedestrian . Then there is a third line , the higher , which encloses the inner area under redevelopment. The row of trees (2 trees every 10 m) is designed with essences of strawberry tree (*Arbutus unedo*), which allow an efficient shading during the hottest months , so as to regulate , in a natural way , the microclimate .

The lighting is designed with lampposts double armor so as to allow an effective illumination of the roadway is that of the pedestrian . The lighting system is designed without the provision of sub-systems or network being photovoltaics.

Widening the road: 406 sqm

Parking: 950.35 sq.m.

Sidewalk: 3264.75 sqm

Cycle path: 4080.50 sqm

Green bounding: 2176.80 sqm

Green with Trees: 805 sqm No. 403 _ 2 trees every 10m

Cord: ml 3167 _ 548 sqm

Bumps: 966.80 sqm ml 4149_

Grids: No. 415 _ 1 grid per 10 ml

Ecological island 41.11 sq.m.

PV street: n. 286

Setting 6

The intervention in its geometry presents fairly ordered , the area is configured as an elongated parallelepiped , with regular perimeter , characterized by the layout of the buildings along the axis of the plug.

The project involves the upgrading of existing roads (2054.50 sq m), the inclusion of 2569 square meters of parking inserted parallel to the central street of penetration (no. 139 stalls) . The parking bays have the characteristic to be paved with lawn having reinforced , ie , the characteristic of being plots of green when the machine is not in park and separated from one another by low hedges .

The pavements (2015 square meters) walking in parallel on both sides of the road penetration , configuring a walk straight along the length of the intervention.

On the short side of the box is also located on the island of 125 square meters ecological placed in a position to facilitate the collection of separated waste .

The adjustment involves the insertion road on the edge of zanelle and grids for the collection of water and stone beads for beading edge road and allow a small difference in height elevation .

The green is expected according to a double register , before a line is formed by low hedges (approximately 672 sqm) which will signal further limit road , located behind the cordon of stone. Then there is a second line , the higher , which encloses the inner area under redevelopment. The row of trees (2 trees every 10 m) is designed with essences of strawberry tree (*Arbutus unedo*), which

allow an efficient shading during the hottest months , so as to regulate , in a natural way , the microclimate .

The lighting is designed with lampposts double arm so as to allow an effective illumination of the roadway is that of the pedestrian . The lighting system is designed without the provision of sub-systems or network being photovoltaics.

The Sanfelician portal in neapolitan architecture of XVIII century

Vincenzo CIRILLO

Department of Architecture and Industrial Design, Second University of Naples, Aversa, Italy.
vincenzo.cirillo88@libero.it

Abstract

Since old times the portal assumed a dual function. Concretely its represents opening, a passage that allows the physical movement from one place to another, from a public space to a private one. Symbolically, its genesis can be traced back to Roman triumphal arch, erected to be crossed as a sign of victory and supremacy, also, in philosophical meanings its represents the knowledge. Specifically in the Neapolitan historical residential buildings, from the XV century, the portal has always been subject to an architectural experimentation geometric-configurative, but in the Baroque period it becomes the protagonist of the urban scene. To rename it is without doubts was one of the main architects members of the Neapolitan Baroque: Ferdinando Sanfelice. Will be analyzed below, the architectural production of the 'Sanfelician' residential building portals, through the examples of noble representation that we will return the critical reading of the genesis of forms and matrices that are typical of Ferdinando Sanfelice.

Keywords: Ferdinando Sanfelice, neapolitan historical residential buildings, portal, architectural survey.

1. Neapolitan historic residential buildings portal

The portal is an architectural element which attracts attention of passers-by's size, shape, material, decoration, and its function as a passage from an internal to an external space. This role of passage, since ancient times, became a tangible sign of distinction between two worlds, two existential conditions, therefore load of symbolic meaning. Functionally, in fact, the portal has a dual function. Physically its represents, an opening that allows the passage, a displacement between different environments. Ideologically, however, manifests a plastic effects research that can impose them, as privileged presence in the territory, expressing a form of representation of families of origin or those acquired by marriage, and, in a more philosophical, from ignorance to knowledge.

Specifically in the Neapolitan historical residential buildings, the portal is one of the most expressive of building interesting expressions, because the portal function is not only linked to the need to cross two different spaces, but it forms a whole with the definition of a path, where the profile of the arch, the shape of the piers and other elements, form the definition of an imposing presence, which highlights the agreement between the harmonic architectural and structural function.

But the analysis of a portal cannot be separated from analysis of the building to belongs and especially it is not possible to extrapolate it from a more complex system, one that allows the gradual separation of public from private: System hall, courtyard, staircase, which defines the gradual move as a space of the report. Whether it's a noble or residential building, the portal has preserved symbolic passage, which, by virtue pattern offered (vegetal, geometric, animal) that the techniques of carving, refers to the figurative tradition of membership [11].

As a result, the portal so full of meaning, has always been object of particular attention: emphasized adorned, banded, (whether it was an entrance to a building or a religious building is that it was access to humble dwelling). This attention, usually manifested by placing the portal in the center of the front building and to endow it with figurative elements, that can give more emphasis both structural and formal.

The planimetric configuration of neapolitan historical residences comes from Hippodamian city scheme adapted to a ground sloping on the sea and to the need to follow the shape of the torrential watercourses, which generated with the rains [6] [7]. Therefore characterized by an urban scheme cardini and decumani and, in general, narrow sections of road, for a result that did not allow residences to be able to show off an architectural composition of the front. So, the program focused expressive in all proscenium portal and scale staircase [5].

Futhermore, thanks to its spatial dynamism (formed by flying buttresses supported by a complex system of vaults) it becomes the real front of the building, giving the context of a multi-dimensionality of which the portal is its means.

The neapolitan historical residential and in particular the presence of the portal, is therefore characterized by elements that take on a different architectural language over centuries.

In fifteenth century, we begin to establish the type of civil residence as an independent issue from architecture in general. Through the portal, the viewer sees a scene which is repeated in each case: a large hall surrounded by a large depressed arch in piperno stone, a courtyard, a loggia with arches resting on massive octagonal pillars on the first floor.

The most frequent catalans decoration present in neapolitan residential architecture is limited to the portal. This element, called the arc-type durazzesco-catalano, both of which structure is archivolted and architrave, is configured in two main variants: the first, most frequent in his joints, arched opening with depressed arches; the second with the addition of clips from the previous frames tangent the extrados of the depressed arch.

In sixteenth, instead, the portal arch's profile assumes a more linear shape, with the adoption of the circular arch and the use of an ashlar predominantly smooth or diamond tip.

At beginning of seventeenth and eighteenth century, was common to reuse some decorations from catalan architecture in various forms: for example, the depressed arch is one of the typical features of the portal and Neapolitan Baroque openings, but presents a matrix with predominantly polycentric.

Among the outstanding examples of what is written is the monumental Sangro palace portal, built by Giuliano Finelli (XVI-XVII sec.) and in which is expressed the contrast of piperno stone and accompanying marble alveolated columns, consisting of blocks that frame the entrance, and they represent a form of attention that the architect gives to the portal, making to pass in the shade the rest of the renaissance front (fig.1-A). During the sixteenth century, also Cosimo Fanzago (1591-1678), designed baroque portals, which the most important was the Palazzo Carafa di Maddaloni where the central arch is enclosed by a composition of tuscanic pillars which rest on a base reinflated ashlar, which ends on an ephemeral decoration marble, while at the sides there are connection vaults [4] (fig. 1-B).

Fig. 1: Di Sangro palace portal; B-Carafa di Maddaloni palace portal.

2. Typological configuration portal : elements and material

The portals of the historical residences in Naples, are Attributable from a structural point of view of two types of building systems: architrave and archivolted. Specifically, the system will allow the differentiation archivolted dictated by the variability of the profile of the arc. The categories of portals archivolted differ based on the use of curvilinear arrays (central arch, depressed arch, ogival) and mixtilinear (sanfelician polycentric type with concave-convex direction) which characterize not only a static language but also an architectural language.

There are several element that make up the apparatus of portal: the piers, the ornamental shelf, the frame classification, the pediment and the architectural order. The figurative and structural configuration of the piers is a function of more general reference system (architrave or archivolted). However, they can be divided into two main cases: the first where the piers are intended as a continuous strip that follows the trend of the portal; the second where the same constitute a more external apparatus adapted to support the entablature [8].

Another feature of the portal is the ornamental shelf, a support structure in horizontal projection, usually located in the upper corners of the gate. The pediment, by contrast, portals residential Neapolitans, may present or not, or appear with the central part missing. The architectural order, however, may appear in accordance with the classic rules or supported by capitals from animal motifs, natural or anthropomorphic [11].

Portals are generally constructed in piperno stone, a magmatic rock in neapolitan area, was born from volcanic activity. This lithified type of rock, different from the yellow tufo, assumes a particular texture characterized by the concentration of lenticular isorientation gray, called flames, surrounded by a matrix of the same color but lighter. The piperno stone was not easy to remove, if not through a subterranean separation of large blocks that were then processed. It is resistant to wear of the atmospheric agents, and for this reason it was very used for the cladding of Naples. Sometimes the piperno stone is accompanied by marble which gives a plastic configuration.

3. The Sanfelician portal

Among the architects who are interested in portal from Naples, Ferdinando San Felice (1675-1748) is surely one of the most important.

Sanfelice worked as apprentice in the workshop Solimena's where he was show his skills at the creation of ephemeral architecture.

After the onset of the implementation of the coffin at the funeral of Charles II of Spain, will then be successively occupied with preparation for the entry into Naples of Philip V's kingdom.

In this occasion the architect had the opportunity to collaborate with Bolognese Francesco Bibienas, considerable ability artist. From the perspective latter diagonal assimilated the characters, the spectacular taste typical of Benini, the traditional architectural style objection and the use of anthropomorphic architectural elements to support trabeations. From Bibienas, Sanfelice will resume and proposed a his dialectic: the plant diamond ashlar pillars, columns and piers of the portals, and where he later adds curvilinear and rectilinear geometries assimilated by the poetry of Austrian architect Hildembrandt.

It 'clear that the lucky of the Sanfelice, was to have had close ties with influential people, starting from customers and ending with artistic personalities of considerable thickness [2].

Examples of greater representativeness of Sanfelice are portals of Pignatelli di Monteleone palace (Calata Trinità Maggiore) and Filomarino (Benedetto Croce street, 12). Respectively, in the first building we see one of his stylistic reinventions given by the presence of arched columns which overlaps another sanfelician dialectic constant: point diamond ashlar, often made of white marble. In the second episode, however, his language moves from the columns directly in the internal profile of the portal and replacing the columns with the rusticated piers, which support a projecting pediment, with central part omitted, in which you place a badge of the house of belonging [3].

But the activity of Sanfelice is not only limited to creation of portals for noble families, but also for residential architecture. Among the many examples we find: Santoro palace portal (Salita Capodimonte, 10), Maciocco palace portal (Salvator Rosa street, 98-103) and the portal of Olivella square, 13; everything characterized by architrave and archivolted concave-convex profile.

Thanks to the classical tradition language, always conducted in a dialectical, and its continuous effort to seek new forms with the use of geometric patterns and modular, and at the same time to give a precise role to its urban factories, imparts elegance and brilliance to the its artefacts. Through the use of forms which he invents himself gives the portal of an attempt to geometric-configurative research, in which there is provided a synthesis between figurative elements and method of construction, giving a dynamic consciousness of the form that cannot be met solely by the old formalist aesthetics and property [2].

The use of a matrix curvilinear-mixtilinear (whether consisting of fluctuating forms), the prominence and the projections of some constituent elements of the portal are reprocessed characters from

Sanfelice conception taken from Hildebrandt architect, with whom he had close relationships during the austrian the austrian kingdom. In addition, the use of ashlar leads to an immediate reading of the sanfelician dialectic used architectural order of the columns, piers or can last a frame or paragraph in the arc. The ashlar also limited to a mere indentation of the lines of junction between the segments, or offer clues to cushion or spearhead.

The richness of the elements that characterize the sanfelician portal are manifold, to which we add, the wooden doors of the gate, these elements becomes the main character of the urban scene. Consequently, with the presence of Sanfelice, the portal is become an architectural attractor an also the urban scene main character [10].

In the scene is possible to see daily life that characterized the relationship between Neapolitan people and the city. There is no doubt, that what is manifested during the Baroque Sanfelice highlights the union between the popular imagination and the shining of the Spanish court [12].

The tendency towards the theatrical and the search for illusionary effects absorbs most of sanfelician expressions especially with the "party machines", this machines are set up in the streets and squares in various civil and religious celebrations. This elements, however, are made, like portals, with a tendency to cancel the separation between ephemeral and constructed reality, changing casually standing in the interim.

In context of the scene, the portal seems to become a permanent place to celebrate the ephemeral presence, and the architectural language of the Neapolitan nobles, but also lower class houses.

Furthermore Sanfelice, was assigned to given an additional feature to the portal, this new meaning is not only the transition between two spaces, or as a clear eloquence to assert vigorously the presence of a noble house. He gives the portal a feature sensory-perception, which, thanks to its shape suggests the extraordinary spectacle that is going to be just beyond the doorway. One show theatrics made with the magnificence of the stairs opened, invaded by a bright light coming from the courtyard that is offered and denied at the same time.

The sanfelician portal, therefore, seems to be an invitation for the viewer to throw in the eye of the hallway to see the theatrical backdrop of the scale that assumed a composition that calls for the imaginary to the idea of an area of illusion.

Characteristics, which are Sanfelice's the best solution to the problem of the front, because from fifteenth century, was the source of experimentation.

The ability to manipulate the space, to translate the architectural composition (which could not occur outside) inside the courtyard, and the transition between the street light, the shadow of the hallway and the light from the courtyard to the full scale, give to the site a symbolic meaning. It is the means to achieve not only a physical place, the light or knowledge, it is the gateway to a theater where the staircase and courtyard becomes the stage where you can see the unfolding theater.

4. Sanfelician model portal: structure and geometric- configurational genesis

The survey of all types of portals, even if is restricted to the city of Naples, it would be almost impossible, because of the the survey would be amost endless. It is preferred, therefore, the investigation of a sanfeliciano sample, as homogeneous as possible, with references deliberately not distinguished to identify the highest linguistic expression, but a kind of vernacular architecture.

There are many contributions for the construction of the portals, which Sanfelice features in the landscape of neapolitan residential buildings, with a focus not only to the high class buildings something like "dialect talk architecture". Mentioning only a few examples, among the most illustrious of the construction that he makes for the creation of portals to stately mansions, we could remember: Filomarino Palace (Benedetto Croce street, 12), Serra di Cassano Palace (Monte di Dio street), Pignatelli di Monteleone Palace (Calata trinità maggiore, 124). These building which have already were the subject of extensive studies (Fig. 2-A, 2-B, 2-C).

The object of research, which is presented below, instead, was moved on a repertoire of attribution and derivation sanfelician portals, which are part of the constructive choral industry, but that sum up the whole dialectic operating sanfelician (fig. 3).

First of all, it is proposed the portal of Sanfelice palace (Arena alla Sanità street), designed and built for his personal residence in the early eighteenth century. The portal shows a broken straight profile, with a rectilinear broken profile, alternating with strip, wrapped and embossed with a diamond tip (Fig. 5 -A).

This type of solution, it will be a recurring feature in other portals, such as the one located in Pontecorvo square. This presents quite similar characteristics with the only variant of the light given by the size and height of the gap, and the size of the section of the molding (Fig. 5-B).

Different solution instead is adopted in the portal site in Salvator Rosa street at number 273, where the profile of the portal comes with a curved array, where the portal has a curvilinear profile.

The molding, even in this case, is of type alternating, bandaged and embossed. The rustication is highlighted with the curtain wall parallel to the road (smooth and projected), terminating in an ashlar diamond, tapered towards the inside of the gate (fig. 5-C).

Fig. 2: A- Filomarino palace portal; B- Pignatelli di Monteleone palace portal; C- Serra di Cassano palace portal.

In analogy with the portal in Salvator Rosa street 273, built for the Palmarice Palace (Banchi nuovi street). In this case, the same type of matrix curvilinear is adopted on, and the only difference is found in the different way in which the molding has been treated, which shows a simple ashlar (Fig. 5 -D). Simplicity, which does not reflect, however, the other portal placed in the same building. In this case, we can read one of the attempts geometric design and layout of the Sanfelice experimental art that strongly contrast with the traditional schemes. The profile is similar to that proposed for Palazzo Sanfelice: broken and ashlar with the upper profile, consists of a matrix curvilinear concave type that connects to the piers in the sides and to the rectilinear band, located in the upper central zone.

This example introduces a feature geometric-configurative, which often assume various forms, and that will be instantly recognizable and attributable to Sanfelice and his school of thought: the portal with concave-convex mixtilinear (Fig. 5-E).

This type belong to their respective portals Santoro palace (Salita Capodimonte, 10) (Fig.4), Maciocco palace (Salvator Rosa street, 98-103) which consist of two portals belonging to two different buildings assembled on the street by a single front, and two other examples which are respectively: Salvator Rosa street, 259 and Olivella square palace portal, 13 (Fig. 6-F, 6-G, 6-H, 6-I, 6-L). These portals are all characterized by the same type of genesis: offering a profile predominantly banded with the presence of the ashlar, placed in the points of discontinuity between the piers and the attack of the arc from the mixtilinear profile (concave-convex) and sometimes in the joints of the key bow. This configuration seems to point out the weakest points from a static point of view and geometric as the most important ones; strengthened and projecting than the other and along with other factors that contribute to ensuring Ferdinando Sanfelice as the most brilliant Neapolitan Baroque architect. The reason of this survey wasn't the completeness, but the indication of a method of interpretation and emphasis on how to intervene without rape or form, or structure; that is, without changing the appearance, as is often the case when working on objects which are not distinguished, and especially unprotected.
