Peer review

Scholars has been invited to submit researches on theoretical and methodological aspects related to Architecture, Industrial Design and Landscape, and show real applications and experiences carried out on this themes.

Based on blind peer review, abstracts has been accepted, conditionally accepted, or rejected.

Authors of accepted and conditionally accepted papers has been invited to submit full papers. These has been again peer-reviewed and selected for the oral session and publication, or only for the publication in the conference proceedings.

Conference report

238 abstracts received from:

Australia,
Brazil,
China, Colombia, Cuba, Cyprus,
Denmark,
Egypt,
France,
Greece,
Indonesia, Italy,
Japan,
Madagascar, Malta, México,
Portugal,
Russia,
Saudi Arabia, Slovakia, Spain, Sweden,
Turkey,
United Kingdom, U.S.A,
Yemen.

About 400 authors involved.

196 papers published.

Preface

The XII International Forum Le Vie dei Mercanti has the aim of promoting a debate on local and international experiences relating to the themes of the conservation and management of cultural, architectural, archaeological, landscape and environmental heritages. This debate is particularly relevant in Italy, with it not only being responsible to the world for housing the largest number of UNESCO sites but also having a natural and landscape heritage of great variety and beauty in a region characterised by an intrinsic geological fragility. The management of this vast heritage requires both a serious planning of the interventions as well as adequate funding. The same goes for the protection of the landscape, which in the past was systematically devastated within a myopic perspective that did not take into account the enormous amount of damage caused by wild speculation and hydrogeological instability.

Furthermore natural disasters, such as earthquakes, have led to the transformation and loss of environments which reflect local identity no less than the cultural heritage, in addition to economic damage and in terms of human lives.

In order to conserve and manage the heritage, it is necessary to adopt an integrated and resilient approach in which different skills contribute to the development of improvement and restoration projects, carried out through knowledge, sharing of decisions and proactive sharing, taking into account the social and environmental sustainability of interventions that should characterise the design method in all its aspects.

The key issue is the exchange of ideas so as to give life to a *technological humanism*, understood as the union between the cultural vitality that has characterized humanism and the Renaissance, producing excellent results in all fields of knowledge, and the possibilities currently offered by technological innovation to create platforms in order to support this knowledge. Thus, Pompeii, the most famous archaeological site in the world, is taken as the prime example of the need to adopt a virtuous cycle of conservation and management, supported by the dialogue between the different skills that interact by sharing the same technological platform.

The international debate can be an opportunity to share prime examples of the conservation, management and development of the archaeological, architectural, landscape and environmental heritage through the integration of ideas and experiences of specialists working in different disciplines as well as geographical and cultural contexts.

The conference is open to multidisciplinary experiences on one or more of the proposed themes. Scholars are invited to present research on either the theoretical and methodological aspects or concrete applications carried out on these issues.

[...]

*Non vivere sulla terra come un inquilino
O come un villeggiante stagionale.*

Ricorda:

*in questo mondo devi vivere saldo,
vivere*

come nella casa paterna.

*Credi al grano, alla terra, al mare
ma prima di tutto – all'uomo.*

*Ama la nuvola, il libro, la macchina,
ma prima di tutto – l'uomo.*

*Senti in fondo al tuo cuore
il dolore del ramo che secca,
della stella che si spegne,
della bestia ferita,
ma prima di tutto – il dolore dell'uomo.*

*Godi di tutti i beni terrestri,
del sole, della pioggia e della neve,
dell'inverno e dell'estate,
del buio e della luce,
ma prima di tutto godi dell'uomo.*

[...]

[...]

*Don't live in the world as if you were renting
or here only for the summer,
but act as if it was your father's house...*

*Believe in seeds, earth, and the sea,
but people above all.*

*Love clouds, machines, and books,
but people above all.*

Grieve

*for the withering branch,
the dying star,
and the hurt animal,*

but feel for people above all.

*Rejoice in all the earth's blessings –
darkness and light,
the four seasons,
but people above all.*

[...]

NAZIM HIKMET

From: *Last Letter to My Son*

Moscow, 1955

Translated by Randy Blasing and
Mutlu Konuk

With Best Practice in HERITAGE, the theme of this year's International Forum "Le Vie dei Mercanti", I would like to return to the centre of the issues of Man, hence the reference to the poem by Nazim Hikmet, who, in his interrelations with others and the responsibility that he assumes in academic, cultural and participatory contexts as well as in the governance of public affairs, has carried out or is planning the conservation, protection and regeneration of cultural heritage.

In order to conserve and manage the patrimony, an integrated approach is necessary in which different and resilient skills contribute to the development of the requalification and restoration projects, carried out by means of knowledge, sharing of decisions and proactive sharing, taking into account the social and environmental sustainability of interventions that should characterize the design method in all its aspects.

The international debate, in fact, is an opportunity to share good examples of conservation, management and enhancement of the archaeological heritage, architectural, landscape and environment through the integration of ideas and experience of specialists working in different disciplines and different geographical cultural contexts.

The key issue is the exchange of ideas and experiences in order to create a technological humanism, understood as a union between the cultural vitality that has characterized humanism and the Renaissance, producing the highest results in all fields of knowledge, and the possibilities currently offered by technological innovation to create platforms in support of knowledge.

Nevertheless, we must act with due care in the use of technology, asserting a predictory record. It is worth thinking of Leonardo, who with his will power "measured sand grain by grain just as mathematicians do", had already laid the conceptual foundations of digital knowledge several centuries earlier. The "grain / pixel" is the carrier/code, and therefore multidimensional, capable of integrating knowledge and skills in relation to the measurement and representation of cultural heritage objects in different scales from the city to the territory of the landscape, the code with the potential to interact and integrate data and information capable of providing results that are always implemented in the pipeline that Leonardo himself refers to as "the endless reasons that are by nature" and which wants to strive to give useful answers to the progress and development of society.

That said, digital technology allows us to have dynamic and biological knowledge. Dynamic since it is possible to discretize, measure and continuously monitor the inherited patrimony in order to re-establish it through knowledge, as biological knowledge and skills acting homeostatically, regenerating, through remedial agents of the genetic heritage in the same way as of stem cells on the roots, identity, contamination, historical social urban fabric, the territorial infrastructures, the environment, the production of art work.

Increasingly, indicating that the fate of the city, the territory is linked to the ability of the people to create Knowledge Factories, to transform its own resources, used as raw materials, with a production cycle that is only valid when the human capital is high, I have proposed a synergetic alliance between the University, Business, Public Administration and institutions bearers of great ethical and social values to make a competitive territory.

Some examples that we have analyzed as an interdisciplinary research group are paradigmatic and among them, it is worth mentioning, Pompeii, the vast territory of the Province of Caserta with an extra extension falling within the boundaries of the Province of Naples which borders the Terra dei Fuochi, the design of anaerobic biodigester of Santa Maria Capua Vetere and the Bourbon Palace of Carditello.

More recently, starting from Pompeii, we have surveyed with sensors such as aviation transported Lidar, Hyperspectral, Thermal not only the area of the excavation site but the entire City.

The complex representation activities of the sensors mounted on aircraft of the Guardia di Finanza and the cartographic data processed in the laboratory are merged into a "data cloud and monitoring knowledge" that with the innovative mobile mapping technologies of Topcon allowed us to compare surveys and aerial monitoring with terrestrial data. (Fig. 1)

Fig. 1: Pompeii Data cloud and monitoring knowledge.

Even for a larger-scale survey and monitoring with an entire bounded territory such as Terra dei Fuochi, suffering from serious pollution, we used the above systems to acquire knowledge aimed at the regeneration and protection of the landscape, the environment and products of the food chain and biological waste disposal system that generates energy and, therefore, excludes the pollution that comes from the combustion of other types of plants. (Figg. 2-5)

The anaerobic bio-digester is also an opportunity to redesign the relationship between the City and surrounding territory up to assuming a wider project involving the integrated coexistence of cultural, social and economic functions in a unitary model of sustainable development.

In conclusion, taking the initial assumption on the primacy of thought, it is worth highlighting that technology allows thought to enter the body of Architecture and the Territory, to control the phenomena of change in progress, to capitalize integrated diachronic and synchronic information and data to provide a material that is not addressed by a reductive broad vision, full, but that allows to analyze the mind of Man from the building blocks that make up the matter in both its generative factors as well as the processes of change that are realized over time.

Therefore, I am convinced that by engaging in a process aimed at increasing the scientific welding between humanism and technology, we will achieve the expected results for a “best practice in HERITAGE” and good governance for the protection and preservation of the heritage inherited.

The Fourth Right – a possible new way to conserve Chinese urban villages

Yu-Huan WANG

Architectural Department, University of Michigan, Ann Arbor, Michigan, USA

yuhuan@umich.edu

Abstract

Despite their reputation for narrow alleys and messy streets, urban villages in China are crucial to the stability of many big cities such as Beijing and Shanghai. Urban villages not only provide affordable living spaces for an enormous floating population that illegally moves to China's big cities, but they also provide a safe and comfortable social setting for them. The urban villages, however, are under constant threat due to continued government pressure as China's major cities become even larger and more modernized, resulting in the replacement of low- and mid-rise buildings with high-rise buildings. On the other hand, as more and more of China's floating population move to urban villages, the government cannot ignore the danger of unrest or even potential riots if the urban villages were torn down too quickly. Recognizing the importance of conserving China's urban villages, this paper looks into the power structure of the existing system and at the principal players involved such as developers, government officials, and the villages themselves, and then proceeds to analyze the factors that could influence the distribution of power within this structure. In conclusion, this paper suggests a new way of conserving China's urban villages – by increasing illegal construction inside the urban villages, thus increasing the compensation costs of tearing them down. This strategy is called the Fourth Right, or silkworm nibbling, and is differentiated from the existing three legal property rights.

Keywords: Urban village, floating population, illegal construction, Fourth Right, silkworm nibbling

Section

Urban villages appear both on the outskirts of and within major cities, including Beijing, Shenzhen and Guangzhou, among many others. The villages normally are surrounded by skyscrapers, transportation infrastructure, and other modern urban construction. Urban villages are characterized by dense, mid- to low-rise buildings, ambiguous private-public space, and shared community facilities such as public bath houses and public toilets. Often they are enclosed by walls with doorways to separate them from the surrounding areas. In 2008, there were more than 500 urban villages inside Beijing alone. With the expansion of city limits, more and more urban villages are forming.

Fig. 1: Urban Villages in Beijing¹

Fig. 2: Xian Village in Guangzhou²

Although there are multiple reasons for the existence of urban villages, the household registration system in China is considered one of the fundamental factors leading to the development of isolated urban villages. The household registration system basically prohibits people in China from moving their households from cities in which they are registered to other cities without undergoing a difficult and painful government authorization process. This has resulted in a large number of old villages that did not modernize or industrialize due to the lack of vibrant commercial activity and innovation. After the Chinese government opened its doors to the West in the early 1990s, this problem suddenly became more prominent. The growth of new industries and the demand for residential and commercial space required that city governments clean up and make available village farmlands for new usage. These farmlands and villages used to be located on the outskirts of cities; they were purchased compulsorily and turned into urban land by the government. Some of the old villages, however, were left alone due to the high social and economic costs of compensating for lost farmland and relocating

the original villagers. Further, the government had to arrange jobs in the city for the unskilled villagers, who mainly were farmers under communist policy.

Over time, the original farmlands in the urban villages underwent dramatic changes. With the rapidly increasing prosperity of areas that bordered or surrounded the urban villages, the villagers began to pursue higher economic value-added activities than farming such as renting apartments and opening restaurants and retail shops. The vast farmlands progressively were over built with illegal structures, i.e., structures built without legal permits. The situation was exacerbated as the villagers attempted to maximize their profits and returns by illegally extending their buildings up and out. Even without selling the land, the village landowners became rich landlords and became unwilling to move. With surrounding land values (or “land use” values because land is owned by the government; only land-use rights are granted to individuals) skyrocketing, the compensation costs for the government to tear down the villages also increased dramatically; this is because compensation values are normally set according to market values with a similar usage. In addition, the urban villages became an essential stabilizing force in major cities, even though they made urban planning by the central government difficult. The important role they played was to serve as a suitable and unique environment for the survival of what is called China’s floating population.

The floating population arose due to unequal working opportunities and wages between rural areas and cities. In 2010, the urban-rural income gap was 3.23 according to Chinese official statements. A study by Professor Jinjun Xue, Nagoya University, Japan and associate professor Wenshu Gao, Chinese Academy of Social Science, shows that the official estimate may be too high; it may be 2.29 to 2.84, but either way, it indicates a significant income gap between rural areas and cities.³ Moving to cities, however, has its challenges. For example, because of a household registration system in China, it is illegal to move to cities from rural areas. This did not stop people from migrating to the cities, however, thus creating illegal migrants, or a so-called floating population. Because they moved illegally, they are not eligible for many benefits while in the cities to which they streamed, including insurance coverage, education for their children, and public housing. As a result, the living standards of the illegal migrants actually may be worse than in the rural areas from which they came. It is hard to generalize a single reason for the illegal rural-urban migration. Some may be trying to fulfill their dreams to become rich or famous, and these individuals may intend to stay permanently in the cities. For many, however, the hope is simply to accumulate as much money as possible in a short period of time, then return home to their villages.

It is difficult to figure out the precise amount of floating population in each major Chinese city because it changes rapidly; however, according to an estimate from the National Bureau of Statistics of China, in 2010 Chinese cities had a combined floating population of about 220 million people, with another 243 million floating population expected by 2025. This would take China’s urban population to nearly one billion people. A floating population by 2025 of about 460 million migrants would represent almost 40 percent of the total urban population. This floating population represents a major social and political cohort in urban China, and it requires each city to create an environment to accommodate the needs of these people.

China’s Floating Migrants = 10 Australias

Fig. 2: Floating population in China⁴

The environment for most members of the floating population is fundamentally different from newly built, high-rise urban spaces. Those in the floating population are not interested in comfort or luxury; they are focused only on economics such as their rent. To accumulate as much income as fast as possible, the floating population seeks the most economical way to survive while in the cities. This has created unique urban environments such as the Ant and Mouse tribes. The Ant tribe is people who subdivide their rental space in high-rises into the smallest possible spaces which they then sub-let to the floating population. The Mouse tribe is people living in underground bunkers below the high-rises. According to a study done by the Chinese Bureau from data that was based on 1,675 entries over the past 18 months from 163 different contributors, the average high-rise resident has 700 square feet of living space with a monthly rent of around 5,000 Yuan, while urban village residents pay 500 Yuan for 200 square feet of living space. Because it is illegal to rent out bunkers as dwellings, there are no official figures for those living in such an environment. According to my visit in June 2012 to more than 10 sites and nearly 50 residents, however, the average Mouse tribe resident pays around 70 Yuan for about 45 square feet of living space. From my interviews, most Mouse tribe residents consider their dwelling to be temporary and will consider moving to an urban village after their income improves. Considering such dangerous and inhumane conditions, urban villages seem to be the only feasible solution for the floating population.

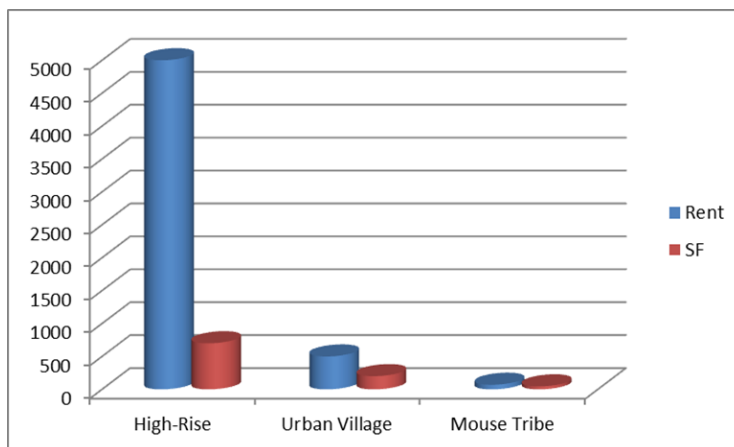

Fig. 3: Rent price and square foot comparison

Fig. 4: Mouse tribe living

The living conditions in urban villages, while better than for the Ant and Mouse tribes, are still different from other parts of the city. To make more money, landlords (the legal land-use owners) in the villages usually not only illegally expand their buildings, but they also sub-divide their rental properties into the smallest possible units. This puts enormous pressure on tenants to utilize smartly their available space.

One of the most common ways for tenants or the floating population to expand their available space is by invading public space for private activities such as cooking, washing, and even for small businesses. These invaded public spaces are among the liveliest areas in some cities and are notable for providing economic and leisure opportunities for newcomers to the city.

Fig. 4: Invading public space in urban village

The growing floating population also supports many other businesses such as small restaurants, traditional markets, barbershops, etc. These small businesses price their products or services according to the purchasing power of the floating population, which normally represents a sizable discount compared with prices outside the village. Urban villages are like small independent towns within cities with their own ecological system. To some extent, it is necessary to conserve the urban villages, not only for the benefit of the millions among the floating population, but also for the stability of China itself.

With pressure to increase the density of cities to accommodate growing populations and business activities, the Chinese central government is eager to replace the low-rise villages with high-rise buildings. This is evident by comparing a Google map of Beijing over different time periods. The main forces that prevent the government from moving forward as quickly as it might like with its plans to demolish villages is the huge compensation that would have to be paid for land-use rights to the landlords and the concern of precipitating unrest or even riots among the floating population due to the loss of affordable accommodations.

In 2007, a property law was passed in China. Chapter 5 of the law defines three property types within the People's Republic of China -- state, collective and private. Chapter 4, Article 40, of the law divides property rights into three types: ownership rights, use rights, and security rights. The law does not change the system of land tenure by which the state owns all land, but in formalizing existing practice, individuals can possess a land-use right, defined in Chapter 10 of the law.

Ownership rights or land ownership rights belong either to the central government or the local collective (the local government). Although urban villages are located within an urban area, land ownership rights are still regulated under the rural land system. In this system, land has not been privatized. Ownership remains "collective", with local officials, typically at the village level, exercising a major influence over the allocation of land and the way households can use the land.

Land-use rights, however, are granted by local governments or the central government for different periods of time and for different usages. For example, the longest duration for a land-use right is 70 years for residential use. This land-use right can be traded like a commodity in the marketplace.

The compensation issue with the urban villages that prevents the government from tearing down the villages at will is for this right.

The land-use right, however, is influenced also by another unofficial right. Here I give it a name – the Fourth Right. The Fourth Right is the right to use public space through time, not law. The Fourth Right is considered a norm in China. People illegally occupying a public area through time tend to claim the right to use the area. Although it is not legal, the government tends to recognize it in fear of conflict or due to the lack of precise survey data and funds to demolish the illegally built structures. Although each city has its own way to reinforce its right to demolish illegally built structures, most of them include some form of compensation. For example, in Guiyang in 2013, the government provided compensation for illegal construction of up to 240 square meters. According to a report from the China Times, these types of practices and cheap construction costs have led to a huge increase in illegal construction over a short period of time.⁵

There is a special name for the act of illegal construction invading public space gradually through time; it is called “Jiang Shi”, which means “a silkworm that is nibbling”. For “Jiang Shi” to occur requires mainly two conditions – duration and boundaries. To declare a right to compensation for such space, villagers need to demonstrate how long he or she has used the space and how large the area is. This can be done with photos or witnesses.

Caochangdi, an urban village in Beijing, is a good example to demonstrate how the Fourth Right and its conditions could be used, especially by changing traffic patterns in the area, to encourage “Jiang Shi”. With increasing “Jiang Shi” behavior, the villagers’ Fourth Right could be strengthened, thus conserving an urban village.

Fig. 5: Google image Caochangdi 2002

Fig. 6: Google image Caochangdi 2008

Fig. 6: Google image Caochangdi 2012

Caochangdi is one of nearly 500 urban villages in Beijing, located near the Fifth Ring Road. Its estimated population is about 1.5 million people. In addition to an enormous floating population that characterizes all urban villages, Caochangdi also has a unique feature that is different from other villages; there are large numbers of local and internationally known artists who have established studios in the area, including the famous dissident, Ai Weiwei. This occurred because local officials have an open attitude toward art and culture.

From Google aerial maps of Caochangdi over different periods of time, we can see illegal construction take place over time, especially near empty public spaces. The pace at which this occurs, however, is different due to traffic patterns; if a road has a lot of vehicular traffic, the pace at which public space is invaded is dramatically slower. With fast and heavy traffic, the two essential conditions of “Jiang Shi” – duration and boundaries – are difficult to establish. Most villagers do not own vehicles, so the fast and heavy traffic in the area is mostly flow-through traffic or those taking short cuts to go elsewhere in the city. To slow down the traffic or even turn the vehicular traffic into bicycles or pedestrian walkways, which are the means of transportation use by most villagers in the area, art pieces could be donated by different artists and placed in strategic positions. Strategically displaying street art through partnerships with the local and international artists in the community would slow down and even change the nature of the traffic in the area, potentially even turning the targeted area into a pedestrian-only zone. This would enable and encourage the residents to exercise their Fourth Right, thus aiding in conserving the special character of the Caochangdi area.

Fig. 7: Art sculptures in Beijing 798 art district

This strategy was utilized in the nearby Beijing 798 art district, although the principal driver for this at the time was to clearly establish the identity of the area as a haven for artists and their art. The effect of this, however, also led to a dramatic change in traffic flows and conditions, resulting in dramatically less and slower traffic and the progressive establishment of illegal construction that invaded public spaces.

To roughly monetize this strategy in the case of Caochangdi, we can use the biggest plaza in the village, the Central Plaza, as an example. The total site encompasses 1,040 square meters. With an average compensation price near the area of 50,000 Yuan per square meter, 900 square meters of “Jiang Shi” construction would increase compensation costs by 45 million Yuan; 450 square meters would increase compensation costs by about 20 million Yuan. When we consider that multiple levels could be built, the effect of a substantial increase in compensation costs on government plans to demolish the area cannot be overlooked.

Turin observe the time Gian Giacomo Plantery

Nadia FABRIS,

Dipartimento DAD, Facoltà di Architettura, Politecnico di Torino, Italia

E-mail: Nadia.Fabris@polito.it, nad.fab@libero.it

Abstract

Turin observe the time Gian Giacomo Plantery, Architect (1680 Turin 1756), uncle and teacher of B. Vittone.

He created his works, between Baroque and Neoclassicism, during urban renewal and the construction of Turin, we are inside the quadrilateral in the Roman port director to plum on the way to France in the axis of enlargement traced by Juvarra current square where the Savoy roads are expanded from 6 meters to 11 meters.

At the time he was commissioned aristocratic palaces with spectacular interiors and sometimes fanciful, such planteriane (Saluzzo Paesana, 1715-18; Cavour, 1729, etc..) And homes for rent. The survey does compare the artifacts of the eighteenth-century city today the charm of time researching and comparing the values found along roads projects iconography and what has been achieved and the charm was that period.

Keywords: Turin, Gian Giacomo Plantery

The analysis carried out to observe Turin at the time Gian Giacomo Plantery, Architect (1680 Turin 1756), uncle and teacher of B. Vittone. He created his works, between Baroque and Neoclassicism, during urban renewal and the construction of Turin, we are inside the quadrilateral in the Roman port director to plum on the way to France in the axis of enlargement traced by Juvarra current square where the Savoy roads are expanded from 6 meters to 11 meters. At the time he was commissioned aristocratic palaces with spectacular interiors and sometimes fanciful, such planteriane (Saluzzo Paesana, 1715-18; Cavour, 1729, etc..) And homes for rent. The survey does compare the artifacts of the eighteenth-century city today the charm of time researching and comparing the values found along roads projects iconography and what has been achieved and the charm was that period.

Among the customers of Plantery are represented, with its very special characteristics typical, the whole range of social categories richest who moved the capital of Piedmont, in the historical context of the whole was favored by skilled and initiatives concerned the royal house. This migration was interested in the new King of Sardinia, the ancient nobility of the province to the capital by transferring their residence wore a result of the great wealth of the agricultural property must give the tone to the baroque splendor of a court.

These palaces wanted to appear palaces, but in reality had to be instruments of income, as they are today our multi-family homes. The large building in Via della Consolata n. 1, occupying 5000 square meters purchased in 1715 by Senator Count Baldassare di Saluzzo Paesana, a

descendant of an ancient race, Knight of the SS. Annunziata, the palace presented as a counterpoint to the palace, had two entrances with doorways through which they passed lavish parades where festivities were held fabulous, actually included many rental housing, adapted by the inspiration of a skilled artist to impress with spectacular precautions. The author himself became a tenant of the bourgeois noble client. Even the building in Via Cavour n. 8 has this character of utility Cavour The palace was built fourteen years after the palace of Saluzzo Paesana, in a stylistic period in which the rococo triumphed in Piedmont at that time we have events in neoclassical style in reaction to the Baroque therefore an important document of an attitude crisis of aesthetics denounced by the difficulty of coexistence of heterogeneous structural and decorative elements. The structures, thanks to the cultural evolution of the architect go from a severe majesty to a simple elegant and graceful, the stucco decorations are affected by the phenomena of elegant taste of the label.

Gian Giacomo Plantery is a characterization investigating some aspects, first drawings of the facades, with which emerges while maintaining a decorative style, a simple background with a pattern almost repeated that identifies today. While the most characteristic feature, is the architect designer of sometimes quite typical for structures and for ornamental purposes defined by the name of planteriane times, these times were to characterize the hallways of the buildings in a unique way, almost to want to make it unique in its appearance interior. Rearranging the times of Plantery chronologically, from the times of the atria and the vestibules of the houses and Novarina Cigliano, sometimes the hallways and lobbies of the buildings and houses and Cavour Paesana Capris and Fontana Cravanzana, spread a single issue that mature formal style true even today.

Checking the drawings he submitted to the Board of ornate, we can see how they were carried out according to the will of the architect, and not tampered with in time, which would need a lot of maintenance but overall the aesthetic simplicity to favorite, their conservation.

The district with the most eye-General, and urban design maintains a balance in the past, today enhanced, by the transformation of the streets in pedestrian areas. As a whole, the redevelopment of the time it remained a cultural resource as a result will be presented drawings preserved in the historical archives of the city of Turin and sample a taste of the photo made by me.

The “illusory space” from wall frescos to “*quadraturismo*”, to cyclorama. Planar and solid representation techniques and restitution of imaginary space.

Antonio MOLLICONE

Department of Architecture and Urban Design, Faculty for the Built Environment, University of Malta,
Msida, Malta
antonio.mollicone@um.edu.mt

Abstract (ID n° 003)

At the advent of descriptive Geometry (*Poncelet 1822*) the representation of illusory space framed by painted and/or solid architecture had reached a satisfactory technique: Donatello (“*stiacciato*”) Borromini (*forced perspective*) Pozzo (“*quadratura*”-“*anamorfosi*”).

With the discovery of the wall roman paintings of Pompeii, the evolution process of the illusion technique is completed that, from the Hellenic theatrical scenography, with the degradation of measurements (“*double ratio*”), the introduction of vanishing points (“*operation of projection and sectioning*”) gets to the illusion of building in a virtual space.

In the presence of whichever *trompe l'œil* Pompeii cannot not be thought of/*revisited: From the world to Pompeii*.

The transfer of the preparatory drawing (*chequered* in advanced) on the surface to paint forces to enlarge it to adapt it to the geometry of the painting plane: it consists of projective problems that found verification in the practical execution of the transfer of the drawing on the surface of the vault.

This paper deals with the geometrical/projective problems relative to the realisation of the wall paintings and presents a confrontation in the restitution of the preparatory cardboard of the space represented in one of the partitions of the barrel vault of the nave of St. John in Valletta painted by Mattia Preti.

Two examples of restitution of the illusory space are presented with the analysis of the vanishing points and the architectural structure that creates the illusion of the *Panorama Mesdag*.

Keywords: Projective geometry ; quadraturismo ; Mattia Preti ; Trompe-l'œil .

1. Scope and Methodology.

In the wall paintings the perspective set-up that frames and/or acts as background to the scene has a fundamental importance to guarantee the illusory effect of an “imagined” space.

The geometrical exercise of the plani-volumetric restitution of the entities painted on the various surfaces reveals the capability of the artists to represent spaces anyway well defined, making use of the visual experience and of some empirical methods without the support of a specific geometrical theory.

2. Projections on planes and primitive surfaces.

The central projection of architectures on the wall limits of (architectural) spaces, has the aim to make the observer believe he is “admiring” or “finds himself in” a real space.

On the vertical surfaces, once having chosen the sight position, the illusory representation is assured by the degradation of the heights/altitudes and in general by the spatial relationships of the parts of the composition.

The composition will be made up of plane curves resulting from the plane section of the visual cone, and in all its area these figures have a bijection function with those “imagined”.

When the support becomes cylindrical or spherical, the curves will be skew and it is useful to overlay a reference grid (*quadratura*) on the perspective view of the desired space, thought of as enlarged and placed on the level of the impost of the vault surface. (Fig.1)

To graphically obtain the successive projection on the cylindrical vault of the initial perspective in true form (preparatory sketch) it is sufficient to note that the lines of the *quadratura* parallel to the generatrix of the

cylindrical vault will have their projections coinciding with the generatrix of the same vault, whilst the lines on planes parallel to the directrix, will turn out to be curved like all the others in generic positions. (Fig. 2)
 On the auxiliary plane belonging to the directrix of the cylindrical surface, the generatrix projection of the line to which the point that has to be projected belongs, is located.
 Having overturned on the mentioned auxiliary plane the projective ray, the distance of the projected point (on the cylinder) from the same auxiliary plane (where the directrix / edge of the cylindrical section of the vault lies) is located.
 But not all the field of the initial perspective, once projected on the cylindrical surface, will be included in its space, or better, in the initial perspective the projection of the edges of the vault must be inserted and hence some projections “will fall” on the vertical walls with a considerable deformation (*anamorphosis*). (Fig. 3)

2.1 ...”way of doing the *graticola* (quadratura) in vaults”...

The idea to project the shadow of the grid of ropes, tensioned at the level of the impost, with a lantern placed at the location of the sight position, even if having merit, must have found difficulties due to the obstruction of the scaffoldings and the distance of the vault from the lantern that would have projected shadows that were not distinct enough.

Pozzo finds a solution using a rope that, tied to the point of observation, is pulled/projected up to the surface of the vault always remaining tangent to the lines of the grid / quadratura.

Another problem is the drawing of the projections of the vertical edges of the imaginary architectural features that, apart from being skew, must appear to be converging at the vanishing point.

The sight position and a rope in tension from the projection of the foot of the imaginary edge to the vanishing point, form a vertical plane that intersecting the vault creates the projection of the vertical edge.

Being placed at the point of observation and pointing the view tangent to the mentioned rope vertical edges can be marked on the vault.

Alternatively, if another rope is considered hung to the vanishing point and left to hang, looking at it so that it coincides with the previous one, it is possible to draw a curve that in its extension will end in the vanishing point. (Fig. 4) [1] [2]

3. The vault of the St. John Co-cathedral in Valletta painted by Mattia Preti.

In the plane development of the first partition (entering), of the cylindrical vault the views oriented the most perpendicularly to the surface can be composed.

Preti invents an architectural frame that, dividing a “common” background sky in three illustrations relative to the life of the Saint, makes the observer believe he can see, in sequence, the development of the story.

Even if the scenes have three different vanishing points, or better, are three central perspectives, the architectural features and the objects, thought of with a side parallel to the frame/picture, have a common vanishing direction coinciding with the generatrix of the vault.

There are few imaginary curves that when projected undergo deformations and the vertical edges are minimal, so much so that Preti prefers to use the “atlantes” instead of columns that, even if adjacent to the edge, would have created problems. (Fig. 5)

3.1 Geometrical model of the represented space.

Having traced the projections of the edges of the architectural features of the first scene (entering to the left), it is noted that they coincide in three different vanishing points aligned on the axis of the composition.

From a geometrical point of view the construction is wrong but, in practice, the observer is forced to raise his view to view the scene completely.

Hence different projection frames “are created” that give rise to a “vanishing axis”.

Majestically, Preti creates a first space at the impost of the vault where he places the figures with the same size of the real oval windows.

These figures are placed on a basement on which rest, on a middle level, the bases of the atlantes and they themselves sit on a raised pedestal whose edges concur to the first vanishing point.

The main scene happens at the level of the middle level and is framed by an entablature with corbels supported by the atlantes.

The base of this frame will be observed before the same scene, therefore Preti provides another vanishing point and in the end the vanishing point for the main elements of the composition, of the background and the higher part of the frame.

From the tracings of the edges the geometrical construction of the perspective that allows to construct the geometrical model of the "illusory" space can be hypothesised and, having chosen an appropriate position for this, the quite reliable reconstruction of the "preparatory sketch" can be made, projecting on the surface. (Fig. 6) (Fig. 7)

The central scene is framed, with view from "the bottom to the top", by a circular balcony being part of the main architectural frame whose model, reconstructed and projected on the surface, must be enlarged to coincide, as much as possible, with the real painting.

In this scene an impossible doric temple is represented that rests too close to the edge of the balcony and does not "continue" in the oculus of the scene to the right. (Fig. 8)

4. The space represented by Giotto.

Previously Giotto had deduced the usefulness of the different vanishing points relative to successive views of approaching the scene or else to a collective view composed with one directed to details.

In the representation of the "Benedizione di Innocenzo III" the views are majestically composed in a way that, whichever the choice for the plane on which the observer is placed (plane of the Basilica or base of the illustration), the model of restitution of the represented space shows us an environment physically adequate to host the actors of the scene. (Fig. 9) (Fig. 10)

5. Forced perspective.

In the panels that decorated the pedestal of the altar in the Basilica di Sant'Antonio da Padova, Donatello represents spaces of a certain depth with architectural features that, in the case of the panel of the "Miracolo del figlio pentito", appear, thanks to the technique of the low relief ("stacciato"), placed from the proscenium up to the backdrop (six levels) where a construction is placed axially with the scene and additionally rotated with respect to the view.

The first building on the right, with a different vanishing point on the line of the horizon, can be considered rotated in plan or else moved to show completely the stairs otherwise hidden by the characters of the scene.

In this case the exercise of planimetric reconstruction of the represented space can be incremented by the definition of a model of the levels of the low relief. (Fig. 11)

6. Cyclorama.

A panoramic view painted on a cylindrical surface and observed by a platform at the centre of the circular hall ensures the illusory effect of a realistic view enhanced by an adequate illumination, by the movement of certain elements, etc.

A first geometrical / projective problem is that to create the painting on canvas in adequate dimensions starting from a preparatory drawing of reduced dimensions.

In the "Panorama Mesdag" (The Hague), the drawing made on a glass cylinder positioned with the axis coinciding with that of the circular hall, is projected, from the centre of the cylinder, on the canvas, traced and hence completed.

In a panoramic view, in general, the alignment of the horizon is evident, or else can be deduced, whilst the lower limit has an irregular flow.

To delimit this lower part of the painting, that represent the part of the scenery closest to the observer, Mesdag builds a real beach from the platform to the canvas modelling the edge so that when seen from the sight positions it overlaps to with the lower edge of the painting.

This second problem is solved, geometrically, intersecting the ruled surface, constructed by the circle located by the various positions of the observer at the lower edge of the painting, with a concentric cylinder to the one of the canvas and at an adequate distance from it. (Fig. 12)

Abstract

Historical parks and gardens are important stepping-stones for the conservation of the cultural and natural heritage in cities, and as such, they deserve a careful management. This can be achieved also through the support of citizens as well as tourists, who have to be proactively involved, so as to increase the collective identity. The involvement, in turn, can be facilitated when the information about cultural and natural heritage is easily and user-friendly accessible, and the communication with the managing institutions is straightforward. To this purpose, an application in English and Italian for smart phones and tablets (both iOS and Android systems) dedicated to the historical parks and gardens of Rome has been developed through a joint venture between public institutions and private enterprises within the framework of an EU-funded project. Through its geo-location system and an interactive discovery tool, the application allows the user to retrieve the information on historical monuments as well as to identify the components (flora and fauna) of the natural heritage, with a total of over 400 entries with iconographical material. In addition, the application can be used to report updated information concerning problems and the possible degradation of the site to the managing institutions. The extension of this system to a national scale, and its potential to improve the economic sustainability of the management of the historical parks and gardens, is also addressed.

Keywords: botanical identification key, citizen science, cultural heritage awareness, historical parks, smart phones-tablets applications.

1. Introduction

Historical parks and gardens are important stepping-stones for the conservation of the cultural and natural heritage in cities, and we know too well how much they require a careful management. This can also be achieved with the support of proactive citizens as well as tourists, so as to increase the collective identity. Involvement can be facilitated when the information on the cultural and natural heritage is easily and user-friendly accessible and the communication with the managing institutions is straightforward.

This process is now attainable also through the use of a system of multimedia guides compatible with smart phones and tablets by cross-platform applications. Today, the widespread opportunity to access the web, coupled with the possibility to use mapping software based on Global Position System (GPS), make this kind of instruments able to give detailed information on any geographical element,

enriched by specific information on several themes: a very useful and important instrument that can be used for increasing the citizens awareness of the importance of the conservation of natural and cultural heritage, in a virtuous circle among fruition, knowledge and conservation.

Moreover, such interactive multimedia technologies are changing - especially among the younger generations - the methods of learning and the way we process knowledge. Through the interaction with program, a visitor can explore the site according to different themes and her/his specific interests, to become a protagonist in the achievement of the information.

According to market analyses carried out by the major telephone companies, smart phone devices are used in Europe today by about 65% of the population. Italian data are slightly lower, but in line with the general trend toward the replacement of old mobile phones with the new ones that offer a wide range of services through Internet access.

With this figures in mind, in Rome, with about eleven million of tourists visiting the city each year, and about three million residents, the present *app* has the possibility to reach and proactively involve a very large public.

In particular, Rome represents a unique and complex case study due to its particular richness of public green open spaces where natural and cultural heritage coexist and have evolved in the course of centuries [1]. Presently, public parks range from true archaeological parks to the magnificent XVIth-XVIIIth-century aristocratic villa gardens to those designed in the twentieth century. The locations of these spaces, and their dimensions are also very varied: we have little belvederes over the city and gigantic parks of 180 hectares [2]. Because most of these parks have an aristocratic origin, they are true open-air museums that ought to have responsible use and management.

2. SmartEcoPhone Project

The EU-funded SmartEcoPhone (SEP) project was aimed at developing a single cross-platform *app* for smart phones and tablets to guide the visits of 25 historical parks and gardens of Rome and its Botanical Garden interactively.

The 26 sites have been selected to give an exhaustive historical as well as socio-geographical panorama of Rome, considering not only the most famous or central parks, such as Villa Borghese, Villa Doria Pamphilj or Villa Ada Savoia, but also less known or “peripheral” ones, such as Villa Bonelli, Villa Lazzaroni, Villa Chigi, or Villa Carpegna, aiming at developing the collective identity. The project has included archaeological parks, such as Oppio Hill – an integral part of the extraordinary complex formed by the Coliseum, the Imperial Fora, and the Roman Forum -, as well as XXth-century bourgeois villas and public neighbourhood parks, such as the Villa Lais, Villa Glori, and Nimorense Park [3]. Many of the selected sites offer striking views over the old and the new city (Orange Trees Garden, Villa Balestra, St. Alexis Park, Villa Aldobrandini), while others, with their extension, offer the possibility of an escape into a sort of countryside, such as the Villa Doria Pamphilj on the south-west and the Villa Ada Savoia on the north-east. Most of these areas were lavish early modern villa gardens, and they still offer - despite great losses - an astonishing rich cultural heritage (statues, fountains, buildings, layout or even age-old trees).

The *app*, available in two languages, Italian and English, was developed for both Android and iOS systems and can be downloaded on the device from the respective *app* markets. The *app* has also a cache memory in order to download background maps so as to reduce significantly the need and related cost of Internet access.

Parks and gardens name	Cultural heritage	Tree species	Animals
Castel Sant'Angelo	10	5	9
Museo Orto Botanico	6	71	16
Pincio	11	31	10
Villa Alberoni Paganini	5	25	9
Villa Fiorelli	1	19	7
Giardino Sant'Alessio	4	7	9
Parco Nemorense	1	25	11
Villa Aldobrandini	3	26	8
Villa Borghese	23	57	23
Villa Carpegna	3	25	10
Villa Flora	2	23	8

Fig. 1: List of the historical parks and gardens, which are at present available in the SEP application, with the number of related entries on plants, monuments, and animals.

3. General structure and contents

Once activated, the *app* displays a main menu organised into three categories:

1 - Info: this section consists of a presentation of the *app*, its contents and main functionalities. Credits and contacts are also available here.

2 - Map: This is one of the two functions that allow the user to plan the visit. Using the GPS, the visitor can locate his position with respect to the location of the parks and gardens on the background map. By selecting a park, it is possible to access the detailed information of the site.

3 – Scroll list: This is the other function that allows the user to plan the visit. The complete list of the sites can be visualised together with a picture and a general description of the garden and its history, focusing on its main transformation.

Once a site has been selected with function 2 or 3, the visitor can visualise general info, such as opening hours, public transport, services, and contacts, as well the general description of the park, with the history of the site and other curiosities. She/He can then discover the site's botanical characteristics through a list of the most significant tree species, as well the site's cultural heritage by means of a list of present historical, artistic and archaeological monuments. In the category of fauna, in addition to the list of native wildlife species recorded in the area, the *app* also offers the possibility of listening an audio reproduction of animal calls, in order to facilitate their identification.

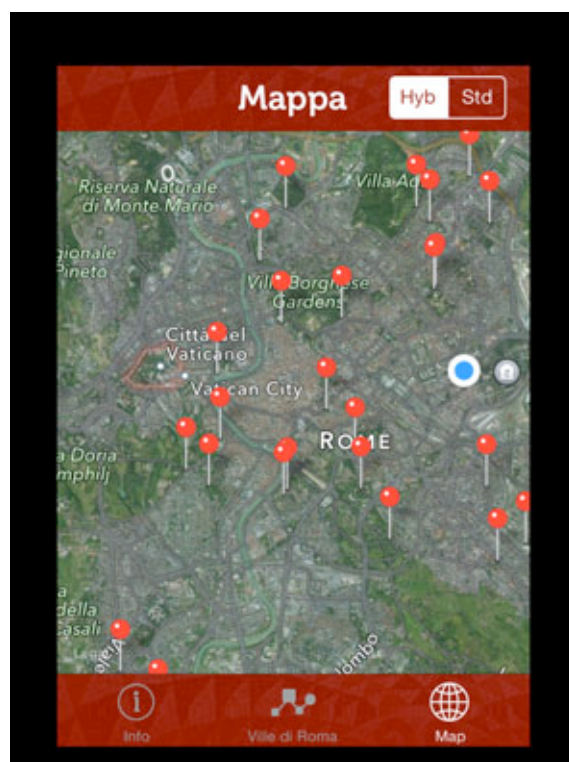

Fig. 2: The Map is one of the two functions that allow the user to plan the visit. Using the GPS, the visitor can locate his position with respect to the location of the parks and gardens on the background map.

Fig. 3: The Scroll list is the other function that allows the user to plan the visit. The complete list of the sites can be visualised together with a picture and a general description of the garden.

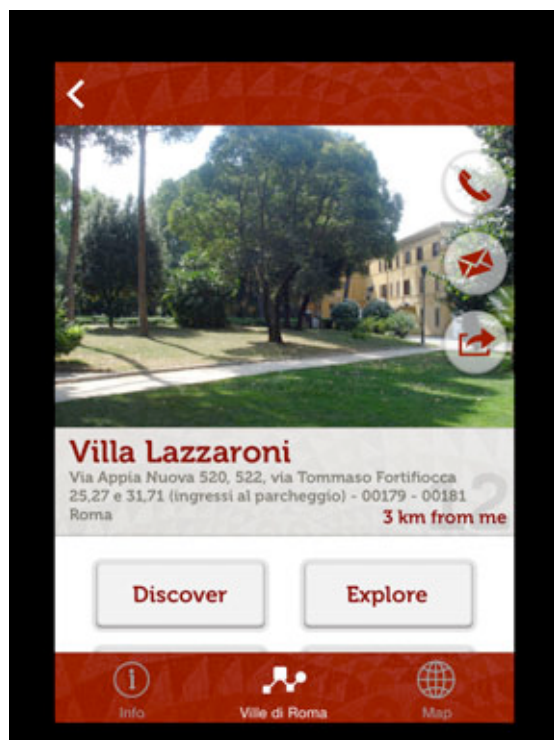

Fig. 4: Once a site has been selected with function 2 or 3, the visitor can visualise general info (opening hours, public transport, services, and contacts) and the general description of the garden.

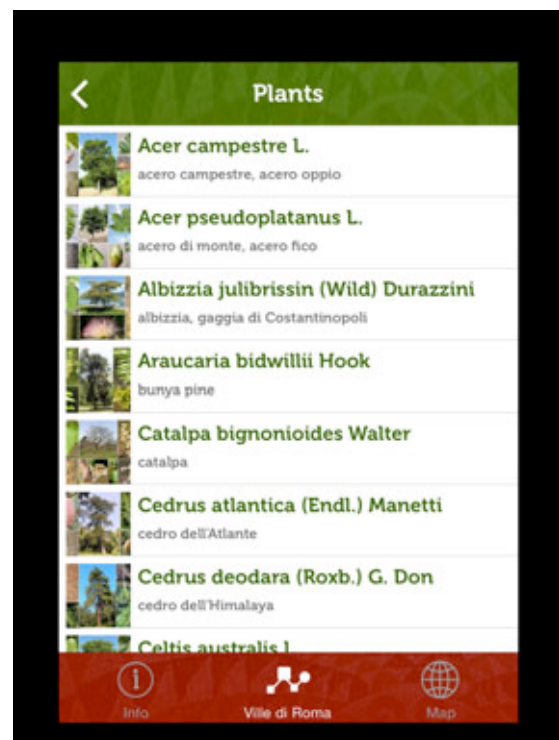

Fig. 5: The visitor can then discover the site's botanical characteristics through a list of the most significant tree species.

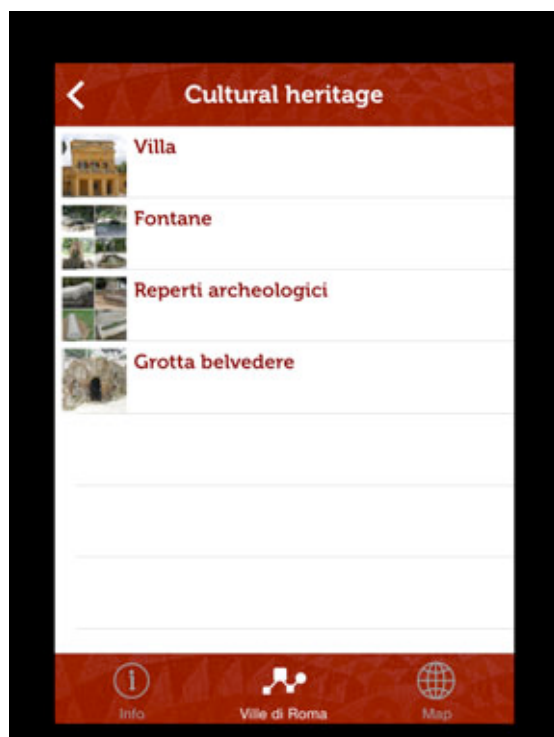

Fig. 6: The visitor can moreover discover the site's cultural heritage by means of a list of present historical, artistic and archaeological monuments.

Fig. 7: In the category of fauna, in addition to the list of native wildlife species recorded in the area, the app also offers the possibility of listening an audio reproduction of animal calls, in order to facilitate their identification.

For each selected object (plant, monument, or animal) a description and one or more pictures are available. Currently SEP offers about 400 entries, together with over 1,000 pictures.

Each selected object can be also displayed on the background map to guide the visit. At any moment, through the GPS system built in into the device, the user is able to identify her/his own position on the map by a blue point. This way of consulting the guide is the simplest as well the most interactive one: by clicking on the different icons nearest to her/his own position, the visitor can receive information about what she/he see during a walk, whether plants or cultural heritage objects.

Moreover, the *app* contains also a tool that allows even non-specialised users the possibility of identifying the 169 ornamental tree species recorded for the parks and gardens of Rome [4] using morphological and anatomical characters. This tool has been developed within the framework of the Dryades Project, which has been implemented by the University of Trieste in order to develop identification keys for plants and animal species [5]. The tool is set up on a choice-based identification key: at every step the user is asked to choose between two options, described textually and by means of pictures and drawings, in order to progressively arrive at identifying the tree species. A botanical glossary is also available to support the identification. When selecting the remaining species, the description of its main morpho-anatomical characters (trunk, leaves, flowers, fruits) and the corresponding pictures allow the user to verify the correctness of the identification process.

A simplified version of the identification key, specifically developed for children, is available for the Botanical Garden. This tool allows a “Botanical Treasure Hunt”, so that by playing with new technologies, basic scientific notions as well as the importance of the conservation of biodiversity can be taught.

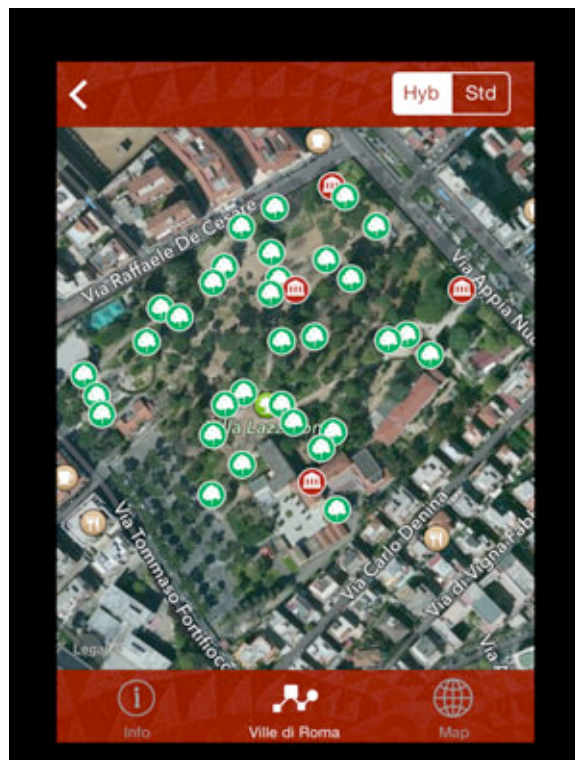

Fig. 8: Each selected object can be displayed on the background map to guide the visit. At any moment the user is able to identify her/his own position, and by clicking on the different icons she/he can receive information about what she/he see, whether plants or cultural heritage objects.

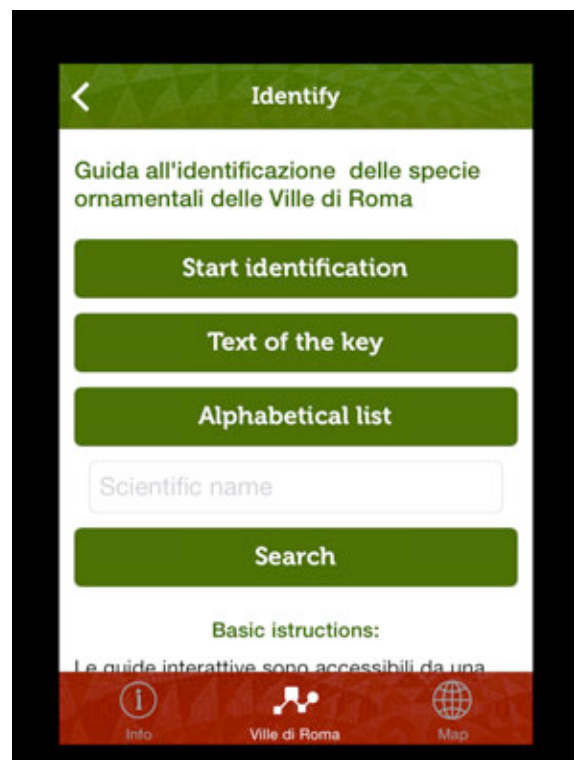

Fig. 9: The *app* contains also a tool that allows non-specialised users the possibility of identifying the 169 ornamental tree species recorded for the parks and gardens of Rome using morphological and anatomical characters. The tool is set up on a choice-based identification key: at every step the user is asked to choose between two options, described textually and by means of pictures and drawings, in order to progressively arrive at the identification of the tree species.

4. Conclusions

The SEP application was officially launched in March 2014, with the official sponsorship of Unesco Italian National Commission.

The application can already achieve several important goals:

- Facilitate tourism of natural and cultural heritage of the historical parks and gardens of Rome.
- Spread the awareness among the population of its importance and the need of a careful conservation.
- Provide the responsible institutions of a tool for receiving information on problems and critical issues.
- Support the general process of "Citizen Science" by involving of non-specialists in scientific activities by means of new technologies [6].

Based on the success such *app* has enjoyed since the first days, the extension of the system at a national scale, and its potential use to improve the economic sustainability of the management of the historical parks and gardens, are the long-term goal of the project.

It would so be advisable to start a discussion on a coordination process involving relevant institutions, cultural and environmental associations and universities, in order to develop a coherent platform to make accessible the enormous natural and cultural heritage hosted by historical parks and botanical gardens of Italy.

Abstract

The paper aims to underline open issues, by proposing even an example, concerning the actual general mode approaching the problems regarding the conservation of the Architectural historic patrimony. Since last decades great amount of studies are available in term of historic documentation, advance technique for geometrical relief and in-situ or laboratory tests on material composition. But the last ring of the chain, the structural rehabilitation designer, generally was not active part of the initial diagnostic phase. As consequence, he has been mostly a “spectator” in drawing Guide Lines, Provisions, that became user manuals, adopted by the authorities, with rigid “prescriptions”, even not clearly scientifically justified, on and how to use/not use materials and techniques for the static safety rehabilitation. However, due mostly to seismic events, the structural safety became a priority; coupling this with the priority of at best saving original texture or even documented modifications, researches to improve the mechanical performance of traditional material are recommended, and still needed, in order to enhance, preserving as much as possible, the original structural response and satisfy the safety requirements. The paper aims to underline, by briefly recalling significant steps, how the need and urgency to save the architectural patrimony still request not only more specific tests on traditional-modified-compatible material, in order to properly enhance the static capacity of the monument, but even reliable/affordable analytical models able to produce a strengthening design, with safety coefficients scientifically proved. Moreover, the aim is of not only saving original material texture and structural system but, not least, proposing affordable total cost of the rehabilitation executive project.

Keywords: Conservation, structural safety, material compatibility

1. The state of the art on structural-restoration approach: brief historic recall and consideration

It is today accepted that strengthening, conservation and restoration works are strictly linked, essentially because they follow the basic principles, of either satisfying the same needs either sharing the common responsibility to give to the future the essential of the manufacture [1].

However since few years ago, and for some decades, the agreement on the above recalled common principles and responsibility was not fully accepted. Different arguing issues and point of view have been underlined as of prior requirements leading the conservation of the monuments. Because of negative strengthening cases, generally due to lack of technical solutions in the details, for years long the “Carta di Atene” (1931) as well as the “Carta di Venezia” (1964) have been recalled and cited as rigid Guide Lines against the use of masonry new components, different from the traditional, with particular reference to the mortar. Even if, however, in the “Carta di Atene” is approved “the wise use of modern technique, and specifically of reinforced concrete”. As a major consequence of some misleading examples, studies and researches and proposals concerning the conservation of historic heritage have mostly developed two antagonist philosophies, unfortunately often producing hidden strengthening interventions not easily deliverable and readable. Therefore, sometime not in accordance with the Conservation School, but even not well suited to the overall static demand of the building, it has been proceeded, in some cases, with an insufficient safety capacity or, on the contrary,

with too redundant interventions. In addition, a not secondary consequence of an “a priori” ostracism for some materials, the knowledge on performances concerning new generations of cement based mortar have been generally neglected.

May be dated at the beginning of the '80 years a different brave approach, open to a wise, intelligent “curiosity” for the properties and use of performant limestone mortars or Portland based materials, with or without fibers as strengthening material, for saving the historic architectural heritage [2].

The more recent seismic events, starting from the Friuli earthquake till the last one in Emilia, have revealed, if it was necessary, the extreme fragility to the seismic loads of our masonry buildings, even of those recently strengthened, some with reinforced concrete elements and some with the so called “performant masonry”. Thanks to a progressive knowledge and analysis models on the behavior of bearing masonry in seismic area [3], the awareness that the aspects of historic-architectonic conservation and structural capacity are strictly linked is opening today new approaches. Anyway, due to the lack of the structural point of view in the broad debate on conservation in the recent past, more research and communication, deeply and sharply oriented, are needed, and, among other, we can underline the following:

- a) confidence and capacity of proposing and using advance, but feasible and broadly proved, numerical modelling able to estimate the structural behavior of either the single different element either as wall, with consistent safety design coefficient, is still needed and evident. The urgent requests of change of the NTC are just one of the proof;
- b) a detailed classification of different comprehensive typology of masonry structures finalized to prove, for each of them, and suggest different strengthening material and technique, based on tests results, by best suited examples;
- c) the study and use of additional, but traditional, materials, compatible with the old masonry and able to enhance the physical and mechanical characteristic of the old one and showing a real capacity of collaborate with it.

In particular, it is the opinion of the authors and it is here chosen, as significant example, the typology of plastered masonry is still requiring particular knowledge on the mutual properties between plaster and internal type of masonry; in many cases the plaster may be not only a finished material, but, due to its components and thickness, may assure a consistent mechanical capacity to the masonry wall.

These are some cases encountered, for example, in historic buildings heavily wounded by the earthquake of L'Aquila (Fig. 1), and not only there peculiar. The thickness of the plaster, from 5 to 8 centimeter, on both side of the wall, may be considered as a very efficient structural strengthening contribution, provided some requirements, like as the compatibility and adherence with the inner masonry, are satisfied, or may be improved, at which instance and stage. The answers to each question are still open for research, because of very few available focused and updated contributions.

In the following, the paper, after consideration based and coming from recent instruction and recommendation, and for the purpose here underlined, will presents recent experimental test and interesting results concerning the c) area of research, above mentioned.

Fig. 1: Typical “Apparecchio Aquilano” masonry wall covered with plaster.

1.2 The role of the recent recommendation and harmonization calling new researches

As already mentioned in the first part of the paper, the strengthening procedures have been proposed and used mostly without considering the history of the building; on the other hand, the problems of conservation of historic heritage have been studied to privilege the ornamental components.

May be dated at the beginning of '80, the concept the two aspects are strictly linked, producing lively debates, for decades ,in Italy, and not only; an interesting overview of such progressive mutual understanding and for finding to be in line with, even in term of the recommendation is given in [4].

As result, it is possible to see, around a common table the two souls, even if the deep understanding of different suggestion need more refined works.

The recent seismic Italian codes NTC 2008 are suggesting, as it is known, the two different approach of way of strengthening an Historic law protected building, structural safety increase or structural adequacy for a given earthquake, which have been introduced and proposed in the Italian recommendation since many years ago [5]. This different mode, of approaching the complex methodology for saving the Historic patrimony, brought, readable nowadays in the code, results from long debating research, more and more now speaking common languages. This is a good point, but the long time divergent goals, brought deep different knowledge, still now not easy to find common agreements. Examples are the huge quantity of researches regarding the use of FRP strips on old masonry, not strictly in accordance with the principle of using compatible, also with the tradition, material; and, on the contrary, very few advance knowledge and practical proved results about the area of mechanical improving of traditional material, or even the advance knowledge on efficacy of structural modelling, responsible to give structural safety coefficients, either numeric either as percentage. Anyway it is today present a grade of harmonization between the two research areas, with open mind to proposals, some years ago, not conceivable.

2. A significant example

The authors want here, in the second part of the paper, to focus on one of these gaps, encountered when they have faced to study the possible rehabilitation design for an historic palace in L'Aquila.

The masonry walls, with typical "Apparecchio Aquilano" [6], made of the so called double leaf masonry, are mostly covered by a thick plaster, as shown in Fig. 1. Enhancing the mechanical properties of the walls, either for vertical and horizontal loads, without changing the thick of the wall, leads to proceed on two parallel techniques: to enhance by injection the core of masonry [7, 8] and to perform a strictly collaboration between the core masonry, and the two lay of the mechanical enhancing plaster. In particular, because of the damages, the plaster may be removed and a new one, more performant, it is worthwhile for the purpose to be studied. To the knowledge of the authors no data were available, and still now the data and results of tests here presented are original, even they need more research and understanding.

The idea was to make a new performant plaster with higher mechanical properties, not only in term of resistance but even of ductility and of adherence capacity. A mix-design was prepared with a low grade of pozzolanic mortar, some mix with stainless steel fiber additives (see Fig. 2), some with mesh steel fiber and one with a mesh basalt fibers, both commercially available (Fig. 3); detailed description of this phase of the research can be found in [9].

Fiber shape	Sinusoidal	Hook (90°)	Hook (180°)	T
				
Diameter [mm]	0,65	0,65	0,65	0,65
Length [mm]	20	20	20	20
Overall length [mm]	28	32	38	44
Energy [kJ/m ²]	4255,30	1954,55	4122,82	5995,40

Fig. 2: Shape and characteristics of the considered stainless steel fibers.

Fig. 3: Steel fiber mesh (a, b) and basalt fiber mesh (c).

Some prior pull-out test and three bending point test on the behavior of the single fiber and of samples have been done at the Politecnico di Milano and S&R i-lab of Italcementi Group; the detailed description of the aim, the different tests and results are reported in [9, 10]. In the Figure 2 the geometric characteristic of different fibers tested are shown, while in Figure 3 the two kind of steel mesh and the basalt mesh are shown; Fig. 4 shows the sample, the test apparatus and the final configuration of the pull-out test and the three point bending test. Even the best performance has been shown by the T-fiber, as shown in the graph of Figure 5, the sinusoidal fibers have been chosen, because of their affordable cost and showing easier features during the preparation of mix design of the plaster, and, anyway, a positive dissipation capacity [10], as shown in the figure.

Here the focus is pointed on some unexpected positive results, that need already to proceed with more research program, because, as it will be shown, may be highly promising in term of mechanical strengthening enhancement of masonry wall, under vertical and horizontal loads.

Fig. 4: Three point bending test (left and middle), fiber in concrete cube for pull-out test of a single fiber (right).

Fig. 5: Stress vs. pull-out displacement diagram.

Fig. 6: Reconstructed wall masonry specimens.

As the second step of the experimental research, wall samples have been prepared, as shown in Fig. 6, with typical texture and material of L'Aquila masonry.

After the due hardening time, the walls, but one for sake of comparison, have been injected with pozzolanic mortar, and after, the reinforced plaster, with different kind of reinforcement, as described above, has been poured surrounding the walls (see Figure 7).

The walls have been tested under a shear-vertical compression combination of loads, according with the UNI EN 1052-3 [11], at the Aquila University Lab, as it is shown in Figure 8; more for curiosity than comparison, even a wall left with the original masonry has been tested, whose behavior does not reserve here to be reported.

The diversified steps, results and comments on the complete tests program have been presented and will be presented in different international congresses [10, 12], and have been submitted for publication to international journals and workshops. In the following of the present paper, the major goal is to show and underline the necessity of knowing and quantitatively giving the grade of mechanical enhancement of an ancient masonry plastered wall provided with the two jointly techniques, i.e. using both performant mortar injection and performant new plaster, without change the original geometry and external appearance.

Fig. 7: Wall specimen: before casting of the reinforced plaster (left) and after curing (right).

Fig. 8: Testing apparatus: layout (left) and during test (right).

2.1 Promising results

The results are, at this first step of the research, of interest from many points of view. Just a recall of the main focus of the paper: after many years of lack of attention by the scholars in the field of searching and proposing compatible more performant mortar to enhance the structural seismic capacity of historic buildings, it is today evident, either due to the recent failure of important monument, either due to progress in the new available based mortar material, a renewed necessity of the more traditional material studies, how to define new rehabilitation technique, and more suitable and reliable analyzing model for Masonry structures. All these three points, different but each other

related, are clearly pointed out by the LINEE GUIDA 2011 [13] and outlined in the reviewing version of the NTC [14].

Here just some consideration on results achieved from the test performed for proposing new rehabilitation material, i.e. the first point above recalled. The graph of Fig. 9 shows the results of all the walls tested with the shear-compression combined loads; the different typologies of strengthening technique, as it is readable on the figure, where all treated with mix fiber additives mortar injection, and 4 walls with steel mesh laying in the plaster, 2 with basalt mesh and 3 just with the fiber reinforced SCC plaster.

But the walls treated with just injection, the initial elastic behavior is similar for all the walls, with an higher pick value for those with SCC fiber reinforced plaster; even the ductility remaining capacity is very similar for all the samples.

Fig. 9: Shear load vs. horizontal displacement of all the wall specimens under shear-compression test.

It is also noteworthy to focus the attention on the behavior shown by the samples without plaster, just injected (Fig. 10): the first elastic behavior is similar, the average value of elastic pick is 70 kN; while the test on sample T1 has been interrupted because of technical problem of the testing machine, T2 and T3 samples show, anyway, a good range of ductility; even for T1 sample it is possible to guess a good ductility capacity.

Fig. 10: Shear-compression test results for the injected wall specimens.

A not secondary behavior of this first set of tests regards the capability of adherence between the old masonry and the new reinforcing plaster; as it is shown by the photograph below. The plaster with net incorporated (either basalt, or steel) has shown progressively detach from the masonry during the test, with a complete spalling of the entire side of the plaster at the end of the test (Fig. 11); this behavior may be also responsible of the lower pick values of the shear load T (Fig. 9, red and green curves). A

very interesting and promising result is due to the samples with reinforcing skin made of fiber reinforced SCC: the skin did not detached from the masonry, resisting in a unique ensemble with the internal wall specimens till the end of the tests (Fig. 12 and Fig. 13).

The graph of Fig. 13, showing not complete test for F2 sample, for technical reason of the testing apparatus, is shown a good agreement of F1 and F3, in term of maximum shear versus displacement, with the results reported in Fig. 9.

Fig. 11: Detachment of the plaster in wall specimens reinforced with mesh.

Fig. 12: Typical shear crack pattern on the external reinforcing SCC (left) and view of the specimen after test, with the fiber reinforced SCC plaster not debonded from the internal masonry core (right).

Fig. 13: Shear-compression test results for wall specimens reinforced with fiber reinforced plaster: specimen and thickness of the plaster layer (left) and shear vs. displacement graph (right).

3. Conclusions

The paper underline, by briefly recalling some significant step, how the awareness that the responsibility of saving the historic patrimony may be at the best achieved with common agreement between the two main point of view, structural safety ad historical conservation, both able to give his

knowledge as service to the other requests. With this awareness, the today debate is now reopening studies and researches that have been, in some way, forgotten, for years. The renewed attention to the use of the possibility, how and when, to increment the resistance capacity of masonry elements, mostly with traditional more performant materials, need to be better pursued.

The times of misleading debate on negative use of cement based mortar, as well as on the inutility, or even wrong use, of analysis model on the first range of possible elastic behavior of a masonry wall, provided in parallel experimental test, are today responsible on a diffuse range of proposals very far from conservation criterions, sometime not well justified, overestimated from the safety point of view and, not least, unnecessary expensive rehabilitation costs.

METHODS AND APPROACHES OF ESTIMATION OF NEGATIVE IMPACT OF PHYSICAL FACTORS IN CONDITIONS OF URBAN TERRITORIES

Andrey V. VASILYEV

Department of Engineering Ecology and Ecological Monitoring, Samara Scientific Center of Russian Academy of Science, Samara, Russia
e-mails: avassil62@mail.ru, avassil62@yandex.ru

Abstract

Physical factors (noise, vibration, electromagnetic fields, ionized radiation etc.) may cause significant negative influence both to environment and to the health of population. It is shown that combined impact of different physical factors may cause different effect of impact to the man's organism and to environment. Damaging impact may be summated, attenuated or amplified. Thus, during of estimation of impact of different physical factors to the health of population it is necessary to take into consideration the impact of different physical factors.

Methods and approaches of estimation of physical factors combined impact to the health of population and to environment are described. Analysis and examples of approaches to estimation of physical pollutions influence to the human's health in Samara Region of Russian Federation are considered.

New methods of estimation of combined impact of physical factors to the functional state of man are suggested. Results of research of combined impact of physical factors are allowing to make the following general conclusions: complex impact of physical factors to the man's health and to environment in conditions of urban territories may significantly amplify the negative effect.

Keywords: Physical factors, urban territory, estimation, impact

1. Introduction

In conditions of urban territories the impact of negative factors to environment and to population is constantly increasing. Among of these factors are physical pollutions: electromagnetic fields, ionization, radon, noise, vibration, infrasound etc.

Electromagnetic fields may cause significant negative influence to the human's health [4-7]. The negative effect of impact of electromagnetic radiation to the humans depends upon the power and the frequency of the radiation. For low-frequency radiation (radio waves to visible light) the best-understood effects are those due to radiation power alone, acting through the effect of simple heating when the radiation is absorbed by the cell. For these thermal effects, the frequency of the radiation is important only as it affects radiation penetration into the organism (for example microwaves penetrate better than infrared). Initially, it was believed that low frequency fields that were too weak to cause significant heating could not possibly have any biological effect.

Ionization may cause significant negative impact and cancer illness. Impact of ionization radiation may cause not only damage if life activity of separate organs and systems, but also of human organism in total.

Noise level is increasing together with the cities growth. More than 60% of population of large cities is living in exceeding noise conditions [1-3, 7-9]. Damaging influence of intensive noise to the human's health is not restricted only by impact to ears. It is known, that noise is affecting to the human's central and vegetative nervous systems, influencing to the human's psychological condition etc. The most serious problems are caused by low frequency acoustic affection.

Vibration may cause impact to the different urban areas (environmental, industrial, domestic) [1]. It is difficult to find in modern town the place where vibration is completely absent. Vibration in urban areas may cause serious negative problems up to the buildings and construction breakdown and inhabitants decease. Vibration and structural noise may cause decrease the operational characteristic, durability, reliability of different kind of power plant and industrial equipment. Among of the negative sequences are destruction of parts and units of machines and equipment, pipelines, junctions of aggregates etc. Industrial vibration leads to workers disease, fatigue breakdown of pipeline and apparatus junction, disturbance of sealing airproof, decreasing of machine operating characteristics, etc.

These and many other examples are proving that physical factors may cause significant negative influence to the health of population and to environment.

To be able to take the required measures for physical pollutions reduction it is necessary to develop approaches and methods of estimation of physical pollutions impact [6, 7].

This paper is devoted to study and to development of methods and approaches of estimation of physical factors negative impact to the health of population and to environment in conditions of urban territories.

2. Essence and main principles of ecological monitoring

Objects of ecological monitoring usually are natural, anthropogenic or natural- anthropogenic systems. Ecological monitoring is not only passive statement of facts, but also modeling and forecasting of the processes.

Main purposes of ecological monitoring are:

- Current accounting of variations of environment and preventing of deterioration of quality of environment;
- Forecasting of variations of environment and connected with it ecological sequences.

Ecological monitoring must include different levels:

- Global (biosphere) monitoring on the basis of international collaboration;
- National monitoring arranging in frameworks of one state;
- Regional monitoring arranging in frameworks of different regions of one state;
- Local monitoring in towns, districts or exactly in enterprises.

Among of the main principles of ecological monitoring of physical pollutions it is possible to emphasize the following:

- Identification of sources of physical pollutions of urban territories and of degree of it potential ecological danger;
- The most dangerous zones of urban territories from the point of impact of physical pollutions;
- Measurements of physical pollutions in conditions of urban territories;
- Processing of experimental data, issue of conclusions;
- Mathematic and calculative modeling of propagation and estimation of physical pollutions in conditions of urban territories;
- Development of physical pollutions mapping in conditions of urban territories;
- Development of measures of reduction of physical pollutions in the most dangerous zones of urban territories.

3. Principles of estimation of combined impact of physical factors to the health of population

During estimation of impact of different physical factors to the health of population it is necessary to take into consideration the impact of different physical factors in combination with chemical factors. Such kind of impact is considered as combined.

Existing and usual method of estimation of the impact of different physical factors do not consider the mutual influence of different physical factors.

In the real conditions different damaging environmental factors are impacting to the biological objects. Impact of complex of different factors to the organism is interdependent and in significant degree is complicating the reaction of organism.

For the adequate estimation of the effects of negative impact of damaging factors of environment it is necessary to carry out analysis and account of different situations of impact of different combinations of factors.

Depending to the quantitative estimation of effects during the impact of several factors it is possible to determine (Fig. 1):

- **additive** impact, when the effect of exposure is determined by the sum of effects of isolated factors influencing to the organism;
- **synergetic** (potential) impact, when the effect of impact of different factors is more than additive effect (disproportional amplification of impact is observed);
- **antagonistic** impact, if the effect of impact of combination of different factors is less than additive impact (attenuation of effects is observed).

Figure 1. Peculiarities of different effects during the impact to the organism of several factors of various nature

Thus, combined impact of different factors may cause different effect of impact to the man's organism. Damaging impact may be summated, attenuated or amplified (Fig. 1), as well as may cause variation of character of influence (e.g., display of carcinogenic effects) [6, 7, 9].

Organism's reaction to the impact of complex of factors depends to it combination and the level. During single impact the additive effect is observed for the substances of narcotic action, irritating gases etc.

One of the reasons of synergism is inhibition by one substance of the processes of biotransformation or metabolism of the other substance. For example, amplification of negative impact has been observed during combined impact of some pairs of phosphorus organic products.

Antagonism may occur during mutual impact of similar damaging substances to the mechanism of impact.

For the practical purposes it is the most important the determination of damaging effect of complex of factors causing synergetic impact exceeding of the sum of efficiency of impact of separate components. It is necessary to consider during estimation of ecological risks connected with impact of different combinations of chemical and physical factors to the man and to environment.

During estimation of ecological risks it is necessary consider the effect of summation (addition of small quantities of different damaging substances). Such quantities of substances separately may do not cause any problems for health of for ecosystem, but in sum it becomes dangerous due to the mutual amplification of effects (synergetic impact).

It is important to note that summation principle it is possible also to use during calculation of complex impact of polluting substances to the man, penetrating in man's organism with air, water and food. For the practice purposes it is admitted to consider that the sum of reduced to MPC (maximum permissible concentration) of values of concentrations of polluting substances having summation of impact, should not exceed value "one", that is:

$$C_1 / MPC_1 + C_2 / MPC_2 + \dots + C_n / MPC_n \leq 1, \quad (1)$$

where $C_1, C_2 \dots C_n$ - the values of actual concentrations of polluting substances; $MPC_1, MPC_2 \dots MPC_n$ - are corresponding values of MPC of it substances.

It should be noted that such effects may be a sequence of combined impact of chemical substances, physical factors, climate conditions, stress impact etc. For example, concentrations of nitrites harmless for rabbits are coming dangerous for increased but also admissible level of ionizing radiation.

Thus, for provision of ecological safety of population of towns it is occurs keen necessity of provision of complex estimation of impact of different factors of environment to the man and to ecosystems. Much importance should be attached to study of combined impact of factors of different nature - physical and chemical - to the man's organism [6].

4. Modern methods and approaches to monitoring of physical pollutions of urban territories

Existing methods and approaches to monitoring of physical pollutions of urban territories are having some disadvantages:

- Dependence of results of measurements from conditions of environment: meteorological conditions (wind, temperature, humidity, pressure), dislocation of buildings and barriers, reflection from soil and from the other surfaces etc.;
- Dependence of the distance of source of physical pollutions;
- Dependence of the final result of measurements from qualification of staff;
- Error effects of the other sources of physical pollutions;
- Significant workload of final processing of measurements results.

It is evident that long-term automated environmental monitoring allows to significantly increase precision of measurements and the quality of physical factors measurements results processing [2-5].

To achieve more detailed knowledge about physical factors it is necessary to collect more detailed data which is difficult to structuralize and to analyze by using of traditional methods and systems of monitoring. Due to GPRS (or ADSL) technologies and to Internet network presently it is possible to carry out automated collection, storage and publication of physical factors measurements data in network in a real time, and also to publish constantly updating maps of physical pollutions in correspondence with measured levels of physical pollutions.

It is suggested to provide automated clock registration of data of results of measurements of levels of physical pollutions and of the other corresponding parameters of environment and the possibility of measurements without the presence of staff. Measurement system includes:

- One or more stations of monitoring (devices for measurements of physical pollutions, systems of electro-feed etc.);
- Central module (processing, analysis and storage of data of measurements);
- Channel of transmission of data of measurements (GPRS/ADSL, Internet) etc.

All stations of monitoring are connected with central station in which processing, analysis and storage of data of measurements is carried out.

Suggested methods and system of automated environmental monitoring of physical factors are having a number of evident advantages.

5. Examples of monitoring of physical pollutions of urban territories

As examples of monitoring of physical pollutions of urban territories in Russia let us describe some results of monitoring of electromagnetic fields and of noise of the living area of Togliatti city of Samara region of Russia.

Measurements of electromagnetic fields were carried out for industrial frequency range (electrical part E, kV/m and magnetic part H, A/m of electromagnetic field strength) and for radio frequency range (electrical part E, kV/m; magnetic part H, A/m of electromagnetic field strength and density of flow of energy, mW/m^2). In total more than 250 measurements of electromagnetic fields were carried out.

Results of measurements of electromagnetic fields strength industrial frequency range in the territory of Komsomolsky district are showing that the most values of electromagnetic fields strength were near to electric power lines Exceeding of sanitary norms was determined for Esenin street situated near to the Zhigulevsky hydro power station. For Central and Avtozavodsky districts the main problem is impact of electromagnetic fields of radio frequency range near to the TV mast / towers. Exceeding of sanitary norms were fixed for Mira street (Central district) and Sverdlov street (Avtozavodsky district).

For noise monitoring as object of study living territory of the Avtozavodsky, Central and Komsomolsky districts of Togliatti city was selected near to the city streets with intensive transport movement. In total over 150 points have been investigated. Measurements of noise levels in places of living territory of Togliatti city adjoining to noise dangerous zones have been conducted in strict correspondence with above mentioned requirements. Near to the Central and Komsomolsky districts of Togliatti city it is situated a number of industrial enterprises united to so called "North Industrial Unit". Noise estimation and monitoring of North Industrial Unit enterprises for further determination of sanitary zone have been also carried out. Measurements have conducted in daytime in weekdays mainly in rush hours and during the lunch-time; and in night time (since 23.00 till 7.00). The most significant excess of standard equivalent noise levels have been observed for the following points. Komsomolsky district, night time: point K-07, Matrosova Str., 60, the value of exceeding of normative requirements of equivalent noise level is 8 dBA, maximal noise level - 6 dBA; point K-12, Yaroslavskaya Str., 11: the value of exceeding of normative requirements of equivalent noise level is 5 dBA, maximal level - 8 dBA; day time: point K-10, Chaykina Str., 67, the value of exceeding of normative requirements of maximal noise level is 9 dBA; point K-13, Yaroslavskaya Str., 61, the value of exceeding of normative requirements of maximal noise level is 9 dBA. Central district, night time: point C-18, Lenina Str., 98, the value of exceeding of normative requirements of equivalent noise level is 10 dBA, maximal noise level - 5 dBA; point C-23, Mira Str., 60, the value of exceeding of normative requirements of equivalent noise level is 12 dBA, maximal noise level - 12 dBA; day time: point C-24, Mira Str., 114, the value of exceeding of normative requirements of equivalent noise level is 4 dBA, maximal noise level - 3 dBA. Avtozavodsky district, night time: point A-32, Dzerzhinskogo Str., the value of exceeding of normative requirements of equivalent noise level is 8 dBA, maximal noise level - 3 dBA; day time: point A-04, Topolinaya Str., 21, the value of exceeding of normative requirements of maximal noise level - 19 dBA.

By using of developed program provision maps of electromagnetic fields and of noise of urban territory of Togliatti city were developed. Map of electromagnetic fields density of flow of energy of Avtozavodsky district is shown in fig. 2, map of noise levels of the territory of Shluzovoy district is shown in fig. 3. In green color values of equivalent sound level below 60 dBA, in yellow color – values of equivalent sound level between 61 and 65 dBA, in red color - values of equivalent sound level more than 65 dBA are shown.

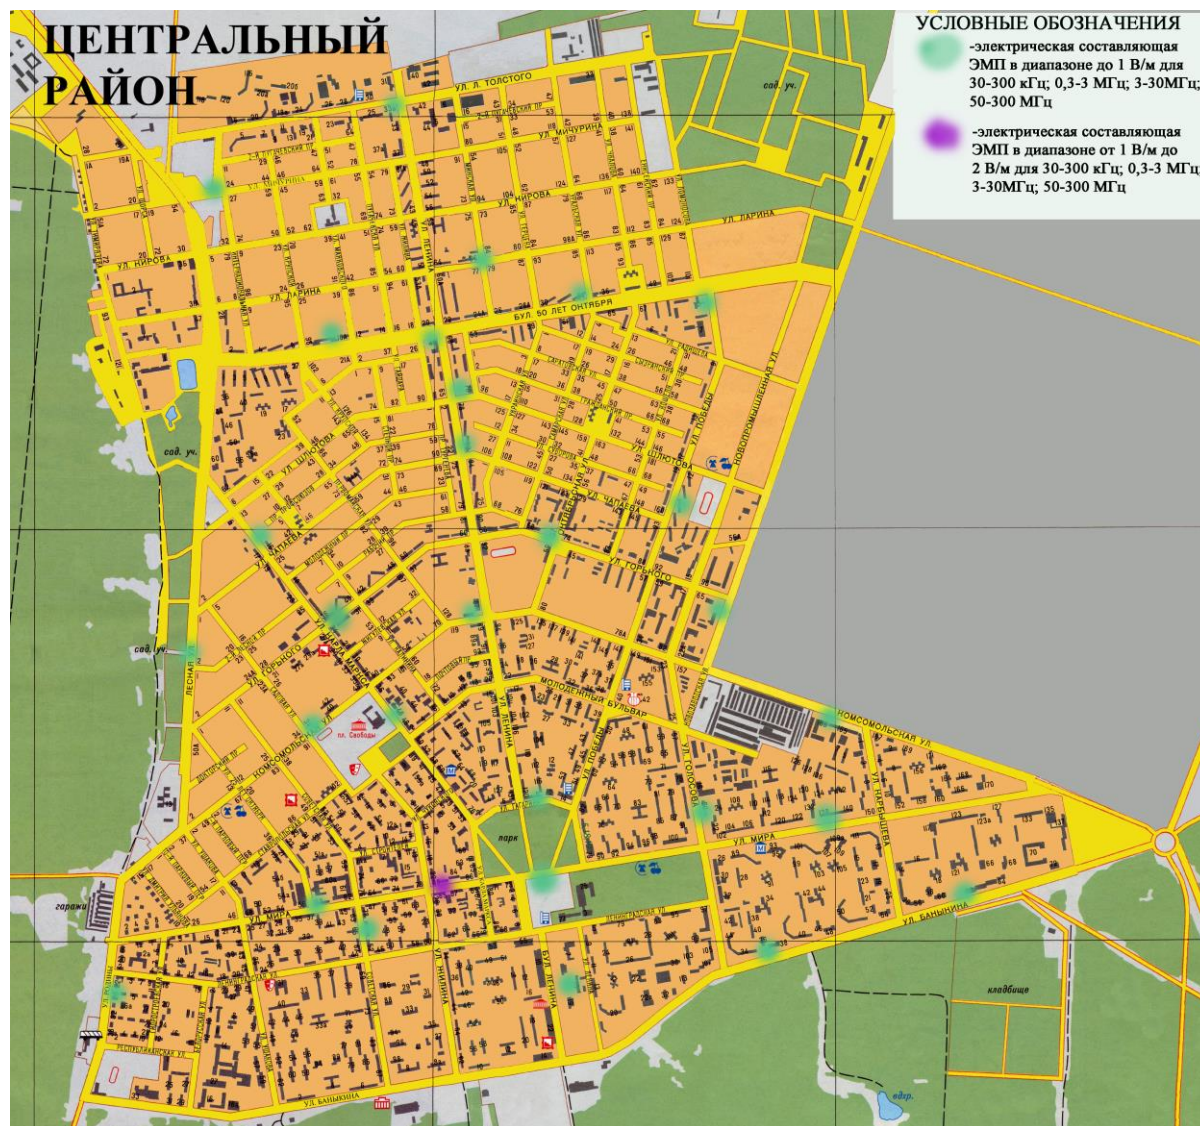

Figure 2. Map of electromagnetic fields density of flow of energy of Avtozavodsky district

6. Conclusions

Methods and approaches of estimation of physical factors negative impact to the health of population and to environment are described. It was shown that complex impact of physical factors may amplify or weaken the system response of organism. Method of continuous automated environmental monitoring of physical factors is suggested. Evident advantages of method are shown.

Some results of monitoring of physical pollutions of urban territories in Russia are described on the example of monitoring of electromagnetic fields and of noise of the living area of Togliatti city of Samara region of Russia. Analysis of measurement results are showing that there are dangerous zones of dwelling territory on electromagnetic fields and of noise negative impact.

In total, the results of work are allowing to forecast and to reduce negative impact of combination of physical factors to the human's health and to environment more efficiently.

Acknowledgement

The author would like to express many thanks to the Russian Humanities Scientific Fund for the financial support of research according to the grant project "Fundamental basics of estimation and of forecasting of impact of electromagnetic radiations to a man in conditions of urban territories".

Abstract

Human activity is connected with negative impact to environment. Maximal number of sources of negative impact is located in industrial regions. Factors and existing methods of estimation of ecological risks of urban territories are discussed. The main steps of complex estimation of ecological risks are pointed out.

New approaches to estimation of ecological risks of urban territories are suggested allowing to consider joint impact of physical and chemical pollutions and to determine the most problematic zones of urban territories. Program provision have been developed allowing not only to store and systemize the information about ecological risks but also to carry out correlation analysis of different data, to modeling and to estimate ecological risks, to forecast pollutions of environment and to ecological ranging of urban territories.

Results of approbation of new approaches to estimation of ecological risks on the example of the territory of Togliatti city of Russia have been described.

Keywords: Ecological risk, urban territory, estimation, impact

1. Introduction

Human activity is connected with negative impact to environment. It is possible to point out many factors as potential negative sources of environmental pollution. Maximal number of anthropogenic sources of risks is situated in industrial regions including collection of industrial, domestic and agriculture zones [1-3, 5, 8, 9].

Ecological risk may be considered as variation from generally admitted principles and norms of relations of man, business subjects, society and state to surrounding environment and from the norms of social relations between them.

For efficient reduction of ecological risk and for decision about possibility of reduction of negative impact of different factors up to the certain limits it is necessary to carry out forecasting and estimation of ecological risks.

Estimation of ecological risks – identification and estimation of probability of occurrence of events having negative sequences for environmental state, health of population, activity of business subject and caused by environmental pollution, disturbance of ecological requirements, emergency situations of natural and anthropogenic reasons.

It is evident that man may be impacted by the negative influence not of one but of the several pollutants, so it is necessary to develop approaches and program provision for estimation on ecological risks.

This paper is devoted to study and to development of new methods and approaches and program provision for estimation on ecological risks in conditions of urban territories.

2. New approaches to estimation of ecological risks of urban territories

For the analysis of multi-factor researches it is important to select adequate mathematic-statistical method of analysis and of generalization of experimental data. Traditional approach with using of multi-factor dispersion analysis and of F-criterion of Fisher for estimation of importance of separate factors and of their combination do not allows to decide the task of forecasting of functional state of man (FSM) by using of values of parameters of external medium and of other factors, participating in it forming. In this case researcher is having the necessity of using of a number of regressive models, describing the interrelation of separate indicator of functional state of man with linear or non-linear combination of factors of external environment (FEE):

$$y_i = f(x_1, x_2, \dots, x_n), \quad (1)$$

where y_i - i-form of values of estimation of FSM, and x_1, x_2, \dots, x_n – of FEE.

A number of such equations (in dependence of the number of used indicators of FSM) may be rather high, and this makes difficult its practical usage. Moreover, in this case it is observed setting of multidimensional (for totality of FSM) task of quantitative estimation of system response of man's organism in negative conditions to several one-dimensional tasks. Such approach is not completely adequate. The most logical is study of multidimensional system by multidimensional mathematical methods.

During the study of functional state of man the main are statistical models of qualitative estimation of system response of organism of man to factors of life activity.

It is necessary to use the methodology of decision of system tasks with consideration of the main peculiarities of medical-biological information, which is an adequate mean of generalization and structuring of medical information in applied medical-biological researches.

Statistical concept, including successive application of methods of factor, canonical, correlation, cluster and component analysis is allowing to synthesize criteria and algorithms of making of decisions during estimation of functional state of man in applied medical-biological researches. Criteria and algorithms of estimation of functional state of man are allowing to carry out the estimation the degree of effort of mechanisms of adaptation of organism to the factors of vital activity.

New approach of determination of integral indicator of functional state of man (FSM) in coincidence with integral indicator of physical factor of environment (PFE) may be carried out on the basis of interrelation of one-dimensional multi-parametric characteristic of system response of organism (L_{sost}) and one-dimensional multi-parametric characteristic of external environment (L_{sr}). In this case $L_{\text{sost}} = L_{\text{sr}}$. On the basis of application of canonical correlation analysis it is determined that there is exist close interrelation of totality of indicators of FSM with totality of parameters of external environment ($\rho = 0.82$; $p < 0.05$).

3. Development of program provision for estimation of ecological risks

New program provision for estimation of ecological risks have been developed by authors. It allows to carry out complex estimation of risks and to carry out joint impact of main chemical and physical factors to the human organism taking to account possible toxic effects. Program provision also allows to carry out automatic processing and estimation of results of measurements of different physical and chemical pollutions and to carry out calculations of integral values of impact of factors of different nature.

Program, provision "Integrated monitoring of physical and chemical pollutions" (IMCF) [10] consists of 3 main blocks integrated with other modules of automated working place «Complex City Test»:

1. Informational block including:

- databases of physical; factors and chemical pollutants of environment of urban territories (air, water, soil);
- informational-reference tables of values of maximal admissible concentrations and maximal admissible levels of main chemical pollutants and of physical factors;
- lists of the main chemical toxicants and of physical pollutions of town;
- lists of the main sources and factors of chemical and physical impact to the population;
- informational databases of medical statistics, databases of ecologically caused illnesses of citizen.

2. Program-analytical block, containing:

- module of automated processing of measurements results of different chemical and physical impacts;
- module of ecological-toxicological estimation of measurements allowing to carry out estimation of correspondence of measurements results to the sanitary-hygienic requirements;

- module of integral estimation and analysis of combined impact of factors of different nature allowing to carry out integral estimation of joint impact of physical and chemical factors to the human health, calculation of ecological risks and integral values of physical and chemical pollutions of environment taking into account indexes of toxic effects of synergetic impacts exceeding effects of summation.

3. Block of mapping of territory (GIS-mapping) containing:

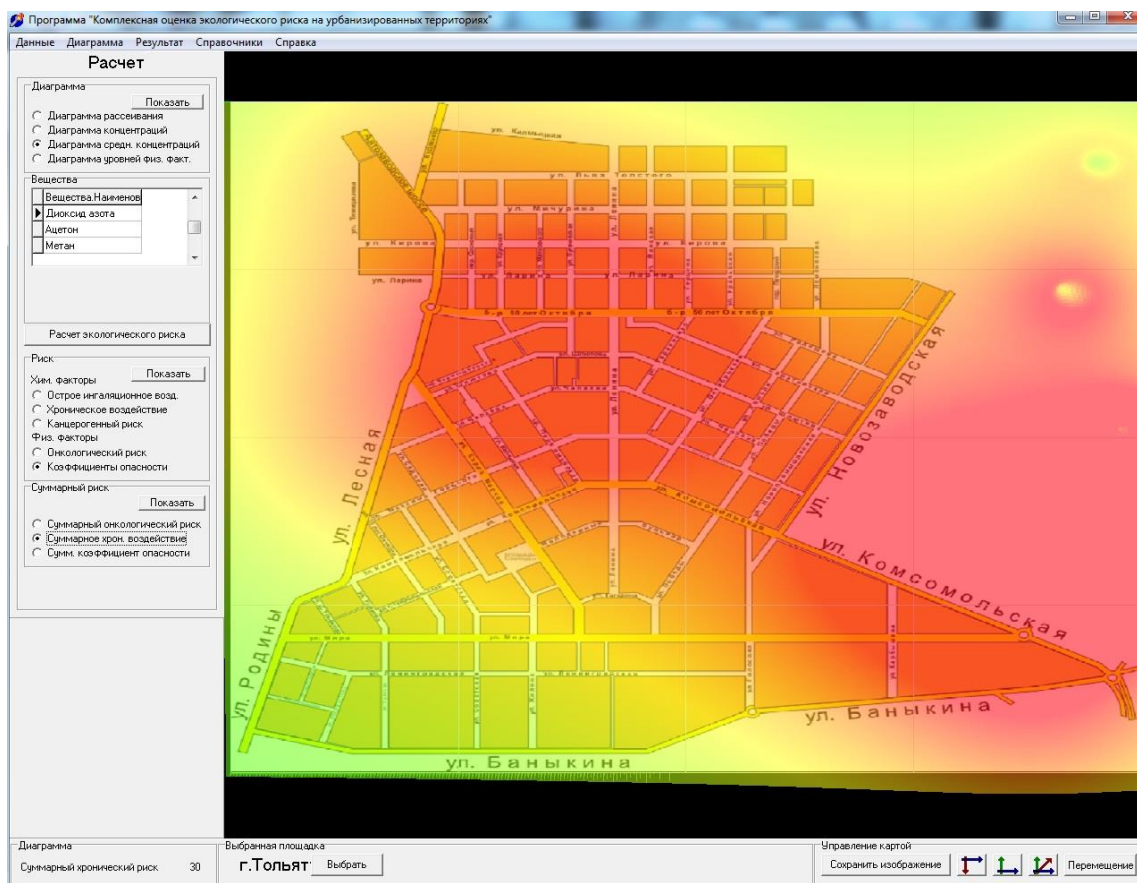

- module of mapping of territory of town for the different pollutants and factors of physical impact;
- module of dynamic mapping of physical fields and of chemical pollutions of town;
- module of mapping of integral impact of limiting factors allowing to create maps according to results of measurements and calculations of integral values of combined impact of factors of different nature, dynamic maps of physical and chemical pollutions (maps of ecological risks, maps of combined impact of factors).

Results of calculations in dependence of a number of values may be presented or as the table of measurements or as the separate field of results displaced below the table of measurements.

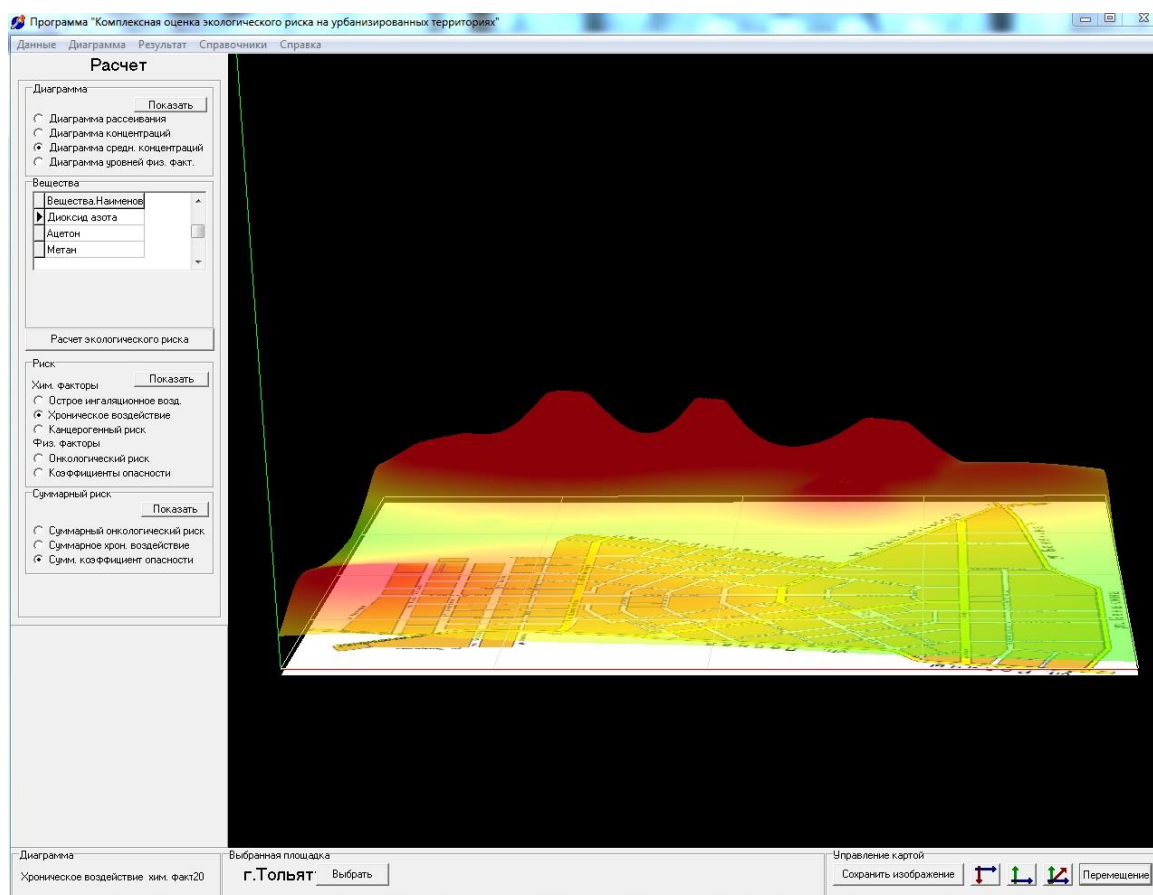

Program allows to input into the database results of measurements of the following impacts: noise (sound); infrasound; ultrasound; vibration; electromagnetic field, ionizing radiation; heat radiation; chemical pollutants; main toxicants.

Automated functions of developed program provision:

- account of measurements of concentrations of chemical components for inhalation input (atmosphere air);
- account of measurements of concentrations of chemical components for mouth input (water, food);
- account of measurements of levels of impact of physical factors;
- storage of data about maximal admissible concentrations of chemical substances and groups of summation;
- account of data of sources of pollutants emission into atmosphere;
- modeling of pollutants dispersion in atmosphere air;
- calculation of ecological risk on the basis of calculated data of ground level concentration of pollutants in atmosphere air during gas-air смеси exhaust from single source;
- calculation of ecological risk on the basis of measurements of concentrations of chemical pollutants;
- calculation of ecological risk on the basis of measurements of levels of impact of physical pollutions;
- complex estimation of ecological risk of impact of chemical and physical factors during combined impact;
- determination of probability of development of cancer illnesses.

b

Figure 1. Two-dimensional (a) and three-dimensional (b) representation of results of estimation of ecological risk by using of developed program provision.

Green color – normative value; yellow color – risk; red color – угроза

As the basis for mapping the graphical two-dimensional map of investigated territory is used.

Program provision allows to determine the most dangerous zones of urban territory from the point of probability of development of chronic illnesses from complex influence of chemical and physical factors (figure 1).

Main modules of informational block of program provision "Main toxicants of environment and human health" are shown in figure 2.

Thus, for provision of ecological safety of population of towns it is occurs keen necessity of provision of complex estimation of impact of different factors of environment to the man and to ecosystems. Much importance should be attached to study of combined impact of factors of different nature – physical and chemical – to the man's organism [4-7, 9].

4. Approbation of new approaches and software for estimation of ecological risks in conditions of urban territories

Authors have approbated developed program provision for the complex research and estimation of ecological risk of Togliatti city. As main pollutants the following components were determined: formaldehyde, dioxide of nitrogen, dioxide of sulfur, oxide of carbon, methane, acetone, sterol, benzopyrene. Together with estimation of chemical pollution analysis of influence of following physical factors was carried out: noise, vibration, ionizing radiations, electromagnetic fields of industrial and radio frequency range, radon.

Using of automated system allowed to obtain the data of probabilistic development of different illnesses in dependence of factors of impact (figure 3 a – chemical factors; b – physical factors) and point out in a map of territory.

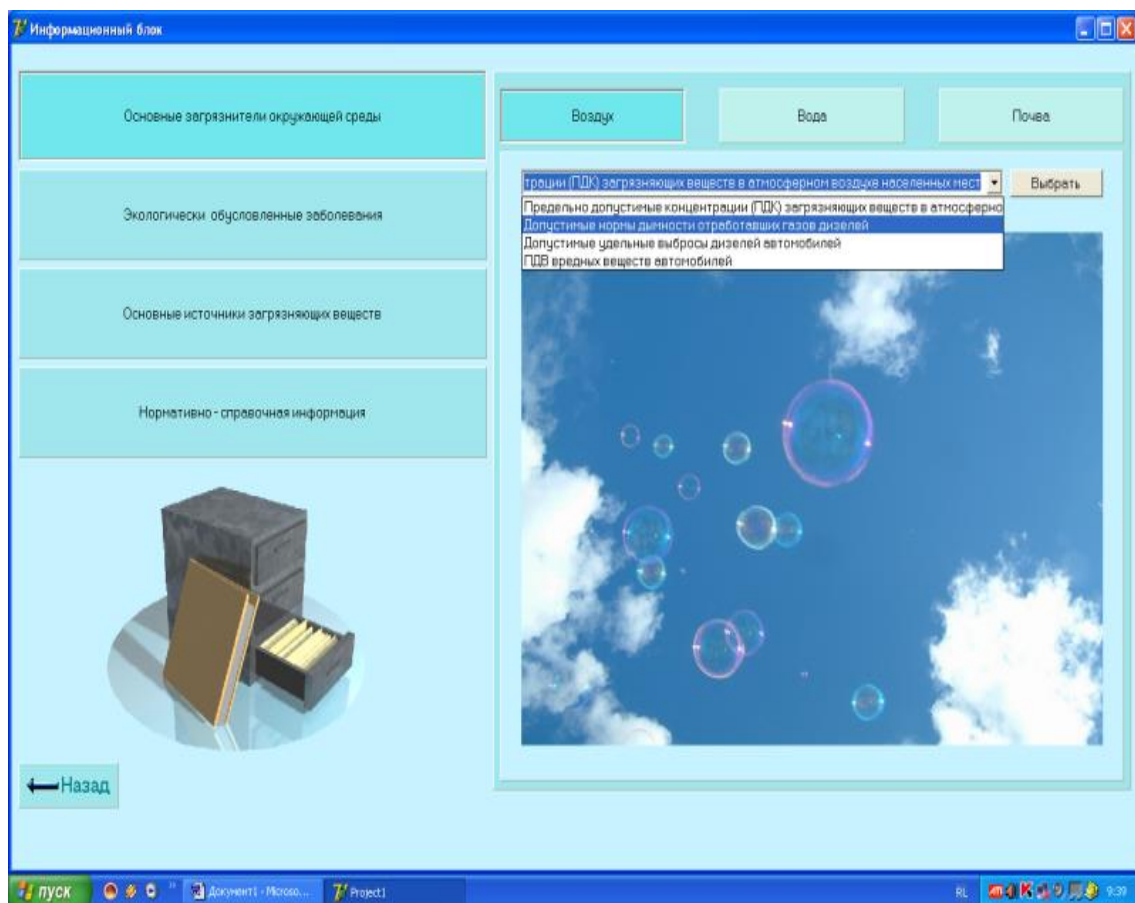

Figure 2. Main modules of informational block of program provision "Main toxicants of environment and human health"

a

b

Figure 3. Example of calculation probabilistic development of different illnesses in dependence of factors of impact

a – acute inhalation impact of chemical substances;

б – probability of development of chronic illnesses from noise impact

Developed program provision allowed to receive the data not only about probability of development of different illnesses from the main chemical and physical factors, but also to estimate it integral impact taking to account synergism effects.

5. Conclusions

The results of research are showing that complex estimation of risks is a prospect approach for efficient control of quality of environment and of estimation of ecological safety.

New approaches to estimation of ecological risks of urban territories are allowing to consider joint impact of physical and chemical pollutions and to determine the most problematic zones of urban territories.

Developed program provision is allowing to carry out not only separate, but also combined estimation of ecological risks of territories and to efficiently forecast risks of ecologically caused illnesses form complex impact of factors of different nature.

Results of approbation of new approaches to estimation of ecological risks and of program provision on the example of the territory of Togliatti city of Russia are showing high efficiency of estimation of ecological risks of urban territories.

IMPROVEMENT AND REALIZATION OF SYSTEM OF WASTE MANAGEMENT OF URBAN TERRITORIES

Andrey V. VASILYEV

Research & Development Department, Samara State Technical University, Russia
e-mails: avassil62@mail.ru, avassil62@yandex.ru

Abstract

Problem of waste management is coming one of the most important problems in all industrial countries. Waste number is growing every year. Waste may cause complex negative impact to the landscapes of territories, to biosphere and to the human health. Examples of waste negative impact are considered. Methods and approaches of reduction of waste negative influence are analyzed. Suggestion to improvement of existing waste management system in Russia are described. It is shown that to decide the task of reduction of waste negative impact to the population and to environment it is possible only by realization of complex approach including waste collection, transportation, disposal, treatment, utilization, education, information of population etc. Results of complex organization of waste management system in Samara region of Russia in framework of cluster of secondary resources are considered.

Keywords: Waste management, urban territory, system, impact, reduction

1. Introduction

In conditions of modern urban territories it is possible to determine many factors causing negative impact to environment and to human's health [2]. One of the main factors is waste negative impact [1, 3-7].

Problem of waste management is coming one of the most important problems in all industrial countries. Waste number is growing every year. In Russian Federation annually more than 7 billion tons of different kind of waste is forming, and only 7 billion tons of waste is using again after utilization. Waste may cause complex negative impact to the landscapes of territories, to biosphere and to the human health. Especially dangerous are toxic waste. The problem of it negative influence to the human's health both in industry and in domestic conditions have become especially important for the last years as due to the significant volumes of it as or the high toxicity [1]. For example, toxic waste of chemical nature may cause different negative impact to the humans leading to the damage of cardiovascular and respiratory systems, skin damage, toxicity poisoning and other negative sequences.

Influence of toxic waste may cause significant negative impact to environment. For example, atmosphere pollution by lubricating cooling liquids impact may occur not only in the process of it exploitation, but also due to evaporation and combustion of lubricating oils. Used lubricating cooling liquids may be considered as dangerous toxic wastes, utilization of which is very difficult [3, 7].

This paper is devoted to the problems of improvement and realization of waste management system of urban territories.

2. Analysis of peculiarities of organization of waste management system in Russia

In general existing system of waste management in Russia may be subdivided into the different directions:

- waste collection, transportation, utilization;
- waste temporal storage;
- waste displacement in special sites;
- monitoring of waste management on the different stages;
- ecological education, organization of efficient system of teaching of specialists in the field of waste management;
- enlightenment and upbringing of population in the field of waste management;
- improvement of legal and normative documentation in the field of waste management;
- development and implementation of methods and technical solutions for reduction of waste negative impact;
- informational provision of waste management etc.

In fact waste management activity in Russia may be considered as a special cluster, the main purpose of which is provision of efficient interaction of all variety of specialists which are deciding particular questions. General purposes of cluster are:

- Integration of subjects of waste management and of secondary resources between clusters and inside of clusters;
- Development of markets of secondary resources;
- Promotion of economics of knowledge in system «upbringing – education – science – production – consumption».

Detailed purposes:

- Initiation of fundamental research of different stages of increased waste vital cycle and on topical directions of resources saving;
- Creation of conditions of accelerated certification of waste with variation of status in system "waste – secondary resource – product».
- Development of logistics of recycling;
- Determination of priorities of projects realization;
- Optimization of regional normative-legal base for reaching of strategic purpose «zero of waste».

Advantages of cluster alliances in the field of waste management are evident, and it is possible to determine it as priority direction of further development and increasing of efficiency of activity of enterprises of industry of waste treatment:

- supporting of creation and functioning of system of using of secondary resources;
- unification of resources on the basis of regional mechanisms for implementation of modern technologies of waste treatment;
- development and implementation of informational-technical systems and it using in frameworks of common informational space;
- joint training of staff of all levels;
- collaboration with foreign enterprises on exchange of advanced experience and new achievements.

In Samara region of Russia there is a special program "Improvement of system of industrial and domestic waste management and forming of cluster of using of secondary resources on the territory of Samara region". Main purposes of the program are:

- creation of joint system of industrial and domestic waste management on the principles of consolidation and unification of state structures with all the representative of professional society;
- finding of investments into economics of Samara region, creation of additional working places, provision of ecologically safe keeping, treatment and liquidation of waste.

In Samara region of Russia investments are directed mainly for construction of sorting stations, logistics organization, establishment of conditions for wastes temporary storage and treatment. In more high technological level are arranged waste collection and temporary storage, new container sites are created. Main task is separation of waste and re-using of resources. It allows reduce negative impact to the environment, to reduce a number of polygons of waste disposal and a volume of waste.

Regional and municipal legislative base of Samara region in the field of waste management is continuously improving. In this case much importance is attached to the development of system of waste management in the big towns of Samara region: Samara, Togliatti, Syzran, Zhigulevsk.

On the territory of city district Togliatti system of industrial and domestic waste collection, transportation and utilization is arranged in the following way. Utilization of solid domestic waste and large size garbage forming as result of vital activity of population of city district is financed by the city budget.

Scheme of industrial and domestic waste utilization in Togliatti city is integrated too the cluster of secondary resources of Samara region and includes such enterprises as "POVTOR" company, solid waste treatment plant, "PLODAR" company etc.

All the volume of solid domestic waste and large size garbage of Togliatti city is primarily delivered to "POVTOR" company, where sorting of waste is provided. Organic waste is treated by bio-thermal composting method in solid waste treatment plant. The volumes of waste that it is not possible to utilize and to treat are disposed in special polygons.

Existing system of utilization of solid domestic waste and large size garbage of Togliatti city allows to provide efficient treatment of waste and to reduce a total volume of waste disposed at polygons up to the value of 25 % from the total value of waste.

Implementation of system of a separate collection of waste is important and complex task requiring a hard work on organization of ecological enlightenment and upbringing, motivation of inhabitants to separate paper, glass, plastic in total waste volume.

It is also an interesting experience of work of association of Samara region "Waste management" uniting as enterprises activity of which is connected with waste forming, disposal and utilization, as educational institutions.

It is necessary to underline that in Samara region of Russia much importance is attached to ecological education, enlightenment and upbringing, including also the field of waste management. Some universities of Samara region are teaching the students to ecological specializations. Mass measures, actions, exhibitions, competitions with active involving of population of region are carried out. For example, in September 2013 in frameworks of international ecological congress ELPIT-2013 in Samara was held international round table devoted to waste management problems with active participation as of heads and of specialists of enterprises, as scientists and of public organizations and citizens.

3. System of waste monitoring in Russia. General methods and approaches of reduction of negative waste influencing.

In Russia there is a system of waste monitoring including observation, control and collection of information at different levels:

- monitoring of impact to environment;
- monitoring of waste displacement etc.

Monitoring of environmental impact assessment provides for control of the following parameters: object of control, methods of research, frequency of measurements, methods and equipment of control, periodicity of measurements data processing and analysis, methods of estimation of environmental impact assessment, methods of estimation of environmental damage. In result it is necessary to implement the measures allowing to reduce the exceeding values of waste negative impact and to arrange control measurements.

Monitoring of all parameters of observation, control and analysis is carried out is provided during all the chain of waste treatment and disposal. Collected information is transmitted to the information-analytical center and then to forecasting center where is modeling of possible events during negative impact to environment is modeling.

The general methods and approaches of reduction of waste negative impact are including:

- collection and transportation of total mass of waste;
- waste separate sorting;
- waste treatment;
- waste utilization and secondary using;
- waste disposal.

Especially important is the task of toxic waste treatment. In Samara State Technical University new method of utilization of oil containing waste is suggested including processes of atmosphere and vacuum distillation with further oxidation. Such solution allows to return to production cycle of oil distillation raw materials in wastes of oil gas industry. It allows to significantly reduce negative impact of oil gas sludge to environment.

4. Conclusions

It was shown that problem of waste management is especially important in Russia due to the negative waste impact to environment and the human health and because of a large volume of waste that is not utilized. Analysis of peculiarities of organization of waste management system, in Russia is proposed. Existing system of waste monitoring in Russia is described including observation, control and collection of information at different levels. Suggestions of improvement of existing waste management system in Russia are considered. The general methods and approaches of reduction of waste negative impact are submitted.

It is possible to conclude that the task of reduction of waste negative impact to the population and to environment may be achieved efficiently only by realization of complex approach including waste collection, transportation, disposal, treatment, utilization, education, information of population etc.

Thus, only realization of complex approach allows to decide efficiently important and topic task of reduction of negative waste influence to the man and to environment.

Acknowledgement

The author would like to express many thanks to the Russian Ministry of Education and Science for the financial support of investigations according to the Program of State task to Russian Universities, project: "Development of resources-saving technologies of utilization of industrial and domestic waste".

Musealization and Exhibit Questions inside the Archeological Site

Abstract

The archaeological area is increasingly seen as a place of connection with the space of the active, cultural and civil life, towards the overcoming of the idea that archaeological sites are places situated on a separate dimension, which is unrelated to everyday life.

This tension obviously implies the need for special attention paid to the problems of preservation and protection, but it opens up the fields of action and research to a growing awareness and management of the communicative possibilities and of the opportunities to spread knowledge through physical and direct experience of the site.

This process is widely evident in all those cases in which fragments of architecture, frequently discovered by chance in stratified cities, interpose themselves within urban routes, public and also private spaces, providing the opportunity for the construction of an awareness of the history of the places even for a distracted citizen, who is not driven by a particular intention of knowledge and of realization of the idea of widespread museum.

But this is also found in the increasing attention paid to the possible, even if temporary, exhibits, achievable within the sites, which allow the general public to a more intense use, and the scholars to an even more depth one, thanks to the use of technologies and techniques, which are less and less invasive in terms of materiality, but more and more effective.

Keywords: memory space, urban life, widespread museum, communication, stratified cities

1. Relationship with the urban context

The problem of archaeological sites located in urban areas allows us to verify the path taken by museum design over the last hundred years in the direction of overcoming an idealistic conception of the cultural legacy as well as in the direction of a progressive reduction of the distance between what is the object of musealization and the daily lives of its users. How this process has been able to sustain the design research of the museum and its setup is the subject of extensive and numerous treatises, reflecting, in the materiality of the spatial structure and manner of presentation, the instances underlying the evolving of the ways of cultural fruition and the broadening of the target audience of museums and exhibitions. In practices related to museums this has resulted in the passage from a contemplative dimension, drawn from the flow of everyday life, of cultural fruition to a greater tension to participation and understanding of the meanings attached to the objects displayed. The architecture of the museum has abandoned its traditional aspiration to being a temple, in favor of the vocation to be a place of communication which is particularly meaningful in contemporary social life. Similarly, the techniques and the exhibiting methods have been refined to facilitate the exploitation of documents and in bringing them to different users, for all ages and interests. The concept of cultural legacy itself has undergone a process of extension beyond the concept of excellence and masterpiece, has included examples of material and immaterial culture capable of returning the complexity of human life and thought in a given time or in a given context. As a corollary of the renewed concept of cultural legacy, a lot of importance can be returned to the context of source and documents and works, as opposed to the process of extrapolation from the target issue and favoring instead the reading of ties

with the physical and cultural environment of belonging, as well as the theory on the idea of widespread museums has deeply investigated.

The area of urban archaeological sites offers the opportunity to read this passage from a situation of exclusivity to inclusivity in the relationship between the site and the context and between the site and the user. Work on sites and fragments found underneath, within, in between the gaps among other existing buildings and layered over them offer the opportunity to make some observations on the relationship between integration and mutual enrichment between architectural design and construction and archaeology. This framework also emphasizes the importance that the spaces of connection between the archaeological sites and the active city, as well as from one site to another have: in fact these are the sites of a link not only physical, but also conceptual, between the values of which the remains are carriers, and contemporaneity.

This discussion does not want to get into the substance of the arrangements for the restoration of archaeological sites, but in the way it deals with the problem of their exploitation and the way it treats the relationship that they weave together with surrounding spaces, in which the vision of the findings dissolves in the most diverse and daily functions.

As in every other dimension linked to the problem of musealization, even that of archaeological sites is struggling between instances of conservation and those of communication, both essential, but in hindsight, in conflict with each other. Paradoxically speaking, from the point of view of conservation, once a site is found, after having studied and drawn the most scientific information, the best assurance of its preservation may just be given by its backfilling.

But this would go against one of the purposes underlying the archaeological interest, which is to enrich the lives of present and future generations with the historical, cultural, aesthetic values substantiated in those remains. Communicating those values, enhancing the sites, and deciding how to treat the problem of their connection with the context is no longer just a problem of conservation, but rather of design, which writes the archaeological site fully into the flow of transformation processes of the contemporary city.

Traditionally, the archaeological site was drawn from this flow, protected and isolated from the environment, even physically, by a wide margin of green area, legacy of a romantic view of the ruins and a symbol of a sort of transition necessary to be able to reach the ruins themselves, from a prosaic and mundane dimension to an "other" dimension, lofty and extrapolated from everyday life.

Fig. 1: Hans Hollein, Michaelerplatz Archäologiefeld, Wien, 1991-1992

This forcing the archaeological site into an *enclave* conflicts with the implicit vocation of urban archaeology to highlight the processes of stratification experienced by historic cities where it is not possible to extract and crystallize the contribution of a given epoch from those preceding and following: almost all European cities clearly show how each building or street, or square has been designed on the trail of pre-existing ones, using this as “project material”, in the concrete or conceptual sense.

The permeability in the arrangement of the archaeological site can allow not only to marginalize the remains and to promote the fruition, but to read the continuity between the various measures of change between the built environment and the human stories that have generated the same action.

An example of maximum permeability, woven by the plan of the arrangement between the discovery and the urban context, is given by the solution of Hans Hollein for the Michaelerplatz Archäologiefeld in Vienna, built between 1991 and 1992. The design of the pavement, of the minimum structures of protection and viewing, summarizes in a contemporary feature the comparison between the signs and sedimentation of the different historical periods experienced by the urban fragment, already the scene of the encounter, as never in history emblematic of architecture, between the Looshaus and the Baroque architecture of the Hofburg.

The permeability and integration between the site and the context must not, however, be seen as coinciding with the lack of boundaries or transparency, which often becomes a commonplace in architectural design solution for the protection of archaeological finds. Like the protective band of green, the frequent use of the *glass box* at times seems obvious and predictable, where building an architecture with its materiality mediates, protects, introduces, interprets or at times evokes, is a more responsible and intentional act, although more risky. Action taken in 2001, always in Vienna, by Christian Jabornegg and András Palffy for the redevelopment of the archaeological area underneath the Judenplatz, with the rearrangement of the Holocaust Monument by the English artist Rachel Whiteread, is an example of strong integration, but not so much visual, as conceptual. The Monument is made up by a rectangular cement block, of approximately 10 meters by 7, almost 4 meters high, consisting of walls of books, objects not normally present in the urban space, a symbol of the stories of the men involved in the tragic events, arranged so as to present the spines inward, thus anonymous; on the base are the names of the places of extermination. The books cannot be read, their decoding refers to a further deepening of the events of the story. The monument, highly *site-specific*, is located above the remains of a medieval synagogue, which was destroyed in one of the many persecutions suffered by the Jewish community, found in recent times. The path that leads to the excavation, completely underground, starts in the arrangement of the pedestrian area where the monument is located and leads within the Mizrahi Haus, where a branch of the Jewish Museum is set up, focused on the life of the Jewish community in the Middle Ages. In this embodiment, both the urban development and the draft of the Monument, and the museum set up and enhancement of the archaeological site flow into the next, materially reflecting the connection among the various interrelated historical events.

2. Hybrid spaces

One area of special importance is given by those hybrid archaeological spaces, oftentimes found casually in the layered cities, where the action of valorization and protection of the site joins easily with projects of places entrusted for the most various functions. These cases constitute realization examples of that ideal of widespread museum that aims at connecting the object of the musealization action with its context of belonging: in these cases the works, the sites, the artefacts, to meet the visitors, who carry out their normal daily activities, showing with evidence their presence, and with that aura of fascination that are capable of exercising, the density of the historical layering of the city where they live and work. The city of Naples continuously offers these occasions of similar interventions, exactly for the thousand year layering on top of the same track: the building of the Line 1 of the Underground railway, about to be completed, took on an important occasion to verify this phenomenon and to test, through various media, different solutions to the fruitful living between instances of efficiency of a contemporary infrastructure and valorization of the identity and wealth of a city full of history.

The excavation works necessary for the building of the Metro have unearthed a huge amount of artifacts, ranging in time from the prehistoric period to the Spanish domination. While this has caused a huge slowdown in the advancement of the works, on the other hand it has provided an important opportunity not only for the advancement of archaeological studies on the city, but also for the work of the designers involved that had to deal with the need to adapt the design solutions to the needs dictated by the finds.

The quantity and quality of the finds was such as to suggest the creation of Neapolis Station, an exhibition space open access that lies along the railway museum and in fact falls below the National Archaeological Museum, of which it forms a part. This showroom is not particularly significant for the display solutions, but rather for being a museum out of its traditional isolation to meet the potential visitors, carrying out the same working approach to the citizen by culture which is at the basis of the general idea underlying the project of the Art Stations by Achille Bonito Oliva, a museum where you find yourself immediately immersed, while tending to your own daily tasks.

Fig. 5: Oscar Tusquets Blanca, Toledo Station, Line 1 of the Metro, Naples, 2012.

If the Neapolis Station brings together small artifacts, sculptural works and utensils, the architectural finds fall into the contemporary project of the stations where they have been found, becoming for instance a key of clear indication of the descending into the various historical and physical layers of the city, like in the Toledo Station, by Oscar Tusquets Blanca, where the wall fragments of the Aragonese epoch talk equally with the materials of the architectural project and the contemporary works of art, like the mosaics by William Kentridge or the “Galleria del mare” [*Gallery of the sea*] by Bob Wilson.

The 1st century temple A.D. found in the area of the Duomo Station becomes the focus of the Fuksas project, visible from outside through a clear cover that can be visited from the inside, along with the other archaeological remains found.

In these projects, the archaeological remains become the protagonists of the architectural projects, together with the works of the contemporary art, combining past and present, but also combining functional and efficient response to the infrastructural needs of the city of the present day with the opportunity to enrich the culture and beauty of everyday life, and not just on special occasions, in line with the most current meaning of the sense of the action of a museum.

This combination of factors ultimately becomes the qualifying factor of the urban invested by each intervention, finally overcoming the enclave status as alluded to earlier.

The most important intervention playing for the urban impact is the one designed by Alvaro Siza with Eduardo Souto de Moura for the area of Piazza Municipio, where a significant and extensive archaeological area has highlighted the port areas of antiquity.

Due to the layout of this area, which will remain largely in the open, even if it includes within it a museum of some vessels found *in situ*, it will be possible to read the transformations from the coastline bringing together the archaeological site with the built landscape, from various ages, with the natural one, something precluded to the underground arrangements.

Fig. 6: Alvaro Siza and Eduardo Souto de Moura, Municipio Square Station, 2000, work in progress, view of the model.

3. Exhibit and space experience

These actions show how extensively archaeology can fuel and substantiate the architectural design, which is forced to evolve with the progress of the excavations and hone its ability to interpret the site and reestablish a connection with the context. As mentioned earlier, every action of interpretation and exploitation becomes an act of design that exceeds the size of the conservative direction of greater bond with the contemporary project.

The architectural design can work depending on the strengthening of its ability for fruition and reading of the archaeological site, acting on its fringes, beside and around it, mediating the relationship with the environment. But it can also act on the inside, with minimally invasive tools on the material plane as effective in terms of the effects obtained. All types of communication support which can be placed inside of an archaeological site, such as plastic panels, showcases containing smaller artifacts and furnishings, can increase understanding of the values of the sites that you visit. They can become tools for reading the spatial and architectural values of the site, not only for the scientific depth and reliability of the information contained or supported, but for project control and compositional sensitivity at the base of the way they are designed: for example, *lining-out* can complete the reading of partial remains or allow to read the position of interventions in different times with a much higher efficiency than that of site plans and engineering drawings placed on the side of the ruins, since the spatial allusion allows to immediately build the distribution and dimensions of the architectural space. A very difficult field of intervention, which can be only mentioned here, is that of protection covers, which can assist the primary function of a cultured interpretation and reconstruction role of environmental effects. Similarly the use of *ghost structures* may return, for instance, the idea of the complexity of the *raumplan* of the Domus, typically mortified in the common perception of only layout reading. Therefore inserting of showcases containing furnishings or projections aimed at rebuilding the treatment of the walls tend to mend relations among the space, decoration and furnishings which were made either by time or mutilated by previous conservation interventions and museums that separated the space from the furniture, frescoes and even decorated mosaic floors.

Fig. 6: Design of a temporary exhibition in the House of the Tragic Poet in Pompei. Thesis of L.Celli, Corso di Laurea Magistrale in Architettura, Arredamento e Progetto, Università degli Studi di Napoli "Federico II".

The use of multimediality and virtuality is rightly seen as an opportunity of huge interest for communicating archaeology, precisely due to the possibility these tools offer to return to the spaces of the past their entirety and completeness through decorations, furnishings, lost colours. Oftentimes however, these reconstructions bring back an image which, although an interpretation, draws the space represented by the flow of transformations, freezing it in a predetermined time. The resulting image is often deprived of many of the qualities that belong to the physical space. The potential of multimediality are huge in helping us see what is not visible, such as what has gone destroyed or what has been backfilled, or even operate network connections between sites and museum contexts among which there are significant cultural and historical ties. Of course the use of the *touch screen*, is very advantageous as with the use of a plain *app* that each and every one of us can download on our phone, allowing us to intensify and widen the information related to visiting the archaeological site. However, I believe it is important to reflect on whether the communication tools offered by augmented reality are seen as useful aids in intensifying the experience of archaeological sites, carefully avoiding the risk of replacing it. The physical and sensory experience of the site is essential despite the success that many exhibitions collect that make use of more sophisticated tools of modern technology: being in front of a screen, although we believe to manipulate and guide the exploration of the images being offered, is absolutely not as meaningful as being inside. Often these exhibitions are independent from the actual site, far from it, as well as alien to the involvement of other kinds of materials. As such they belong more to the operations connected to on line museums than those actions aimed at valorising the actual sites. Even when making use of technologies that bring together the body gestures with the images projected on the screen, borrowing systems widely used by the world of videogames, as in the case of the recent exhibition in the Palazzo Te at Mantova, "Order and light. A virtual tour in the evolution of interior spaces in the history of Greek architecture up to the Renaissance", not all too convincing however is the discounting of the subject of the study to pure image, its stripping of all those meanings linked to the sensorial experience, the tactile dimension, the opportunity to read the relationship with the context and landscape, and, last but not least, the possibility of measuring the space to the bodily dimension, that's to say all those aspects intrinsically connected to the actual architectural space. The importance of the physical experience remains essential in my opinion, the role of the design and construction of a museum may be of great weight in the effectiveness and intensity of the experience of this reality, whose value also lies in the fact that it has "materially" come to us. The massive and above all unique appeal to virtuality moves in the direction of spectacularization and discounting to pure image of the architectural heritage and may for that matter proceed towards distancing this from the actual and cultural life, in the opposite direction of the work accomplished by modern museums.

Abstract

This paper concerns the restoration of the castle of Ventimiglia family in Castelbuono; the initial part, come from the medieval period (XIVth century), underwent considerable transformations in the XVth century by Giovanni Ventimiglia, Count of Geraci. He transformed the old castle, which is primarily defensive, in their own home and restored the chapel dedicated to S. Anna, then reconfigured in 1683. Since the XIXth century the castle had a progressive deterioration and in 1920 it was purchased by the Municipality of Castelbuono. The postwar years were characterized of a further deterioration of the castle; it was remedied with partial actions since 1978. These interventions have been coordinated by the State Department for environment and historical buildings and by the architect Rodolfo Santoro.

A significant intervention involved the consolidation of the foundations through the creation of micro poles and execution of archaeological excavations. Then, using a research agreement with the University of Palermo, the surveys, structural and geotechnical investigations were completed. In 1994 the opportunity of draw up a plan gave it a designation for exhibitions and conferences.

The works of monumental restoration, aimed mainly at the *Palatium*, concerned:

- The static restoration through the consolidation of the foundations, the walls, floors and roofs;
- The architectural restoration;
- The reuse of the complex with the outfitting of the interiors.

Keywords: architectural restoration, architectural history, construction techniques.

1. The castle over the centuries

The castle of Castelbuono enjoys an elevated position on top of the hill called San Pietro, at the foot of which lies the town. On the basis of archival sources its foundation, by count Francesco I Ventimiglia, dates back to 1317, as demonstrated by a document with which the bishop of Patti grants in exchange for the count the hill of San Pietro belonging to the Church in exchange for a certain area of land in the territory of Castelbuono [1].

Its construction, according to tradition, was linked to the desire of the noble Ventimiglia's family to adopt a feudal residence alternative than that of the highest and cold Geraci, capital of the feudal state [2]. More recent studies [3], however, have reduced the residential role of the castle, also in view of the existence of other dwellings owned by the Ventimiglia's (as the *Domus Magna* of Cefalù), rather than tying the construction of the building to the role of homeland defense. The castle, in fact, due to its strategic location, not only was a safe protection and a refuge for the population of the neighboring houses, but closed the access road to the Madonie.

Between 1454 and 1456 Giovanni Ventimiglia did perform works likely to make the castle more comfortable and suitable for residential functions and in the same year moved from the chapel of the castle of Geraci, where he had previously kept, the skull of St. Anna, that become subsequently the patron of Castelbuono. Probably this date can be traced back the first reconfiguration of the chapel, presumably dating from the early XIVth century.

In the XVIIIth century further processes were performed, which gave the castle its final form. In particular, in 1683, Francesco Rodrigo Ventimiglia did reconfigure the old chapel which at that time was fully covered with a magnificent decoration in *stucco*, by brothers Giuseppe and Giacomo Serpotta. At the same time can be traced restructuring of many interiors and the realization of the internal staircase to the court, to replace the old medieval scale, traces of which can be detected in the presence of two pointed arch doorways currently bricked, and which thresholds do not coincide with the landings of the staircase. Were opened large balconies on the northern elevation of the building and was made the painted wooden ceiling that covers the main hall of the castle. Finally, in the inner court was built a theater later transformed.

The castle remained in use throughout the 1700s and early 1800s, receiving some damages from the earthquakes of 1818, 1819 and 1823, which caused the collapse of some of the battlements and roofs, initiating the process of degradation of the product.

The northern slope of the hill on which the castle stands has been subject to landslides which resulted in years of instability phenomena, together with the seismic events. In particular, the earthquakes of 1693 (Val di Noto), 1818, 1819, 1823 (with an epicenter between Cefalù and Pollina) produced many damages.

Purchased in 1920 by the town of Castelbuono was subject to a first restoration and was allocated a school inside the castle. In the 70's were made partial actions: the town restored the "great room" and the tower of the south-east, while the Superintendent of Monuments intervened in the roofs and in the chapel of St. Anna.

A global project for the restoration of the castle was drafted in 1980 by the architect Rodolfo Santoro, whose works were concerned essentially the realization of some archaeological essays and restoration of the static foundations through the injection of micropoles depth of 15 m along the north and west sides. In fact, the castle had a large crack pattern that affected most of the exterior and interior walls. The wall of the west elevation was characterized by a high spin that had required the construction of buttresses. The vaults had diffuse small lesions and the wooden decks were characterized by significant depressions. Having to complete the interventions of consolidation was drafted a comprehensive restoration in 1994, extended to these structures, drawn up by the aforementioned architect Santoro.

During the course of the works, carried out between 1996 and 1999, it was necessary to prepare a variation to the original project. In particular, in April 1996, during the leveling of the cordoned ramp to the allocation of the premises intended for technical installations, were found some human skeletons and architectural wrecks, causing the suspension of works, waiting to develop a special expertise to start their continuation. In May of the same year, during the tests for the assessment of the plans of laying the foundations of the cellar floors called "formaggiere", came to light the great defensive archers. Following this discovery the State Department for environment and historical buildings annulled the creation of local technical services under the cordoned ramp and prescribed the execution of essays with stratigraphically at the premises called "formaggiere". At that point, it required the drafting of a new project that would address the above issues, that was approved in 1997.

2. The architectural configuration

The monumental complex consist in the *Palatium* (that represent the castle) and the surrounding area defined by the wall circuit around that.

The layout of the castle consists of a quadrangular body with five square corner towers, four of which are square and the fifth cylinder combined with the square tower of the north-east. The building is spread over three floors above ground and a basement. Inside the castle there is a small open-air courtyard with a staircase connecting the floors.

The construction is characterized by massive limestone walls on the ground floor with thicknesses between 1,5 and 2 m. The load-bearing walls are made of quarzarenitic stone having different sizes and different degrees of squaring bound with lime mortar. In some parts of the castle, the stonework is made of large blocks of stone arranged in parallel horizontal rows, while in others it is characterized by grossly blank and shapeless stone and has many fragments of stone and brick in the interstices. The roofs of the rooms of the ground floor are made of real barrel vaults and cross vaults, made of stone and lime mortar, while the first floor is covered mostly by wood floors, with the exception of a few areas where remain vaults. The roofs are made of trusses and wooden beams.

Originally the castle consisted of a series of squares, and accessory units, enclosed by walls, which the Arch of St. Anna opened towards the city, which was the main entrance to the castle.

Fig. 1: South side of the castle.

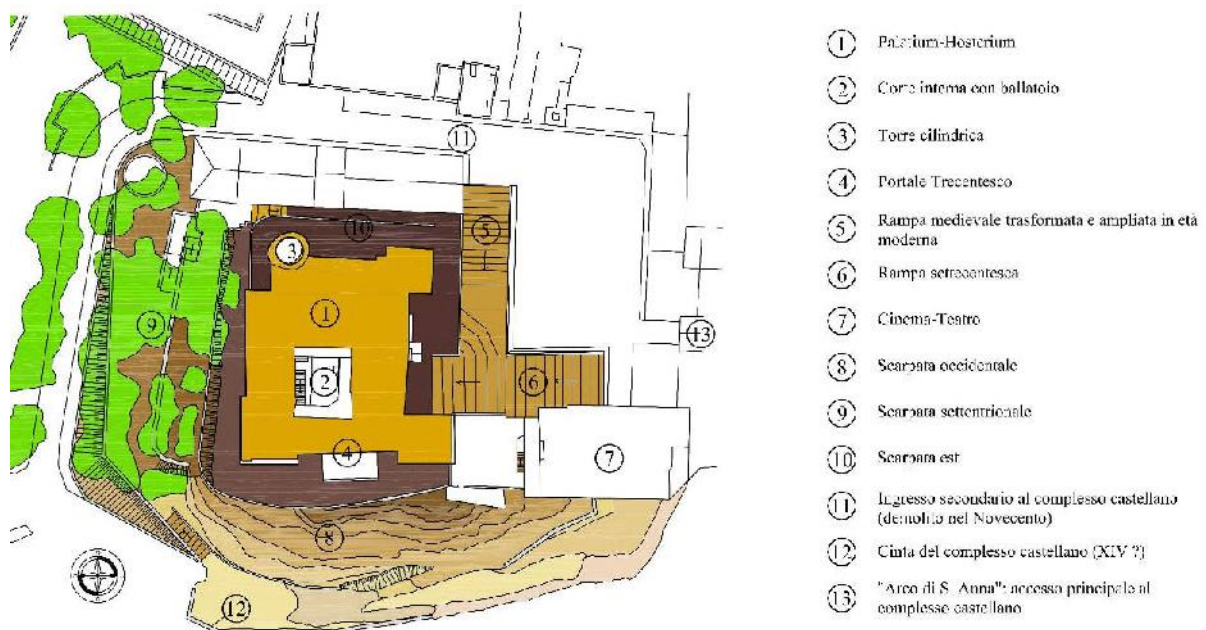

Fig. 2: Planimetry of the castle from the original project.

2.1 The great scarp accommodation

This is basically an extended sloping scarp on earth and rubble covering the artificial "Motta". This in ballast stones of varying size mixed with earth and well tamped has an extraordinary importance both for the era in which it is supposed was made, both for its presumed functions (static and defensive) and for its uniqueness in the almost feudal castles in Sicily. The hypothesis on the dating system of the great scarp should be assumed to date back to the late XIIIth century. The scarp should be dated to a period that could coincide with the confiscation directed this feudal territory (1269-1282) because only the royal "protomasters" knew and applied the scarp as other defensive devices introduced after the trip to Sicily of Federico II in the Holy Land (1230).

2.2 External sides

Currently there is a considerable stretch of the outer curtain wall stationed at the foot of the West great scarp, but it is lined on the outside by a wall built behind in the '60s. The throw light on this part of the wall was crucial for defining the outer perimeter of the castle and also for the dating of the curtain wall itself estimated by the early XIVth century.

Until about thirty years ago, on the western side, was still visible a large portion of the upper surface of the medieval scarp, later covered by natural vegetation. It was a wall of blocks of stones in various sizes linked by residues of lime mortar covered at the top by a gray gradient that defined a smooth

surface with constant incline. Before the restoring works the soil and vegetation had covered everything. Weeding and the cut have returned the physical evidence of the old scarp.

Then was expected an excavation to 2 m depth where was accumulated by gravity the greatest amount of land also carried by the wind over the centuries. Quantity that weighs statically on old wall, especially when it soaks water due to the rains.

The accommodation on the northern scarp of a "public garden", made a few decades ago, was a solution that unfortunately was planted on a medieval defensive item valuable from the point of view of history, then completely unknown to the medievalist culture. Walls, stairways, masonry benches were constructed and trees were planted. The latter, of no value, grew up in the decades after finishing to create a thick curtain of branches and foliage that completely hides from view the prospectus north of the building of the castle, the statement that it is the least known.

The eastern side (especially at the corner of SE) is presumably the point of arrival of the oldest access ramp, the one linked to the first implant of the castle dating from the late XIIIth and early XIVth century. The previous medieval configuration, however, was partially devastated by the earth and the masonry of the following centuries.

On the southern side there is the most important entrance of the castle. Assuming that the current curbs ramps are works from the XVth to the XVIIIth century, these have shattered the previous medieval arrangement referred to a planivolumetric trend of the palatial building that is completely different from the current one.

3. The restoration of the castle

The interventions carried out between 1996 and 1998, were made on the basis of the draft prepared in 1994 by the architect Santoro, who was also director of the works [4].

They were mainly in reference to the so-called *Palatium* and consisted of:

- the static restoration of the building through the consolidation of the foundations, walls, vaults, floors and roofs;
- the architectural restoration (cornices, pilasters, balustrades, exposed brickwork, plastering, fixtures, etc.) that aims to restore figurative dignity to the building;
- the reuse of the complex through the layout of the building interiors for effective allocation of the new functions.

The restorations of the artistic decorations (plasters, carved wood and painted murals) were instead carried out between 1998 and 1999.

The actions planned, thanks to a research agreement signed with the University of Palermo, were preceded by a campaign of surveys and investigations carried out by the consultants that were part of the Department of Representation, the Department of Structural and Geotechnical Engineering and the Department of Project and Building Construction, as well as the Institute of Archaeology, which made the archaeological excavations.

Surveys "in situ" and laboratory tests were carried out in order to evaluate the chemical and mechanical characteristics of the building and of the foundation soils, as well as endoscopic and thermographic investigations.

These interventions have been inspired by conservation, reversibility and compatibility policies in compliance with the applicable technical standards [5].

3.1 The static restoration

Structural interventions carried out on the castle were inspired by reversibility policies and guaranteeing the minimal alteration of the original static behavior.

The static restoration of the building has involved the consolidation of the walls in elevation, of the vaults, of the wooden floors and roofs.

The walls in elevation have been consolidated by injecting lime mortar in order to fill all the voids that existed within the wall structure. As regards the toothings, were performed crossed perforations with hot galvanized steel bars with improved adherence. To achieve a greater constraint between the walls, and in particular to stabilize the northern outer facing, were arranged tie rods consist of both bars with threaded ends, both strands in harmonic steel sheathed in graphite grease.

Fig. 3: Detail of tie bars.

Fig. 4: Detail of harmonic steel rods.

For the damaged vaults was performed the disposal of the upper pavement and emptying of the material until the structural extrados of the vault; later was provided for the sealing of the lesions, the insertion of the connectors and to the jet of a thin backvault thick 5 cm in concrete with non-shrink additive, reinforced with mesh. Finally the whole thing was filled with a lightweight inert material (expanded clay), reconstituting the screed and the floor.

Fig. 5-6: Interventions on the vaults.

In two specific cases, the advanced state of instability of the vaults involved the disposal and subsequent reassembly:

- the cross vault that covered the vestry, for which it was decided, by mounting a special bending wood, the disassembly of the upper part, the numbering of all segments shaped, and the subsequent replacement;
- the cross brick vaults, that covered the landing of the middle floor, for which was carried out the reconstruction.

Fig. 7: Preparation of the cross vault ribs.

For wooden floors, was proceeded to the disposal of the flooring above and dismantling of the plateau and the wooden structure in load-bearing beams. Then the main beams found in good condition were relocated and it was decided to replace the deteriorated with new beams of the same size. The new plank made of boards with a thickness of 4 cm was placed, above which was made a reinforced concrete slab, after construction of a steel structure having the function of connection of the perimeter walls, together with the above slab constrained to the walls with dovetail joints, completing the work with the screed and flooring.

Fig. 8: Detail of the painted wooden ceiling.

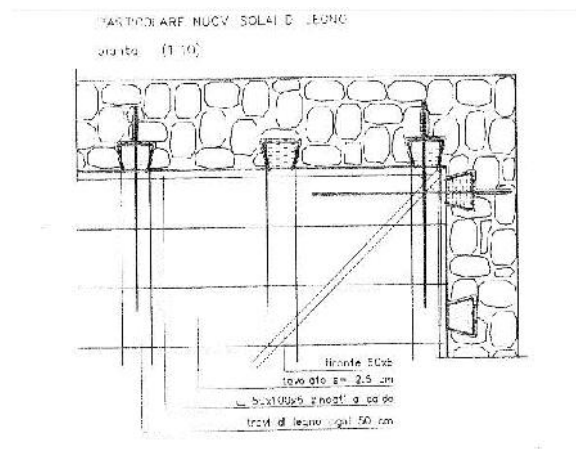

Fig. 9: Plan of the new wooden floors.

During the disposal of hedges have been avoided damages to the wooden trusses still in good condition, presenting in remaking the original typology, paying particular attention to gutters and downspouts, the first made of copper driving rainwater in to descendants in terracotta (*catusi*).

Fig. 12: The new coverage of the cylindrical tower.

3.2 The architectural restoration

The architectural restoration was conducted with the aim of respecting the historicity of the building, allowing the reading of the castle as it stands the XVIIth century, when the artifact received his final and most lasting configuration.

Was proceeded to the disposal of plaster of recent bill, which had concealed some rooms, highlighting the original wall hangings and the loopholes, buffered ports, dials arches, yet guessed thanks to the presence of the characteristic splays. The realization of the new plaster was performed proposing the types of the original ones (earthenware, tufopesto), the composition of which has been developed through specific laboratory analysis.

Were then consolidated the upper battlements of the walls drowned in the subsequent masonry highlighting with appropriate scrapes.

Another intervention involved the divestment of most of the floors, some of which are of recent construction, not congruent with the history of the building, using bricks and terracotta flagstones.

The realization of new partitions, in order to limit as much as possible the alteration of the original distribution, only involved toilets.

For the realization of some elements, such as doors and windows, railings of the balconies and the closing railings of the windows of the ground floor, as well as some works in stone (shelves balconies, cornices, pilasters, bases) has been followed the principle of stylistic restoration, through the repetition of elements executed in imitation of the original ones.

The restoration also covered operations on elements in wood, restoration of fresco paintings and restoration of stucco elements.

Fig. 13: Intervention to restore a wooden floor.

3.3 The reuse of the complex

The reuse of the complex provides for the placement inside of the museum of Castelbuono, assigning the castle to museological activities and conferences, functions that have been found to be compatible with the reconfiguration, the number and capacity of indoor spaces that characterize the castle.

The principle that has guided this intervention was the enhancement of the building, while preserving as much as possible its original configuration compatible with the new features provided.

In this sense, the intervention tried not to alter the distribution structure of the building, limiting the construction of new masonry partitions to only necessary, for example, the creation of new toilets.

The general objective that was tried to achieve was to make the castle a point of reference for the social and cultural life not only of the town of Castelbuono, but of the entire area of the Madonie, placing it at the center of a series of museum and cultural activities, and conferences. In order to the social use of the complex, moreover, was considered not only the *Palatium* itself, but also the area of the outer court, that, especially in the summer, was the place chosen for the realization of outdoor cultural events, such as plays and concerts .

The digitalization of Cultural Heritage's tangible & intangible dimensions

Davide MEZZINO¹

⁽¹⁾ Ph.D. student in Cultural Heritage, Interuniversity Department of Regional and Urban Studies and Planning (DIST) Politecnico di Torino, Turin, Italy
davide.mezzino@polito.it / davide.mezzino@gmail.com

Abstract

The paper aims at discussing the advantages and challenges of the digitalization of the Cultural Heritage. Within the application field, historical and cultural sites are recognized as keepers of traditions and values, which run the risk of extinction due to the fast growing phenomenon of globalization. This essay presents an overview of the strengths and weaknesses of the Building Information Model (BIM) as a dynamic, graphic, and multidimensional platform for the management of the tangible and intangible attributes of the Cultural Heritage and for the generation and dissemination of culturally nuanced information related to materials, the state of conservation and the methods of construction. This paper analyses BIM's potential when it is applied to new fields such as the Cultural Heritage, its documentation, conservation and management. In addition, it discusses the connection of BIM with the Geographic Information System (GIS) in a multi-scaled approach. The integrated use of these Spatial Information Systems allows us to disclose and explore, new dimensions at an architectural and territorial scale, such as the dimension of time (4D) and of the intangibility of the Cultural Heritage. The integration of these Spatial Information Systems - GIS and BIM - would support the documentation and conservation process. In addition, it would be able to communicate historical, religious and cultural values to current and future generations. These values are intrinsically connected to the Built Heritage. GIS and BIM can provide a platform for the creation of new meanings stemming from the interaction of different users and stakeholders engaged in its preservation and enhancement.

Keywords: Cultural Heritage, documentation, conservation, BIM , 3D content model.

1. Introduction

In the last few years, the acquisition and use of geo-referred data and 3D modelling have become a growing field of interest in architecture and planning.

Currently, these processes are also being applied to the domain of Cultural Heritage.

Moreover, the current innovations in the Information Communication Technology (ICT) field, especially as regards the uses of open and restricted data, have revolutionary consequences on many different sectors of human activities and is also influencing the Cultural Heritage today.

In addition, open-sources and freeware solutions encourage any user to experiment and learn freely.

According to these considerations, it is interesting to explore the advantages and challenges brought about by the so called 'Digital Revolution' for Heritage conservation and enhancement.

2. The challenges of the digitalization of the Cultural Heritage

The use of multimedia technology to integrate and enhance the presentation of complex data was studied and conceptualized since the advent of advanced ways to visualize images and videos (P. Faraday, A. G. Sutcliffe, 1997). Furthermore, the potential of the integration of 3D data with other types of information was clearly set right from the beginning of Internet. Unfortunately, their use was

delayed by the lack of a standard format for data and visualization. Nevertheless, virtual environments enriched with textual information have been thoroughly studied in all their aspects, adding to virtual navigation, the disposition and readability of the text (H. Sonnet et al. 2005; J. Jankowski et al. 2010), and the usability of interaction paradigms (D. A. Bowman et al., 2003).

Large-scale digitization and information aggregation projects for the Cultural Heritage provide an unprecedented wealth of knowledge. Technological advances with new and alternative instrumentation and processing software allow for the creation of immensely detailed 2D or 3D representations of material objects and audio-visual data which allow us to capture events of the intangible Cultural Heritage. Indeed, the understanding of the Cultural Heritage comes from comprehensive access to the diversity of phenomena and plurality of views, as well as from understanding the context of information and the provenance of the knowledge of Cultural Heritage. On one hand, large-scale information integration fosters comprehensive access. On the other hand, it obscures context and provenance. Interpretation of data that is obvious in a local framework may become ambiguous or incomprehensible taken out of context. In order to be able to offer a balanced view, we have to face the problem of objectivity and reliability.

A possible solution to this issue would consist in: disclosing data, communicating procedures and results, getting open solutions, enabling final results to be verified, establishing methods, enabling anyone to be able to reproduce the project's procedures, updating databases and optimizing final outcomes. By making data available and systems interoperable, such a methodology is capable of improving these outcomes and, at the same time, guaranteeing the quality and reliability of the output. Taking into account all previous considerations, potential perspectives may be studied as part of the research on further methods and instruments, so as to guarantee the conservation of the Built Heritage and the preservation and communication of "The spirit of the Site" (World Heritage Convention, 1972), indicating all those cultural and traditional aspects characterizing the identity of a monument and of a place.

An interesting field of research could be the in depth analysis of BIM's potential, strictly connected to the use of GIS applied to the Cultural Heritage, for its documentation, conservation, management and promotion. An integrated use of both system would have some benefits. Firstly it would guarantee a completed analysis, documentation and representation at both architectural and territorial scale. Secondly the integrated use of these two instruments allows us to disclose and explore, new dimensions, like the one related to time - temporal dimension (the so called 4D) - and the intangibility - immaterial dimension - of the Cultural Heritage.

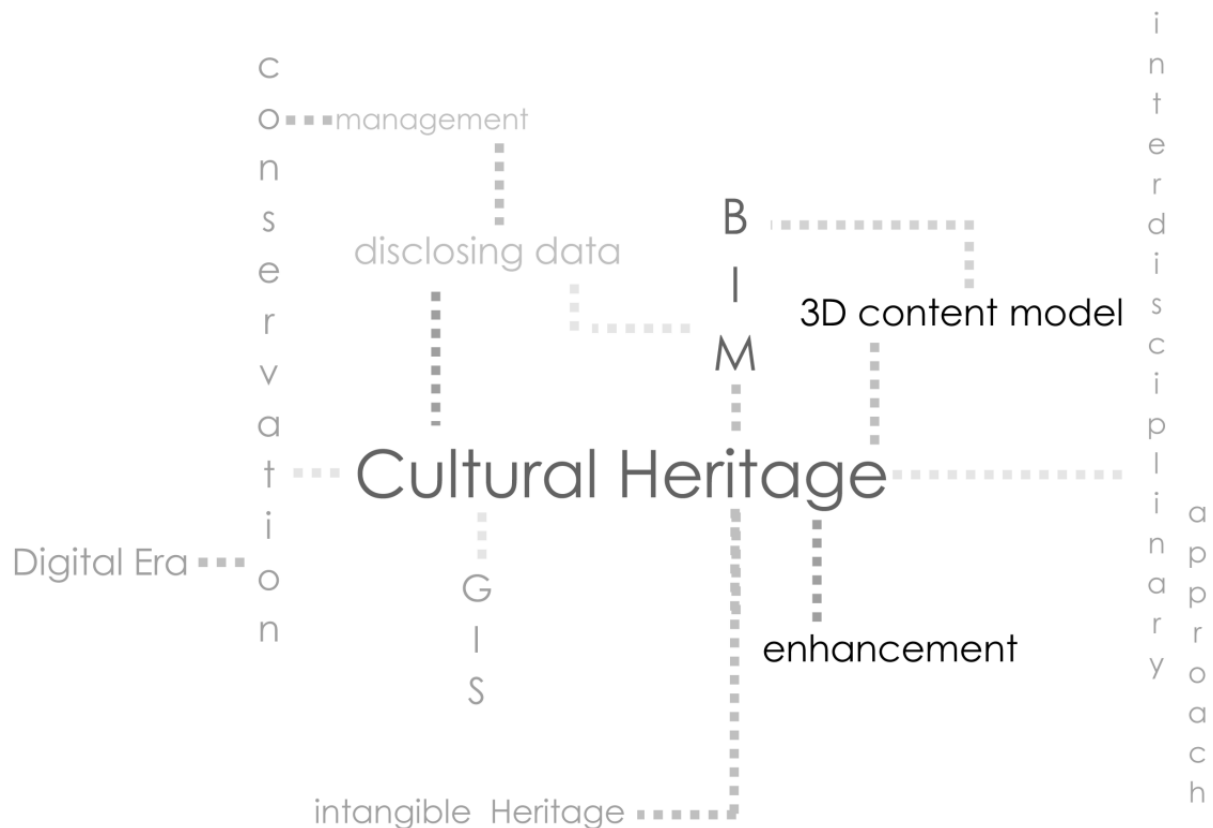

Fig. 1: Features related to the digitalization of the Cultural Heritage.

3. The Building Information Model (BIM) for the Cultural Heritage

Within the framework of the 'Digital Revolution' it is interesting to consider the great challenges offered by Information and Communication Technologies (ICTs) in the documentation, conservation and promotion processes of the Cultural Heritage. This is not just a matter of introducing new Information Technologies (IT) systems (A. Osello, 2012). On the contrary it has much to do with new working methods and allocation of roles developing better integration between the different disciplines to manage and enhance the Built Heritage.

Digital modeling is an excellent tool for learning to visualize complex shapes and their interactions, a skill that is of greater importance than simply tracing superficial information without a deeper structural understanding. Currently, the digital instruments are playing a key role in the 3D modelling sector. Moving from the 3D surface modelling of buildings and urban contexts to a semantic description 3D model it is possible to improve the quality of information, increasing the efficacy of the documentation and guarantying the efficiency of the management.

According to these consideration, the Building Information Model (BIM) system is moving from the application in the Architecture, Engineering and Construction (AEC) sector to the development of the application of new devices for the Built Heritage. With BIM technology an accurate virtual model of a building can be digitally constructed containing any kind of information about the construction, specification and detailed documentation of the features of each building. The system is composed of a set of processes that can be applied to catalogue, record, manage, communicate and disclose information. In other words, the BIM is a data rich object oriented, intelligent and parametric digital representation that can also be used for the Built Heritage.

Indeed views and data can be extracted and analyzed by different users (A. Osello, 2012) in order to generate information that can be used for diagnostics, planned preventative maintenance, restoration project and promotion activities.

In addition BIM does not only represent an opportunity to transform the documentation from separate models into 3D semantic models, but it is an extended methodology placing the focus on process improvement, the optimization of documentation and efficient collaboration between different aspects related to the Built Heritage (i.e. surveying, historical analysis, restoration project, economical management, etc.).

Fig. 2: Possible BIM's application fields within the Cultural Heritage areas.

3.1 BIM's weakness

In writing about BIM, David M. Foxe points out that *"the certainty and precision of the model are only as powerful as the knowledge and accuracy that went into creating it."* This is certainly true, and a primary concern with the use of this technology is the potential to confuse the accuracy of a model with its precision.

Due to the nature of digital modeling, a very high degree of precision is possible -much higher than can be readily measured in the field. Because of this, digitally modeled 3D elements appear to be accurate, but in fact may not be. This is particularly true and evident in the historical buildings characterized by asymmetry, irregular shapes, etc.

A second general shortcoming of BIM, especially in regard to recording historical structures, is the inability of BIM to readily model non-planar surfaces. Another concern with the use of BIM is the digital obsolescence (M. Hedstrom, 1998), a problem shared by all rapidly evolving electronic media. While the digital model may be useful today, it will be worthless tomorrow without the means to read the file. Beyond the above general limitations of BIM, there are also specific limitations to the use of BIM in the field of the Cultural Heritage.

First and foremost, it is important to outline the interoperability issue. Indeed, only one member of the recording team is usually a trained operator of the software. This is a problem because it greatly slows the input of data. If more than one team member could use BIM, multiple aspects of the building could be recorded simultaneously, either in a single, shared file or through the use of multiple files which could be later combined.

BIM's weakness	General BIM trait	Specific to Built Heritage application field
Confusion of precision and accuracy	⊗	
Inability to quickly model uneven surfaces	⊗	
Digital obsolescence	⊗	
Too few trained software operators on project		⊗
Difficult to operate in inclement conditions		⊗
Difficult association of pure geometry to irregular objects		⊗
International Framework for Dictionary (IFD) not exhaustive per the historical building domain		⊗

Fig. 3: Table of the BIM's limitations.

3.2 BIM's strengths

Beyond the obvious visual and spatial comprehension benefits of using a 3D model to describe and exchange information, it is interesting to deepen the usefulness of some general characteristics of BIM for the Built Heritage.

Firstly, the model itself serves as the single repository of all information and this attribute is useful for its economy.

Secondly, the model is the only basis for all outputs that are internally consistent.

Thirdly, BIM can rapidly generate any 2D view (elevation, plan, section, perspective or axonometric projection) and 3D view (internal, external, section, etc.) of the model that is desired. Finally, BIM can export to compatible software for further manipulation and interpretation such as the creation of 3D animations, demonstrations of construction sequencing, or any number of lighting, energy, or materials analyses.

BIM's strenghts	General BIM trait	Specific to Built Heritage application field
Model is single repository of all information	✓	
Consistent basis for all output	✓	
Generate any 2D and 3D view	✓	
Model can be widely shared	✓	
Consolidate collected data		✓
Demands understanding of 3D structure		✓
Walkthrough inspection for completeness		✓
Simultaneous cross-check of measurements		✓
Expand from isolated data		✓
Interoperability instead of a documentation coming from separate sources		✓
3D manipulations to compare it to the building itself and inspect it for accuracy and completeness		✓

Fig. 4: Table of the BIM's benefit.

Used as a tool for the exploration, recording, and analysis of a historic building, BIM serves as a single, unified, and consistent repository for information on the dimensions, location, condition, and any number of additional parameters on elements of the subject building as they are being discovered or uncovered.

Additionally, the creation of a BIM model simultaneously allows and demands the user to understand the elements comprising the totality of the actual building as its virtual simulacrum is assembled, piece by piece. As eloquently expressed by John A. Burns, *"there is no way to appreciate an existing, working structure...like making a careful drawing of it."* This statement is even more true when the construction of a fully articulated 3D model of a structure is undertaken. The model can be viewed in any of a multitude of projections and sections, and subjected to 3D manipulation to compare it to the building itself and inspect it for accuracy and completeness.

In addition, the BIM model allows for the simultaneous cross-checking of measurements across multiple dimensions.

For example, measurements taken of interior rooms can be easily compared to measurements taken from the exterior of the building, not one elevation at a time but as a volume. As John A. Burns has noted, *"with the help of architectural and engineering documentation one can study a building...without necessarily visiting it"*. Constructing a detailed model of any sort is an excellent means to understand a building. It is a methodology of visual and cognitive dissection, a protocol for the careful examination of a building. John A. Burns writes in *Recording Historic Structures*, *"quite apart from whatever value measured drawings may have as a historical record, the process of measuring and drawing careful records to scale is the most effective way to gain an understanding of a building's fabric."* This perceived value is noted elsewhere by Edward A. Chappell, who writes that *"measuring a building encourages the recorder to recognize relationships among different parts"* and that *"doing measured drawings of a building is the best way to discover some of its consequential secrets."* A key to BIM system as an approach to studying and operating on Built Heritage is the thorough understanding of the fabric and its parts, through a careful and detailed inspection and recording of all elements that contribute to unveiling the features and the meanings (the "secrets" of Edward A. Chappell) that they hold.

3.3 On-going development

BIM is more than just impressive renderings representation. It is the creation of a common database that can be shared by all project participants in both two and three dimensions. Further, as George C. Skarmeeas wrote: *"if the model is properly structured and can be used in the future, it can be the proper vehicle to monitor the behavior, performance, and deterioration of a building, using meaningful metrics that can help its long-term preservation."* It is certain that a well-constructed and supported BIM model can have an extended and expanded utility in the service of Built Heritage Preservation. Each building component can be accurately measured and located in a complete digital model that emulates the original construction very closely.

In addition BIM's potential consists in the ability to query the parametric model with hypothetical 'What if...?' questions (F. Lèvy, 2011). To this potential we have to add the benefits of the BIM model as a data base for the systematization of the information within a 3D semantic model to extract views from. This powerful tool would also allow us to explore and visualize the so called fourth dimension – the time – and the intangible one, revolutionizing the approach to the research and the work on the Built Heritage.

Through this instrument of multifunctional representation it would be possible to preserve and bequeath the density of tangible and intangible (cultural, historical, ethno - anthropological) meanings of the Heritage to the future generation.

4. Integrated and multiscale Spatial Information System for the Built Heritage

The cultural significance of the Built Heritage is what guides the management policy and consequent strategies for protection and preservation. To aid this task of cultural resource conservation, management and enhancement, many planning tools are available.

The Spatial Information System: Geographic Information System (GIS) and Building Information Model (BIM) are such tools for putting policy into practice. The Geographic Information System is a set of computerized tools to collect, archive, manage, retrieve, analyze and output geographic and associated attribute data.

While GIS is already used to assist Cultural Heritage managers in a wide variety of applications (P. Box, 1999) the BIM systems has not yet been applied to the Cultural Heritage field but is now under development.

The BIM is based on simplified parametric models - suitable for: archeological sites, monuments, ancient buildings and historical compounds, that can be applied constructively to Heritage documentation and management of the data on conservation and enhancement practices.

Moreover, a Building Information Modelling could be implemented in order to collect different kinds of specific data on historical areas (i.e. dimensional, geometrical, state of conservation, historical information, intangible values and constructive techniques).

As already said, BIM could support preventive conservation, information sharing and knowledge dissemination of both tangible and intangible Heritage dimensions for professional and non-professional users, researchers, local administrators, for institutions and experts involved in decision making process.

Preliminary studies showed the adaptability of some BIM's function related to heritage documentation and specifically to:

- Decomposition of building elements into categories;
- Contextual creation of graphic elaborates in 2D and 3D;
- Obtaining information from associated database;
- Interdisciplinary work settings.

As far as the potential of GIS is concerned, such technique may turn out to be particularly suitable to the documentation and the restitution of information in time and space dimensions. GIS may also be able to integrate History with Geomatics, by creating a multidisciplinary platform for the innovation of development strategies for the knowledge and use of the Heritage.

Furthermore, the integrated use of these systems would allow us to understand the outstanding value of the site by answering questions. Some examples are: Is the place associated with a historically significant theme, person or event? If it's a building, does it possess any specific features of interest for its architecture or design? Does the place have special meaning because of its landmark, spiritual or cultural associations? Consequently, the integration of more datasets within a unique conceptual system, able to provide simultaneous consultation to a wide range of users and stakeholders, who in turn can become providers of further information and interactive feedback on experience of the use of Cultural Heritage.

Fig : Representation of an integrated multi-scalar Spatial Information System for the Built Heritage.

5. Future perspective

Currently the historical and cultural sites which are recognized as keepers of traditions and values run the risk of extinction due to the fast growing phenomenon of globalization. However, they should be understood neither as static relics of a distant past nor as the passive objects of techno-bureaucratic knowledge and expertise. On the contrary, the act of conserving and enhancing tangible and intangible “goods” confers to Cultural Heritage an agency that is strictly associated with discourses of remembrance, techniques of governance and the affirmation of social, cultural and political identities enacted by the communities engaged in the endeavor preservation. Nowadays, as already mentioned, the use of 3D digital tools for recording, documentation, and information management for Built Heritage (e.g. Building Information Models, Computer Aided Drafting applications, 3D modelling, active and passive web-design, surveying instruments, photogrammetry, image processing, 3D laser scanning, and digital presentation) is demonstrating an incremental growth. According to this trend, it will be interesting to deepen the investigation on how to combine a bi-dimensional Geographic Information System (GIS) and a 3D content model with a Building Information Modelling (BIM) for an improved documentation, conservation, management and enhancement of the Built Heritage. Finally, according to the smart city's context, an integrated and multi-scalar system would lead to a more efficient management of the urban historical centers through a more efficacy and interoperable documentation of all its elements.

Accessibility of historical students' accommodation: methods and solution

Alessandro Greco,¹ Matteo Locatelli²

⁽²⁾ PhD Student, University of Pavia, Italy, XXIX Cycle

matteo.locatelli01@universitadipavia.it

Abstract

Historical buildings were built without any kind of attention for persons with disabilities, but nowadays they are still used for a society where there is a new consideration for weak persons, as demonstrated by the UN Convention on the Rights of Persons with Disabilities (written in December 2006 and adopted in Italy with the National Law n. 18 in 2009). The architects and engineers have a new task: to improve the accessibility to historical places and cultural heritage.

In February, 2013 "Collegio Cairoli" (an historical students' accommodation of the University of Pavia) and EDiSU (Institution that manages services for students) decided to improve the accessibility of the building, inserting a new lifting platform.

The building was realised in 1781 in the downtown of Pavia, near the University. It is a students' accommodation since 1948 and it houses also visiting professors.

The area chosen for the platform is near the old church in the south – east side of the building, in a place with three differences in level. The lifting platform has to link the ground floor with the first floor (where there are some common spaces open also to people not living in Collegio Cairoli).

The project (project March 2013, realisation January 2014) was developed following the idea to preserve the original character of the building (limiting the intervention on the walls, both demolition and new construction) and to ensure the complete reversibility.

Keywords: Accessibility, historical buildings

1. Accessibility of historical and cultural buildings

Our cities have a large number of historical and cultural buildings from different ages. If we think about Italy, the buildings are from Roman age to nowadays and many museum, public offices, exposition and cultural halls, are inside these old buildings. This is very fascinating and richness for everyone, but it is not for everyone at all.

If we consider for example the Milan's Cathedral, Fori Imperiali in Rome, the downtown in Venice, the accessibility is not easy for everyone in order to morphological, material and constructive reasons.. This doesn't happen only for famous situations, but also for our everyday life.

Many people, old people, pregnant women, child, injured people or disable people, have a lot of problems and difficulties to reach some points of interest. In the centre of the cities, especially Italian cities with medieval origin, there is a great number of historical buildings with offices and services inside: it is our fortune and a memory of where our culture comes from. We have not to change them, we have to use and preserve our memory and our culture, but this could be for everyone.

"For everyone" is the most important theme of U.N. *Convention on the rights of persons with disabilities* (2006): "To enable persons with disabilities to live independently and participate fully in all aspects of life, States Parties shall take appropriate measures to ensure to persons with disabilities access, on an equal basis with others, to the physical environment, to transportation, to information

and communications, including information and communications technologies and systems, and to other facilities and services open or provided to the public, both in urban and in rural areas. These measures, which shall include the identification and elimination of obstacles and barriers to accessibility, shall apply to: buildings, roads, transportation and other indoor and outdoor facilities, including schools, housing, medical facilities and workplaces [...]” (art. 9.1) and “States Parties to this Convention recognize the equal right of all persons with disabilities to live in the community, with choices equal to others, and shall take effective and appropriate measures to facilitate full enjoyment by persons with disabilities of this right and their full inclusion and participation in the community, including by ensuring that: persons with disabilities have the opportunity to choose their place of residence and where and with whom they live on an equal basis with others and are not obliged to live in a particular living arrangement [...]” (art. 19).

Art. 30 of U.N. Convention suggests to improve participation of people with disabilities into cultural life recreation, leisure and sport and Italian college are very important systems to take part to the life of the city

Students’ accommodations are an opportunity for students from other cities to have a place to study and to spend their lives; these buildings are housing with facilities (such as rooms for studying, music, computer, etc.), where everyday students return to study and to rest. In Italy and especially in Pavia, students’ accommodations are principally in old buildings in the centre of the city and they aren’t only students’ accommodations, but also cultural centres for the city.

Accessibility and usability are fundamental requirements for valorisations and conservation of cultural heritage. The response to standards about accessibility often comes after important decisional moments about distribution, materials and functions.

A multidisciplinary and participate approach is very important to find solutions to satisfy different needs with simple solutions for construction and for reversibility.

The method used in the University of Pavia is divided into four phases:

- analysis, that is divided in two different aspects (general analysis of the buildings and the surrounding and the analysis of the function inside);
- knowledge , that is the study of the solutions for improving of the accessibility;
- project, with the proposal of new solutions;
- communication, to sensitize society.

The historical building is an element inside a more complex system made of relationship between the building and the surrounding and it is a point of a physical web that is a characteristic of the identity of a place.

Designers must know the history and culture to make a net project with function that are compatible with the morphological, typological and constructive aspects to decide to use new or old material but different from original technologies to make the project recognizable.

2. Students’ accommodations in Pavia

Pavia is a city with a very long history, whit different kinds of buildings and expansions. This town, especially for the presence of Ticino river, was occupied by Romans that created the plan of the downtown with Cardo and Decumano and the castrum system. After that Pavia was occupied by Longobardi, which made it capital until the arriving of Carlo Magno. In 1360 Pavia was enclose to the Duchy of Milan by Galeazzo Visconti that built the Castle and the park from Pavia to Certosa.

In 1361 there was a Studium Generale that had the same rights of the University of Bologna and Paris, and in 1485 it became the University of Pavia.

Almo Collegio Borromeo and Collegio Ghislieri were the first student’s accommodations in the city since the XVI century and with Collegio S. Caterina and Collegio Nuovo they are the four student’s accommodations for merit.

Emperor Giuseppe II of Austria founded Collegio Cairoli in 1781 as German and Hungarian college and it became a military barracks from the French occupation in 1796 till November 4th of 1948 when the University restructured the buildings and called it Collegio Fratelli Cairoli.

Today there are eighteen students’ accommodations divided in: for merit (4), EDiSU (11) and private (3) with more or less 3.500 students (more than 15% of the students attending the University).

Collegio Cairoli is a students’ accommodation managed by EDiSU that is an entity of the University to coordinate and managed services for students.

It accommodates 95 students (only men) and 10 guests and it is in the centre of the city, near the main building of the University and other students’ accomodations: Collegio Ghislieri and Collegio Fraccaro.

There is a long and strong tradition about student’s accommodations in Pavia. Every year there are a lot of events in which students from different structures oppose (football, basketball, volleyball leagues) and there are events for the city and for other students as parties and cultural encounters.

Students’ accommodations have different stories and different approaches to the life of the city and they are very proud about their students: for example Carlo Goldoni studied in Collegio Ghislieri,

Federico Borromeo in Collegio Borromeo (that was also a film set for some films) and Alberto Arbasino studied in Collegio Cairoli.

So colleges are very important for Pavia and its history, they also manage courses for students and cultural events for citizens and for the University.

3. Collegio Cairoli

The college was built on the Monastery of S. Francesco according to the draft by Leopoldo Pollack with Piermarini's consultancy. Collegio Cairoli has a typical plan of buildings of the XVI century: it is a four-floor building with an internal courtyard and a double row of arcades on the ground floor and on the first floor.

On the ground and the first floor there are public spaces as art atelier, computer rooms, gym, music classrooms, rector's offices and house, canteen and an old church.

The ground floor is lower than the first floor and it creates an interesting effects entering in the internal garden. It is also in a lower level than the external spaces and the arcade is very simple unlike the arcade of the first floor that is higher and characterized by double columns.

The main facade is brick and in the main entrance there is a very interesting stairs with two ramps in white marble that lead to the first floor, near rector's office.

The courtyard is a typical Italian garden with two perpendicular main axes that meet each other in a circular point.

On the ground floor, rooms and public spaces are not at the same level of the arcade and the garden and there are many differences in level between inside and outside.

The first floor is the grand one and there are rooms with frescoes (as in the Aula Magna) and a big library with more than 65.000 books

Student's and guest rooms are on the third and fourth floor that has some terrace to watch the city.

4. The project

There aren't elevators or mechanical system to overcome differences in level inside the building. EDiSU, the entity that manages Collegio Cairoli needed to solve this problem and to create places for everyone where have meetings, cultural events and to allow people to enter in the building.

Today there are some ramps that try to solve the differences in level between the internal arcade and the rooms on it but there are also 4 stairs that don't allow people to moving free inside the building.

It was very important to maintain the historical assessment of the building and to control the project in order to preserve the internal structure and architecture.

Fig. 1: map of Pavia with students' accommodations.

Fig. 2: aerial photo of Collegio Cairoli (google earth).

4.1 Design choices

Considering the willingness of the customer and visiting the buildings, the idea was no to delete existing lofts to create a place for the elevator but to choice a place completely free where putting a new structure.

The idea is to put the elevator in the south – east side of the building, near the church, where there is a double high space. There were no possibilities to create a system that allow people to enter in the elevator at the same level of the arcade on the ground floor. It was primary maintaining the internal facade and using removable system in order to preserve the original structure.

The place is also near a technical room useful to put the electrical unit of the elevator.

The project tries to follow some simple themes:

- integrability;
- reversibility;
- easiness of construction;
- easiness of running.

4.2 The project and the historical importance of the building

When an architect or an engineer wants to make a project in an historical building there are some constraints that are important to follow.

Fig. 3: project area.

Superintendence of Cultural Heritage has an important role in deciding strategies and making demands. Collegio Cairoli is an historical building inside the old town of Pavia, so the Superintendence controls the interventions on it.

One of the requests of the owners and the Superintendence was to preserve the existing window and to maintain the existing colours around.

The first step to realize the elevator is to modify the existing ground with: the loft between the internal path and the space inside is on terrain so there are no problem to create a pit. The pit is 10 cm bigger than the elevator to allow the installation and it has small walls to support the pavement around, On this walls there are granite slabs to maintain the same materials of the existing.

The existing window is modified to change the overture of the door and to fit the structural elements to the measures of the elevator.

The wood of the existing window is used to create new structural elements and to do finishing works around it and the modified doors are stacked to be reuse in case of damage or to use it to fix other windows.

The elevator is completed illuminated from the inside to be recognized from users and to be easily identified inside the building.

As there are steps between the elevator and the internal path the project provides to modify the existing ramp to create a new one that is more comfortable for users.

There is also another ramp between the floor of the entrance of the elevator and the floor of stairs and church and also this ramp is modified as the first one. Both the ramps are completely removable to don't modify anything inside the building.

4.3 The elevator

According to the D.P.R. 236/89 the elevator has some minimal measures (1.20 x 0.80 m) with an entering platform in front of it. The choice is not to use this minimum measures but to considering them as a starting point to have something that could be useful for our project.

Considering the existing window, it was decide to maintain a blocked measures (half window, 1.3 m) and to use the dept of the space to create the other measure (1.6 m).

Having blocked measures, there was a problem for the entering doors: sliding doors are not possible to do, but, according with the company responsible for installing and the Superintendence we decide to have simple doors with automatically opening.

The elevator is steel and glass structure, that's because it is very important to have something light and to do allow people to watch the internal courtyard and the double arcades.

This kind of elevator is very specific for existing buildings: it need only 10 cm for the pit so it is very simple to modify the existing floor with a little foundation plate.

To put it in the floor the project expected to modify the intermediate existing stairs using the stone of the first step to underline the entrance of the elevator.

We decide to use the landing to create on arriving point for people coming from the ramp between the ground floor and the landing and for people entering into the elevator.

Fig. 4: ground floor and first floor.

Fig. 5: ground floor - project.

The high of the elevator is defined by the structural elements of the window and there is a vertical element on the glass of the elevator to have the same draw of the window. At the first floor the railing has been modify to create the exit of the elevator and it is not in contact with the loft of the first floor but there is a little gangway to link the floor with the elevator.

Doors are automatic and the user has not to control the overture. The internal cabin is made of glass and steel with a functional pushbutton with Braille and a simple system to call in case of emergency.

Fig. 6: first floor - project

Fig. 7: front of the existing window with the integration of the elevator.

Fig. 8: section of the project.

5. Conclusions

A project inside an existing building is complicated and fascinating. Architects and engineers have to consider many variables and there is not always a precise knowledge of what can be found inside. Making an accessibility project is another challenge for designers. It is not simple to explain to owners and citizens the importance to make an accessibility element.

In XXI century, accessibility should be an established data in a project and elevators, ramp and system that allow people to use a place are important as the building itself.

Designers have an important role inside the choice of this elements: producers as many different kind of products that can satisfy architects' and engineers' desires, but to make a good project is necessary to create an object for a specific situation and building. Making an original and contextualized project is important to maintain and to respect existing buildings.

Reversibility is fundamental for a project in an historical building: the project must be recognizable and defined, but we have to use simple elements that can be assembly directly in the project area with minimum size. It is impossible to don't modify something existing inside the building when you are working on an historical building, there is always some intervention to do: architects and engineers have to make some choice to decide what is really important for the building for its history and its cultural value.

It is also very important to find products with high quality: maintenance and deterioration must be minimal and there are some situations where these elements have to work differently and they have to work everyday.

It is also important to understand that a new element inside an historical building could be a way to make something for everyone: accessibility is not an excuse to put something inside to have a more comfortable situation but accessibility is improving the efficiency of a building and to add a new value to it.

It is important to remember that sometimes in our life we could be disable for a period, but we need to be sure that our temporary disabilities is not a problem for us and for other people.

Accessible cities and buildings are one of the themes of the U.N. Convention of Rights of persons with disabilities and historical buildings are a great challenge to maintain a memory of the past and make it accessible in the future.

Abstract

The dramatic effects of the earthquake that in September 1997 devastated Umbria and Marche are notorious. The electronic camera eye documenting live collapse of the tower lantern of Foligno municipal building provided viewers of every latitude with images that are still etched on their memory. Fifteen years after that event, the balance of the post-seismic reconstruction is certainly positive, so that the management model tested and the cultural know-how acquired during this experience have been exported and replicated in analogous emergency situations such as the 2012 earthquake in Emilia. Thanks to an interdisciplinary approach and contaminations between different scientific fields Foligno succeeded in becoming a city lab, able to adopt either conservation or transformation, depending on the occasional specificity.

By comparing the frame of the lantern during the instant of collapse with the picture of the Calamita cosmica by Gino De Dominicis surrounded by the amazing showcase of the former church of Annunziata, it is possible to realize that not only was the city of Foligno able to restore damaged buildings but also it deeply reinterpreted them. Under the sign of virtuous development, which derives from a shared knowledge.

Keywords: earthquake, interdisciplinarity, survey, design, Foligno

1. Introduction

Sadly, the disastrous effects of the September 1987 earthquake, which devastated Umbria and the Marches, are well known, fixed rhetorically and indelibly in the memories of TV watchers the world over by the live broadcast of the collapse of the lantern atop the tower of the Foligno Town Hall. As is the case in all earthquake situations, after implementing a timely response to the housing emergency to provide shelter to the homeless, conducting a careful survey of the damage to the built environment, and taking measures to ensure the safety of buildings subject to a risk of collapse or further damage, there comes the moment for planning the reconstruction. A phase both strategic and concrete, which can be undertaken with a variety of approaches, all of which, however, have in common the lessons learned from the great earthquakes of the past. In fact, after all earthquakes, "it is necessary to assume a retrospective point of view" [1] since "looking back at what was (...) is the only path to follow" [2] for planning and then implementing the measures necessary to ensure a return to a state of normalcy. Of course, the new state of normalcy will not be the same as that which preceded the earthquake, but it must, just as certainly, ensure the population the chance to look toward the future insecure and comfortable conditions. The city, lacerated by so much destruction, becomes a continuous construction site, in which the provisional nature of shoring up coincides with the perennial nature of transforming the city's original image. Every fracture, every subsidence, every collapse of the urban fabric, constitutes the hard datum of a theoretical problem that must be formulated from scratch,

backed by the results of previous experiences, but which never presents itself in exactly the same circumstances because each building, like each person, has its own history and its own identity. It is necessary, therefore, to establish an objective (generally *reconstruction*) toward which all project design is directed, including not only architectural, structural, and technological planning, but also economic, social, and cultural planning. Reconstruction systematically presents itself as a dilemma, whose solution is strictly tied to the memory “that belongs (...) to the community which inhabits a territory or a landscape.” In some situations, “it is necessary to apply the celebrated formula ‘where it was, as it was’ (...). In other cases, it is better to proceed by way of opportune *overlapping dissolves* between what remains of a monument and interventions that allow a historical building to reassume its former role. In still other cases, it becomes necessary to demolish the ruins of even important structures, replacing them with new buildings. In this last case, the problem becomes whether to design and build the new structures in harmony with the shared *memory* of what has been destroyed, or to propose a completely different or partially new urban image.” [3] Foligno, which has made an interdisciplinary approach a strategic element of its reconstruction planning, has constructed its own image as that of a city-laboratory, capable of adopting a conservationist approach or a transformative approach depending on the specific circumstances. In this sense, more than fifteen years after the earthquake, the Foligno experience (of which this present contribution wishes to provide further positive testimony, supplementing two previous periodical reports on post-earthquake reconstruction [4, 5], appears to be exemplary in terms of the profound redefinition of a local environment and a resolute affirmation of community identity. The city has demonstrated how to heal the wounds inflicted by the dramatic events of 1997, but has also treated those losses as an occasion for architectural experimentation and strengthening the city’s economic and social fabric. Although hampered at times by the physiological weaknesses [6] that are inevitably part and parcel of any experimental approach, the reconstruction management model that has been developed [7] and the cultural know-how acquired in the process have been exported and replicated in analogous emergency situations such as the Emilia earthquake of 2012. A comparative examination of the pictures of the collapse of the city’s historical symbol and the image of itself that the city projects today, illustrates how Foligno has successfully perpetuated the DNA of a city that has grown up from its own roots, making good use of the rule of “building on the built” without renouncing the city’s present expressivity. It has restored to its inhabitants a fabric of places not only admirably restored, but also and above all, profoundly reinterpreted in the pursuit of a virtuous valorization rooted in shared knowledge.

2. Architectural Surveys Conducted by the Department of Civil and Environmental Engineering of the University of Perugia

Conducted in two different periods, the architectonic surveys of the two outstanding monuments in Foligno's historic center, Trinci Palace and the Town Hall, are testimony to the City's constant attention for its own history as well as a useful snapshot of the characteristics of these two monuments.

In the case of Trinci Palace, the survey made it possible to document the historical events that characterized the transformation of a portion of the residential fabric (some row houses and a tower house) consolidated first into a noble residence and later into a papal residence. The survey revealed that the palace "was formed slowly over time by disdaining the use of the pre-existing buildings, or better, by availing itself of them and aggregating them harmoniously into an architectonic whole on which variations have been systematically overlaid, gradually giving rise to a unified complex." [1]. Some of the salient stages in this evolution (the creation of large internal salons, functional modifications, the restyling of the courtyard, the demolition and reconstruction of the external stairway) belie the gradual transformation in accordance with an overall design intended to bestow on the palace a more institutional air. Above all, however, the realization of a masking façade, overlaying the pre-existent one, employed as a consolidation strategy for the main entrance following the earthquake of 1832, was in line with the common practice in nineteenth century Umbria. This strategy also served as a pretext for conferring on older palaces with irregular and asymmetrical façades a more orderly geometric design, generally informed by neoclassical canons.

The same practice distinguishes the other building that was surveyed, the Town Hall, whose façade facing Piazza della Repubblica was the object of half a century of design studies, involving a series of the most illustrious engineers and architects of pre-unified Italy. After the earthquake of 1791, in fact, an initial design based on the "overlay of a masking-façade" [2], elaborated in 1795 by the Chamber architect, Virginio Bracci, later became the basis for the proposal presented by Luigi Poletti in 1833. Poletti's design aimed to give rhetorical emphasis to the palace's figurative presence by way of a narrow and thrusting central forepart. The proposal was not fully supported by the City Administration, which announced a competition for the development of a definitive solution. Of the three designs submitted, the commission selected the one presented by Antonio Mollari, in which the institutional image of the palace is entrusted to "a gigantic Ionic colonnade superimposed on an arched ashlar-work base [2], which was faithfully constructed in 1839.

3. The Public Library by Arrigo Rudi

The great “opportunity” of the 1997 earthquake allowed the city of Foligno to move forward with its program of a complete renewal of its historic center, expanding on a project initiated in the 1980s with the rehabilitation of the delicate complex structure of the Trinci-Deli palaces. The commission was awarded to Professor Arrigo Rudi, a renowned architect who trained under Carlo Scarpa, and who worked for twenty years on an organic project of urban and architectonic regeneration, centered on the restoration, construction, and outfitting for museum use of new volumes destined to house the municipal archive and public library.

The historical evolution of this rich portion of the city, now meant to be joined to the palace complex, found in the cultivation and poetics of its new maker some special qualities that were synthesized in the intentional attenuation of the principle architectonic dichotomies: the relationship between modern and medieval; structure and form; interior and exterior; plan and elevation; solid and void; light and shadow; whole and fragment; city and architecture.

The new façade is detached from the posterior body, until then characterized by the ruins produced by the bombardment of 1944, and redefines the significance of the piazza. Its hierarchical monumentality clearly expresses substantial “political” reflections on the role of culture and of architecture, while dissimulating the insatiable search for the “unity of inclusion” proper to the history of the building. Its design of alternating horizontal bands, a historicist reference to the contiguous architectonic structures, blends with a certain continuity into the alternating bands of the pavement of the piazza, also meant to conceal a substrate of markings, which emerged during the work performed in 2008. The correlated centrality of the passage is expressed simultaneously in the contemporary reinterpretation of the juxtaposed portico, in the philological reassembly of the city’s vital spaces obtained by way of semi-open tracings wedged into the volumes, and in the continuity between interior and exterior expressed by the semi-closed *promenade*.

In all of this, drawing, of which Rudi is such an expert, is shown to be a research tool, supporting and condensing reflections which are then gathered together in the spatial plan: from the sketch, which suggests the development of the project and the typological urban analysis, to the project drawing, which implicitly recalls the experience of Arienti in Perugia. The project drawing also cites, perhaps more deliberately, Rossinian motifs, with an obligatory passage through the surveys conducted by the University of Perugia, whose findings regarding the evolution of the architectonic forms contributed to the discovery of the meaning of the place.

4. The Italian Center for Contemporary Art by Giancarlo Partenzi and Getulio Alviani

"The earthquake as research opportunity" expresses perfectly the case of the CIAC (Italian Center for Contemporary Art) designed by Giancarlo Partenzi and Getulio Alviani. A work of contemporary architecture in the heart of the historic center, between the Church of Saint Francis and the Art Nouveau row houses in via Campanile, where, after the 1997 earthquake, all that was left were the ruins of a building that had been a milk plant and later a Post Office. The new building was financed by the Cassa di Risparmio di Foligno Foundation which, in collaboration with the City of Foligno, decided to give concrete expression to the city's growing attention for contemporary art and artistic experimentation with a dedicated cultural center. The ruins and empty spaces left by the earthquake have thus been transformed into an opportunity for architectonic and cultural requalification and renovation.

The CIAC presents itself as a compact and massive monolithic structure in COR-TEN steel, disruptively inserted into a highly historicized context, displaying its force without altering the preexisting equilibrium but, on the contrary, conferring on the space a symbolic value of architectonic continuity between past and present. A reinforced concrete box wrapped in a rust-colored facing constituted by a smooth and continuous surface interrupted only by a deep-cut void, which identifies the main entrance to the museum. Externally, the purity of the volume is denied by the weaving effect produced by the joining of the steel plates and, above all, by the changing nature of the material which, by oxidizing at varying rates over time, confers a dynamic character on the perceived space.

The sensation of an impermeable exterior is countered by the surprise of an open and luminous interior space developed on two levels, one of which is partially underground. Passing through the entrance, which houses the bookshop and restrooms, you arrive in a spacious environment of significant height: an exhibition hall completely refinished in white plaster and illuminated by a square skylight, the only light source, emphasized compositionally by four pilasters, which define its planimetric dimensions.

The semi-interred level, connected by a series of vertical passages, opens itself to multiple interpretations: it is a depository for works not on exhibition, a laboratory, a warehouse, and at the same time an ulterior exhibition hall illuminated artificially by light sources encased in the ceiling which, arranged in a regular pattern, give the space a regular and characterizing cadence.

5. The Church of St. Paul the Apostle by Massimiliano Fuksas

This work is the winning project of a national competition held in 2001 by the Italian Conference of Bishops for the design of new parochial complexes. It is composed of three elements identified with the functions of the religious center. The first element, the church, is a purely geometric monolith, almost cubic. The second element, a low, elongated parallelepiped, houses the sacristy, rooms of the pastoral ministry, and the rectory. A third translucent body, which houses the weekday chapel, unites and distinguishes the two principal volumes. Streams of natural light, which cut vertically and transversally through the space, create a sense of spirituality and contemplation directed toward the principal elements – the altar, the ambo, and the baptismal font. The imposing volume of the church is reached through the parvis, a long paved parvis that leads to the entrance: a crisp horizontal cut in the absolute compactness that characterizes the front elevation, a piece of periphery, and a possible attraction of signs and forms.

The perception of the entire complex is modified by the works of several artists, including Enzo Cucchi, with his monumental sculpture *Stele-Croce* in concrete and white marble from Carrara, an architectonic element in itself, placed in the parvis, and Mimmo Paladino, with his Stations of the Cross in the interior of the liturgical space.

The vision of the generic church handed down through history is that of a two-dimensional exterior (the façade) and a plan that defines a three dimensional and numinous interior. This formulation is quite clear for anyone interested in studying places of worship located in consolidated urban environments. This traditional interpretation, however, has been applied much less frequently in contemporary churches, which are characterized primarily by strong exterior images located in semi-suburban open spaces, reserving a subordinate role to the distribution of the interior space. With his design for the Church of Saint Paul the Apostle in Foligno (2001-2008), Fuksas brilliantly resolves this dystonia through the use of a double-layered envelope, body and soul, the intimate dimension and the communicative dimension. He rewrites the exterior space in the confrontation between the exterior volume and the surrounding context, while at the same time refusing to renounce the study of liturgical spaces and the human dimension with the smaller interior volume.

6. The Former Church of the Annunciation by Guendalina Salimei and T-Studio

The devastating shocks of the 1997 quake in Umbria have become a propulsive force, which in Foligno, has transformed the tragedy into a fly-wheel of regeneration of urban structures fallen into disuse. A paradigmatic example is the former church of the Annunciation (1760-1775), an uncompleted work by Carlo Murena, deconsecrated in 1860 and since then almost never used. After the earthquake it passed under the ownership of the City of Foligno, in view of the post-quake renewal program, with the objective of determining its re-use as one of the sites of the Italian Center for Contemporary Art (2011).

The concept of the project is evident in the conservative restoration and structural consolidation of the church, while its new function is emphasized by an extraneous body that parasitizes the building and gives rise to an expository itinerary. Entry is by way of the octagonal hall on the east flank, which houses the information point, the ticket booth, and a bookshop. This area gives access to the main hall, illuminated by a newly designed skylight on which is mounted a fixture which filters the sunlight to create suitable lighting for exhibitions. On the upper levels, the exhibition itinerary alternates between inside and outside and concludes with a panoramic overlook, which flanks the hall of the church, and which constitutes a true and proper viral architecture of steel and glass [1]. The COR-TEN, which forms its outside skin, and the parapets that define its limits are decorated with a pattern of irregular solids and voids, which dematerialize it and at the same time allow for its illumination by natural light.

The museum houses the sculpture *Calamita Cosmica* (1990) an enormous humanoid skeleton which fills the central, poly-lobed hall. The alien origins of the creature are betrayed, aside from its dimensions, by its bird-beak nose and the gold rod planted in the middle finger of its right hand: a magnet/antenna oriented toward extraterrestrial worlds. The work synthesizes the spirit of the entire project, in that what appears to be inanimate is a true and proper medium of communication with other worlds [2]. In the same way, the uncompleted and later deconsecrated church becomes a contemporary jewel case, which concretizes the relationship between art and architecture and signifies the dynamic by which cultural sustainability (inherent in the activity of design, which synthesizes knowledge, research, and redesign) not only “sustains architecture,” but contributes in a decisive way to the renewal of Foligno [3].

7. The Archeological Museum of Colfiorito by Roberto de Robertis

The new Archeological Museum of Colfiorito, designed by Roberto de Robertis in collaboration with "mtstudio" (Matteo Clemente and Tommaso Empler), is the product of the prolific collaboration between the City of Foligno and the Umbrian Superintendence for Archeological Heritage. Nonetheless, the MAC concedes nothing to mimesis and even less to its pseudovernacular surroundings, fearlessly displaying its own spatial dynamism, arrogantly wedging itself, almost like a piece of shrapnel gone awry, into the residual void between the walls of two small decommissioned military buildings belonging long ago to the infirmary of the Colfiorito internment camp. All of this, obviously, without renouncing a style that is boldly contemporary, in terms of construction as well as composition. Its metallic roof, in fact, in retracing the triangular shape of the lot, exhibits a spatial dislocation, which embodies in a single form the difference in height (almost eight meters) between the higher and lower parts, and resolves itself in a decidedly monumental point, realized with a large cantilevered element. This dramatic sign, embodying the metaphor of an arrow shot into the air by history, transfixes the intersection in front of the new museum, exuberantly announcing its presence. Equally bold is the entrance façade: a large tilted glass strip which, its upper edge running just under the roof line, incorporates and in a sense protects, the two preexistent buildings (which remain unchanged in semantic contrast with the new volume), functionally connecting them by way of a pedestrian bridge overlooking a surprising exhibition space; surprising because it is three stories high and because it has a panoramic view of the Apennine landscape. The exhibition, in fact, curated by Laura Bonomi Ponzi, is organized on three levels. Of these, the first two, which present archeological finds related to the Plestines (an Umbrian people whose period of highest development was between the VII and V centuries BCE) from the excavations conducted over the last fifty years on the high plateau of Colfiorito, also involve the two preexistent buildings, while the third level, meant to house temporary exhibitions, is served by a secondary entrance reached from the city street that runs above the museum.

8. Design for the ex-Sugar Refinery by Gae Aulenti

At the end of the nineteenth century, the sugar refinery in Foligno represented a turning point in the economic development of the city. The refinery, designed by G. Aidmond, chief engineer of the “Société Anonyme des Ateliers de Construction” and built on behalf of the “Società Italo-Belga per la Fabbricazione degli Zuccheri,” is situated in triangle-shaped urban area and occupies a surface of 6.3 hectares [1].

The sugar refinery ceased operations in 1980, when its installations were dismantled and the land sold. During the 1980s the degradation of the plant was so severe that its potential rehabilitation was threatened. In addition, the seismic events of 1997 further aggravated the already poor condition of the structure, leading the City Administration to proceed with measures to ensure the safety of the plant or to demolish the buildings in danger of collapse.

The land was acquired in 2000 by the Coop Central Italy group, which promoted its rehabilitation within an overall plan for the rebirth of the city of Foligno. In 2011, Gae Aulenti, who died the following year, presented her preliminary proposal for the rehabilitation and reconversion for the area occupied by the refinery.

The project calls for the retention and consolidation of the remaining structures of the ex-refinery – the smokestack, the distillery, and the carpentry workshop. Following the indications of the Implementation Plan of 2004, Aulenti’s project provides for 14% of the area to be occupied by buildings, 39% by parks and gardens, and the remaining 47% by infrastructure and services, including parking lots, open squares, and sidewalks [2].

Gae Aulenti’s design highlights the role of innovation and productivity played by the sugar refinery through the insertion of an element capable of reaching the same degree of productivity and the creation of new jobs – the Science and Arts Park.

The symbolic element of the whole design is constituted by two towers 78 meters high to be constructed with prefabricated structures and destined to house multiple functions. The towers are a completely new element of urban design in Umbria. The region, in fact, has always been characterized by constructions whose development is primarily horizontal rather than vertical. The insertion of these two remarkably high buildings at the entrance to the park, adjacent to the surviving smokestack of the refinery is aimed at reducing to a minimum the occupation of the land, so as to ensure an improved and more coherent livability and usability of the multiple activities planned for the area.

9. Education and Training by the Department of Civil and Environmental Engineering of the University of Perugia

Disegnare Foligno tra storia e utopia [1] (Designing Foligno Between History and Utopia) is rooted in a simple but not banal idea, founded on a visionary simulation in which the field of intervention is represented by the Foligno of 1819. Its executors are nine Italian urban designers (AtelierMap, Ruggiero Baldasso Architects, Alessandro Bulletti, Ceschia and Mentil Associated Architects, studio KUADRA, MARC, Francesco Matucci, nEmo Group, and Giovanni Vaccarini). The designers have been assigned the task of redesigning the city's future urban development through the design of architectural projects inspired by nine ephemeral *folios*, designed by Foligno's Giuseppe Piermarini and digitally reconstructed in the courses of "Architectural Relief" and "Representational Techniques" in the graduate degree program in Architecture and Building Engineering. The new buildings are to be situated on the edge of the historical built environment, in the urban park within the perimeters of the XII and XIV century city walls, with the objective of imagining a possible future of the city's urban structure.

Una nuova porta Urbis per Foligno (A New City Gate for Foligno) is the slogan of the joint didactic exercise conducted in the courses of "Digital Design" and "Digital Design Laboratory," taught respectively by Paolo Belardi and Alfiero Moretti in 2012-2013 as part of the Graduate Degree Program in Architecture and Building Engineering [2]. The exercise addressed the theme of the strategic and figurative redesign of the Porta Romana (Roman Gate) area. The area is situated on the edge of Foligno's historic center and, more than the city's other gates, it represents the urban design concepts of evolution (from defensive bulwark to diaphragm between city and country, and, most recently, traffic node) and stratification (from the homogeneity of the hypogean archeological finds to the heterogeneity of the twentieth century constructions). On the basis of seven project proposals, the area has now been transformed into a pedestrian gallery conceived as a city gate of the third millennium.

A.A.A. Comunità Offresi [3] (Community on Offer) is the slogan of the recovery and refunctionalization project for the industrial-archeological site of the Hoffman kilns in Foligno. The project offered the opportunity to experiment with a new model of contemporary urban living – cohousing – applied in a context rich in historical-symbolic value. The project is characterized by a functional mix in which the cohousing experiment exploits the advantages of reduced environmental resource management costs (natural and energetic, infrastructural and organizational), provides greater opportunities for new forms of socialization (mutual aid, sharing of common problems), enables the recovery of an agricultural concept of architectural design (roof gardens, hanging gardens, vertical agriculture) and returns work-home and home-services relationships to a human scale (through the introduction of self-managed services, and agricultural and artisanal activities). *A.A.A. Comunità offresi* is an experimental and contemporary project design for a new relationship between form and function, inserted in and enhancing a preexisting built environment where architecture becomes an active contributor to the formation of a new way of living.

Paris Saclay - Urban textures

Anna MANDIA,¹

Dipartimento di Cultura del Progetto, Facoltà di Architettura, Seconda Università di Napoli Luigi Vanvitelli, Napoli, Italia
anna.mandia@fastwebnet.it

Abstract

The area of intervention was one of the sites in the European 12 competition in which we took part. This area is located to the south of Paris, a few kilometres from Versailles, and hosts a large multi-campus university called Paris-Sud. There are currently several projects underway in this area, involving town planning as well as construction, for both the medium and the long term. These projects and programmes have the aim of radically changing the future of Paris-Sud University and its surroundings. The precise zone of intervention is southwest of the university campus in an area designated as the “western entrance”. The competition was for a project that would tackle the various problems and requirements currently affecting the campus. First among these were the isolation of the campus with respect to the surrounding towns of Yvette to the south and Orsay to the east, the neglected natural spaces by which the campus is enveloped, improved protection of the areas along the river Yvette which runs through the campus from east to west, the lack of new housing for students and researchers, the repurposing or demolition of a building known as “220” and the provision of new commercial facilities on-campus to replace existing ones which are insufficient.

Keywords: European 12, Paris Saclay, University Paris Sud

1. The project

The project aims to respond to all the requirements mentioned above, based on the resources and potential currently existing in the area.

The project focused on 5 broad sectors of intervention and for each of these analysed critical issues, resources and development potential:

green spaces and landscape
network/transport
sports facilities
services and commerce
housing/social activities

Fig. 1: General framework and five 5 broad sectors

1.1 Green spaces and landscape

This sector was in turn subdivided into three sub-systems defined by the area's own morphology: large green spaces, urban green spaces on-campus and riverside green spaces along the banks of the river Yvette.

The first sub-system (the large green space) could accommodate a series of activities that would bring improvement and would encourage citizens to enjoy the natural heritage available in their territory, with a view to actively safeguarding it.

Given the size of the area and its morphology, it would be suited for use as a themed park – specifically, as “an adventure park”.

Naturally, in the context of such specific activities, existing trails would have to be refurbished for walking, hiking, cycling and, last but not least, horse riding.

The second sub-system (urban green spaces on-campus) would be refurbished in order to make a pleasant campus environment, eliminating areas lacking in environmental quality.

The project includes the planting, in the green spaces delimiting the roads across the campus, of a variety of trees, specifically for all times of the year, so that there will always be something in flower all year round.

The large green areas along the road Voie de la Faculté, currently unused, will be given over to “urban vegetable garden” activities. It will thus be possible to create specific projects and programmes for all types and levels of school, such as for example projects connected with nature and food education. Opening the gates to young people and children through the schools will be the first step towards integration and a system of relations between the campus and the town. The third sub-system (riverside green spaces) comprises the areas along the riverbanks. Here the project foresees just areas for relaxation, simply laid out as lawns, with a Wi-Fi connection from the campus making it possible and enjoyable to work on one's laptop, sitting comfortably on the grass.

The large natural spaces of the campus that currently have no specific function but which are extremely beautiful could host installations of works of art, expressions of Land Art. Art and Nature together will bring to the campus a variety of activities and interests that will attract the attention of different kinds of visitors from month to month and at different times of the day.

1.2 The second sector: road network

This sector has also been divided into two sub-systems: the road system outside the project area and that inside the campus. On-campus, where possible, provision has been made to widen the roadway. Here, a light mode of transit is envisaged (cycle tracks) and it will only be possible to drive by car to some points, where easy parking will be available. The road network outside the campus has been improved and some roadways, where possible, have been widened and given cycle tracks.

1.4 Third sector: equipment for sport

At the heart of the project area there are spaces and equipment for sport. The project intends to increase these areas with tennis and basketball courts and an athletics track, partly already existing. A little sports city, open not only to students but also to young sportspeople and children coming from outside. Sport is undoubtedly a very strong form of aggregation and as such should be encouraged, thereby creating a more vital campus, where mothers and children could mix with professional athletes.

Fig. 2: Green spaces and landscape - road network - equipment for sport

1.5 The fourth sector: services and commerce

There are currently no shops inside the campus, so students are obliged to drive to the nearest shopping centre. The project includes a commercial building to the north of the campus, overlooking Rue de la Guyonnerie. This will not be built along the roadside, instead a broad green space will divide it from the road. The building has been conceived with low environmental impact and attractive colours, entirely clad in colourful wooden planks. The widening of Rue de la Guyonnerie and the capacious parking area, which will also serve as access to the “Adventure Park”, will make this area a hub that stimulates various interests.

1.3 The fifth: housing/social activities

There are various residential buildings within the campus, some undergoing renovation. The projects for these properties envisage enlarging rooms with a consequent reduction in the numbers of beds and a need to provide more beds, both for students and for researchers with their families.

The project foresees new residences in an area to the east of the campus, aligned with other residential building complexes, in a zone where there are no planning restrictions.

In line with the current demands of young students today – low costs, shared spaces, versatile buildings – we decided to suggest a project already tested in other European cities - the use of shipping containers.

These modular elements are light, versatile, eco-compatible and can be made aesthetically very attractive – all reasons behind this project choice, which is in line with the theme of “adaptable campus” and in tune with the rhythms and requirements of the evolution of time. While we used a criterion of minimal space for the students, a different concept was adopted for the residences of researchers and their families, who would be housed in a wing of Building 220.

NEW TRADE CENTER

CURRENTLY THERE ARE NO SHOPS WITHIN THE CAMPUS, YOUNG PEOPLE ARE FORCED TO TAKE THE CAR TO GO TO THE NEAREST SHOPPING CENTER. THE PROJECT INVOLVES THE CONSTRUCTION OF A BUILDING FOR TRADE NORTH OF THE CAMPUS, OVERLOOKING THE RUE GUYONNERIE. THE BUILDING HAS BEEN DESIGNED WITH LOW ENVIRONMENTAL IMPACT AND EYE-CATCHING COLORS, FULLY LINED WITH COLORFUL WOODEN SLATS. A CUBIC SHAPE HAVE BEEN SELECTED, THREE “SCATTERED” CUBES ON THE FLOOR AS THREE DICES ON A TABLE. THREE CUBES MADE OF COLOURED WOOD SLATS. DIFFERENT COLORS TO CATCH DI ATTENTION AND WOOD TO SUCCESSFULLY INCLUDE EACH NEW STRUCTURES IN THE NATURAL ENVIRONMENT. OF COURSE LOW POWER CONSUMPTION EVERY WHERE IN SUCH BUILDINGS.

TWO NEW SPECULAR BUILDINGS _ STUDENTS HOUSING

Projects overlooking the Sea, between stone and leaves

Cesare Ajroldi, Flavia Schiavo

Department of Architecture, University of Palermo, Italy.
cesare.airoldi@unipa.it, flavia.schiavo@unipa.it

We intend to deal, in this paper, an important subject: the restoration of the modern project and the recovery of landscape, through two significant Sicilian examples, two impressive lesser-known structures, today abandoned. They are inside a “natural” context, endowed with a strong identity: three hangars, two by Nervi, bordering the coast near Marsala, and one by Garboli in Augusta, on top of a little green hill, next to the bay. These building complexes were analysed in the PhD at the University of Palermo. The results of this research will be part of our paper. Therefore, the restoration project takes advantage of the consideration around the *rules* of the architectures explored (which are examples of *Order*). These rules are “roots” of the new project and stronghold of *scientific* coherence. Regarding landscape and its relationship with buildings, the paper will shed a light on how, in the unity territory/architecture, it’s possible to rethink and to “redesign” a place, activating synergies that correlate the landscape values with the anthropic values. In both cases the landscape and architectural recovery is focused on redesigning the landscape options, for example the botanical species planted, or to design landscape as a garden, which embraces inside and holds in itself great examples of architecture. Thus, the architectural territory, made of stone and living vegetation, “lives”, as an open air garden, by and bordering the sea. A long and deep waterfront between city and nature.

Keywords Architecture, landscape, Sicily, order, scientific project

Projects overlooking the Sea, between stone and leaves

This paper concerns two different themes, firstly, the relationship between architecture and landscape and secondly, projects involving the restoration of modern works. These will be applied to two little known, but important, large-scale industrial structures in Sicily, which are now abandoned, and part of an extremely connotative, seminatural context - the two hangars by the sea at Nervi, Marsala and the Garboli airship hangar at Augusta, which rises up from a small green hill overlooking the bay.

These buildings have been studied and reprojected in the context of the Palermo Architectural Design Doctorate and the results regarding them form the basis of our reflection. The restoration projects were begun after a careful examination of the rules regarding the architectural structures involved (which are examples of order); these rules are at the foundation of the restoration projects and are a guarantee of their scientific value. For these reasons, therefore, the planning operation, together with an in-depth analysis of each building, have formed the basic element of the doctoral thesis.

Furthermore, in both the cases examined, the projects are in a non-urban context, and in the period when the buildings were erected, were part of a rural setting in strict correlation to the sea and to several pre-existent historical factors of great impact, in one case the ancient city of Augusta and in the other the small area of sea known as the Stagnone, almost opposite the tiny island of Mozia. A doctoral thesis together with a separate project has been written by Giulia Argiroffi, who has tried to conserve the large unitary space involved and to approach the project without losing sight of the fundamental rule regarding the original construction of the building, which involved the assemblage of its various component parts. For this reason, an abacus of these component parts was prepared, and this then formed the foundation of the planning process. The project concentrates on the architectural structure, considered apart from its relationship to the landscape. This relationship must be examined

extremely carefully, not only because of the quality of the context involved, extremely connotative right from the beginning, but also in order to resolve the human pressures which have totally transformed the historical set-up in which the building originated. Today the area is overrun by an uncontrolled building sprawl which is gradually breaking up the rural areas, once covered with productive vineyards.

The idea of using the two buildings respectively as a marine museum and a sports center was suggested by their owners, the Provincial Administration of Trapani. This choice has made it possible to maintain, for the most part, the perception of the large space involved in the twin buildings and to use light materials for the reconstruction, which can be erected directly on the ground and linked to the various parts of the elements of the large arched roof.

The context is characterized by a system of great value that is based on the seniority of the historic city of Marsala, in which the matrix based on the Roman quarter and Hippodamian schema, is still present. In addition to the city, which today seems burdened by a development which came to be frayed at the back, both on the coast with comb-shaped second houses, the scope bears the traces of one of the most interesting productions of quality in Sicily: sea salt, Slow Food Sicily. This production has given rise to an environment of almost surreal beauty that is the "border" between land and sea, the Stagnone, where Mozia is.

In this case, the project of restoration of the landscape must face the sea front and the interior, mitigating the visual impact of the settlement without edges that interacts with a flat earth that does not have morphological limits. Had they been present, they would have curbed the wide expansion which covers rather evenly throughout the country.

The beauty of the sea front suggests, for the redevelopment, a walkway between the urban and the natural, which should put with great lightness and delicacy, visual and physical connection to the key places of the system, including salt marshes which, mirror water in the ground, multiply the light. In this system, water blades that change colour with the seasons, there are white and impressive windmills.

On the model of some waterfronts you should follow what the landscape suggests, with the skills that the integration between urban planning and architecture, move. Also strengthening the use of perceptual aspects whose values could be traced to some matrices of great architecture of the twentieth century, like those of Kahn, made of air, light and silence.

In addition to this it is important to work on the scale of the scope project, so that the regeneration of the landscape is integrated with that of the scale of architecture, thinking over, then, the space between the buildings, regenerating and interconnecting it with the seafront and the entire context.

The Augusta airship hangar, projected by the engineer Antonio Garboli in 1917, presents similar problems. It is situated on a small hill covered with trees, not far from the sea, near the fifteenth century forts of Garcia and Victoria, and a little further away, Augusta, the city of Frederick II. This is also therefore, an extremely stimulating area, and the doctoral project of Giuseppe Borzellieri has emphasized the aspect of the landscape, on the one hand, and the particular impact of the large space of the hangar on the other. His project involves nothing more than a bordering trilithon structure which supports in corten walkways leading to the various floors, the rearrangement of the main staircase and very little else. The use of the building as a museum also offers the possibility of exhibiting a copy of the original airships.

In this particular case, the theme of the landscape is directly linked to the pre-existence of the hangar, which is the strongest feature of the building. From this point of view the landscape as such becomes less important and the massive, stimulating view of the sea forts more so.

In the peninsula where Augusta is located, next to the mainland, there is the Castle which is visible from the site where the hangar stands. For the visible space, for the perception of the landscape, for the visual horizons and for the presence of historical architectures among which the sea fortresses Garcia and Vittoria, the context which is, among other things, next to Megara Hyblaea, has a enormous value and has a great fragility.

Besides on the waterfront, in addition, to the south of the hangar, there is the Giuseppe Samonà Electric Central Enel, among the best known industrial buildings in Italy, still working, but on the point of being disposed. Enel society plans to transform this site into a Museum, exposing the internal structures of the building. This possibility, however, that is being explored by the Architectural design Doctorate, suggests more questions to develop. In addition to the restoration and upgrading of the buildings, the hangar and the Samonà Central and the historical architectures, there is the focal theme of the redevelopment of the landscape as a whole and, specifically, a framework that brings together natural values, "ab ovo" present, anthropogenic values, those of historical and newer architectures, already mentioned, and strong negative values, the result of a uncontrolled transformation, the most

glaring that our nation has registered, the transformation that has eroded resources and changed the facial appearance of the area. So to deal with Architecture means also to face, in a caring and different spirit, the context in which the architectures themselves "live". The context, in fact, made from "scraps" unresolved, suffers with major fractures, visual and material breaks. Among these, for example, the area intended to Esso, which at this time would need to design solutions to mitigate the very strong impacts.

Another node is related to the transformation and growth of the settlement system. Difficult node that should be dealt with the planning instruments to ensure not only ground zero consumption, but also strategies for integration between plan and project, based on the ecology of the landscape.

It is obvious that the examination of a monument involves a great many commitments, but as Kahn said, the creative process is enriched and not hindered by such commitments. This approach means that the architectural operation presents a particular theory, since only a theoretical operation can be transmitted and described, in the same way as a teaching operation; in our opinion, this is how every architectural project should be. We maintain that architecture is a branch of learning, with its own, consolidated statute.

We are well aware that there exist different points of view regarding the idea of theory. We must not forget the words of Aldo Rossi who states that there should be a theory of architectural design, with a fundamental point consisting in the study of monuments; other ideas regard architectural forms and the understanding of the city.

On the other hand, Purini states that theory should be mentioned only *a posteriori* and not *a priori*, since architecture is an artistic science, or a scientific art, which may include not only the creation of forms, with their unpredictability, but also the construction of a scientific apparatus.

As we have mentioned, these are different positions, but they all accept the idea of the fundamental role played by theory. There should be a logical foundation in planning, even though each project may involve something new and unconventional; in this context it is interesting to remember the quotation of Diaz by Martí Arís in "Le Variazioni dell'Identità" ("*The Variations of Identity*") "planning a new project involves going against a particular type of project by means of a logical decision" (in our own paper we might call this infringing the rules.)

With regard to theory, we would like to mention the last, brilliant paper written by Bernard Huet, on the state of theory in XXth century architecture, in which he underlines the difference between doctrine and theory, stating that most of the production of the XXth century is made up of various doctrines only. He, in fact, defines the difference between doctrine and theory, the first is what every architecture says he or she sees in architecture, it is the explanation of a point of view, of an attitude towards architecture, while theory involves the systematic organization of the knowledge regarding architecture and of architecture; this is what makes it possible to consider architecture as an intellectual product, in order to be able to construct a theoretical object known as "architecture" (starting from the elaboration by Leon Battista Alberti).

Both the doctrine and the theory involve a conscious, intellectual organization, always based on the three categories of Vitruvio: *firmitas*, *utilitas*, *venustas*.

We certainly shall not forget the doctrines regarding modern architecture; Monestiroli, for example, states that the last theoretical elaboration is the classical one. We all know the work "*Vers une Architecture*" published in 1923 and the 5 points for a new style of architecture presented by Le Corbusier in 1927, used in their entirety for the project regarding Villa Savoye.

Every elaboration, whether regarding theory or doctrine, involves a system of rules which are applicable as long as the elaboration lasts. Let us consider, therefore, not only the 5 points, but also the contemporary reading by Le Corbusier of the 4 compositions, by means of which he analyzed four villas (La Roche, Garches, Citrohan at Weissenhof, Savoye), using parameters based on the project procedures. But we must not forget Leon Battista Alberti, who believes in the correctness of the relationship between pillar and arch, since they both belong to the masonry system, whereas the column should be associated with trabeation, since it belongs to the architrave system. This involves a clear relationship between the architectural and the constructive system, which we will come to later.

A system of rules can be read during the analysis of a monument (this is Rossi's position) and form the basis of the project choices to be made with regard to the monument itself, as in the case of the projects under discussion.

On the other hand, we agree with Grassi that the main part of the branch of learning known as architecture is made up of all the forms of architecture either built or planned. Architecture, therefore, is taught through architecture, by studying, deconstructing, modifying past works. This is a position which makes it possible to prevent modern architecture, in its more fashionable forms, from being transformed into a purely artistic form.

As previously mentioned, nowadays we are faced more and more with an attempt to refer back to the avant-garde position of the beginning of the XXth century, which also saw the start of the M.M., which claimed almost absolute creative freedom, typical of artistic production, not intended to be "useful" to anyone, whereas architecture should basically be concerned with human needs. In this way, such movements completely ignore what, in my opinion, are the foundations of architecture; there are no forms without order, but only aggregations. We must not forget that for Kahn, as for Mies, form is order.

Writing of the relationship between order and construction, Kahn says:

"The project involves the composition of form into order. Form emerges from a constructive system. Growth is construction. The creative force exists within order. The unknown can be revealed to the architect by what space represents.

From order, he or she can obtain the creative force and the power of self-criticism in order to give a form to this unknown. Beauty will evolve".

Le Corbusier also considers the idea of order as fundamental; this can be seen in the long process of the Modulor, during the war years, with the desire to reach not only a measurement system linked to human beings, but also a harmonious relationship, such as the golden section, seen in many aspects of nature, and the Fibonacci series.

Another fundamental problem of architecture regards the *construction*. We remember in this sense the words of Perret, in the aphorisms making up his text *Contribution à une Théorie de l'Architecture*. "Construction is the mother tongue of architecture; the architect is a poet who thinks and speaks in construction".

"Architecture is the art of organizing space, expressing itself through construction".

For Le Corbusier too the construction is the heart of the foundation of the new architecture. For him, the bearing structure of the building coincides with its logical structure.

An architectural project, especially in the case of the doctoral thesis, must be scientific, analyzable in scientific terms, and must give a solid answer to the definition of *the project as an instrument of knowledge*, emerging from the fruitful phase of the elaboration, especially Italian, which has led to the profound transformation of schools of architecture from professional institutes to places of cultural reflection on this branch of learning and its foundations.

Here we are dealing with a restoration project, but we must not forget the definition of restoration as an architectural project; it is superfluous to mention that nowadays, the majority of projects are concerned with previously-built constructions.

In any case, the modification of the use alone, involving almost all the examples presented, is made up of a project.

In conclusion, the problem of the scientific character of the project, revealed very explicitly in certain positions, especially in Italy, to consider the theme, is faced in our own case by means of *reference to the rules of the building* (to be restored), which gives a connotation of *scientific* to the procedure followed, thus going beyond a merely "intuitive" practical position of the project.

The development of Bad Nauheim as Jugendstil spa complex

Elena MANZO, Manuela PISCITELLI

Department of Architecture and Industrial Design, Second University of Naples, Italy
elena.manzo@unina2.it; manuela.piscitelli@unina2.it

Abstract

The buildings of the spa complex at Bad Nauheim (Germany) are among the most important examples of Jugendstil architecture in the world, but the place or the architect Wilhelm Jost are not mentioned in scientific works.

Salt water springs in this area were already exploited by the Celts and the Romans. The village of salt producers began to change into a spa in the first half of the 19th century, when the curative power of the salt water from wells was recognized.

At the beginning of 1900, changed hygienic and aesthetic ideas and expectations required the construction of new bathhouses. At that time, Bad Nauheim belonged to the Grand Duchy Assia-Darmstadt. The Grand Duke Ernst Ludwig of Hessen had commissioned artist of Jugendstil to decorate rooms of his New Palace in Darmstadt, and had summoned seven artists of Darmstadt to found an artist's colony. The new spa complex of Bad Nauheim absorbed the ideas emanating from Darmstadt, and the layout of the whole town was arranged according to the modern precepts of Darmstadt Jugendstil.

The paper describes the transformations and reuse of Bad Nauheim until nowadays, and analyzes typologies and decorative motives of the spa complex, excellent example of early Jugendstil in Germany, from the point of view both of history of architecture (Elena Manzo) and geometrical and morphological analysis of elements (Manuela Piscitelli).

Keywords: Spa architecture typologies, thermal city, Jugendstil, kursaal.

1. Best practices, conservation and management of architectures for spa tourism. The exemplary case of Bad Nauheim in Germany* (Elena Manzo).

On the basis of estimated objectives, it is now recognized that, today, thermal baths are one of the largest and most productive fields of the economic balance of the each nation¹.

The recovery of their historical and cultural identity, as well as their validation as a heritage to preserve even more than businesses that offer health and beauty treatments, a network of protected or marked sites has been developed, that has been able to awaken an intense movement of tourists.

Thus, the historical-anthropological approach has proved particularly effective in their revaluation, especially when it is thinking in terms of the economic potential of their architectural heritage. Thermal baths, in fact, thanks to the activation of a series of related multiple activities and services and supported by careful development policies, have played an important role in the tourism industry².

Spas, which were initially made popular during the Roman times and rediscovered between the fourteenth and fifteenth centuries, have lived intermittent and conflictual phases: during the Grand Tour, they were travel destinations in Italy, as well as other regions of Europe, as an upmarket resort for the bourgeois élite from England and Germany (consider Ostend, Baden-Baden, Bath, Monte Carlo). Finally, they reached their period of maximum splendor and development in the late nineteenth century, when the urban land expansion of the Industrial City was organized on the basis of

homogeneous areas and gave rise to new types of architecture, responding to advances in science and technology as well as changes to social needs³.

Similar to bridges, stations, department stores, headquarters of new institutions, galleries, even the baths were the mirror of the emerging bourgeois class but their typological schemes were able to obtain models from the ancient repertoire.

Thus, the shape of the plan of the whole hydrotherapeutic factory was simplified not only to ensure a clear distinction between the areas frequented by women and men, but also to allow more joint and a faster connection between different rooms, which was increased with those primarily intended for social activities and entertainment, such as reading rooms, restaurants, or, as in the case of the Kursaal with dance halls, theatres, casino and other rooms for recreational activities⁴.

On the other hand, the area reserved for ablutions, the model of which was traditionally composed of *caldarium*, *tepidarium* and *frigidarium* and where, in the ancient Roman Empire, also activities of social and political-economic relations took place, as well as exchanges in the space reserved for private moments and intimacy. The bathroom becomes private, reserved exclusively for a single guest or, at most, for three people and, therefore, equipped with single tanks and *séparé*⁵.

Modern thermal baths, therefore, were founded while the Industrial city was consolidating, namely when the hygienist culture emphasized the importance of the therapeutic and curative properties of water and, just like the seaside resorts, the awakened interest in the health and physical well-being increased and promoted more frequent building programs for mineral springs.

Looking for an ideal climate, pristine water sources, soothing landscapes, intimate atmosphere, escape from daily routine, the thermal baths were proposed as an alternative to the urban chaos.

Developing as autonomous cities or suburbs, according to a phenomenon very similar to what had been the basis of *Company Towns*, they are built around a self-sufficient urban organism, whose morphological choices are traceable to common interpretative categories: on the one hand, the rooms for health treatments, with appropriate structures and modern irrigation and ablution systems and leisure rooms, on the other, the organization of open spaces, where long arcaded paths, made in brick or wood or iron and glass lightweight structures, were built among parks and gardens, according to the fashion of the time. This is the case, for example, of Vichy, renovated by Napoleon II, like a grand *Villes d'eaux*, making a prevalence of gardens and green areas and the architecture of Baden-Baden, which integrates itself with surrounding nature of the Black Forest.

On the other hand, Camillo Sitte had suggested to his contemporaries that «From the point of view of hygiene, the answer seems simple: more green is better. Thus, everything has been said. However, the same is not true for art, for which there should be due care on where and how to resort to greenery. Making use of this in the new neighbourhoods of modern villas is the most frequent and fortunate application of villas: in the famous fortified walls of Frankfurt am Main, in the urban parcelling of Währing near to Vienna, on the edge of the old town of Dresden, as in the residential neighborhoods of all thermal cities, such as Wiesbaden, Nice, etc...»⁶

Among the greenery, that sanitary engineering culture considered a healing and purifying element like water, rest areas were designed and outfitted, with scattered pavilions for tea or reading, sports facilities and chalets, which suggested the icons of the Alpine or seaside resorts, the Cassa Armonica or the Kursaal, more and more frequently, in isolated locations in relation to the residential and treatment buildings. Every individual building or architectural element today should be considered monuments of these new types of extra urban settlement, like cathedrals, fountains, castles, monuments of the traditional city.

In contrast to the so-called “Towns of Work”, following the categories suggested by Max Weber, a system of attraction poles emerges, represented by the “Spa Towns” as new sites for the bourgeois and elite tourism. They were the “Leisure Towns”, that put together the pleasure of the *otium* and the taste for social entertainment with the therapeutic treatment for the body and mind care. Thus under the pretext of care and physical well-being, the main value of the bourgeoisie in the second half of the nineteenth century, the new class emerging made its free time “fruitful” and “profitable”, without having any scruples of unproductive idleness.

The awakened interest in architectural, structural and technological aspects of the Thermal baths emerges since studies of the contemporary scientific assays and books. French manuals are rich of examples, consider the attention given by the *École des Beaux-Arts* as well as the numerous competitions, organized for the *Grand Prix de Rome*, or the texts of M. Durand-Fardel, J. François, P. Planat, to name a few⁷. In Italy, however, this topic has had a significant systematization in the “treaty” of *Il Costruttore*, published between 1886 and 1907, in the repertoires offered by the *Enciclopedia delle Arti e Industrie* as well as in the important volumes edited by Daniele Donghi. However, wide resonance can be found in the pages of some of the most important magazines of that time, such as, in particular, *L'Edilizia Moderna* and *Rivista di Ingegneria Sanitaria*⁸.

Today, the spa towns are known by the term most widely Spa, so called from the Belgian town Spa, southeast of Liege, famed for its healing cold springs that has been frequented since as early as the 14th century but in the second half of the 19th century, it underwent an enormous development and

became a destination prized by the country's aristocracy or bourgeoisie as well as those of its neighbours. Moreover, the first casino in the world was founded here, with building being started in 1763 by the prince-bishop of Liege.

However, by the early decades of the twentieth century, spa buildings have had a gradual and progressive decline; but, in the last twenty years, as previously stated, are again at the centre of revaluation of programs. This is due to a renewed interest in the physical care prompted by anti-aging medicine, which calls for the "prevention" of treatment and even more importantly, the management of their own health in terms of "promotion" and "exploitation" of conditions of physical well-being. In addition, it is now an established fact that State investment in the spa industry has important results due to the economic return on both a national and local level, in terms of increased tourism and employment. a wider interpretation of the idea of the tourist resort spa has therefore developed, which, among others, has shown that the thermal system produces a significant increase in jobs. In Italy, in particular, the experience of the other more advanced European countries in this area have undertaken legislative programs to facilitate management tasks, such as the passage of the former spa Eilat from the state to local authorities.

In May 2010, the European Historic Thermal Towns Association (E.H.T.T.A.), approved by the Council of Europe was recognized, with it being an International network aimed at the valorisation and preservation of the thermal cultural heritage in Europe to promote some routes towards approved important spas as well as to find a new strategy to increase a dynamic cultural thermal tourism⁹.

It is implicated in the realization of showing «unique urban personalities of the towns by drawing on their common points: a thermal culture, which, in all its variety and local characteristic differences can truly be called European», of encouraging «the integrated development in thermal towns and to preserve their cultural and architectural heritage, in return for experiences at a European level», of promoting «the network, in close collaboration with the European institutions and with the support of European programs», of encouraging «the research development, analysis, studies and statistics in the thermal sector, in particular history, artistic and cultural heritage» and of «creating a new development strategy for the thermal sector which will take into account the potential for culture and tourists, contributing to the economy of the culture and the aim to achieve the objective of the Lisbon strategy»¹⁰.

On these topics, Bad Nauheim could be considered an interesting and explanatory example. Bad Nauheim, known as Bathhouses of Hessen's State Spa, is a small town situated in the western part of Germany close to Munich, whose salt water springs were exploited by the Celts and Romans, which have been the reason for its economic welfare and its tourism to date. Although Bad Nauheim never lost its vocation linked to the exploitation of water and thermal resources and is one of the most important examples of Jugendstil architecture of spa in the world, it is understudied and is not mentioned in many scientific works of architectural history, since until 1981 most of its buildings had fallen into neglect. The river USA overflowed and seriously damaged many buildings, above all the *Sprudelhof* (Courtyard of the Major Spring), that was the landmark of the thermal city and the Bathhouses with their ornamental courtyards.

The Grand Duke Ernst Ludwig of Hessen and Rhin, extraordinary figure of enlightened sovereign sensible to culture and art, especially to Jugendstil, was the soul and mentor of the project, that was started while the Darmstadt Artists' Colony in Mathildenhöhe was developing under the leadership of Joseph Maria Olbrich with the collaboration of several important artists of the Art Nouveau in Darmstadt, including Peter Behrens, Paul Bürck, Rudolf Bosselt, Hans Christiansen, Ludwig Habich and Patriz Huber.

Bad Nauheim, in fact, was planned between 1902 and 1912. Wilhelm Jost (1874-1944), *Großherzoglicher Regierungsbauinspektor* (Building Inspector of the Government) at the Grand Duchy of Hesse, was the Director of the project, based on a uniform and organic design, which included the health resort. Graduated from *Tecnoche Hochschule Darmstadt*, Jost had a prestigious fame from the experience of the Bad Nauheim that, in the 1912, when he was just a member of the *Deutscher Werkbund*, was appointed City Planner to Halle¹¹. Under his direction, a large number of artists were involved in carrying out the whole thermal complex, including Johann Josef Belz (1873-1953), the sculptor Ludwig Habich (1872-1949), who was one of the founding members of the Darmstadt Artists' Colony and among the "first seven" artists who took part, Heinrich Jobst (1872-1952), his successor at the newly establishment teaching workshop for applied art of Darmstadt, the Austrian painter Fritz Hegenbart (1864-1943), best known for his works of graphic and publicist based on grotesque and allegorical subjects, especially those which appeared in the *Jugend* magazine, the architects Leonhard Kraft (1876-1965) and Albert Marx (1877-1977), Ernest Riegel (1871-1941) who was the most important goldsmith of the Munch Jugendstil and so clever to win the gold medal at the Universal Exhibition of 1900, the *Regierungsbaumeister* Heinrich Petry (1880-1940)¹². Most of these artists, seventeen of which worked on the design and execution of *Sprudelhof*, worked on Mathildenhöhe too and were members of the Darmstadt Artists' Colony.

Fig. 3: Bad Nauheim, *Sprudelhof* and the long pedestrian street from the station to the park.

Sprudelhof could be considered the main building of Bad Nauheim and one of the most significant examples of Jugendstil in Germany. It was built between 1905 and 1912, it is possible to see on the shaft of the columns, upon which the date of the construction of the arcades surrounding a large rectangular courtyard is carved. Located just in front of the station, *Sprudelhof* is a place where there are the spaces for the thermal treatments: seven Bathhouses in which there are both, on the first floor, 240 bathroom cubicles, cells for royalties, new fountain basins and, on the ground floor, halls, ballrooms and restaurants. The long arcade running around the perimeter of the rectangular courtyard, delimiting it, unifies the buildings, which are linked to the German tradition of living and of construction but the decorations conform the whole complex to the Jugendstil.

The courtyard has the value of the square. In fact, a large stone fountain welling thermal water with gardens surrounding are in the centre. A long pedestrian street, an imposing perspective axis, crosses the court, cutting it, and visually connects the station, that is the point of arrival in Bad Nauheim, with the surrounding park, where there are scattered buildings – *Stadtbücherei* (the Library), *Gärtnerei* (the gardening and horticulture), *Trinkkuranlage* (the mineral water complex, so called the “Pump Room” complex), *Kurhaus* (the Kursaal) with the theater, *Benekebrunnen* - and some artificial lakes.

The fountain, made by the sculptor Heinrich Jobst, is decorated with allegorical subjects carved in stone, such as cornucopias or baskets of fruit, that symbolise copiousness and benevolent nature, which allude to the management and government of the Grand Duke Ernst Ludwig and promise health and well-being to the patients gathered around the spring¹³. It consists of two adjacent stone circles, supported by a base with figures of young males and females, represented with classical bodies. There are two springs of carbonated thermal saline water inside and, on the top, there is the Hessen's coat-of arms.

From 1910 to 1912, while the *Sprudelhof* was being built, the *Trinkkuranlage* was finished too. It was a horseshoe-shaped closed on big courtyard where there is a rectangular water basin with a shell-bandstand for the orchestra behind it. It is possible to see all the thermal city from here. The drinking hall or so called “Pump Room” is inside. It was a place for social gatherings.

The architectonical language used for the main buildings of the *Trinkkuranlage* is more classical than that of the *Sprudelhof* and this is because the aim of Jost was to inspire simplicity, calm and peacefulness.

As in the Darmstadt Artists' Colony, the influence of the theories of John Ruskin and William Morris is also evident in Bad Nauheim, especially the idea of achieving the “Guild of handicrafts”. These two places are the expression of how the Grand Duke was able to realize his ambitious motto «My Hesse (my country) is to flourish, and the arts are to flourish in it». Everything is coordinated in accordance with the principle of *Gesamtkunstwerk*, which is the total artwork professed by Henry Van de Velde and both are, on the one hand, the recovery of *Heimatkunst*, interpreted nationalistic, that is as “the art of fathers and ancestors”, on the other, the most progressive expression of art in this region of Germany. However, if the Darmstadt Artists' Colony famously consists of all different houses, built according to the plans of each artist, that is one of the its main qualities, Bad Nauheim was characterized by a strong formal and stylistic homogeneity.

Fig. 4: Bad Nauheim, *Sprudelhof*. Decorations on the pilasters of the arcade.

Fig. 5: Bad Nauheim, *Sprudelhof*. Dates carved on the shafts of the columns.

Fig. 6: Bad Nauheim, *Sprudelhof*. The fountain made by Heinrich Jobst.

Fig. 7: Bad Nauheim, the Jugendstil fountain in the park.

The theme of water is the Common denominator of the decorations and it emphasizes the uniformity of the composition. Thus, the atmosphere of Bad Nauheim is reassuring and magic, just like in a fairy tale but, at the same time, recalls the ancient technique of carving in the medieval cathedrals. Marine subjects, such as shells, crabs, fishes, octopuses, waves and mythological figures, in fact, are represented in every architectural elements, especially in the *Sprudelhof*, where the Tuscan capitals of the pillars of the arcades and their projection on the pilasters are different from each other, repeating a rhythmic sequence.

Jost, as it has been pointed out, «[...] had originally planned wide wall friezes with figures compositions for the upper zones of the administrative buildings and Bathhouses; but he eventually decided in favour of wave-like horizontal patterns cut into the render and incorporating gilded spherical shapes reminiscent of carbon bubbles rising from mineral waters. This is a much more abstract ornament than the original scheme, and many have been influenced by Olbrich's ornamental decorations of around 1900. Architects like Olbrich also taught Jost to make each façade different, so that a visitor walking round a building is constantly surprised by a new view. Jost used this formal device particularly in the administrative buildings»¹⁴.

The *Kurhaus*, namely the Kursaal, although is the result of different projects, is a homogenous building which is perfectly integrated with architectonical language of the thermal site. It has been just built in 1864 and in the 1880 it was added with theatre and with wider restaurant and terraces.

In 1900, it was necessary to satisfy the requirements of a multipurpose complex room, for increasing visitors and for a wide variety of musical performances, festivals, conventions, which factors contributed to the enrichment of the building's role both in the thermal complex and in the city. In fact, between 1902 and 1904, Jost began the extension and a new concert hall, which, today is the theatre, conforming the language of his buildings and that one Neo-Renaissance of old ones behind a long arcade. At the same time, he established an architectonical dialogue with the surrounding park and with the *Sprudelhof*.

Inside, all is in Jugendstil design but the influence of Viennese Secession is evident, especially the reference to Josef Hoffmann.

So, the project's concept is extremely simple and clear and the final result is the most important Kursaal in Hessen.

Bad Nauheim began working by 1981 and, recently, has been admitted to the European "Réseau Art Nouveau Network" as the first German city.

2. Documenting spa architecture. The complex of Bad Nauheim. (Manuela Piscitelli)

2.1 Elements and typologies of spa architectures

The origins of spas and balneology can be seen in the antique era, especially in Roman thermal baths, as it is still testified by numerous remains of public baths in the territory of the Roman Empire, in Rome, Pompeii, Baiae, Trevir, Baden-Baden, Bath, Bulla Regia, Timgad, etc. These baths are closely related to other structures that had over the centuries become standard elements of spa architecture (balnearium, nymphaeum, stoa, colonnade, vaporarium, valetudinarium, lavatrine, latrine).

This tradition never got lost, and many older spa locations underwent renovations during the Baroque and Classicism era, but a real boom of spas could be seen in the 19th century. For numerous spa locations, this can be identified as a “golden era”. The main spa centers grew up in large fashionable, globally famous spa centers as Karlovy Vary, Baden-Baden, Wiesbaden, Bad Ems, Spa, Vichy, Aix-les-Bains, Biarritz, Bayonne, San Sebastian.

A second boom, in the period known as Belle Époque, is attested by magnificent Neo-Baroque and Art Nouveau style complexes built in many spa locations as Vichy, Contrexéville, Bad Nauheim, Bad Kissingen, Bad Elster, Karlovy Vary, Mariánské Lázně, Teplice, Jáchymov, Poděbrady, Luhačovice, Jeseník.

The new indications about diverse healing treatments determined the structural and architectural appearance of spa facilities, thus leading to the creation of specialized spa buildings with particular structural forms, such as spa houses, large spa complex called *Stabilimento* in Italy, *Bain* in France, *Kurhaus* in Germany; inhalatoriums; warbling places; colonnades; pavilions; drinking halls; conversation halls; casinos; theaters; and overnight accommodation places. All these specialized structures put together form a typical spa architecture. Direct exploitation of the healing power took place either directly at the source, as in the case of springs, or in the surrounding buildings.

From the mid-1850's, the appearance of many large bath houses was modeled after ancient thermal houses with a private courtyard in the middle, the interior oriented towards the courtyard portal's corridor, giving access to individual rooms partitioned from the main room by anterooms with bathtubs adjacent to the main portal.

The original bath house composition with the central elevated pavilion and side-wing pavilions remained fashionable until the 20th century.

The need of structures capable of providing protection against unfavorable weather to a greater number of visitors, and simultaneously were suitable for socializing and promenading determined the use of long colonnades. The interpretation of the pure lines of antique compositions in the form of colonnades found application primarily in Germany during the first quarter of the 19th century in spa complexes like Baden-Baden, Wiesbaden, Bad Pyrmont, Heiligendamm, Lauterbach, Puttbus; as well as in the Anglo-Saxon localities as Cheltenham, and Leamington Spa.

The architecture of most spa locations has become the symbol of cultural integration in the European environment. Spa towns made enormous effort to build up luxurious, magnificent spa complexes that were to become their “attraction”, not only by their architectural elements, but also by the quality of the treatments they provided, always using the latest medicinal knowledge and scientific methods. Their magnificent interiors combined extraordinary comfort with state-of-the-art medical technology.

Many spa towns represent unique architectural complexes with numerous historically valuable elements and objects. In many cases they still demonstrate extraordinary integrity and authenticity, as well as preservation of their genuine urban and architectural value and spa functions, with historically buildings still used for spa operations.

In addition, the most prominent spas cities have a special *genius loci* that is accountable to their unique architecture. Many spa locations combine the health treatments with the beauty of natural environment, creating unique complexes and compositions where natural and man-made structural elements give the convenient comfort of the spa environment.

Documentation of spa architecture can thus be relevant to preserve and valorize exceptional testimony of cultural tradition, buildings, technologies, landscapes of European identity.

2.2 The spa complex of Bad Nauheim

The complex of Bad Nauheim, with its Art-Nouveau architecture and cosmopolitan characteristics, is one of the well-known spas of Europe.

The design of this genuinely unique Art Nouveau complex - Sprudelhof and Trinkkuranlage, Kurhaus and Theater, Inhalatorium, Trinkkuranlagen, Thermalsolebad, Kurhaus, Gradierwerke - is due to the architect Wilhelm Jost, who was able to realize the ideas of the Grand Duke Ernst Ludwig of Hessen and Rhin.

Fig. 14 Johann Vincenz Cissarz, "Bad Nauheim", 1904. Promotional poster in Jugendstil graphic style.

Jost had the opportunity to study important modern spa layouts and furnishings built at the turn of the century at Berlin, Bad Elster and Karlsbad.

The landmark of the city of Bad Nauheim is the “Sprudelhof” (the Fountain Courtyard) which surrounds the bubbling mineral springs, justifying Bad Nauheim's vocation as a city of health.

The “Sprudelhof” creates a total work of art, which includes both the train station and the one kilometre distant Johannisberg. His basic concept was an artistically sophisticated frame of the main springs. An avenue should lead the arrivals from the train station over the spacious staircase, on whose sides are located the administration buildings, characterized by an elaborate and complex design.

The eye is drawn to the “Große Sprudel” (Large Fountain) and moves from there across the vast courtyard and the historic “Kurpark” (Spa Gardens) up to Johannisberg.

That means that the Sprudelhof is not only the centre of the new spa complex, but it is also the focus of the axis leading from the railway station to the town. In this way, the layout of the whole town was arranged in accordance with the modern precepts of Darmstadt Jugendstil.

Even if the continuation of the urban axis from the station to the large circular fountain is the centre of a symmetrical layout, this overall regularity is broken by a variety of interior courtyards and irregular details.

The curving roofs, portals and ornamental surfaces textures superimpose Jugendstil lines on a more classical overall design, while the varying heights, particularly of the roofs, create a diverse overall complex.

Between 1905 and 1911, immediately next to an existing park, Jost built the central engine hall including the boilers, a laundry and new buildings for operations of the salt production. Being functional buildings they are cut off from the spa complex proper by the railway line. They are carefully designed, even if they are functional buildings, and integrated in the overall layout, like an entrance for the spa visitors, even at the back of the station.

Fig. 15 The axis from rail station, passing through the Sprudelhof, till the spa gardens.

Jost also integrated his major buildings in the overall layout of the town, in particular the Pump Room Complex which replaced a covered iron hall. Jost created an inner area, made of horseshoe shaped walks, closed off from the road, but open on the adjacent park to the north.

At the first glance, many features of the central courtyard are reminiscent of late 18th century. But the clear arrangement of a path leading down a wide flight of steps into the courtyard with the basin of the Major Spring is not just reminiscent of baroque layouts, as it is also a variant of the layout plan of the 1901 exhibition by artists' colony at Darmstadt.

Two phases can be discerned in German Jugendstil: an early one, before 1900, that is mainly floral in character, rooted in English Art Nouveau and Japanese applied arts and prints; and a later, more abstract phase, growing out of the Viennese work of the Belgian-born architect and designer Henry van de Velde.

In Bad Nauheim both kind of decoration, natural and abstract, are represented.

The various ornaments are made up of organic forms as well as the geometric shapes typical of the style of the Vienna Secession. Common of all these ornaments is the subject of water, its plants, animals, and the mythological figures associated with it. Architecture, sculptures and garden design combine in a total work of art, rooted in the decorative principles of Jugendstil.

Jost was helped in the design of the complex by the sculptor Heinrich Jobst, Jakob Julius Scharvogel and Wilhelm Kleukens.

The many different stone sculptures used as architectural decorations represent another variant of Jugendstil. Aquatic animals, tritons and small mermaids decorate capitals, door frames and friezes in a humorous fashion. They are reminiscent of Munich rather than Darmstadt models, for example book illustrations or other graphic works.

Portals, quoins at the corners, mansard roofs, gables and large roofs turrets are only a few of the features in the modernised baroque style that Jost used here. But his buildings are not neo-baroque in the sense of an historical revival; all stylistic elements are reinterpreted from a Jugendstil perspective, and he reduced ornamentation to a few significant examples.

The treatment of the corners with their pilasters follows the formula of past architectural styles, yet the ornaments are more freer and modern.

The facades are decorated with wave-like horizontal patterns incorporating gilded spherical shapes reminiscent of carbon bubbles rising from the mineral water. This kind of abstract ornament may have been influenced by Olbrich's ornamental decorations of around 1900.

Stylized waves and bubble-like shapes are the leitmotiv of the Bad Neuheim spa, appearing also in ornamental details of the balustrades in the arcades, and even in the simple geometric ornaments of the fingerplates on the doors.

Regarding the prevalent colours, the interplay of grey shell limestone and rough white render, red roof tiles and the green bronze cladding of the roof turrets and gutters, creates a cheerful ensemble of contrasting colours. The stained glass present a prevalence of blue, recalling the water as most of the decorative motifs.

Abstract

Literally, revitalization has been regarded as an understanding of an activity or an effort to vitalize back an area within city or part of the city which was vital before. An area need to be revitalized because this area had been suffered or has degradation in infrastructure, utilities, as well as socially and economically. The process of revitalization of this area includes improving physical, economic and social aspects. Revitalization approach must be able to recognize and exploit the potential of the environment (history, meaning, unique location and the image of the place) that supports the local wisdom of an area or region. An effort of revitalization will support the identity of the city.

An activity of an area's revitalization as well as building's revitalization should be applied through a variety of aspects from physical and non-physical. In this case, physical aspects will include building form itself and its infrastructure, and non-physical aspect will be related to social, economic and culture of the community who live within surrounding area. It is intended to deliver positive impact for the surrounding area, particularly to enhance the quality of the environment and the community as well.

In the theory of revitalization which has been related to urban planning, revitalization could be categorized as a highly complex activity. In the implementation of revitalization, it is not only related to buildings, but also related to the area and the surrounded environment which will be linked to urban planning.

This paper is a comparative analysis between the three case studies in the application of revitalization concept for port area which has been known as an icon as well as an identity of the city. Case study of Clarke Quay-Boat Quay Singapore has been conducted as a succeeded case study of revitalization for port area in Singapore. On the other hand case study of Albert Dock Liverpool has been conducted to represent as an old area which has been designated as grade 1 of conservation area in Liverpool. And finally, the third case study is Sunda Kelapa Port in Jakarta, as an old town of Jakarta which had been designated as a conservation area in Jakarta. As a conclusion, it will be delivered a characteristic of three of port areas as an identity of the city.

Keywords: revitalization, port area, preservation, identity of the city

1. Introduction

In the activity of conservation either area's conservation or building's conservation, there are some terms to be underlined as follow: conservation, preservation, adaptation, conversion and revitalization.

Either revitalization or conservation, both of them have the same objective. Those activities have aimed to conserve and preserve historical sites/ areas or historical old building which become an icon or an identity of the city. Although both of those activities have the same objective, they are also having different concept in the understanding and the implementation. If the concept of conservation will be implemented to an object such as old buildings for example, on the other hand the concept of revitalization will be implemented not only to old buildings but also to historical sites/ areas. Literally, revitalization has an understanding as an activity to re-vitalize a function of an area which is lack of utility and not livable anymore.

Purwantiasning in her research about Conservation and Economic Development (2004) stated that conservation can be defined as a breathing life into old buildings, especially those that have the character of historical and has a meaning for a city. This surely cannot be left without any effort to preserve it. But the old buildings will not only require preservation efforts without referring back to the original function of the respective historical masterpiece. To this old buildings need to be breathed a life, thus that the figure of concrete is no longer like meaningless blister plant, but could be kept alive and give each image in accordance with its character.

Rypkema and Tiesdell (1996) in their book about revitalization of old buildings in cities, alleging that the old historic buildings mostly does not have adequate utilities so that the building is not feasible and does not have a value in accordance with their respective functions. The weakness in most of the old buildings in the end causing the buildings not functioned as it should be. With all those problems, revealed various efforts to revive old buildings in some countries that have historic building legacies. One example is in United Kingdom especially in the city of Liverpool, the town that has a lot of old buildings. From this background, then the research was started so that the success of the city of Liverpool, one of the cities in the United Kingdom which has many old buildings may be adopted by Indonesia, as a country which also has many old buildings were abandoned. Certainly can always remember about a statement that a great nation is a nation that always appreciates its legacies of history.

Furthermore, Purwantiasning in her article about “Aplikasi Konsep Konservasi Pada Kawasan Bantaran Sungai Studi Kasus: Clarke Quay” – “An Application of the Concept of Conservation on the River’s Banks, Case Study: Clarke Quay”, has discussed that the areas of conservation which have been regarded as an old historical sites with lack of utilities and not livable anymore, could be revitalized as a new place with new function. This effort will support the condition of social, economic and culture of the area. And as a result the succeed implementation will improve the quality of the environment as well as the quality of the human being within the area.

Revitalization is not only an activity which has been oriented to the physical solution, but also has an aim to enhance the economy of the community as well as their culture. To implement the activity of revitalization, there are some parties who need to be involved, because it will not work by government’s fund only, the roles of the community and their involvement are important as well. It should be underlined that the involvement and the roles of community will become main component of the activity of revitalization.

Basically, the activity of area’s revitalization in Indonesia has begun since 2001 which has been regarded as a sustainable program by central government which had delivered a stimulus fund to the local government. By delivering the program from central government, local government should be encouraged to enhance and improve the condition and the quality of historical sites within their city and could maintain their city as an identity of the city.

2. General Definition of Conservation and Preservation

In the 19th century, a jurist of the University of Copenhagen, Denmark, JJA Worsaae said that, “*Big nation is a nation that does not just look at the present and the future, but would like to turn to the past in order to see their passed historical journey*”. Similar to the speech above other expression emerged which confirmed by philosopher Aguste Comte with his tagline “*SavoirPour Prevoir*”, which means studying the past, see the present, to determine the future. Looking at the past that expressed by looking the physical existence of ancient building is certainly not only by seeing the figure of physical building solely, but the value of its history which attached to and wrapping it as a culturally meaning. Because the appearance of this meaning-wrapper can joined to determining the identity for urban area functioned in the future.

However, the problem that arises is how close we will be able to understand the term “Conservation”, which is now has undergone a change comes up with a new term, “Old-Historical Building”. In fact the

term conservation and preservation itself, has been used with various meanings. Preservation is a type of intervention aims to protect and repair of historic buildings, and in general the preservation term is widely used in America (USA). Similarly, the Conservation is an action to keep intact to as much as possible of the existing historic building's elements, one of them is with the traditional repair method, or with synthetic materials and current technology, and the term of conservation is more widely used in the UK and Australia (Larsen, 1994). With its diversity of understanding, finally other opinions appearing regarding about the preservation term as an effort to create or bringing back something where exactly as the original state without any change, including efforts to prevent the destruction, while in conservation term, conservation is an effort to conserve old building, efficient the usage and set the direction of development in the future. Even in the Burra Charter, conservation definiton may include all maintenance activities and in accordance with local conditions and situations and may also include teh act of: preservation, restoration, adaptation, reconstruction and revitalization (Purwantiasning, et al, 2013).

3. Illustration of Revitalization

Revitalization in Indonesia could be defined as an activity to preserve cultural heritage without doing any changes. For example, the activity of revitalization in Indonesia could be shown in the revitalization of Prambanan Temple in Central Java. As one of impact from natural disaster in 2006 – earthquake – the revitalization of Prambanan Temple was aimed to restore the authenticity of the cultural heritage of Prambanan Temple and to strengthen the structure which could be accounted in historical aspect, archaeological aspect as well as the technical effort in preserving a cultural and historical heritage. On the other hand, Borobudur Temple also one of historical temple which had been revitalized, but these days Borobudur Temple had degraded in quality, thus Borobudur needs to be revitalized again. Local government as well as Central Government have concerned with this condition, because Borobudur Temple has been regarded as the biggest Buddhist Temple which has high historical value. The potential spiritual value of Borobudur Temple and the surrounding environment have encouraged government either local or central to get some funding from many sources either from local or international who concern about historical heritage

The activity of building or area revitalization could be implemented through some aspects from physical or non physical. Physical aspect will cover the form of the building itself including the infrastructure within the building and non physical aspect will be related to social aspect, economical aspect and cultural aspect from the community who live in the surrounding areas of historical site. It is aimed to give positive impact to the area itself and surrounding area, particularly to improve the quality of the environment as well as the community. Thus could be concluded here, that the activity of revitalization should be related to the role and involvement of the community itself. The needs and interest of the community could be delivered into this activity. The program itself could be combine one to another within community development program through revitalization program.

Fig. 1: Complex of Fatahillah Museum which is regarded as a part of Jakarta Old Town. This area is one of designated conservation area which had been chosen by government as an object for revitalization of historical heritage.

Source: Private documentation, 2013

4. Revitalization of Historical Site

In the theory of revitalization, revitalization cannot be separated from urban planning. Related to urban planning, revitalization could be defined as a complex activity which should be related to some

aspects and parties. In the implementation, revitalization is not related only to the building, but also related to the surrounding area and environment within it. In the implementation of revitalization, it should carry out through several stages and will require certain period of time. It because in this activity will need some different thought and understanding in some aspects. Stages in revitalization will cover some important things as follow:

1.1 Physical Intervention

Physical intervention is an initial physical revitalization activity and will be implemented in stages, will cover the improvement and enhancement of the quality and physical condition of the buildings, green line, transportation system, signage and open spaces within historical site. Referring to the statement that image of the area is related to visual condition of historical site, thus this physical intervention will be needed to attract visitors. Issue of environment particularly sustainable environment become an important matter, thus this physical intervention should concern about environmental context.

1.2 Economical Rehabilitation

Revitalization which has been initiated with the process of urban artefact rejuvenation should support the process of economical rehabilitation activity. The improvement and enhancement of physical area in short period should accommodate economical activities either informal or formal (local economic development). These economic activities should enhance the value of urban area. In the context of revitalization, there should be delivered mixed use function within historical sites which will support the activities of economical and social within area (new function or new vitality).

1.2 Social Revitalization

The successful of revitalization could be indicated by the environment itself, the environment should become an interesting place to be visited, the environment should be a liveable place for the community surrounding historical area. It is not about a beautiful place after revitalization, but it is about how the place becomes an identity of the city which could bring positive impact to improve the quality of life for the community either social life of the community or economical life of the community.

Ridwan Kamil in his article has stated that an area could be revitalized if the place has some reasons as follow:

- a. Degradation of economical activity
- b. Degradation of spatial and physical quality of the buildings
- c. Degradation of the image of the historical area
- d. Lacking of area's infrastructures

5. Case Study of Clarke Quay and Boat Quay

Boat Quay and Clarke Quay is one of several conservation areas in Singapore. This area has been designated as an area of conservation since many years ago. Today the area of Boat Quay and Clarke Quay become place of interest for tourist either domestic or international. This area had been changed from an old port area to be an interesting commercial and business area in Singapore.

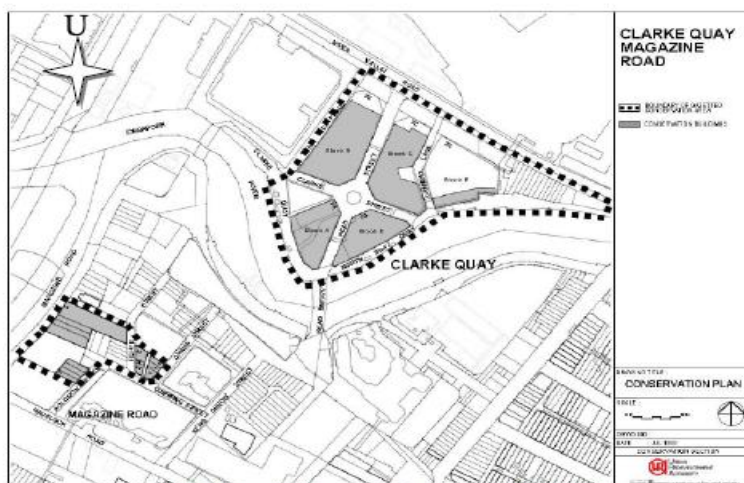

Fig. 2: Map of Clarke Quay and Boat Quay area. This area had been designated as conservation area in Singapore

Source: Urban Redevelopment Authority, 2013

Condition of this area before revitalization was very bad; Singapore River was a dirty river which supports the lacking of infrastructure of this area. Boat Quay and Clarke Quay used to be a port area which had many fishermen's boats and local traders. This condition had made the river full of economical activities and the condition of the buildings all the way Singapore River was very bad. The buildings were lack of utility, the areas were lack of infrastructure, and the buildings were almost completely destroyed. This condition had encouraged government to see the potential of this historical site as port area. By delivering revitalization program, the area of Clarke Quay and Boat Quay had been changed dramatically; the improvement of building appearances, the quality of economical aspect, social aspect as well as cultural aspect had been improved gradually.

The activity of revitalization within Boat Quay and Clarke Quay was based on conservation consideration from Urban Redevelopment Authority (URA) which has a specific criteria and requirement to decide which buildings of areas that feasible to be preserved or conserved. An area could be designated as an area of conservation if the area has some criteria such as specific character, historical value; the area will contribute in enhancing and improving the quality of the buildings as well as the surrounding area.

Fig. 3a, 3b, 3c: The condition of Boat Quay and Clarke Quay before revitalization
Source: Urban Redevelopment Authority, 2013

Fig. 4: Colourful buildings within area of Clarke Quay
Source: Private Documentation, 2013

Based on the above requirements, the area of Boat Quay and Clarke Quay had been designated as a conservation area, because this area have specific historical value and this area could be regarded as a combination of several cultures from Chinese, Indian, and Malay. It has been shown in the form of the buildings within area. As a result of the revitalization of this area, this area becomes colourful and livable, and become an interesting place to be visited as a tourism place.

Fig. 5a, 5b: Buildings within area of Boat Quay, the buildings used to be warehouse of port area, but today those buildings had been revitalized become new function as bars, restaurants, and cafes.
Source: Private Documentation, 2013

6. Case Study of Albert Dock Liverpool

Different country should have a different ambience and different environment. As the biggest port area in England, Albert Dock in Liverpool will represent the succeeded of the implementation of revitalization concept in England. As one of several designation area of conservation, Albert Dock in Liverpool has a specific character to be observed. As we recall, this port area has been known as a place that Titanic had been berthed many years ago before sinking.

Generally, city of Liverpool after World War II had been faced by destroyed environment including housing, business district and the city center as well. Within 1950s and 1960s, Liverpool had been encouraged to redevelop its city center and the neighborhood particularly housing for the community which is feasible and affordable such as flats. After the highly development within city within 1950s and 1960s, Liverpool had been declined economically and socially within 1970s and 1980s, it because the economical recession. This condition had affected the city of Liverpool. Liverpool became abandoned city in the past 1980s and become the highest unemployment city in England.

Fig. 6: Map of Albert Dock area. This area had been designated as conservation area in Liverpool
Source: <http://www.myliverpoolconference.com>, 2013

On the other hand, in the same year 1980s, area Albert Dock which has been regarded as dock and warehouse area in Liverpool had been designated as a historical area by local and central government. The activity of revitalization in Albert Dock area has been implemented in stages. New function within area which covers leisure (bars, restaurants, cafes), business (rental offices, shops), residential (rental apartment, hotel) and entertainment (museums, gallery) had been delivered. This concept has a similar concept with port area in Singapore-Boat Quay and Clarke Quay. Central government had seen the potency of the area and develops it as a commercial area. By delivering a concept of revitalization within area, the historical site of Albert Dock will not altered and remains the same atmosphere without changing the character of the buildings and potency of the surrounding area.

Fig. 7a, 7b: pictures of old Albert Dock in 1930s and 1980s, left picture shows the condition of Albert Dock which full of fisherman boat, crowded and the buildings look like abandoned buildings. And the right picture shows the face of another side of Albert Dock area.

Source: <http://www.chesterwalls.info/gallery>, 2013

It has been stated that area of Albert Dock has been part of Liverpool's landscape for over 160 years and remains a key feature of Liverpool's world-renowned Waterfront. Several old buildings within area of Albert Dock and Waterfront had been designated as a Grade I listed old building status in 1952 in Liverpool and become a conservation area in 1976. Those buildings had been transformed with new function in the early of 1980s and had been developed into the most popular tourist attraction and place of interest for domestic and international tourist. The changing of Albert Dock and the surrounding area will encourage most of private sectors to invest their fund. This condition will improve and enhance the quality of the area as well as the community within the surrounding area of Albert Dock. The historical and architectural importance of the Albert Dock become a special character of Liverpool City. This area of Albert Dock remains the same as an identity of the city of Liverpool. Tourist either domestic or international will feel the ambience of the Albert Dock as a former port in Liverpool.

Fig. 8a, 8b: Today's pictures of old Albert Dock, left picture shows the view of Albert Dock which still remains the same character of red bricks and red pillars, this row of building consist Tate Gallery, Museum of Maritime, Cafes, Restaurants and Bars. And the right picture shows the face of another side of Albert Dock area which consist new modern building – Museum of Liverpool which contextual with the character of waterfront area.

7. Case Study of Sunda Kelapa Jakarta

Sunda Kelapa, Jakarta is a part of Jakarta Old Town Area which has been regarded as a conservation area in Jakarta. Sunda Kelapa is a former name of Jakarta, is has been known as a port area in Jakarta. Sunda Kelapa was an important place because this place is a heart of Jakarta as economical activities had been centered within it.

Fig. 9a, 9b: Map of Sunda Kelapa area. This area had been designated as conservation area as part of Jakarta Old Town Area. Left picture shows the area of Sunda Kelapa, and the right picture shows several old buildings within Sunda Kelapa area which have been designated as a listed old building.

Source: Google Earth, 2013

Today, Sunda Kelapa has been known as a tourism area which deliver some attraction within area. The area of Sunda Kelapa has several place of interest such as Menara Syahbandar (harbor tower), Museum Bahari (Maritime Museum), Sunda Kelapa Port Area, Galangan VOC (VOC Dock), Masjid Luar Batang (Mosque). These old buildings have been designated as a listed old buildings within Jakarta Old Town Area. The condition of these buildings are relatively bad, physically these buildings need to be revitalized. Several proposal either from private sectors or NGO who concern about historical sites had been submitted to government, but there are still no significant action has been implemented.

By presenting two case studies in Asia – Singapore and in England – Liverpool, researcher will gain more experiences to present some alternatives solution for better quality of Sunda Kelapa area. Sunda Kelapa area has many potency to be explored, thus this will become main commodity for Jakarta particularly and Indonesia generally.

Fig. 10a, 10b: Today's view of Sunda Kelapa area. Left picture shows the Museum Bahari (Maritime Museum) view from Menara Syahbandar (Harbour Tower). Right picture shows the situation of Sunda Kelapa Port with building material's freighter.

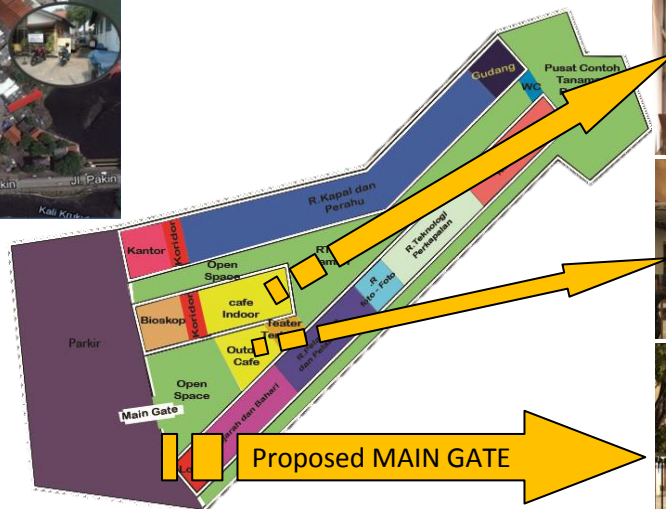

Source: Private Documentation, 2013

Several buildings within Sunda Kelapa area had been transformed into new function. For example, Galangan VOC which used to be a ship workshop, had been transformed into restaurant and cafe. And in the future, Museum Bahari (Maritime Museum) will be revitalized into new function as an outdoor cafe which still keeping the atmosphere of the museum. This building used to be a warehouse

A photograph of a traditional Indonesian courtyard (pekarangan) with a paved stone floor, white buildings with red-tiled roofs, and a green metal pole in the foreground.

An aerial photograph of a residential area in Semarang, Indonesia. The map shows several streets, including Jalan Paksi, Jalan Krayan, and Jalan Bawor. A red rectangle highlights a specific building complex. Three circular inset photographs provide closer views: one shows a street scene with parked motorcycles; another shows a group of people standing near a building; the third shows a view from a vehicle looking down a narrow alleyway. Labels like 'Masjid Darussalam' and 'Kali Kranggan' are visible on the map.

Requalification of historic buildings with special reference to the typological, technical and energetic aspect of collective residences

Elena ROMANO

DICAR – Department of Civil Engineering and Architecture, University of Pavia, Pavia, Italy
elena.romano@unipv.it

Abstract

The theme of the requalification and reuse of historical and architectural heritage is a topic of great interest in a country like Italy, where many of the public functions are located in buildings of the past, for the excellent location and for the socio-cultural value that they have had over the centuries.

From here comes the interest of an investigation to improve technical and energetic performance of historical student residences in Pavia.

These buildings were constructed in very different historical periods compared to the times we are living. Today student residences should not only provide shelter, but they must "accommodate" students by offering them space in which to study, where to meet and share experiences.

The aim of this work is the definition of a useful tool for assessing the condition of a collective residence based on objective parameters through which define the possible actions on the same.

The assessment tool is organized in thematic areas, requirements and indicators to which are assigned different weights depending on the different incidence. For each thematic area are identified the requirements that must be met, and its system of indicators, which are associated the scores; the tool returns an overall score, determined by the sum of the partial scores for each thematic area. The different scores can determine the strategies and action priorities.

Keywords: Rehabilitation, Reuse, Assessment, Student residence, Performance

1. Introduction

The issue of requalification and reuse of historical and architectural heritage is a topic of great interest in a country like Italy, where many public functions are located in the buildings of the past, for the excellent location (often in the center of the city) and the socio-cultural value that have taken over in the centuries. These are buildings (sometimes entire blocks or parts of town) that have become benchmarks not only for the community living in them daily, but also of the entire Italian population and, in some cases, their reputation has been beyond national borders.

Considering that approximately 40 % of the artistic and architectural heritage of the world is in Italy, it is easy to understand that the requalification and reuse of this heritage is a challenge but also an opportunity for substantial growth. The challenge is the need to work in buildings and urban spaces of conscious and respectful of its history and identity, in order not only to preserve the image quality, but also to improve it. The opportunity for its development is given by the great "demand" of the culture that exists in today's society, where the possibilities of travel have increased in the past and said "cultural tourism" motivates thousands people (including students) to exhibitions, events and places that produce culture, motivated by the desire to share and learn and the desire to close the gap between him and the object of culture. The identity of Italian culture, at this time in search of survival and recovery, see precisely in the new forms of relationships between heritage and users new opportunities for development.

Fig. 1: Orthophoto of Collegio Cairoli.

From this awareness, the research group of the University of Pavia (coordinated by prof. Alessandro Greco) conducts researches on requalification and reuse of historical and architectural heritage, with special attention to the historic buildings used by university students, such as student residences managed by EDiSU (Organization for the Right to University Study).

Pavia is a small town (about 65,000 inhabitants) in northern Italy whose the University has a history of over 650 years; the life of the city is so closely linked to that of the University, attended by over 22.000 students, many of whom come from other regions and from other States. To this demand for temporary residentiality, the EDiSU responds by offering around 1,400 beds in 10 student residences located in the city, some of them in the centre of the city and others in more suburban areas. Among these student residences some have historical origin, such as Collegio Castiglioni (1429), Collegio Cairoli (1783) and Collegio Fraccaro (1800), that result to be inadequate under the typological, technical and energetic aspects.

This paper presents the theoretical foundations and the methodology used in the research phase for the requalification of an historic university student residence of Pavia: the Collegio Cairoli.

2. Energy improvement of historical and architectural heritage

The historic buildings now play a greater significance to the community compared to what happened in the past when it was hard to identify their importance. Such constructions in fact, beyond their beauty and the recognition of their value, are essential as bearers of our historical identity, testimony of the period in which they were built.

Although, sometimes, the legislation allows invasive interventions not recognizing the building in question enough important to make it the subject of protection, however appropriate, considering the historical value that covers, subjecting it to a real restoration.

In the restoration, as is known, does not lie the solution more economic or practical, but the one most appropriate to the quality and value the object, by definition unique, unrepeatable and unrecoverable once it is been irreversibly damaged.

The category of so-called historic buildings, including both buildings defined cultural heritage, both worthy of being passed down to their historical-documentary or artistic value, contains a comprehensive set of buildings and consequently, a considerable variety of characteristics, values and constraints.

The amplitude of the topic makes it difficult to establish interventions operationally valid, for the inability to govern such variety in a limited time. In order to establish a practical way to proceed, it is therefore necessary to define the scope of investigation, focusing on a specific area, which allows to restrict the variables.

The limitation of this research to student residences in Pavia, a field of investigation limited by the geographical point of view to a region with own legislation on the subject, and limited from the point of view of the type of building to historic buildings typical of the area, allows to assess in detail the operations that are compatible.

The interest for these buildings, beyond the variety of characteristics they have, comes from the fact that today are often subjected to transformation operations, in order to make them appropriate to the needs of the present.

At present can not be ignored the carefully evaluate to energy aspects of the restoration project, though, for the analysis of the regulatory framework at international, national and regional level, this type is excluded from the scope.

The restoration intervention will not be so transformed, but only enriched by a component necessary today that, when integrated with other aspects of restoration, not be more invasive but placed evenly throughout.

In the first place there must be compatibility between the intended use and building; result essential verify that the selected function does not require a reversal of the physical substance and form of the building to be restored, not only in terms of loads, but also what are the facilities and microclimate conditions necessary for the establishment of such a function.

Reasoning to the scale of the building it is possible to evaluate every single technological element, every system and every bioclimatic device, in order to propose interventions that are compatible with the possibility to modify parts of the building object of intervention.

It follows that, analyze the characteristics of the building and taking into account the regulations, you will have to assess whether and which interventions are practicable.

In this sense it is important to understand where to stop: it is not always possible to find a meeting point between conservation and energy upgrading.

3. Typological and technical improvement of historical university

To achieve a good design on the intervention of the typological and technical improvement of a university residence is essential to understand what are the current needs of users: university students.

To do this it was necessary a temporal analysis of various university residences, taking into account both the Italian and European experiences.

To allow a comparison between the different entities, has been prepared a card - type which have been identified the particular characteristics of the university residence buildings. For each project are explained the technical data, space-time, quantitative and qualitative data based on the development of some parameters.

These are:

- Place. The geographical parameter reveals the residential tradition established in different countries and makes it recognizable the cultural and projectual matrix.
- Time. The historical data is important to understand the pattern of spatial organization in relation to economical and political trends of the society that has produced the space.
- Characters morpho-typological. The compositional and formal indicator is closely linked to the previous two, because it's determined by the building traditions of a place or of a given period.
- Quantitative data. The dimensional aspect is a fundamental parameter on both the quantitative and qualitative terms of the project. It is also able to determine the level of socialization of users and their interaction with the environment.
- Localization in the area. The university residence requires a high degree of integration with the environment, such as to establish three types of relationships at three different scales: relations with the region, relations with the structure of the city and relations with the university.
- Qualitative characters of the building. Through the reading of elements such as the provision of services and facilities you can determine the degree of attractiveness of the residence.
- Qualitative characters of residential spaces. The data for the model of organization of the group, the type of group rooms and their approval, allow to identify the size and modes of socialization.

Fig. 2: Card – Type of university student residences.

To the model of student no more massified, with different needs even within the same environmental and social context, corresponds the analysis of international projects, even more recent, of university residence from which it is deduced as compared to the types identified even in the most updated manuals on the subject, the reality present a multiplicity of formal and organizational solutions very rich and varied.

The traditional and simple organization to hotel remains in a smaller number of cases, but with different joints ranging from the case where each room is equipped with bath those where every bathroom is attributable to two or more users.

Alongside this classical solution appear most complex joints such as those of integrated core (rooms that share a number of services, including kitchen/living room) or studio flat (complete and autonomous residential units for the presence of bathroom, kitchen and living room).

Unlike the organization as a hotel, the integrated core and studio flat record more spatial and functional articulations able to realize life environments less uniform, more stimulating from the point of view of perception and appropriation space.

These types also adapt well to different distribution organizations of the building, are them a corridor or central core and allow the design of residential unit size variable (from two to four rooms).

The organizational models of integrated core and studio flat, in some aspects, are the negation of collegiate life by increasing the maximum privacy, while reducing to the minimum the opportunities for socialization that arise from the sharing of activities to carry out in the common areas.

As regards the number of beds per room the majority of the residential units includes single rooms; double rooms are in Italian and American student residences, while in England and Germany these cases are negligible.

The living room, TV room, games room, study room with adjoining eventual library and laundry are the collective services most widespread and mainly located on the ground floor and distributed to the floors.

The kitchen as a centralized service and unique for the entire structure or even for multiple neighboring facilities and managed by staff (canteen) tends to become widespread service available to a contained number of students taking mostly the configuration of the kitchen at floor in order to allow the self-management of meals at least once a day to users that even with respect to this function follows different and individual rhythms of life.

Bars, cafes, restaurants and shops, which are present in a number of student residences, are nearly always expected open to the neighborhood and designed to avoid phenomena of spatial segregation and social marginalization resulting from strictly monofunctional territorial planning. Exceptional and only in some foreign residences there are nurseries for child custody of students and chapels managed by religious communities for students of the theological faculties.

Fig. 3: Graphical comparison of organization model, distribution system and collective facilities distribution in Italian and European student residences.

Fig. 4: Graphical comparison of collective facilities in Italian and European student residences.

Fig. 5: Graphical comparison of technological elements in Italian and European student residences.

4. APUR-tool: Assessment Performance University Residence

The inadequacy of the technical-typological aspects is found in the different parts that compose a student residence (accommodations and rooms, communal services and building distribution) and in construction systems, typical of historic buildings (bearing walls poorly flexible and adaptable, shortages of plant equipment, ecc...). From the point of view of energy saving, the historic building usually presents problems related to the absence of building components (thermal insulation) or the absence of a programmed maintenance of the casing.

The aim of this work of research is the definition of a useful tool to assessing the conditions on the state of the art of a collective student residence based on objective parameters through which define the possible actions on the building to improve the energetic, typological and technical aspects.

APUR tool (Assessment Performance University Residence) is organized in 5 thematic areas (Site quality, Comfort and well-being, Accessibility, Functionality and Safety), 15 requirements and 45 indicators to which are assigned different weights depending on the different incidence.

For each thematic area are identified the requirements that must be met, and its system of indicators, which are associated the scores; the tool returns an overall score, determined by the sum of the partial scores for each thematic area. The different scores can determine the strategies and action priorities for the improvement of functional and energy performance of the building.

The purpose of the indicator assessment tool is to illustrate the overall performance of a student residence evaluated in structured way. The calculations are made possible by the Excel tool.

The user of the tool needs first of all to fill, in the phase 1, a general information sheet of the building which is dedicated to the collection of general information regarding the building under analysis; this information is used to provide a synthetic description of the building, with an indication of the dimension, the activities performed and the number of users.

Indicator evaluations are done in the phase 2 with an assessment sheet.

Each indicator is assessed by defining a level from A to E. This is done by using the letter "x".

The Exce tool computes values that describe the quality of the performance as an overall APUR score. The APUR score is a value between 0 and 100 representing the performance of a student residence in respect of the APUR framework.

The indicators are divided into five main thematic areas:

- Site quality.
This category assess the location of the residence in the city, the closeness to public transports and the security of the area.
- Comfort and well-being.
This category includes the evaluation of the parameters related to the healthiness of the indoor environment and the comfort of people living in the building or simply visiting it.
- Accessibility.
This category includes the indicators related to the easiness in using the building by people and the easiness of movement inside the building.
- Functionality.
This category is related at the adaptability of the spaces, at the maintenance of the building and at the quality of the facilities.
- Feeling of safety.
The last category is mainly related to the building structures and equipments that could improve the security and safety perception of people and object inside the building.

4.1 Site quality

This section contains the indicators identified to assess the level of site quality of the student residence. Three performance indicators have been identified in this thematic area:

1. Location. The location is related to the insertion in the urban context of the city and at the closeness of the Universities.
2. Transport. Transport refers to the closeness of public transportation, of car and bike sharing point and the presence of bicycle racks, parking area and cycle paths to city center and to universities.
3. Security. This indicator assess the presence of personal and material security in the building and in the external area and the distance of crosswalks from the entrance of the student residence.

4.2 Comfort and well-being

This section contains the indicators identified to assess the level of health and comfort for the indoor environments. Eight performance indicators have been identified in this category:

1. Thermal Comfort External Wall. Thermal comfort is related to the thermal conditions of an external wall, based on the transmittance and thermal lag values.
2. Thermal Comfort Roof. Thermal comfort is related to the thermal conditions of the roof, based on the transmittance and thermal lag values.

3. Thermal Comfort Ground Floor. Thermal comfort is related to the thermal conditions of the ground floor, based on the transmittance and thermal lag values.
4. Thermal Comfort Windows. Thermal comfort is related to the thermal conditions of the windows, based on the transmittance value and type of glass.
5. Indoor Air Quality. Indoor Air Quality is related to the quality of the indoor environment in terms of temperature and relative humidity and the presence of mould growth risk and air polluting substances in the indoor microclimate that could be a hazard for human health.
6. Water Quality. Water quality refers to the availability of water and the presence in it of chemical or biological pollutants. The indicator evaluation includes the presence and the quality of system for water re-use.
7. Visual Comfort. Visual comfort assess both the illumination of common spaces and private spaces. The presence of light in a room also has a positive effect, psychologically and biologically, upon human well-being.
8. Acoustic Comfort. Acoustic comfort is related to provide acoustic conditions in a building that facilitate clear communication of speech between the users of the building, and silence whenever needed.

4.3 Accessibility

This section contains the indicators that play an important role in the evaluation of the easiness of use of the indoor environment of a building for people living. One performance indicator has been identified in this category:

1. Usability. Usability, is concerning the quality of use for a building meaning that it is efficient in use (use of resources, productivity, effectiveness, rationality) and that offers the desired effect in use (increasing the value). Usability mainly focuses on accessibility and the easiness of movement inside the building.

4.4 Functionality

This section contains the indicators identified to assess the level of functionality in use. Two performance indicators have been identified in this category:

1. Adaptability. The adaptability of student residences could be defined as their ability to be changed or modified to make suitable for a particular purpose. Adaptability includes aspects of flexibility and convertibility. Good adaptability of a student residence should assure its functionality over time and during changes in user demands and needs, and new ways of using the building.
2. Service and maintenance. Service and maintenance is related to the quality of the collective and private services of the student residence and to the level of planned maintenance.

4.5 Safety

This section contains the indicator identified to evaluate the building structure from the point of view of safety, considering the building, the people working or living in it, the visitors and the valuable objects inside it. One performance indicator has been identified in this category:

1. Safety. Safety is related to the evaluation of the possible risks that could pose a menace to people and the objects in the building. This indicator considers the presence of adequate escape routes and the compliancy to national regulations in terms of safe environments.

Abstract

Preserving our cultural heritage, particularly when the economic resources are lacking, is not only a matter of techniques, but, first of all, a matter of priorities. Defining these priorities is not an easy task and it is subjected to social pressures and to subjective judgments. This paper proposes an analytical model aimed at parameterizing the intervention priorities through objective criteria, in order to obtain a uniform picture of the vulnerabilities in a defined territory. The final product is an ordered list of both architectural and artistic-cultural assets, which need urgent actions for their conservation and for which the time factor is crucial.

The proposed algorithm is able to quantify the level of urgency of a possible conservative intervention, evaluating simultaneously different parameters on the level of decay, on the risk conditions and on the touristic and cultural potential of the single asset. It represents therefore a fundamental instrument to optimize the available resources, concentrating the interventions where there is correspondence between maximum risk and highest efficacy in stopping the decay.

The model was applied factually to the area of the Parma province, obtaining the hierarchical identification of the urgent interventions to be carried out for the safeguard of its cultural heritage.

Keywords: vulnerability, cultural heritage, intervention priorities, economic planning, preservation management

1. Introduction

In a period of crisis, the substantial reduction of the economical supplies forces any organization aimed at the conservation and enhancement of cultural heritage to optimize the interventions, with a specific strategic attention. Which scientific criteria, rigorous and shared, can be adopted to choose the destination of the limited resources available? Is it possible to spot with homogeneous criteria the cases in which the time factor is crucial to allow the transmission of our cultural heritage to the future generations?

In order to elaborate rational and sustainable intervention strategies in this field, the Fondazione Cariparma, a bank foundation operating on the Italian province of Parma, has developed a strategic research project in co-operation with the Department of Civil, Territory, Environment Engineering and Architecture of the University of Parma.

As for most parts of Italy, Parma and its province boast a huge historical, artistic and cultural heritage. Fondazione Cariparma, in its decades of activity, has given a great contribution to preserve and promote this wealth. The study presented in this paper, carried out from 2011 to 2012, was aimed at identifying which cultural assets (settlements, monuments, artefacts etc.), among those liable to

funding by the Foundation, were threatened by impending dangers. The results of the research were then summarized in a Catalogue of vulnerabilities of the Cultural Heritage of the Parma province.

2. Existing methods for priority lists related to different risk typologies

The issue of defining priority lists for the interventions on the cultural heritage is not a novelty: the very large quantity and high quality of the architectural, artistic and cultural assets prevents any private or public organization from facing the whole of the necessities for the conservation and recovery of the cultural heritage it owns or has competence upon [1].

From a theoretical point of view, the largest problem faced by whoever has to take these decisions is the correct definition and quantification of the risk level, in order to evaluate as objectively as possible the priorities in intervention and conservation. Already in 1984, the Varnes and IAEG report for UNESCO [2] defined an equation for the risk level which later found a quite large diffusion. Although it was originally defined for the hydro-geological risk, in order to define landslide hazard zonation, this equation can be adapted to other situations and it was chosen as a basis for the present study. It is based upon the distinction of the concepts of hazard, vulnerability, exposition and risk:

- Natural hazard is the probability of occurrence within a specific period and within a given area of a potentially damaging phenomenon.
- Vulnerability means instead is the degree of loss expected from the occurrence of a natural phenomenon of a given magnitude.
- Exposition is the value (economic or social) exposed to the hazard.
- Risk is the expected degree of loss due to a particular natural phenomenon and it is obtained multiplying hazard, vulnerability and exposition.

Other ways to obtain a priority list were elaborated for other types of risk [3, 4, 5]. Recently, in Italy, the law for the reduction of the seismic risk [6] on cultural heritage [7] has introduced a new model to define the vulnerability at a territorial scale. This model, limited to the architectural heritage and based on a typological subdivision of the built heritage seismic behavior, has shown some limits in the application [8].

These few examples show how difficult it is to find a valid, efficient and shared solution for a single typology (listed architectural assets) and for a single risk typology (the seismic one). Therefore, it is even more difficult to define a comparable and objective criterion as the scope of application widens (to architectural, artistic, archeological, archive assets) and the possible damage sources considered increase.

3. An instrument and its first application

In the proposed model, the wide set of the cultural heritage was considered as an integrating part of the economic, social and historic context [9, 10, 11]. It was then divided in two categories: the architectural assets and the historical-artistic assets (artworks, relics, archeological remains, books, documents, etc.). For each category, a suitable file card, detailed in a specific paragraph, was developed in order to identify the asset and to collect information on the preservation status, the risk evaluation, the perspectives for its use and enhancement. All these parameters were then considered in order to define an index of the appropriateness of the intervention.

It is important to underline that this research is based on the fundamental concepts of conservation, restoration and development, in a modern conception of preservation of cultural heritage [12]. This requires not only the single asset to be protected, but also to be integrated synergistically with the needs of society, making a good use of it, also with an economic and social value. In this integrated vision, all the interdisciplinary competences available in the Parma University Departments charged with this study (DICATeA and LASS) were applied, looking for the collaboration of all the stakeholders involved.

3.1 Structure and parameters of the file cards

The file cards are divided in two parts. In the first one, the asset is identified through its name, date of execution, author, client, execution technique, dimensions, transformations or changes; then, it is analyzed from a historical-artistic point of view through a brief comment based on the bibliography reported in the footnote; some pictures and (if meaningful) graphic representation complete the first part. The second part takes into consideration the aspects that affect more directly the urgency level (U) of the intervention. These quantities were evaluated through direct surveys, interviews with the stakeholders, consultation of technical documents, specific bibliography. The preservation status (S) considered both the structural stability of the building and the aspects related to the image conservation of the artistic assets, with a qualitative assessment of the decay phenomena. The final judgment on the preservation status was then modified in consideration of the actual possibility to use safely the container building. For example, in case of roof damage with water leaks, the parameter S becomes very high, indicating a great urgency for the intervention, given the very fast decay produced by the presence of water inside the building.

The risk assessment (parameter R) considers the external phenomena which can jeopardize the preservation status of the asset. They are divided in two typologies: environmental risks (floods, landslides, earthquakes or pollution) and criminal offences (quantified through the number of vandalism, theft, breaking and entering in the past opposed to the presence of alarm systems or surveillance. At last, also the possible risks induced by the asset itself on public safety are taken into account. Without entering into difficult technical assessments, these risk levels were deduced from existing specific maps, e.g. seismic or hydro-geological zoning.

The enhancement and potentiality parameter (V) summarizes in a single value the expectations and the abilities to promote the asset, i.e. its re-launch potential. This is an important parameter, rarely considered, to understand the intervention impact on the cultural life of a community. The intervention to preserve a specific asset, if seen from a territorial point of view, has more effects if the asset has a strong historical, artistic and architectural value. At the same time, it will be more efficient if it is not a white elephant, but it is already included in a network of enhancement activities and touristic development. Therefore, the parameters taken into account are the cultural value, the touristic potential and the enhancement activities ongoing. Another parameter considers the potential increase in cultural value that a building can have based upon the goods it contains: an architecture which is also a treasure chest should have a higher urgency level, in order to preserve both. This is particularly relevant when immovable artworks, like plasters or frescoes, are concerned, as the removal (even for conservation purposes) of artwork conceived for that specific container involves a general loss in cultural value.

3.2 The “urgency algorithm”

The large variety of damages and risks encountered during the fieldwork has suggested considering in a critical situation all the assets whose static integrity or material existence was threatened to a point that the aspect is modified or the functions are limited or obstructed. The appearance is thus considered as the main feature of the artwork, together with the possibility for the future generations to benefit from it. The fieldwork has allowed to evaluate the real conditions of the assets and to define the parameters useful to quantify the level of urgency. On the base of these data, the following step was to compile a priority list for the conservation and enhancement interventions.

To this aim, a number was assigned to each input data (preservation status S, risk assessment R, enhancement potential V), even when these were qualitative rather than quantitative.

A specific algorithm was then elaborated, in order to supply a synthetic index (urgency level U) able to compare cultural assets with very different characteristics. The synthetic index is aimed at quantifying how opportune a possible funding would be: a high level of U corresponds to a high level of urgency, to the presence of risks and to the benefit for the community. Thus, a sort of Emergency List can be obtained, useful to evaluate the possible funding requests for conservation and enhancement interventions, concentrating them on the ones with higher priorities.

For the quantification of the urgency level, the previously described UNESCO equation [2] for hydro-geological risks was adopted as a reference. In that equation, the total risk was obtained multiplying the vulnerability with the hazard and the exposure. Arising from this model, a modified algorithm was then elaborated taking into consideration the probability of occurrence of a damaging event (risk assessment), the vulnerability of the assets (related to the conservation status) and the possible loss for the community (quantified in cultural value and enhancement potential).

As aforesaid, this computation system was applied separately to two different fields: architectures on one side and other cultural assets on the other side. This partition corresponds to the Italian partition of the different government departments responsible for cultural heritage and helps to reduce, within each field, the heterogeneity of the characteristics to be considered and of the possible decay phenomena. Of course, this entails two different priority lists, but this is also coherent with the large difference in the economic resources required to make interventions on a building or on an object.

The two file cards exposed in Figures 1 and 2 report the highest urgencies for the two different categories. On the architectural side, the XVIII-XIX century Casino dei Boschi, with its collapsed roofs, diffused decay, induced risks for public safety, high cultural value of the content and of the container, needs an immediate intervention to prevent the total loss. On the artistic side, the late XVII century frescoes in a baroque oratory, partly stained and detached, risk to lose their readability if not promptly restored, together with their container.

Besides taking a synchronic picture of the situations encountered on the analyzed territory, the model also allows, thanks to the use of a worksheet, to update easily the single files and also to add new cases or to cancel the ones that have been solved. Each change in the input data automatically modifies the U values and the ranking in the Catalogue Emergency List.

TRASFORMAZIONI/MODIFICHE SUBITE

BREVE DESCRIZIONE:

Nella complessa decorazione del Serraglio si ripropose il binomio, già sperimentato in ambito bolognese, del connubio tra figurista e quadraturista: le ricercate soluzioni prospettiche di Ferdinando Galli Bibiena si alternano sulle pareti dell'Oratorio con l'estro da frescante di razza del Ricci.

Le soluzioni proposte dal Ricci circa il complicato allegorismo mariano, tema su cui si innesta tutta l'iconografia decorativa dell'Oratorio, sono il tentativo di rielaborare in chiave personale le esperienze luministiche di ambito veneto, soprattutto del Veronese, mediandole con i fermenti più vivi e eloquenti del linguaggio emiliano del Correggio, dei Carracci, del Cignani e dell'Anselmi. Su un edificio a pianta centrale, con alternanza di absidi poligonali e semicircolari, la decorazione del Ricci si sviluppa su tutte le pareti e le volte: nella principale, raffigurò una scenografica Assunzione, di evocazione barocca, in cui la Vergine è sorretta al di sopra delle nuvole da un vivace nugolo di angeli visti, nelle pose più svariate, di sottinsù mentre ne agevolano l'ascesa al cielo. La posizione della Vergine, con le braccia aperte e viso rivolto verso il Figlio, la spazialità dilatata e la luminosità dorata, oltre che gli arditi scorci, sono un richiamo sentito alla cupola affrescata del Duomo di Parma mentre la plasticità e la cromia delle vesti, nella varietà dei rossi e degli azzurri e la facilità del colorire

non ignorano la maniera dell'Anselmi. Nei quattro angoli della navata, alternate a paraste a candelabre monocrome la *Modestia*, la *Semplicità*, la *Castità* e l'*Umità* scorciate di sotto in sù secondo i canoni individuati dal Ripa nella sua *Iconologia* appartengono alla complessa simbologia decorativa che si ipotizza ideata dal Prevosto don Cristoforo Cornacchia. Le paraste a candelabre, in voga nell'ambito quadraturistico felsineo, circondano le allegorie del Ricci interrompendole all'altezza delle absidi laterali per aprirvi nuovi scorci architettonici in cui, il Bibiena, sperimenta l'innovativa visione per angolo a due fuochi. L'illusoria apertura sulla nicchia est è costituita da due portici sorretti da colonne binate, distaccate per poter permettere di riguardare negli interstizi, con ai lati due brevi rampe di scale, appena scorciate sul fondo. Il colonnato sorregge una balaustra, decorata con inserto vegetale, in basso, e con vaso di fiori in alto. La compatta solidità della parete è alleggerita dalle strutture portanti di cui è difficile definire l'appartenenza ad un interno o ad un esterno. L'uso precoce, e per di più in ambito sacro, della visione per angolo superando quella con punto di fuga su asse centrale dell'epoca barocca costituirà il vero elemento innovatore. Del Bibiena sono anche gli scudi con gli emblemi mariani nei pennacchi del cupolino.

Durante il sopralluogo è stato possibile verificare la presenza di numerose infiltrazioni di acqua sulla superficie muraria. Nella cupola, in uno degli angeli al di sotto della Vergine, si è registrata la perdita di alcune parti di intonaco. Altro distacco piuttosto esteso si rileva in uno dei telamoni. Il custode, laddove possibile, ha prontamente conservato tutte le parti distaccate.

4. Work phases and stakeholders

The research was articulated in phases and lasted overall twenty months. The analysis of the province territory started with the interlocution with the stakeholders which could possibly receive funding by a bank foundation (thus excluding the private bodies). The width of the examined area suggested a partition in macro-areas. Within each macro-area, the Municipalities and the Dioceses were identified as the first privileged contacts. After a first letter presenting methods and aims of the research, the stakeholders were requested to supply the lists of the architectural and historic-artistic assets they owned and possibly the spokespersons to be contacted for the on-site surveys. These first lists were the starting point of the work, then compared with other sources, like art, history and tourist guides. Based on these lists, the identification of the most urgent cases could be done, analyzing each case with bibliographical in depth analyses, cartographic studies, archive documents and direct surveys.

The meetings with the local authorities, both civil and religious, revealed different approaches from the interlocutors: it was quite easy to obtain detailed lists of architectural assets, thanks to their fame, but it was far more complicated for the artistic-cultural ones, often neglected. For all the cultural and artistic assets which had not been pointed out by the Municipalities, the direct surveys were fundamental. The several meetings with the people in charge of the different objects, helped to obtain the minimum amount of information required.

After the survey, combined by a photographic reportage to increase the documentation available, a work phase was carried out aimed at deciding whether to insert the asset in the catalogue or not, considering its cultural value and its present state. From an operative point of view, the peripheral areas were faced first, leaving the more dense city of Parma for a following phase. This operating choice was caused by the lower level of knowledge and acquaintance with the farther areas, normally less considered by historians and also by conservative attentions. The inspection on the city of Parma and its surroundings was left for the final phase also because the city was under compulsory administration until May 2012, causing long delays in the acquisition of the documentation, notwithstanding the numerous requests to the offices concerned with the art collections and the historic buildings. In the absence of notices from the owners, direct surveys were carried out to verify the conditions of the assets.

The same kind of requests were made also to the four dioceses of the analyzed territory, in order to obtain lists of endangered assets and the authorizations needed to access to the worship buildings and to all the wide artistic and cultural heritage owned by the church. After the first requests, a dialogue was started with the cultural representatives of the dioceses, who signaled some particularly urgent cases. The most efficient method was found to be the direct survey, as some interlocutors were not very willing to fill out detailed questionnaires on the management of monuments and artworks. Some general information supplied by the diocesan administration helped to fill in the gaps and widen the research horizon: in particular, the highlights given by the Parma diocese on the critical situations encountered during the latest seismic events – many churches damaged by the December 2008 earthquake are still impracticable – allowed an efficient planning of the surveys. It was instead more difficult to overcome the limited willingness encountered during the information gathering on artistic and cultural assets: the assessments on architectures can be carried out also with limited accesses to the buildings, while it is impossible to assess objects and ornaments, often stored in non-accessible spaces. The attention was focused on the artistic assets stored in severely deteriorated buildings, as in these cases the possible heritage loss is multiplied: the damage can hit both the container and the content.

Besides the Municipalities and the dioceses, also the Province Administration and the several religious or private Foundations of the area were relevant stakeholders contacted during the on-site research.

The different areas showed different levels of criticality: a higher concentration of urgencies was found in the areas close to the city. Possibly due to the gradual decline of the relations and of the traditions of the rural world, the farmland disrobed in favour of the city, turning the surrounding plane into a dormitory-satellite of the urban centre. In this way, lands rich in history and millennial customs ended up losing their roots and the awareness of its own vast architectural, anthropological and artistic heritage. On the other side, an opposite tendency has been observed in the mountain areas, which for logistic reasons are less subjected to the daily commuting towards the urban area. The preservation practices of the common historic memory of these communities looked more fruitful, often reaching a real promotion of the cultural heritage for the re-launch, mainly touristic, of the territory [13, 14].

5. The instrument's potentials

The proposed method for the filing and assessment of the cultural heritage at risk can be potentially applied to any context. The highest synergies, at a national level, could be obtained involving also the Department for Cultural Heritage, the Universities of the territories involved, other bank foundations and other patrons, in order to make an emergency list of the cultural heritage based on transparent criteria and certified by the local government departments responsible for monuments and other treasures. This constantly evolving catalogue should be available on-line and be intended as an

instrument to inform and raise awareness for whoever, with different roles and means, would like to support salvage, preservation and restoration interventions on cultural assets [15]. From local authorities to bank foundations, from lending institutions to businessmen, from voluntary associations to private citizens, everybody could consult the priority list and adopt an asset or chose to contribute to the intervention costs, working in full sight to expunge the chosen asset from the “black list” of the most serious urgencies [16].

Optimizing the resources induces incalculable benefits in terms of time, exactly in those cases where the highest risk corresponds to the highest efficiency in stopping the decay, preventing more serious losses of parts or of the whole of the cultural asset to safeguard, with clear economies for the subsequent phases of recovery and enhancement. This model, at last, would also bring advantages on the side of scientific research and of job levels in the field of cultural heritage cataloguing, of territorial management, of touristic promotion and of the connected service sector, not to mention the meaningful cultural repercussions in terms of social awareness and of consolidation of cultural and identity values of a territory.

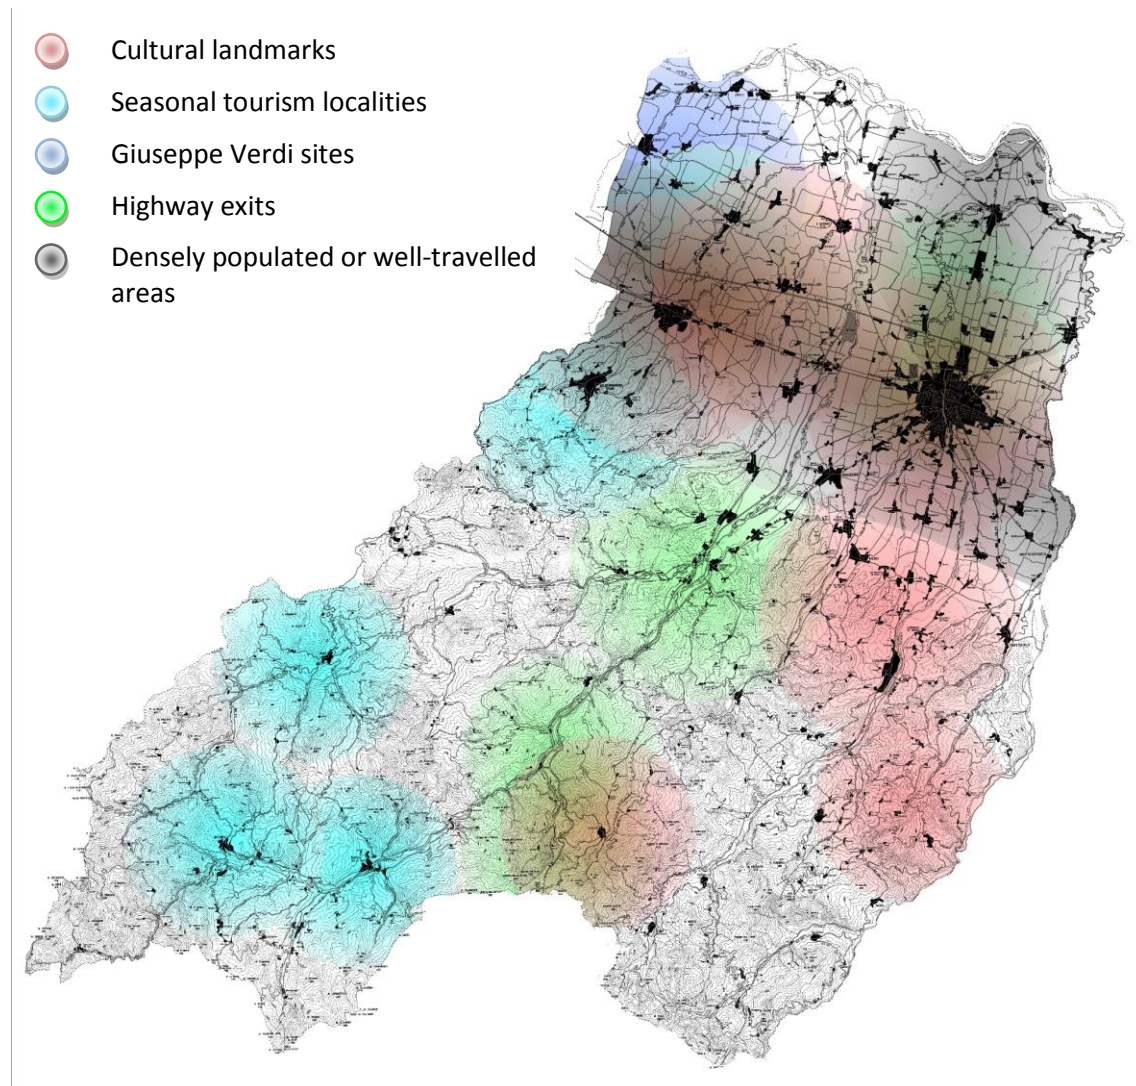

Fig. 3: Map of the touristic and attractive areas of the considered territory.

6. Acknowledgements

First of all the authors want to remember Prof. Carlo Gabbi, former President of Fondazione Cariparma, whose heartfelt interest in his territory cultural identity was the spark for this research and will long be missed.

The authors are also grateful to Prof. Ivo Iori and Carlo Blasi, scientific supervisors of the project, for the fruitful advices given during the work.

At last, a special acknowledgement goes to arch. Stefano Negri (operational coordinator of the census) and to dott. Paola Uberti (art historian): without their precise and passionate work these results wouldn't have been possible.

Green Road Project: Promoting Art, Food, Mobility and Energy.

The Green Road project is a tool to promote local heritage of a Territorial System, focused on the principles of Green Economy, Sustainable and Wise Tourism, which covers the rural areas of the Hundred Country Houses in the Ionic Arc in Puglia (Italy), including 11 municipalities for a total area of 415 Km².

The main distinguishing features of the project are: territory (enhancement and integration of rural areas), aggregation (creation of local coalitions to build an eco-sustainable territorial system), inclusion (development of an inclusive model focused on community and solidarity economy), internationalization (starting from the local to conquer the global), innovation (creation of social capital based on research, professionalism and competence), sustainability (green design + design for all).

The creation of the identity reflects the guiding principles of the Green Road: the sign chosen to synthesize "the value" of the Project has, in terms of meaning, the prolific stretch of the biological element, in order to reduce the social imaginary to the current guidelines of policy in the field of landscape, culture, environment and technological innovation. The functional elements along the route (signage system, benches, recharging points, waste container....) are designed according to the values of efficiency, authenticity, complexity and safety of the project.

Keywords: Territorial identification, Food, Art, Movement, Energy.

Green Road Project: Promoting Art, Food, Mobility and Energy.

One of the main objectives of the territorial realities is to reach unitary identification, that is to say the identification and contextualization of all attractive, both tangible and intangible, within an extended area which goes beyond the concept of Municipality or Region. The territorial identification allows to redefine geographical and political boundaries in favor of a more representative grouping which is aware of its own territorial identity, that is a territory composed of economic actors, institutions and citizens who consider themselves united by traditions, gastronomy, natural endowment or simply united by common goals of development or preservation.

The territorial identification and the concept of destination have many scientific implications of observation, especially in relation to a tourist point of view. To date, the audience of tourists is absorbing all the profound changes in the global economic system, radically re-formulating its own demand. Among the changes which materialized within the sphere of the preferences the emotional and experiential implication offered by the destination seems to have become a distinctive aspect to the tourist. Therefore, it is essential to segment the supply by customizing and specifying which attractive is available within a particular destination. For this purpose, through the territorial identification a concrete organization of available resources becomes possible, by the identification of a management policy which allows to structure a modern and focused product supply.

All this also becomes possible thanks to the Destination Marketing, such as the discipline which deals with the strategic link between destinations and markets, establishing relationships with tourists, outgoing organizations (tours operators, transports, agencies) and new media.

The activity of the Destination Marketing consists in publicizing the image and awareness of the destination in the target market, with the aim of facilitating the marketing and improve the appeal of the supply. It is clear that this discipline cuts through various territories which are synergic and complementary to each other, however, a real market strategy is still to be developed, since in the set of markets which is being taken into account within the destination it is difficult to talk about competitive positioning.

The combination of cognitive evolution of the territory, the new concept which is associated with Destination Marketing, but mostly the study of new tourist developments, therefore the modification of the demand in favour of the desire to know the place, to capture the essence of uses and local customs, and to live a very personalized experience (sport, culture, gastronomy), ensures the opportunity to refer to the destination as the organized and managerial translation of a rural territorial identity endowed with peculiar characteristic attractions. By analyzing the core-activities of the Destination Marketing (information, reception and tourist entertainment) we can observe that this discipline has as its main role that of structuring the territory in order to inform, accommodate and to ensure the territory itself to be visited also as a way of promotion.

So far it has been possible to observe the most theoretical essence of the birth of the destination and of its structuring. The European Union, through the article 62 of the EC Regulation n.1698/2005, predicted the birth of Local Action Groups (GAL) that essentially consist of an organization of operators belonging to different functional ranks who decide, after having been provided with an organizational structure, to pursue a common goal through the use of structured policies and actions in harmony with each other, building synergies between the public and the private sector. The whole area has an endowment of natural attractions extremely varied, which go from the surrounding Mediterranean "Maquis Shrubland" to the excellent and internationally award-winning gastronomy, with wine, extra virgin olive oil and typical products.

The territory is also rich of attractions with regard to architecture, due to the presence of the so-called "Trulli" in the area, but also of country houses, ancient farms and sites of agricultural production. GAL Ionian Hills' activity includes the territory of the "Hundred Country Houses", that is the aggregation of some rural buildings dating back to 15th to 19th century, some of which are also walled with protective rock and endowed with rocky churches. The whole area is witnessing more than twenty-five hundred years of history, having been a crossroads of cultures over time leading to a mix of nature, art, history, tradition and a well-known hospitality that make it accessible in any season of the year: worthy of attention is also the local handicraft, Grottaglie being an artisan centre for ceramic.

The GAL Ionian Hills is divided into two main themes, such as the creation of new productive activities in non-agricultural sectors and the development of existing services, and the improvement of the quality of life through the provision of local services (Local Development Plan, GAL Ionian Hills).

On the other side, the objectives which characterize the GAL are: the diversification of agricultural activities, the development of extra-agricultural micro enterprises, the promotion of services for experiential rural tourism and the conservation and requalification of the rural heritage of the destination-area through its preservation. The action strategy, instead, involves together agricultural, tourist, craft and commercial sectors; it also tries to combine productive human and natural resources of the territory to the needs of an environmentally sustainable development; lastly it favours the rural-territorial identity with innovative projects.

The fundamental assumption which guides every action of this Group is to think and act "green", that is everything has to take into account the respect for the environment according to the concepts of eco-sustainability that the Group itself promotes through the use of renewable energy, biomass and electric cars. Among other tasks, there is that of managing available funds and make them efficient through the strengthening of territorial visibility and the use of new information technologies and media, being aware that ravines, woods, olive groves and crops become resources to be safeguarded and enhanced through an active, but also respectful management.

Other important elements are: the partnership, the cross-action, the agglomeration and the opportunity for citizens to actively cooperate in the development of the area; moreover the complementarity of agriculture, tourism, handicraft and services which are together leading to the development of a strip of agricultural territory around the city, through: allotment gardens, sub-urban parks, educational farms, pet therapy and also multifunctional agricultural parks, walking and cycling paths and bridleways in order to connect the environmental resources to the historical and cultural ones.

The Local Action Group has as its base value the identification of the individual in a territorial context that he considers his own, thus leading all subjects belonging to it to do their best in the safeguard of the environment and of its cultural heritage, and consequently to commit in its organization, development and/or marketing promotion. In this field, the GAL is tool that allows to coordinate and promote the ideas of aggregation whether they are economic or cultural.

The Green Road project is a representative tourist product of a Territorial System, focused on the principles of the Green Economy, of Sustainable and Wise Tourism, which covers the rural areas of the Hundred Country Houses in the Ionic Arc in Puglia (Italy), characterized by the significant presence of old houses, country houses, handicraft workshops, art places and natural resources.

Green Road represents a new tourist philosophy focused on the geographical factor and on the aggregation both of the internal stakeholders, who represent the short network of endogenous development, and the external operators, who represent the extensive network of stakeholders and exogenous investments.

The rural area and seaside in the province of Taranto, on which the strategic project planning is focused, is aimed at creating a tourist product that could trigger a systemic development which, having as its reference area the whole Region of Puglia, potentially extends to the neighbor Region of Basilicata.

Green Road will promote a new rural tourism linked to the traditional seaside one, to agricultural production and gastronomy, to local handicraft, according to a perspective based on a new "model" of green territorial productive reconversion, which could be exportable and replicable, where possible, to international level.

The road, which is 17 km long, covers a 200-beds accommodation offer, which soon will be joined by other 200 beds, thanks to the refurbishment of country houses and historic houses and represents a strategic project of 11 Municipalities of the Ionic Arc – Taranto area (Puglia) that, having as its starting point the territory of the "Murgia dei Trulli", extends in a landscape configuration of amphitheatre.

The Green Road develops between agritourisms, bed & breakfast and 4-5 stars country houses, old houses, rocky settlements, caves and woods, Mediterranean "Maquis Shrubland" and lush green countryside, along which the wines and foods of the area can be tasted, and where the peasant civilization and the legacy of Magna Graecia can be admired.

The main distinguishing features of the project are: territory (enhancement and integration of rural areas, both seaside and urban characterized by artificial intelligence dynamics), aggregation (creation of local coalitions to build an eco-sustainable territorial system), inclusion (development of an inclusive model focused on community and solidarity economy), internationalization (starting from the local to conquer the global), innovation (creation of social capital based on research, professionalism and competence), sustainability (to restore the centrality of the quality of life: "New Green Life Style").

Through the recovery and reuse of the typical environmental heritage of Puglia from a "Green" perspective, old houses and country houses, from being places of remembrance have become multi-purpose companies (such as agricultural, zoo technical, rural and educational country houses); a new tourist accommodation where it was possible to build a strategic guideline never had before, from which to develop a form of rural tourism.

Adopting Green philosophy, it has made it possible to qualify the territory from a tourist point of view, diversifying agricultural activities, creating new activities and improving the quality of life, expanding the attractive of the area, and all this with the aim of encouraging an eco-sustainable economy and a development of the artistic, cultural and gastronomic heritage of the territory.

The guideline on which the Green Road project is developed aims at acting on the existing as well as on those structures which are already organized to participate actively in the tourist supply, both through the restoration and enhancement of the architectural structures that can help to create harmonious relationships in the rural world.

A tourist demand focused on the search for environmental richness, eco-sustainability, cultural traditions in order to support local companies in the process of transition towards sustainable development models, to motivate and support the rural tourism industry in adopting new production paradigms in the name of quality and sustainable development.

Using the advantages of the aggregation, the Green Road is able to present the tourist supply of the country houses both at a level of "product" (location, natural resources) and of "services" (booking, brand), integrating the different activities of the production chain found in the reference environment (hospitality, catering, wellness, local typical products), in the spirit of the destination community model. Last but not least, a resource of particular importance is represented by the "brand equity", determined by the ability of the destination management to enhance the local identity and to create an image sought by the customer.

The creation of the visual identity reflects the guiding principles of the Green Road Project: the sign chosen to synthesize "the value" of the Project has, in terms of meaning, the prolific stretch of the biological element, in order to reduce the social imaginary to the current guidelines of policy in the field of landscape, culture, environment, sustainability and technological innovation. A meaning and aesthetics search which locates in the elementary botanic form of the "leaf", giving back recognition and communicative immediacy both to the territory and to Green Road through a simple iconographic mode, clear, readable and above all more flexible than the different uses expected.

The brand image has been identified through a complex series of actions such as: the brand of destination (Green Road), signage system, fidelity cards, smart box, web and mobile applications,

editorial publication, artistic and hand-made gadgets, thematic fashion brand, co-branding operations. Green Road becomes an implementing tool for strategy that makes of change its backbone, in particular, through the implementation of infrastructural, economic, cultural and innovative environmental interventions, it aims at achieving a transformation of the territory, together with an enhancement of his vocation and his identity.

Green Road will be developed according to this philosophy and it will become in the next few years the “destination” of an increasingly articulated and attractive tourist supply system, considering the fragmentation of companies and the small size of the facilities, which will thereby get more support by being uploaded to the web but also by being connected to the other operators in the area. Even small-sized structures will be given the opportunity to enjoy communication and marketing tools which would otherwise be complex to acquire, as well as they will come in contact with buyers who ground their demand on dimensional requirements too.

The rural tourist destination “Green Road” is an example of excellence by virtue of the factors of attractiveness and natural landscape. It shows clearly how some attractors such as landscape and natural beauty, typical architecture, the relax and tranquility, the climate, reaches, on average, very high values.

The motivation for the achievement of these values lies mainly in the absolute and total respect, protection and enhancement of the natural resources of the territory. In this context, the local community is actively involved in making the above factors increasingly homogeneous harmonizing and allowing that they can interact with each other.

We are dealing with a form of aggregation, arose spontaneously and ungoverned, but over time is gaining greater awareness, confidence, strong aptitude for collaboration between local actors of the destination, such as rural communities, country houses, public institutions; in thus it aims to enhance the tourism system consists of attractors, material resources and intangible resources to the competitiveness of the destination in order to offer multi-stakeholder systems.

The tools that give shape to the better enjoyment of the rural tourist destination are undoubtedly the GAL – Local Action Groups, deeply rooted in the territory and reached the highest expression of the union between public institutions and private entities, in a common perspective of sustainability.

The Green Road represents an innovative philosophy of sustainable tourism, combining material factors, such as old country houses or trulli, dry stone walls, unimaginable in other destinations, with intangible elements such as a green perspective, the total use of the territory, the variety and complementary of new services.

Earthen Architecture: the ancient experiences as basis for the development of contemporary architecture

Alice PALMIERI

Department of Architecture and Industrial Design, Second University of Naples, Italy
alicepalmieri@hotmail.com

Timeless Architecture

Earthen constructions have always been deeply influenced by economics, social life and local traditions. This has produced numerous architectural languages different from each other, but all characterized by formal richness and technical cleverness. The Great Wall of China and the fortifications of Marrakesh are just some ancient records of earthen buildings, which deny the widespread cliché that ascribes the earth architecture to the poorest countries of the planet. These ancient experiences should be the basis for the development of modern architecture: the local tradition can merge with new technical and constructive methods. For the optimal achievement of the new buildings, both the contributions of traditions and the new technologies are required. Furthermore, raw earth has a huge potential in the field of ecologically sustainable materials, because of remarkable availability, excellent thermal insulation and it is an absolutely non-toxic and transpiring element. Construction methods most commonly used are adobe, a mud brick built with a mixture of earth and straw, and pisè, that is rammed earth compressed layer by layer in a framework of the size of the wall to build. Earthen buildings are often considered a symbol of backwardness and poverty, due to a social prejudice; on the contrary, they could represent a sustainable resource for construction practices in developing countries from an environmental and an economic point of view.

Keywords: sustainability, earth, tradition, development

1. Building with earth

Next to issues of conservation and management of cultural heritage, today we find always the question of environmental and social sustainability of interventions that should characterize the design method in all its aspects. In this way of thinking architecture are placed earthen buildings. Building with earth means to actualize an ancient technology to answer current needs of sustainability, both in the field of construction and restoration. In the history of architecture there is the existence of important examples of earthen buildings dating back thousands of years ago; just think of Babylon, Jericho, the Great Wall of China. Signs of ancient and majestic civilizations that have used the loam to create fortifications and monumental buildings. Egypt, Perú, Morocco, Tunisia. They are only a few countries which present landscape strongly characterized by different applications of the same material, evenly spread across the planet.

The considerable technical and expressive potential that provides the raw earth as construction material, is the reason why today we have such a wide range of experience, profoundly different one from the other. Unfortunately, we often come across with the cliché that earthen buildings are intended for the poorest countries and inappropriate to European culture. But there are many different opportunities of research and experimentation for contemporary architects.

The first one is architecture for development, that encourages the construction of housing, health care facilities, educational and social structures in Third Countries, in order to allow a growth adequate to their culture and taking advantage of a cheap and readily available material. Experiments of this kind, have already been done by some Italian architects as Emilio Caravatti or Arcò Group from Milan, which have realized schools, libraries and residences, mainly in Africa, using local materials, mainly

raw earth. But one of the most important contemporary architect working with earthen buildings is Diébédo Francis Kéré. Born in Gando, a small village in Burkina Faso, today Kéré lives in Berlin and he is an expert in preserving and developing traditional clay technologies and architectural heritage. Since the beginning of 2013 he teaches at the Academy of Architecture in Mendrisio and despite this, he still finds time to go back to his community in Gando, and to take his projects forward.

Over this possibility of research, many considerations on sustainability have focused right on constructing with earth, which is an eco-friendly material, easy to dispose of and with excellent insulating properties, features that satisfy the new requirements of the building. One of the first countries to open up to these new architectures is New Zealand, which included earthen building in its local strategic plan because of their considerable earthquake resistant properties. And other contemporary experiences are also present in Great Britain, Switzerland and Germany.

Another field of experimentation with this material is the architectural restoration, in fact the rammed earth is useful for both interventions of consolidation and as ingredient for earth-based plasters. Few, but meaningful were the operations already done with loam on existing buildings. In Italy there have been just small interventions, but the restoration of the Tower Bofilla Betera (Valencia, Spain) is certainly of international importance.

This variety of use is allowed from the infinite forms and techniques experienced during the course of the centuries. Clay is a material with which the populations of the world have produced an extraordinary range of architectural styles, each has highlighted the cultural characteristics of the people who used them. The spirit of place and community is fully expressed in these buildings that are adapted to specific socio-economic, geographic and climatic environments. The technologies and methods used in earthen construction are the most varied, many date back to the origins of the architecture and are continually refined and improved. Construction methods most commonly used are *adobe*, a mud brick built with a mixture of earth and straw, and *pisé*, that is rammed earth compressed layer by layer in a framework of the size of the wall to build.

1.1 Working with earthen blocks

Blocks of earth produced manually by throwing wet earth into a formwork are called “adobes” or “mud bricks”. Adobes are made either by filling moulds with a pasty loam mixture or by throwing moist lumps of earth into them. There are several techniques for the production of bricks, but the most widespread provides that a sandy loam is mixed with water, and cut straw is usually added and the whole formed into a paste that is thrown into wooden moulds. The greater the force with which the loam is thrown, the better its compaction and dry strength. The surface then is smoothed either by hand or by a timber piece, trowel or wire. Adobe bricks are only sun-dried, not kiln-fired. When used for construction they are laid up into a wall using an earth mortar. Before drying out, the finished walls are smoothed down. Often a clay plaster is applied as a surface coating.

Today adobe construction has been partially adapted to economic, social and technical changes. There has been a lot of research on this technique with the result, that rational engineering solutions can now be applied to structures in Adobe bricks. In countries with a big demand, adobes are produced mechanically in commercial brick making yards or there is the option of hiring a brick making machine to make adobes on site.

Fig. 1: Adobe bricks left to dry in the sun, Algeria (Ph. Gérard Degeorges)

Construction using adobe bricks is sustainable as no natural resources are abused and therefore guarantees a low carbon footprint. Adobe walls are also good sound insulators. Step into a room made of adobe bricks and you will feel a soothing quietness and calm that blankets you from loud noises outside. Their thermal mass stores heat during the day, thus keeping the room cool. Throughout the evening and night, they slowly release the heat. With adequate protection for exposed areas and simple maintenance, adobe structures can last a long time.

Fig. 2: School Extension, Gando, Burkina Faso (Kéré Architecture)

1.2 Rammed earth

On all five continents, rammed earth has been well-known for centuries as a traditional wall construction technique. In fact, rammed earth foundations have been found in Assyria dating as far as 5000 BC. With rammed earth techniques, clay is poured into a formwork in layers, and then compacted by ramming. The formwork usually consists of two parallel walls separated and interconnected by spacers. This technique is called *pisé de terre* or *terre pisé* in French and this is the name by which it is best known.

Pisé walls were traditionally made by hand, without the use of formwork and after every rainy season the buildings needed to be repaired. But over time the technique has been refined and structures have become more resistant. In nearly all traditional rammed earth techniques, the formwork is removed and re-erected horizontally step by step. This means that earth is rammed in layers from 50 to 80 cm high, forming courses of that height before the formwork is moved. When one layer is complete, the next course that is rammed has more moisture than the one already in place, which is partially dried out; therefore, there is a higher shrinkage in the upper course than in the lower. This method can be dangerous, since capillary water can enter this joint and remain, causing swelling and disintegration. So with the French *pisé* technique, this problem was solved by using a layer of lime mortar above each course before laying a new one.

Fig. 3: Climbing formwork (Building Research Laboratory - Minke, 1984)

1.3 Chapel of Reconciliation, Berlin Germany

In 1894, the Church of Reconciliation, an imposing neo-gothic building, was erected in Berlin. With the division of Berlin into occupation zones the community of the church found itself divided: the church was located in the Soviet area, most of the members of the community lived instead in the near French sector. When the Berlin Wall was built in 1961, it passed directly in front of the church and from that moment, it was no more accessible. So the church fell into disrepair until demolition in 1985 when the Church was blown up. The empty lot on which it was at this time was covered with grass and bushes. While the main concern was to remove traces of division as quickly as possible, the community of Reconciliation looked for a way to behave appropriately to save this site and its history. Locals decided to build a new chapel on the foundations of the old church, with the simplest tools and materials. A modern building that would do justice to present needs and protect the traces of the past, without rebuilding what had been lost. The proposal of the project was composed of two oval parts of the building, placed one inside the other, but with the axes rotated in opposite directions to one another. The oval exterior was made of wooden slats and took the orientation of the old Church, instead the inside oval was rammed in earth and took the orientation west-east, usual in churches. The earthen structure was built under the direction of the Austrian builder Martin Rauch, specialized in clay works. The earth still wet was placed in a formwork to form layers of 30 cm, compressed one at a time. On 9th November 2000, for the eleventh anniversary celebrating the fall of the Berlin Wall, the Chapel of Reconciliation was inaugurated. This is the first official public earthen building for over a hundred and fifty years in Germany and at the same time, it is the first German church in raw earth.

Fig. 4: Chapel of Reconciliation, external and internal

2. Social sustainability

Talking about social sustainability in architecture means to deal with social, cultural and environmental commitment of construction, urbanism, conservation and environmental design. This includes to support vulnerable and disadvantaged communities, to promote an architectural culture based on appropriateness (ethical attitudes, technologies and respect for environmental and local identity values) and to develop knowledge exchange, joint projects and processes underlining the educational potential in raising awareness on social issues. There are some architectural offices in Italy engaged in this sense. For examples Arcò, from Milan, deals with social projects in Palestine, to provide important services to the population, with particular attention to educational facilities. This attitude is really meaningful because it reveals a deep human contribution that architects can give, in response to political and social difficulties of certain territories. In the photo, the “earth-bags” school in the desert in Gaza strip. This children’s center has teamed up with MCA Mario Cucinella Architects. It is a combination of the technique of earth-bags, made with the local community, an iron covering system that is ventilated and sloped to ensure recovery of water and the integration of solar panel. The technique used is based on filling with earth long bags, to ensure building stability and insulating performance.

Fig. 5-6: Earth-bags School, Gaza Strip (Arcò Group)

2.1 Kéré's experience

In Europe, one of the most committed architects is Diébédo Francis Kéré. He lives in Germany now, but he is from Africa and, despite the distance, he never forgets his origin and his home. So most of his projects have been realized in his country, using new techniques perfectly in line with the tradition and local culture. Kéré planned his first school in Burkina Faso in 1998, in his home village of Gando. The project was realized with loam three years later, with the help of villagers. Until then many had looked down on his work with condescension. But the clay building was standing after the first rainy season and further buildings followed: a school extension, a residential building for teachers and an infirmary. A chain of people helped to build the outer walls of the school, in fact for Kéré is important teaching the people of his country concepts and techniques which later can use autonomously. The Burkina-born architect had always built his buildings using bricks made from local clay and this is the technique chosen for the primary and secondary schools, but for the houses for teachers he has changed his construction method. He treats earth as concrete cast on the spot. The clay doesn't have to be sieved anymore either, just add gravel, sand and lime to the earth that comes out of the pit. This makes it more compact and saves working steps thanks to a simple process.

Fig. 7-8: Teacher Housing, Gando, Burkina Faso (Kéré Architecture)

Kéré said that at the end of the construction, he didn't have to indicate the wall thickness on the plans, because the local people knew exactly what had to be done. All the people involved in the project management were native to the village, and the skills learned here will be applied to further initiatives in the village and elsewhere. The way the community organized itself has set an example for two neighbouring villages, which subsequently built their own schools as a cooperative effort. The local authorities have also recognized the project's worth: not only have they provided and paid for the teaching staff, but they have also endeavoured to employ the young people trained there in the town's public projects, using the same techniques.

The village of Gando has changed a lot in the past ten years: the school has become the region's educational and examination center. Kéré is currently building a further project set away from the schools: a women's centre. Here the intention is for women to meet and talk while learning to read and write. The architect is particularly proud of this project because it is not so obvious in Africa to devote an entire structure to women.

3. Raw earth as a material for architectural restoration

There are many buildings *ex novo* in raw earth and it would be appropriate to extend its use in restoration projects for the large number of material characteristics such as good insulating properties, wide availability, low cost and absence of risks to health in disposal. Raw earth in restoration, in fact, is useful for both interventions of consolidation as an ingredient for earth-based plasters.

The restoration of rammed earth walls, whatever their type and materiality, represents a technical and conceptual problem that is hard to solve. In the first place, the amount of mass missing from the walls tends to determine the type of intervention in most cases. If the loss of mass is limited to the external surfaces and adopts the form of a patina or superficial erosion, the structure will not be compromised and the restoration can leave these surfaces as they are so as to emphasize the age of the wall. On the other hand, if the loss of mass involves serious erosion or a lack of volume and particularly if this occurs in the lower part of the construction, the structure may be compromised to such an extent that the restoration works cannot ignore its presence and must take steps to guarantee the survival of the building. A fairly common example of the latter situation is the loss of volume in the coping of the building, which does not usually affect the structure directly because it is at the top, although it may lead to the progressive degradation of the rest of the building, so it is necessary to deal with it in some way. Behind the intention to alleviate this degradation, there is often a desire to replace the missing volume of the building, using solutions that involve restoring old forms and crowns that attempt to satisfy both requirements at the same time. The use of the original building methods in the restoration

(but not necessarily the reconstruction) of a historic building is always commendable and predictable, but not at the expense of contrast or an increase of distinguishability. Indeed restoration does not imply volumetric restitution or reconstruction of the building, but rather repairs at certain places, where the original techniques may and at times should be used in order to guarantee physical, chemical, structural, construction, and other kinds of compatibility.

Nevertheless, on the one hand, this procedure is impossible in the restoration of rammed earth walls because it cannot be applied in a lateral direction and, on the other hand, it is feasible but produces many aesthetic side effects. So the first precaution would be not to fill in missing parts of the rammed earth wall unless it is absolutely essential to ensure its structural conservation. Given that it is not possible to reproduce the same techniques in the restoration of rammed earth walls, specific intervention methods must be created to guarantee compatibility between the historic wall and the added parts. A significant example of this is the restoration of Bofilla Tower, in Valencia, restored by Mileto and Vegas architects.

3.1 Bofilla Tower: from defensive fortress to a yard of knowledge

Gold winners section works for the International Award Domus Restoration and Conservation 2011 Mileto and Vegas architects, are the protagonists of a symbolic restoration of a rammed earth Islamic tower, monument representative of Muslim Spain.

The architects were aware of the request to preserve the historic and symbolic value of the tower, so they chose to maintain the historical patina, minimizing interventions and maximizing results in terms of elimination of the degradation and structural instability. Intervention work became a real construction site of knowledge, providing evidence that the raw earth, so humble and simple, but at the same time, economic and sustainable, could become a powerful tool for the restoration. The choice of using such material, as well as for its known intrinsic characteristics, was given by the compatibility with the existing material and respecting the dogma of restoration.

Bofilla Tower is an Islamic watchtower that was erected in a hurry at the beginning of the 13th century, when the inhabitants of the area were aware of the advance of the Christians in the Reconquista, which ended in 1238 with the conquest of the town and the nearby city of Valencia. Its construction was rather hasty because home-made formwork, connected by means of nailed posts, were used to build it. The planks available were insufficient to cover the whole perimeter of the tower, so that the tower was built with a "U" shaped formwork that was moved after the earth had been compacted to complete the perimeter, thus avoiding any joints at the corners that might weaken them. The joints at the middle of the tower had weakened the whole structure, so they took the precaution of alternating the joints in the successive courses so that the entire ensemble would look well bonded, not only at the corners, but all over.

Fig. 10: Building system used alternating the available "U" shaped formwork (Vegas & Mileto)

Fig. 11: State of the tower before the intervention (Vegas & Mileto)

Before the restoration, the state of conservation of tower's walls was relatively good, despite the loss of the roof and floors and the neglect to which the tower was condemned for some five centuries. The wooden floors had disappeared completely, probably due to a fire, of which traces could be seen. The restoration was urgently required mainly for two reasons: the ruin of the stone of the double arch at the entrance, causing the partial collapse of the interior surface over it and the hole at the entrance to the tower at the southwest corner, leaving it suspended in the air instead of resting on the ground.

The first intervention was superficial. In fact the surfaces of the tower in a good state of repair were hand-cleaned with brushes, without attempting to leave the surface immaculate, since that would have involved unnecessary erosion of the historic surfaces. These well-conserved walls did not need further interventions, due to their healthy appearance after no fewer than eight centuries.

The real problems were the gaps in the rammed earth mass, which required repairs and reintegration. The gaps at the southwest corner and the hole inside the north façade were filled with stone masonry

bonded with mortar comprising of earth, gravel and hydraulic lime. As much local earth and gravel as possible were used, and were collected and sieved at the foot of the tower, so that the resulting mixture would not suffer from using gravel from a different place. It was deemed necessary, corrugated fiberglass rods were introduced to act as connectors. Perforations were drilled with the utmost care to avoid percussion, because several areas were found to be in danger of immediate collapse. The stones that had fallen from the tower were used again, placed inside the wall. Several possibilities were considered, at the crown, in order to secure the surfaces in danger of immediate collapse and in the north side and in the east and west sides whose merlons had lost stability due to erosion at the base.

Fig. 12: Bofilla Tower before and after the intervention (Vegas & Mileto)

Fig. 13: Details of the restoration, facade and interior (Vegas & Mileto)

Finally, it was decided to use the same procedure to fill in the gaps. The intention was not to restore the tower to its original shape, so these gaps were filled and the degraded top was respected in the areas where material did not need to be added in order to secure or stabilize the fabric. The architects gave a central role of the intervention to the contextual integration, performed on the exterior, that sought to harmonize the degree of degradation, patina and colour of the pre-existing adjacent areas and guaranteed a better integration of the parts added to the building.

4. Conclusion

The aim of this paper is to show how tradition can form the basis for a new growth, in full accordance with cultural and environmental heritage. An ancient technique as the earthen construction brings an enormous potential in itself, with a wide range of applications, both in new construction and restoration. Kéré's experience shows us his continuous research in the experimentation of new application possibilities, always having in mind the necessity to use a poor and readily available material. Different is the case of the Chapel of Reconciliation, where the choice of materials serves as a testimony to the history of the site and as a test using the combination of different materials to optimize both needs. These experiences, so different for places and formal languages, are virtuous examples that give value to the architectural heritage of landscape and environment. They will represent a valuable reference for future generations, not only for the choice of natural materials at the expense of almost uncontrolled industrialization, but as a method and approach to architecture. An ancient tradition, able to adapt to different places and languages, reveals an interesting key to understand contemporary needs and allows the combination of remote experiences in building with new requirements of sustainability.

Abstract

The goal of this paper is to show the process of adaptation and technological innovation and environment adaptation made between the 1940's to 1970's, whose results are observable in spatiality, volumetric and climate adaptation which characterize Yucatan modern architecture. In first place it shows the background technology and thermal performance of pre-modern architectures in which predominate the envelopes thick and heavy and with a predominance of the mass on the void. Followed by the discussion about the introduction of the ideas of modernity in Mexico and Yucatan considering that initially only architectural forms were taken without considering the social and environmental conditions of each region and how it tried to reconcile both aspects. A characterization of constructive technology of modern architecture through a chronological journey is made from the years 40's up to the 70's, pointing out the building systems used in residential architecture and architecture of equipment. Then sets the transit between the architecture of large thermal mass to architecture that changes the articulation of spaces and lighter thermal mass through the dominance of the void on the mass. And finally the Yucatan modern architecture that manages to combine the architectural and technological solutions with the climatic conditions is exemplified.

Keywords: Modern architecture, constructive technology, thermal adaptation

1. Technology and thermal performance previous to functionalism in Yucatan

Rapoport [1] raised, referring to housing, considered here applies to a vast production of architecture in general, its shape not only responds to factors such as climate, materials and technology, which gives the status of secondary or modifying factors, but is the result of a whole range of socio-cultural factors seen in their broadest terms

This is exemplified with the architecture developed so far in Yucatan, where the consequences of secondary value that is given to the choice of technology and climatic conditions has resulted in buildings that not respond adequately to the need to provide a comfortable environment. So most of the population, which does not have sufficient financial resources, must suffer thermal discomfort, those who do have them recourse to energy-intensive appliances to ensure their thermal comfort, diminishing their capital, using non-renewable resources and harms the environment.

The hypothesis that is handled in this paper is the architecture that has been practiced to date in the region comes from imported models, made on other sites with different climates. Such is the case with architecture that was made from the Spanish colonization. Models that work well in home sites, which achieve an interesting syncretism with local technology was imported, but with very different climatic conditions to Yucatan. From the Diaz period of Mexico due to the economic boom based on this peninsula henequen industry will be a major transformation of architectural forms and even building technology [2]; but the reasons for change are of aesthetic sense and not because heat better environmental performance is sought; models exemplifying emerged in France and Italy, it is the historicist architecture and Eclectic. This architecture will be present in two ways in the region, first stylistic elements will coat the old buildings and on the other, new buildings will create. In the first

case, of course, the changes have no effect on the internal environmental conditions in the second case, yes there is a drastic change in the forms and architectural technology, but the envelopes are still thick, heavy and solid predominantly on vain. When buildings are separated from the front and side boundaries are better ventilated also the spaces of public roads will be improved, because there will be greater permeability between the wooded backyards and unpaved public roads, plus it will stop urban canyons formed [3]; however the internal thermal conditions will not change substantially. After the Mexican Revolution, we can distinguish two stages architectural features that are being analyzed. A first post-revolutionary period, characterized by the need to reaffirm the revolutionary ideals and, above all, of the new political class. This architecture results in works of social care benefit, such as housing, health and education, and in search of architecture that symbolize the nationalist character of the revolution. In this period remain in effect the use of technologies that emerged during General Porfirio Díaz period, masonry materials and reinforced concrete roofs, as well as forms of eclecticism, although in the last years the first half of the century will begin using the materials most used in the second period, precast concrete: the block, the beam and slab, so, interior thermal conditions are not substantially different from previous periods.

2. Introduction of the ideas of modernity

The introduction of the ideas of modernity in Mexico represented a profusion of works that repeated forms of modern architectural promoted mainly by great architects as Gropius, Mies Van der Rohe and Le Corbusier. In many works were not taken into account, in general, contextual, conditions of climate and appropriation. In 1956, Gropius himself complained of this formal and indiscriminately copy by architects who did not take into account the intellectual process that made possible a new spatial vision, so he said that: "... *the outer forms of modern architecture are not whim of a few architects eager for innovation, but product and inevitable consequence of the intellectual, social and technical conditions of our time*" [4].

In that sense, Waismann says that initially the modern in Latin America was a fallacy because not realizing the socio-economic conditions in which was born the modern movement original, not an organic development of the movement it led. Thus, original ideas, to be transmitted in an environment not ready to receive them, lose its richness and its complex controversial character, to be understood only in the less subtle features. One speaks then of concepts such as functionality, new techniques and materials and a clean and bare, expression than out of context and not part of a cultural movement, established as dogma.

On the other hand, Cosco recognizes, in 1953, that Mexican functionalism has expressed something more than what could be expected from simply translating national internationalist movement and is located in the presence of a true, own, original and authentic, architectural language expressed in works of high quality in a period of more than thirty years of development and maturity [5]. However this author does not present the way in which this architecture took into account the context and the specific climatic conditions of each region.

At the beginning of the 1960s, Henriquez said that Mexican architecture has been developed in two aspects, the Rationalist based on the classics, Le Corbusier, Mies, Gropius and Neutra, who in general have bright but obvious achievements in terms of the origin of the forms; the second which is less abundant so far, but is richer in depth and future, "... *intend to achieve the assimilation of forms and modern principles to the expressive demands of Mexican contemporary life and its tradition*"; This aspect has been its main promoters in Barragán and Del Moral who have produced works of quality and solid interest, result of a synthesis process deep of the principles of modern architecture with the principles of the past [6]. In that sense, Villagrán declares that this modern and regional position pursued with much work, the solution of the problems local, regional or national in accordance with the conditions and limitations own. By your local target, understood and sometimes not appreciated locally, is ideology rarely achieves success with their works, to the strength of international critics pressed by the internationalist current. However, when in the field regional, originality is fed with real talent goes beyond local boundaries, to project itself internationally; in expert hands and creative minds produces authentic architecture that is at once modern and regional and joins the universal [7].

Achieve the combination of modern architecture with the particular conditions of each region in terms of the natural environment and climate became a challenge that was not easy to accept by the architects. Toca says that part of the errors of modern architecture was the inability of certain architects who uncritically in applying the recipes of modernity, designed buildings that were almost impossible to inhabit by errors of operation and inadequate climate [8]. For his part, Acosta suggested, in the 1970s, that modern architecture should open the housing of the man and put him in communication and continuity with nature, and that it should represent a perfectible instrument, whose function consists of enabling a good adaptation of man to the landscape and the climate [9].

Another important aspect is related to the construction technology used in the realization of modern architecture and which involved, according to López García, on the one hand the incorporation may not of generalized form of materials and local construction systems of each region and, on the other

hand the process of adaptation experienced technologies external to the conditions of each geographical area and the social and economic circumstances of the country [10].

In Yucatán, with the dissemination of the ideas of the modern movement reflected in new technological and architectural canons was aside everything that represents the traditional architecture. In this regard, Carlos Castillo said in 1946 that tradition did not necessarily imply an inability to change or adjust to new building techniques or new social forms. It also ensured that the traditional heritage is very rich and modern style is not in conflict with many of the traditional trends. He didn't see anything antagonistic to the horizontal lines, flat roofs, functional distributions, or large windows; although he recommended that the large glass surfaces should be reset, for being impractical to sunlight and Yucatecan climate and that should attenuate with shutters and blinds. Likewise, Castillo raised some principles of a "living architecture", some of them coming from the international style as shapes, materials and methods based on biological and technical canons adopted around the world; the expression of the light of some modern materials, the introduction of the use of glass products; delete the idea of the Chargers walls; the raw material has shaped as a structural material [11].

For the decades of the 1950s and 1960s some architects had the interest of achieving formal, functional and technical solutions to the canons of modern architecture, sunlight and ventilation conditions, as well as private construction systems of the region.

3. Construction technology of modern architecture

In the early 1950s, construction technology and structural knowledge already had a degree of maturity that enabled architects to achieve modern architectural forms based on structural and constructive solutions with the volumes and spatiality required by modern housing architecture and architecture of equipment, among other architectural genres. In this architecture, the structural form is consistent with the architectural form in the sense that raises Charleson, where both are not integrated or opposed, but there is among them a clear and proper relationship, likewise, the versatility of the architectural form allows that different structural systems coexist [12].

In this sense, the use of the technological components and systems and existing building materials in Yucatan, allowed that residential modern architecture could be configured, in general, by prismatic volumes juxtaposed with horizontal or sloping porches. In this way, the architectural form of the residential housing is formed by two constructive systems: load-bearing walls and structure of columns and beams or girders, together in a mixed structural system that characterizes it. In the interiors there is a clear distinction in formal and structural resolution thus, in social areas predominates the domain of the vain on the massif, consisting of columns, girders and corbels or overhangs, while in services and private areas predominantly the domain of the massif on the vain configured for load-bearing walls and enclosures.

These modern architectural forms also permeated in the socio-economic level medium expressed in volumes and planes with a lower hierarchy than the residential scale. The popular housing remained the sobriety of the simple game of volumes overlooking the massif on the opening through the system of load-bearing walls.

On the other hand, the buildings of equipment were constructed, mostly, with structures composed of columns, beams and slabs of reinforced concrete, and architectural forms were generated based on the juxtaposition of rectangular prisms.

3.1. Construction system of load-bearing walls

The system is configured for load-bearing walls with two proprietary construction variants of housing architecture: a) block walls and slabs of reinforced concrete load-bearing walls; and, b) load-bearing walls of block, metal columns, columns, beams and slabs of reinforced concrete. Below and describe examples of both variants.

Towards 1947, colony Miguel Aleman is built with thousand houses for workers with all the hygienic advances including collective sanitary drainage, being the first colony of the city to have it [13]. In order to ensure the supply of materials to the colony was installed a factory block solid concrete and mosaic of paste [14]. Design assembly and the architectural scheme correspond, according to González Canto, the theoretical and technical principles of the gestation of architectural modernity. The plant consists of two bays, in the first; living room and the dining room are placed, while in the second, bedroom and bathroom were. In the construction of dwellings were used foundations of stone masonry; load-bearing walls are solid concrete block; windows reinforced concrete beams are integrated into the slab; slabs are reinforced concrete and reinforced with reverse beams of the same material. This was the first time that they were employees systems and building materials industrialized in horizontal supports and slabs in homes in series, using the stone as a regional material for foundations only.

For the decade of the fifties already seen solutions of functionalist type in the management of the horizontal planes and volumes set, as in several homes in the Miguel Aleman colony, which were

expanded or modified, in which the portico of the garage and the main entrance consists of a slab of reinforced concrete with parapet of block, which continues lengthwise as an overhang at the front of the volume and ending in a block, supported by a cantilever lower wall. The porch slab is supported on one end, into the wall charger the volume, to the center, in a metal column and, at the other end, in the support column and plinth block.

Fig. 1: Garage of the dwelling projected by Fernando García Ponce at colony México. Image: Arturo Román.

Solutions similar but with best quality formal and constructive, arise in residential architecture designed by architects trained in the functionalist in universities in the center of the country or from abroad. Such is the case of housed in the colony García Ginerés, designed by the architect Alberto García Bolio, a graduate of the University of Notre Dame, in Chicago. The architectural plant presents a scheme "L", located to the north and front of the House, are the social areas and services, while the intimate area is located on the cost side to the east, corresponding to the best orientation by sunlight and ventilation. The residence is set by the slab of the portico of the main terrace linearly coupled with the glazing volume of the social area, the slab is reinforced concrete, supported at one end by a slender metal column in scissor, whose top opening occupies almost the entire width of the slab; the center, in a metal column embedded in the windows of the volume and, on the other, by a wall charger block. The garage is attached to the west of the social area and exhibits a slab "V" sustained at one end by the charger block wall and on the other a set of metal columns; form which was used with different formal and constructive qualities in homes in colonies of the city of Merida, like Miguel Aleman and Mexico.

The decade of the sixties, housing architecture presents a higher quality and complexity of formal, structural and constructive solutions that in the previous decades. Most of the residences were designed and built by architecture and engineering professionals and are located in some colonies and residential developments in the north of the city, as the colonies Mexico and Buenavista and the Campestre neighborhood. In a few cases, horizontal cover and support elements will have a predominantly formal and structural participation and, in others, the volumes are the most important determinants of architectural and structural forms.

Example of this is seen in a residence built in 1964 in the Mexico Colony, designed by the architect Fernando García Ponce, a graduate of the National Autonomous University of Mexico with the collaboration of the engineers Álvaro Ponce Peón and Ulises González (See fig. 1). Architectural diagram is linear in "I" deprecated in two parts, in the first, garage and the bedrooms are located, these are looking eastward which is best facing climate; social and service areas were located in the second body. The portico of the garage is configured by a slab of reinforced concrete with parapet perimeter of block or concrete; the slab is supported by a series of inverted girders of reinforced concrete that waged a 10 m clear and are based on longitudinal bearing walls; in front of the last beam, slab excels in overhang more than one meter; on the left side, the girders continued toward one end forming a series of "pergolas". Side volume of the bedrooms hangs a cantilever compound by a slab of reinforced concrete tops, in the end, with a series of "pergolas" of the same material, which serve as protection to the sunlight.

3.2. Construction system of reinforced concrete structures

The system is formed by structures of reinforced concrete with a constructive variant used primarily in equipment buildings and commercial: structure with columns, beams and slabs of reinforced concrete; and dividing walls of block or masonry.

Fig. 2: Main façade of Faculty of Medicine of the University of Yucatán. Image: Felipe Báez.

In the year of 1945 builds the Center School Felipe Carrillo Puerto who was one of the most notable examples of the functionalist in Yucatan. The whole school was set by modules in three plants distributed orthogonally generating different courtyards [15]. Salons were oriented towards the north with clear short in doors and windows, overlooking the massif on the vain; while the hallways looked to the South overlooking clear over the massif, denoting a clear intention of the architects Amábilis, father and son, protect the halls of southern sunlight with halls and privilege for the lighting of these north-facing with this. The building was met with a structure composed of foundations, columns, beams and slabs of reinforced concrete; the stone masonry was used only for the dividing walls and closing.

The Faculty of Medicine of the University of Yucatán was completed in 1952 and presents a symmetrical composition scheme on the ground in the form of "E". Displays two levels, the body to the front is home to the lobby, the vertical circulations and the academic and administrative offices. The three remaining bodies contain classrooms and other educational and services spaces are oriented from north to south; the main façade is oriented westward, and dominates the massif on the vain. The structure of the building is resolved with columns, beams and slabs of reinforced concrete, the walls of masonry as a closing of the spans of the porticoes were used (See fig. 2).

The building of the General Treasury of the State was built by engineer Mario Duarte at the end of the 1950s and consists of three levels and a basement. The architectural form is a plain rectangular parallelepiped with horizontal openings and solid perimeter bands alternated; the longitudinal façade orientation is west, the short at North, and do not present any kind of climate protection in the structure. The structure's foundations, columns and beams of reinforced concrete supporting slabs of beams and blocks; the dividing walls are concrete block.

The Library Carlos R. Menéndez was designed and built in 1964 by architect Leopoldo Tommasi, graduated in the University of Seville, Spain. In this building, Tommasi *"... used all codes of modern architecture: open plan, spatial fluidity, accomplished by the large windows, large eaves supported by slender columns of iron, as well as a pronounced horizontal in its volume"* [16]. The plant presents a scheme of inverted "T" and following a compositional diagonal axis with respect to the orthogonally of the terrain. The main body of the two plants has a south-west orientation; on the ground floor a Hall front perimeter set up by a thin slab of reinforced concrete supported by thin metal columns it displays, and serves as a protection from the sunlight to the space occupied by the reading room; the first floor exhibits a large window surrounded by a cantilever short perimeter that very little serves as protection to the sunlight to the offices.

4. Technology and thermal performance of the Yucatan functionalist architecture

The second period after the revolution, covering 1950, when the post-revolutionary political system has established, to 1973 which is the date the emergence of the first school of architecture in Yucatan. It is the period in which the practice of architecture derived from the modernist movement was consolidated discussed below.

In addition to the assumptions established for previous periods, which is also valid for this, about the lack of compatibility of imported architectural models in relation to local climatic conditions, should be mentioned as explanatory data the lack of adaptation of buildings to weather conditions, the architecture that served as a model in this region was conducted by architects, engineers and builders trained abroad [17] not necessarily with any previous link to Yucatan. Although theoretically in training who performed the works that served as an example for the local architecture being questioned the importance of taking into account the climate, the practice based on typologies, which prevailed even before the advent of the modern movement, had an area of successful limited applicability to what extent the technology used in the period 1950 to 1973, full affiliation to the modern movement, responds to climatic Yucatan conditions?

A constant in the Yucatan architecture from the colonial period to the practice of the modern movement is the use of heavy construction systems, of much thermal mass. The effect of the thermal mass is to reduce the oscillation of the internal temperatures and the extreme delay. When the thermal mass is greater, the sensible heat tends to remain constant and equal to the average of the outer. The extreme example is the interior of the caves.

For Yucatán, the effect of thermal mass buildings is very convenient reduction of the maximum temperatures that are very uncomfortable, but maintains high temperatures at night and in the early mornings when it is cooler outside. The studies we have done comparing exterior and interior spaces of a residence of colonial period called the "House of the Young" clearly show that fact. In this case the oscillation of the outside temperature is 14.4 degrees and the interiors are 1.0, 1.8 and 3.0 degrees.

Yucatán is one state that is located on the peninsula of the same name, which is part of the Mexican Republic. It is a region where the Mayan culture settled. It is a region that has two types of climate, rain Tropical (A), specifically Aw sub humid with summer rains covering by far the greater part of the peninsula, and Dry (B), which occupies a small strip of coast [18]; this strip is dry when you take into account the rate of rain, but the humidity is very high, due to the sea and surrounding wetlands. Its bioclimatic conditions are hot uncomfortable for most of the year. Using temperatures capital as representative of the rest of the state, they are very similar, having no conditions that make change, except for the proximity to the coast, the average temperature is 26.3 ° C, the average maximum 34.2 °, the maximum annual temperatures often reach or even exceed 41 ° C. The average minimum temperature is 18.4 ° C, but can be downloaded annually to 10 ° C. Because of these conditions, one of the most difficult challenges of architecture in this region is to provide comfortable environments.

The approaches of the modern movement in Merida are consolidated from the 50s of last century, according to González [19], which is attributable to two conditions: the first is concerned with the widespread promotion of public works through government policies modernization implemented in the country since the 40s and the second, with the construction of private architecture, mainly housing, promoting a group of new professionals in the region, all trained at the center of the republic and the abroad. As mentioned, the first school in Yucatan architecture will open in 1973, within the Autonomous University of Yucatán.

The architecture of this period does present significant changes that impact their thermal behavior and will be studied in more detail in subsequent work. Changes shape as the spaces are connected and decreasing the thermal mass of the envelope, which is the determinant of the internal environmental condition of the previous architecture. More specifically, changes the ratio between the massive relative to the openings in walls, which become thinner and less mass per square meter when the precast concrete hollow block appears.

In the envelopes of the architecture endures functionalist using stone materials but increases the percentage of vain. Beams, bricks slabs, and concrete cast on site: As construction system precast blocks predominate. The windows were first made of wood or steel and glass, and currently, mainly aluminum and glass. The windows are used with simple glass, as the weak regulations governing the envelopes in the use of energy (ENER NOM 08 and NOM 020 ENER for non-residential buildings and residential buildings, respectively) are not respected. During the period analyzed much front and rear porches covered with roofs supported by columns or cantilevered sometimes protected insolation windows were used, although the profuse use of cloth or plastic curtains show the need for sun protection in many cases.

It can be considered that modern architecture, to put aside how to design based on established typologies within the academic repertoire and raise a methodology that can and should consider all features to be covered by architecture, in addition to a wider range of resources for solution requirements; enables search architecture more consistent with the environment.

But the failure of the architecture of the modern movement to propose appropriate solutions to the requirements of comfort came to the fore, even in their places of origin, to present oil crisis in 1973, as the reliance on the use of air conditioning became apparent to achieving comfort inside buildings. This situation led to the impetus of the statements made by Olgyay brothers, who in 1963 established the basis for the practice of architecture according to the weather by passive means, bioclimatic design,

which does not permeate the entire architecture. The bioclimatic design today, day after day is enriched by the contributions of researchers and designers who build this discipline.

Fig. 3: Dwelling projected by Félix Mier y Terán at colony México. Image: Elvia González.

Examples of Yucatecan architecture that constitute as models for distributing the modern movement are mainly residential homes, where air conditioning use is also made what is a disadvantage that does not encourage the search for better solutions to achieve conditions environmental liability means, since there are no strict rules that restrict irresponsible use of energy. Thus there is inconsistency between reduced electricity rates by weather conditions and the lack of standards for care use.

The first buildings originally developed and became example of functionalist architecture does not clearly respond to regional bioclimatic requirements. Most seem to obey formal, functional intentions, which provide comfortable environments.

The operation of the building envelope made with technology of this age is not very different from the colonial period or Díaz. On the one hand, modern buildings due to the greater freedom for the arrangement of windows can have better ventilation, but on the other hand, negligence in controlling the entry of the sun counteracts that advantage.

5. Examples of Yucatecan architecture in consistent with the modern movement

Examples of architecture in keeping with the modern movement, dominated examples where prevailing formalistic type considerations at the expense of environmental. In general it is clear the modern language of architecture based on the use of technology, which constitutes leading expressive element, which is part of the bold handling of reinforced concrete and steel beams and columns used in supports and roofs cantilever, whereby large areas are achieved, what the use of glass in large windows adds to achieve transparency connecting the indoors with the outdoors.

5.1 Positive examples of functionalist Yucatan architecture

Among the most distinguished and prolific architects of this period is Felix Mier y Terán, a native of Yucatan, who trained as an architect at the Rensselaer Polytechnic Institute in Troy, New York, supported by a scholarship from the Carnegie Foundation Hall (1940 - 1943). During his early years he practiced in Cali, Colombia, Mexico City and later in Mérida, Yucatán, where he did most of his career [20]. In many of his works effort in caring for protection against the sun sign, but is neglected in some others.

This architect was very prolific and his work includes various genres such as banks, shops, factories, offices, temples, residences and many others. All that work is fully ascribed to the modern movement, one of the main drivers of this current in Mérida, especially the organic trend in the decades of the 50s and 60s of last century.

Especially in the work of Felix Mier y Terán, among exponents of the Modern Movement in Merida, the handling of form away from the rigid composition of the academic architecture, it tends more to the organic architecture of Wright, the far the straight lines of the schemes available, symmetry and simple juxtaposition (See fig. 3). Use the stone, wood, vegetation and detail similar to that pioneered the way organics. Also in the space is the Wright management influence, for example in the fluidity between interior and exterior achieved through transparency and continuity that accentuate the ruffles, joists, and vegetation. The gardens play a very important to emphasize the relationship between internal and external role, but also constitute an element of thermal conditioning.

Fig. 4: Main façade of Library Carlos R. Menéndez. Image: Arturo Román.

Technology also plays an important role in the work of this architect. The steel, concrete and glass are part of their formal language, but also the medium that allows the achievement of the other functions of architecture, such as finding a comfortable atmosphere. Su manejo es novedoso, para el período analizado de la historia de Yucatán, de la forma, el espacio, la tecnología y la vegetación hacen suponer que sus diseños conllevan un funcionamiento térmico diferente al de la arquitectura precedente, que resulta importante conocer, comprender y valorar. En el análisis de sus obras se puede apreciar el cuidado de la elección del emplazamiento, de la orientación, de la ubicación de la vegetación, del uso de terrazas, volados y todo tipo de protecciones de los vanos que muestran su clara preocupación por atender las condicionantes climáticas del lugar. These reflections are the justification for the quantitative analysis of this work by means of thermal simulation, corresponding to a next phase.

5.2 The negative functionalist of Yucatan architecture

In contrast to the work of Felix Mier y Terán there is another version of the modern movement. One with a less comprehensive consideration of architecture that does use elements of formal language of the current as well as the handling of space and functionality, but it neglects the constraints of environmental outcomes, that is, the location, orientation for protection against sunlight and to achieve good ventilation, handling outside to create outdoor indoor conditions favoring, among others; maybe this position is related to the confidence of having the artificial arrangement which elsewhere put in crisis the modern movement got momentum and stronger every day. The Carlos R. Menéndez Library which uses modern language but ignores one of the basic principles of architecture which is to provide a comfortable environment. This piece of open plan and glass facade is oriented towards the south west, one of the worst guidance for Yucatan. As a result a large protective curtain is used. (See fig. 4) Architecture held in Yucatán from the Spanish colonization emerged and developed in Spain and responds appropriately to the weather conditions in that country, but not to the Yucatan in accordance with the analysis performed using bioclimatic chart Givoni. That is because they are structures built from materials with high thermal mass and its compositional system is based on the simple juxtaposition of spaces between which the air flow is difficult, as well as with the outside. In Yucatan the effect of thermal mass buildings is very convenient reduction of the maximum temperature, they are very uncomfortable, but also maintain high temperatures in the evenings and early mornings when on the outside are pleasant or less hot. On the other hand, the lack of wind flow is not conducive to reduce the sensation of heat from users. Although in the later stages, even before the period analyzed, technological, formal and spatial innovations occur, thermal conditions change little. During the reporting period there is already almost complete innovation of construction technologies. In this period prevails using thinner walls than masonry used in the previous period; is first built with solid concrete blocks and then with hollow blocks. The roofs were initially solid concrete, hollow block then supported by reinforced concrete beams and cast-in-place, then pre stressed joist and hollow concrete slabs.

Conclusions

Architecture held in Yucatán from the Spanish colonization emerged and developed in Spain and responds appropriately to the weather conditions in that country, but not to the Yucatan in accordance with the analysis performed using bioclimatic chart Givoni. That is because they are structures built from materials with high thermal mass and its compositional system is based on the simple juxtaposition of spaces between which the air flow is difficult, as well as with the outside. In Yucatan the effect of thermal mass buildings is very convenient reduction of the maximum temperature, they are very uncomfortable, but also maintain high temperatures in the evenings and early mornings when on the outside are pleasant or less hot. On the other hand, the lack of wind flow is not conducive to reduce the sensation of heat from users. Although in the later stages, even before the period analyzed, technological, formal and spatial innovations occur, thermal conditions change little.

During the reporting period there is already almost complete innovation of construction technologies. In this period prevails using thinner walls than masonry used in the previous period; is first built with solid concrete blocks and then with hollow blocks. The roofs were initially solid concrete, hollow block then supported by reinforced concrete beams and cast-in-place, then pre stressed joist and hollow concrete slabs.

As a positive example of Yucatan architecture developed during the first and subsequent years of functionalist period has analyzed the work of Felix Mier y Terán interesting because of its response to climate issues in the region. Overall their show careful exposure to insolation, the placement of windows that allow air flow and relationships between interior and exterior landscaped including air flow is encouraged. The analysis performed is qualitative but are being monitored and analyzed through simulation software. Among preliminary results found reduced swing, offset temperature extremes and easy to achieve ventilation. There is no difference in the oscillation and internal thermal lag relative to the previous architecture, but more likely wind flow

Moreover, the analysis of multiple works in which all elements of the language that is associated with functionalism is present was made, but which illustrates the lack of criteria for achieving adequate indoor climate conditions, especially sun exposure , demonstrated more with the profuse use of curtains used to remedy the mistakes made

The paper being done clearly shows that deficiencies of Yucatecan architecture of the period analyzed, like the preceding periods is not the most suitable for the Yucatan region. A complete rethinking of the architecture is urgent to address the challenge of creating comfortable architecture for Yucatan.

An Advanced Model to Represent and Manage Knowledge in Cultural Heritage

Caterina GATTUSO

Professor Dep. DiBEST, (Biology, Ecology and Earth Sciences), Univ. of Calabria Rende (CS), Italia,
E-mail: caterina.gattuso@unical.it

Abstract

For the delicate and complex process of knowledge acquisition in cultural heritage to be controlled and managed, it is necessary to plan and properly guide actions considering monuments from a holistic perspective. Thus, data and information should not be simply collected but they should be processed in order to highlight possible connections and implications and to define a correct knowledge base.

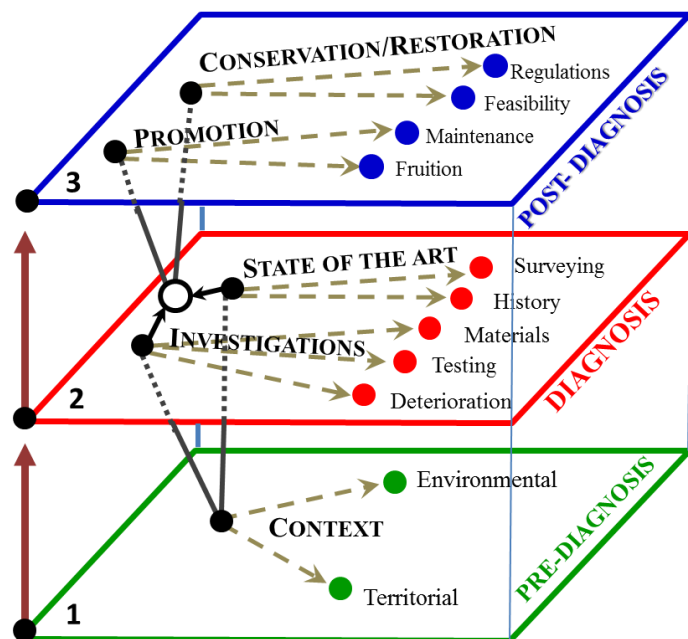

This paper proposes and illustrates an innovative and original method that can be referred to with the acronym CMK (Coordination, Management, Knowledge). The method includes interconnected and multidisciplinary phases and aims at defining in detail the operational procedures which lead to the

definition of the knowledge base and to the consequent identification of adequate and responsible proposals for actions.

The method can be adapted to the level of detail or to the specific information required as well as to the needs emerged during its application.

The main phase of the method, which is devoted to build the knowledge base also through the creation of an interactive and digital case sheet, is introduced by a preliminary phase, during which the monument is first approached in its broadest context. In its turn, it also supports a final more proactive phase devoted to the definition of the conservation and restoration actions to propose.

Finally, an application to a real case is presented in order to clearly illustrate the proposed method.

Keywords: Knowledge, Cultural heritage, advanced methodology

1. Introduction

The rapid development of all cultural sectors has allowed an exponential growth of knowledge. On the other hand, it has highlighted the need for the various fields of knowledge to be better coordinated and to interface with each other blurring the boundaries between disciplines in favour of a recognized and effective action of collaboration.

This trend is even clearer when dealing with cultural heritage conservation and restoration, where the interaction between the professionals concerned has always been considered indispensable to enable

the construction of knowledge meant as a precondition to define and plan correct and adequate actions [1,2].

Therefore, it is of the utmost importance to outline an effective methodological approach that allows identifying the most suitable procedure to knowledge, which entails the coordination of a considerable amount of heterogeneous information from varied and interacting competences in each of its development phases [3,4].

2. The methodological procedure

Knowledge acquisition and management are basic actions in the study of historic and architectural assets, above all if this is aimed at restoration or conservation actions.

Owing to the typical complexity of historic and architectural monuments, in order to obtain knowledge, it is necessary to refer to a rational methodological procedure which is carried on through analyses and syntheses and relies on the synergic collaboration of complementary and interacting competences. The objective is to favour the understanding of problems and to implement control systems to identify and filter possible errors coming from the single parts so that corrective measures can be taken [5].

A useful tool to ease and properly systematize the gathering of information during the construction of knowledge is a digital case sheet elaborated for the specific monument by means of the interesting digital systems which are the result of the latest developments in the technologies of the sector.

The proposed method, which can be referred to as CMK (Coordination, Management, Knowledge), is based on a global approach to the monument that addresses the whole procedure to knowledge with a rational attitude which coordinates and integrates the different cognitive spheres in a harmonic and intelligent manner. Such an approach organizes knowledge acquisition in hierarchical phases that allow defining actions starting from the contextualization of the monument [6].

The level and type of knowledge can depend on the materials, if the monument is considered as an envelope, or on structures, if, on the contrary, constructional and structural aspects are examined. Moreover, the method can be organized and adapted flexibly in relation to the quantity and quality of

information to gather so as to obtain basic, specific or detailed information, or general or sectoral information, depending on if the monument as a whole or its specific parts are considered (Fig. 1).

If the monument is considered from a holistic perspective, it can be compared to an organism to protect, safeguard and enhance. Hence, it is crucial to understand how to treat it by developing an Anamnesis, a Diagnosis and, finally, an appropriate Therapy, as it happens in medicine. Therefore, it is necessary to follow a procedure which is repetitive, adaptable to any monument and yet specialized, according to the information that has led to the definition of the knowledge acquired through the procedure itself.

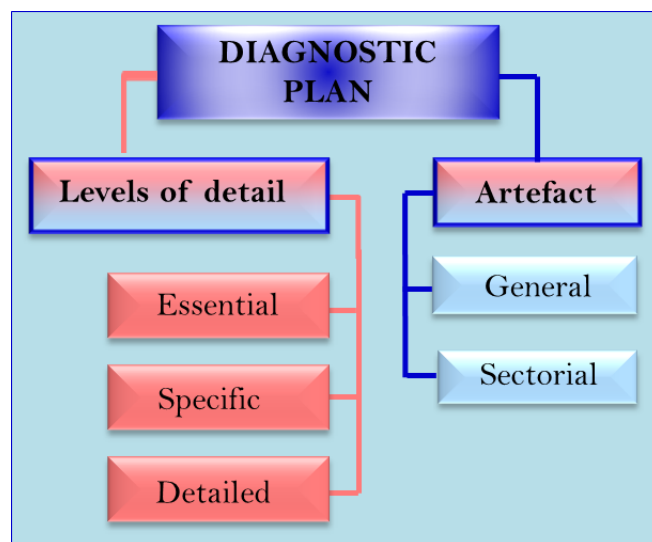

Fig. 1: types of study

3. Structure of the procedure

The proposed procedure derives from a study which has progressively evolved over several years of research and didactic activities also through comparisons with other methods that have been developed in Italy and abroad [7,8].

The above-mentioned method comprises three crucial phases: a preliminary analytical phase of pre-diagnosis, in which the monument is considered in its temporal and spatial context; a second analytical phase of diagnosis, devoted to pursue the actual knowledge of the monument in its physical, stylistic and architectural dimension by means of analytical methods for the characterization of materials, of structures and of their state of conservation [9]; finally, a proactive phase of post-diagnosis which connects data and information and uses the results obtained to identify all the possible and appropriate solutions for the restoration, conservation and enhancement of the monument, taking into account the most advanced cultural and regulatory directives.

3.1 Pre-diagnosis

Tendencies to deterioration, which allow tracing also its causes and processes, can be found in the environmental context in which the monument is located. In particular, weather conditions, environmental events (winds, rainfalls, marine aerosol...) and air pollution (due to the presence of industrial and other facilities) are detected and referred to the specific territorial context and then, going into further detail, to the various types of urban systems and settlements.

3.2 Diagnosis

This phase is devoted to the actual understanding of the conditions and of the state of conservation of the monument. As a result, it requires the synergic contribution of all the experts who can provide input in various ways.

Besides collecting and processing data, this phase should allow grasping the connections between the different parts in order to express an overall evaluation and thus define a judgment, being certain that all aspects have been examined. To that purpose, it is necessary to compile appropriate digital case sheets considering the following elements:

- 2a - *anamnesis*

The whole case history of the monument is useful to put the monument in its historical context, specifically referring to its transformations, restoration and use over time. A historical archival research based on the systematization of historical sources (annotated bibliography, land registers, archival documents, historical cartography, views, literary and travel sources, iconographies, etc...) is carried out always checking their reliability and authenticity through verification and comparison [10].

- 2b - *Graphic and photographic analysis*

Graphic and photographic documents can be developed with traditional, innovative, direct and indirect methods and are aimed at producing a dossier containing modern and historical photos as well as the field surveys needed to map the monument with a view to highlighting various kinds of data [11,12]. High-quality graphic design can be obtained by means of 3D laser scanning and autosynchronized scanning, which allow suitably processing, visually representing or modelling information through graphic representations on various dimensions. Surveys enable to disaggregate or overlap various categories of information and to concentrate it in summary maps characterized by specific themes (map of constituent materials, of the deterioration of materials and structures, of the surface treatment, of chromatic values, of the stylistic and architectural characteristics, of restoration works, etc.) [13,14].

Furthermore, documents resulting from the stratigraphic survey are fundamental. In fact, the records of stratigraphic units of masonry allow recording and highlighting the stratigraphic relations of the building as well as graphically representing them through Harris matrix (Matrix). Through the analysis of the actions that left a trace on the masonry, i.e. adaptations, restorations or demolitions, etc., the stratigraphic reading leads to the identification, reconstruction and outline of homogeneous portions of walls and to their stratigraphic succession. The stratigraphic survey and, particularly, the identification of homogeneous areas are of the utmost importance since they allow planning the sampling of materials and degradation avoiding wrong operations which may nullify all the following instrumental analyses [15].

- 2c – *Constituent materials and their degradation*

It is crucial to know the characteristics of the constituent materials of historic buildings usually made of masonry. To that purpose, it is possible to use techniques commonly adopted to study minerals and rocks, which allow establishing their chemical, physical, mineralogical and petrographical composition. It should be considered that, owing to their heterogeneity, the minerals constituting rocks show diversified behaviours and react differently to environmental (physical, chemical, biological) actions depending on their size, crystalline form and spatial relations. Therefore, the study of the materials of a monument is closely linked to the analysis of the degradation of the external surfaces interfacing with the environment.

Thus, in order to carry out correct investigations, it is necessary to plan an adequate on-site sampling plan that, considering the stratigraphic survey and the state of conservation of the monument, allows identifying and taking samples which, though reduced to the minimum possible, are representative of the situations and enable to analyze intact and degraded parts. To that end, it is essential to define the identifiers of degradation since the distinction of deteriorations allows not only evaluating the state of conservation but also finding possible causes and reconstructing degradation processes through the analysis of phenomena [16,17].

Investigations should be planned carefully and include a system to process and record samples according to the type of test to perform. If properly processed, the data obtained from tests, which

are planned depending on the type of information required, will allow formulating interpretations that can be compared to literature results and help understand the representativeness of the values acquired, also in statistical terms. Based on reference standards, this would enable to obtain reassuring confirmation [18,19].

Although the procedure can be reproduced and replicated, in the case of Cultural Heritage it does not lead to predictable results. It allows the rigorous and flexible management of knowledge and information and enables to achieve solutions which are not guided by intuition, but professional, participatory and shared (Fig. 2).

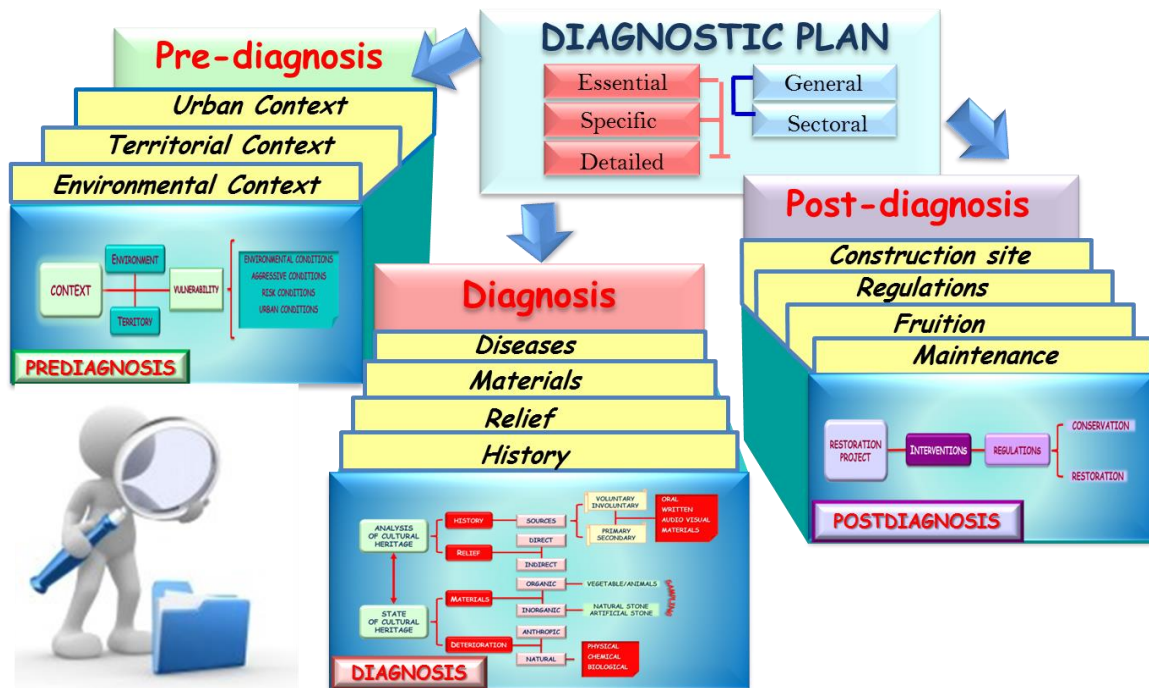

Fig.2: Diagram of the diagnostic plan – digital case sheets of the phases

3.3 Post-diagnosis

The whole procedure contains all the elements of a methodological process within which the intervention to carry out is organized and developed.

Similarly to the above-mentioned diagnostic method, three main phases are outlined: a first phase of pre-intervention, which includes the whole diagnostic process; a phase in which the intervention is actually carried out; and a final phase of post-intervention devoted to the elaboration of a project of enhancement aimed at improving fruition and creating activities, economic development and new opportunities of business around the monument. Certainly, all these actions should be characterized by a continuous control and monitoring of the asset so as to actively contribute to its adequate conservation in time.

4. A representative example: application of the diagnostic plan to Colloredo Monastery

Finally, in order to show the practical applicability of the procedure described above, the representative case study of Colloredo Monastery, whose ruins are situated in the Municipality of Morano, Calabria Region, is proposed.

During the pre-diagnosis phase, the geographical context was outlined, while, in the diagnosis phase, the anamnesis, including the graphic representation and photographic dossier, was carried out. Moreover, a representative example illustrated the types of laboratory analyses which were performed on samples of stone materials taken from the Monastery. Based on these samples, during the post-diagnosis phase, a sort of “atlas” was obtained by means of specific case sheets containing the description of each material constituting the Monastery. Such case sheets were useful not only to define actions to protect the monument, which is now in ruins, but also to provide a set of documents for its enhancement as part of tourist cultural itineraries (Fig.3).

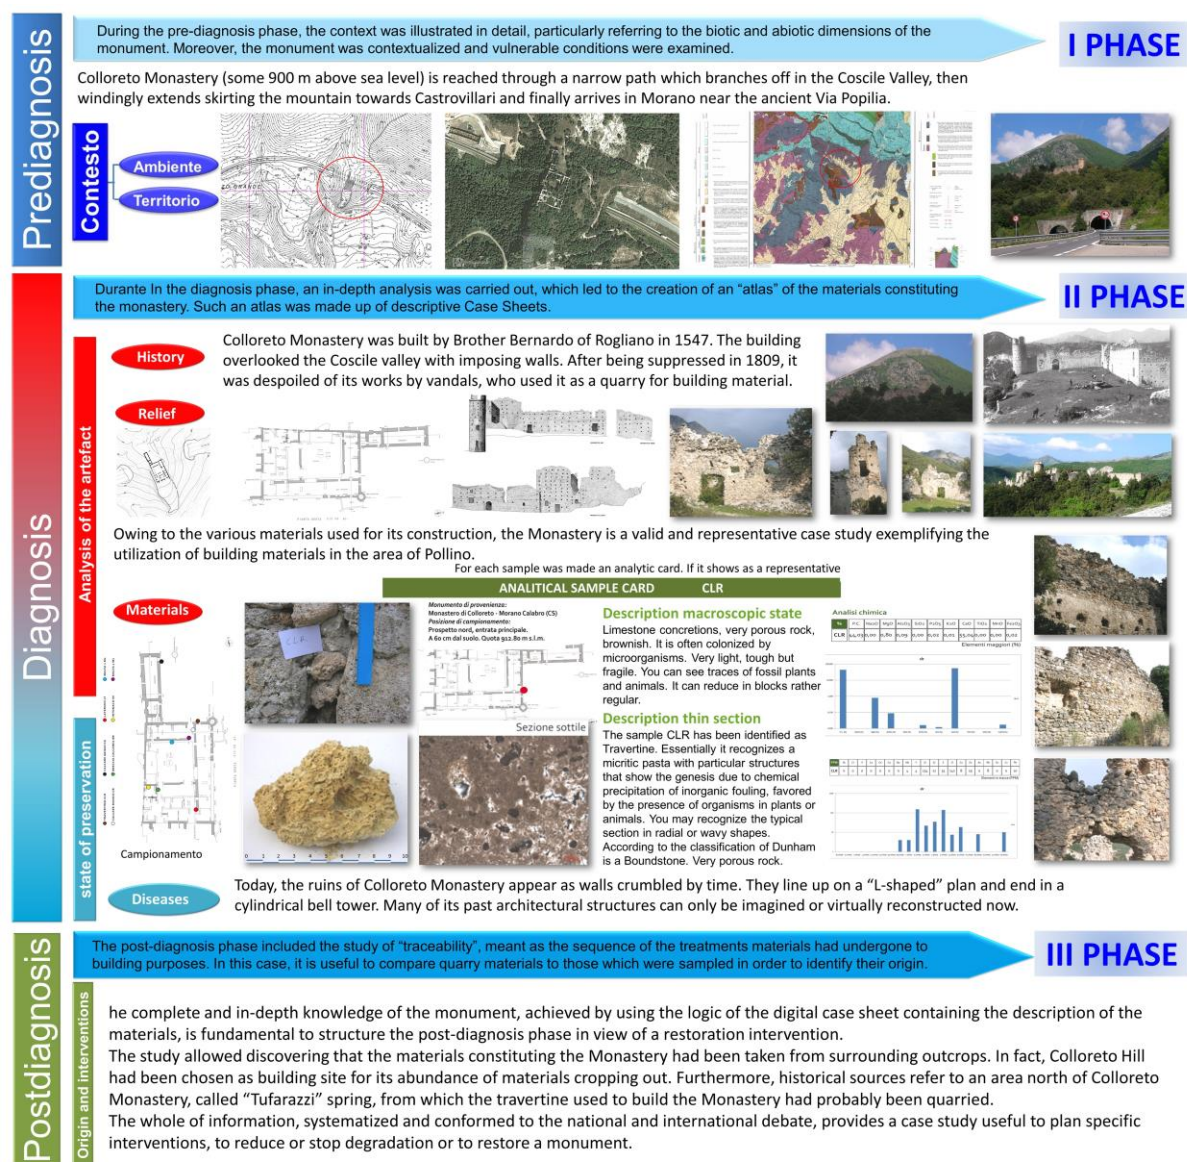

Fig. 3: The diagnostic plan applied to Colloredo Monastery

5. Conclusions

This study aimed at providing guidelines to direct and support knowledge management in the field of cultural heritage. The strong need for a multidisciplinary approach, which is peculiar of this sector, requires that varied expertise should be systematized and harmonized in order to focus all efforts on the definition of interventions which take into account the national and international debate, comply with rules and derive from an advanced diagnostic plan that may create synergy and lead to shared solutions.

Owing to the complex and considerable information to manage, it is necessary to set a protocol that allows coordinating all the aspects concerned in a flexible manner, trying to reconcile scientific components and requirements with those of humanities.

The paper proposed a comprehensive scientific research method organized in three essential phases: the first phase of contextualization outlines the pre-diagnosis conditions and introduces to the actual diagnosis, thus leading to the final definition of interventions by means of diagnostic investigations.

Abstract

In recent decades, the landscape paradigm has defined a new approach to conserving and managing the cultural heritage, starting specifically with a change of scale, which now takes into account not only the single elements of cultural heritage but also the heritage in its context, i.e., territorial, social, cultural and economic.

Cultural itineraries are described in this framework—in their wide, complex meaning—as a network that connects historical structures, territorial elements, and landscapes (i.e., ancient towns, historical buildings, routes and paths, rivers and valleys, ...).

Furthermore, cultural itineraries lead to the possibility of interpreting and developing new meanings for cultural heritage, even rethinking their roles related to contemporary landscapes and contemporary values.

From these premises, cultural itineraries also become a strategic objective of urban and territorial planning, since they are linked to territorial improvement and allow for new models of governance to be experimented with and innovative scenarios of sustainable development to be defined.

This paper explores the meanings of cultural itineraries by studying the landscapes of the Lauretana pilgrimage route, a historical route that winds across central Italy through a network of paths leading from Rome to Loreto. It explores the relationship between ancient modes of travel and the contemporary way of slow walking, and it shows the relationship between cultural and territorial networks as well as ecological and environmental ones.

Keywords: cultural itineraries, environmental networks, heritage, slow paths, landscape.

1. Cultural Heritage and Cultural Itineraries

Many different requests that attest to the changeable nature of a “nomad concept” [1] are coming together today in the field of cultural heritage, evolving with the evolution of society, its values, and its rules.

Recognition of the value of heritage began on a worldwide scale with the preparation and adoption of the Convention Concerning the Protection of the World Cultural and Natural Heritage (World Heritage Convention, 1972) by UNESCO. Since then, an awareness has matured, spread, and consolidated that links the cultural heritage not only to cultural objects that are well recognized and protected on the national level, but also to objects that appear on a smaller scale closer to daily life and which reflect local diversity linked to the production of culture and techniques as well as the understanding of non-material goods, i.e., the intangible heritage.

The release of the local dimension has also allowed relationships between communities and the heritage to be looked at in an ever-wider view of the heritage, as is reflected upon in The Framework Convention on the Value of Cultural Heritage for Society (The Faro Convention, 2005), which “for the

first time offers a holistic definition of cultural heritage. It expresses the principle that preserving this heritage is not an end in itself but has the aim of furthering the well-being of individuals and the wider expectations of society" [2].

This openness and evolution should also be related to confirming the landscape paradigm as expressed by the European Land Convention (ELC), which highlights its complex and changeable relationship linked not only to excellence, but also to marginality, and introduces the population's role in recognizing their own landscapes.

Starting with the notion of "landscape", rethinking the concept of "heritage" means using a perspective that moves attention from the object to the context, highlighting the relationships between elements that articulate the landscapes themselves. In this view, the heritage is no longer just a casual combination of goods or resources of various types and independent value, but becomes a complex system that is more or less coherent and is interconnected with the historical, cultural, natural, tangible, and intangible inheritance, affinities, and networks of relationships that link places and social structures [3].

Talking about the territorial heritage then seems to be the concept that best expresses inclusion of the heritage in territorial networks and confers a specific mandate on planning in the heritage area as well. In this framework, the concept of "cultural itinerary" is a key concept in dealing with the relationship between the heritage and the landscape from a territorial point of view, identifying the relationships between history and modern day, and interpreting contemporary landscapes through plans and projects aimed at territorial transformation.

In matters of cultural itineraries, the main references in Europe are two different but somehow complementary documents that specifically confront the theme of cultural itinerary with the additional aim of trying to define it.

The Charter on Cultural Routes prepared by ICOMOS speaks about this in terms of heritage category, a complex cultural object whose components are not only the timely elements that constitute it and which represent the manifest content, but also the natural context of reference, its overall meaning, dynamic character, and geographical and territorial means contained in the itinerary. According to this vision, a cultural itinerary is not placed above other heritage categories, but becomes a tool to reading the heritage and contributes to recognizing, improving, and enriching it with meaning [4].

The second document, prepared by the Council of Europe and expressed through a specific resolution (Resolution CM/Res(2010)53), defines a cultural route "as a cultural, educational heritage and tourism co-operation project aiming at the development and promotion of an itinerary [...] for the understanding and respect of common European values" [5].

In general, cultural itineraries are configured as a system of networks and relationships that develop over time and space and which represent evolutionary, interactive, and dynamic processes in human relationships linked to the specific phenomena of mobility and exchange. Their innovative character resides precisely in being composed of dynamic factors that over time take on different territorial configurations, repeatedly charging themselves with new meanings that make it a model for reading and interpreting landscapes and directing territorial transformations.

Following its path—the first characterizing element of the itinerary—the study of the *via Lauretana* starts by identifying the territorial configurations that have represented its landscapes over time, those territorial and social configurations that have characterized it, and which the road itself has contributed to mould.

The *Via Lauretana* is a historical pilgrimage route that connected and still connects Rome to Loreto. It consists of a network of paths that cross very different landscapes: the road intersects urban and rural contexts, runs along valleys, and crosses the mountainous Apennine chain; it winds through small hill towns and landscapes in the Marche region, reaching the Marian sanctuary of Loreto containing the Holy House; it finally continues towards the sea and the port of Ancona, and connects to other roads [Fig n. 1]. Over time, this road has taken on different connotations: it has been a commercial route, a pilgrimage trail, a postal route, and also a travel itinerary in the era of Grand Tours [Fig n. 2,3]. It is currently configured as a high-speed route that modern needs have made ever more functional for vehicular mobility, pushing aside the possibility of identifying the different ancient traces that intersected the towns and ran alongside rivers.

The current situation is therefore a fragmented system where the relationship between history and modern day is reflected in the landscape, where ancient forms face more modern structures. This is valid both for the architectural structures and urban centres and for the natural areas and resources.

The temporary synchrony of these landscapes makes it necessary to find new codes to interpret the traces of a history that is both recent and remote, and to reconstruct a cultural fabric that is capable of recognizing and improving the territory's history. At the same time these codes should be able to innovate and transform the landscapes to enable them to evolve while maintaining their quality and resources.

The cultural itinerary allows new forms of productivity to be elaborated for these landscapes along with forms of contemporary use, reconnecting to themes (such as tourism) that are becoming ever more

cognizant, sustainable, and widespread, and exploring strategic territorial relationships (such as the relationship between the cultural and natural heritage).

The first aspect consists of the possibility of identifying new stretches and constructing new experiential methods that allow for the landscape use through walking and slow mobility. The second aspect tends to expand the range of territorial resources and standardize them, finding new markets and serving as the driver for new models, as well as managing the landscapes themselves.

According to this planning map, a cultural itinerary is not the combination of a road or the plan for a themed route that connects points of interest. It is rather the combination of projects and transformations that cultural networks and linear systems are capable of conveying, intercepting areas in which the cultural and natural resources together are transformed within their landscapes in a dynamic vision, which is the landscape itself.

2. Cultural Network and Landscape

If investigated through the opposition of descriptive categories gleaned from the historical (ancient/modern) and urban planning (city/country, central/suburban) disciplines, there is no doubt that the territory that modern day has produced is indecipherable. Next to signs of nature and history, new types of space continue to become stratified. They are often difficult to define according to a simple relationship of proximity or through a relationship of belonging to the place. Even when observed through the lens of identifying images in the culture of the communities inhabiting the territory, the current territory returns an effect of territorial detachment. Questions of ecosystem and landscape fragmentation are added to the condition of settlement dispersion, which therefore alter the consolidated local identity.

The temporary spatial acceleration dictated by the new world order has broken apart the relationships between citizens and inhabited space, between places and production materials. If in the past it was possible to discern a tight correspondence between places, uses, and meanings, today history and nature, ruralism and urbanism are again called to propose their own values within a new cultural context and a different territorial arrangement.

The territory has become the place in which many values and meanings recognized by different territorial players are overlaid in a manner that is often not shared and not infrequently also ingrained. Its indecipherability, therefore, is strictly linked to the economical and cultural dynamics of our time. This dynamics constitutes a fact with which the strategies and actions planned for individual territories should be confronted, with the general aim of constructing conditions of local sustainable development.

One response to this complex and multi-layered territorial condition was proposed by the new landscape paradigm introduced by the ELC. The landscape, recognizable to its inhabitants from its own natural and cultural resources, both material and non-material, becomes the place for dialogue [6], common good, and the entire resource through which to imagine sustainable development perspectives for the individual European territories.

The inclusive and complex dimension of the landscape, among other things, has returned landscape dignity to all parts of the territory and has reawakened attention to some space-usage practices (the practice of walking, for example) as forms of perception and knowledge of the place.

Moreover, the ELC has reiterated the newness of the network vision of the landscape, highlighting how the vitality of different landscapes is linked to the existence of multidimensional relationships between individual territories.

Among the numerous components recognized within territorial complexity, cultural networks certainly play an important role, in particular for their capability of favouring the process of resource recognition for sustainable local development. This renewed landscape vision projects cultural networks into a systemic and relational dimension by relating them to other heterogeneous networks, and no longer imagines them only as signs of connection between more or less distant points.

It is precisely the network dimension that characterizes our time. Different types of networks (transport, technological, natural, historical) and nature (material and digital networks) cut through modern territories, thereby constructing the new geography of relational systems in which we live. In the literature, the image of "hyper-landscape" has been coined [7]. This proposal derives from the possibility of considering the landscape in its hyper-textual dimension. A landscape, like a hypertext, has a network structure, is denoted by a determined degree of complexity, is composed of heterogeneous information, both material and non-material, and is not equipped with a unique organizational centre, but rather displays multiple centres. In this vision, proposed not as univocal and absolute, but rather as a possible interpretive key of landscape complexity, the cultural networks can be better understood both in their material and non-material nature as well as in their coexistence with other networks.

Investigating cultural networks in a hypertext key favours the recognition of historical fragments, which are often catalogued as historical/cultural goods deposited in the territory not as isolated points but as

nodes pertaining to a navigational path in an interconnected and interdependent system. Even more clearly, cultural networks express their material and non-material landscape nature in the presence of traces of the old roads and in the points they connect; as such, it is possible to find them continuous and integral today. Such points are not only nodes in the cultural network, but also in the landscape hypertext. They are, in fact, the depository of a series of material and non-material informational data, whose knowledge can activate links with other nodes in the hypertext, even those not directly related to the cultural dimension. In the same way, the old roads are today overlaid by new means of travel connected to their nodes and to other meanings. These travel systems, nevertheless, pertain to the same local landscape mosaic crossed by the road. It is their consistency in different eras and different relational systems that render them distinct but necessary parts of the current landscape hypertext.

Expanding upon this metaphor, cultural networks in hyper-landscapes are configured as networks within other networks. The vitality of the single landscape is given precisely by the interdependence of the different networks. In the hypertext image, different networks can co-exist, be overlaid, intersect, and be used by the hypertext user—the individual—in their different, also ingrained, contents. Communities today have thus built their own landscapes, accepting the coexistence and conflict between traces and multiple meanings.

If this theory tends to favour an understanding of landscapes, it is not always destined to provide a strategic solution to planning. However, it may be interesting to apply the hypertext metaphor to specific ways of using the landscape, which may simulate hypertext navigation to verify possible paths for innovation.

One of these is certainly the practice of walking the landscape. It is not by chance that in precisely the era characterized by phenomena that have altered the space-time dimension and virtuality that this return to the slow dimension of landscape use is registered. The emphasis accompanying the multiplication of proposals for discovery along slow paths in some places could be interpreted as an antithetical response to the paradigm of modernity with its characteristics of speed, virtuality, and dislocation. In fact, individuals face difficulty in interpreting the places where they live and that “anxiety of reconciliation with one’s own history and with nature” arises, “which is born as a reaction to uprooting and deterritorialization processes that tend to cancel out any relationship with places and which modernity had dissolved” [8].

Travelling slowly on foot or with other light means of transport, imagined not within the specialized closed infrastructure of external relationships, but along the traces of the old road, thick with interference from other tracks and networks, becomes a tool to favouring the perception of culture by the traveller, not in an isolated way, but rather within the hyper-landscape.

On the one hand, this use/perception method can protect from the risk of separating the material and non-material cultural dimension from the rest of the territorial context. Such a condition would limit the risk of imagining conservative strategies separate from the perspective of sustainable development of the place.

On the other hand, it could stimulate the design of new forms of using the space within a larger compatible improvement of the landscape resources, and protect it from the temptation to turn the cultural object into a museum.

Developing such planning ability within the image of the hyper-landscape can facilitate the conception of cultural networks within the widest and most complex landscape system. The act of walking can therefore become a useful instrument for plans directed at stimulating the knowledge of the local culture, favouring a new, more aware interpretation of it, and place coordinated actions in the field to conserve and promote endogenous resources.

3. Cultural Heritage and Environmental Networks

The concept of “environmental network”, more commonly known as “green infrastructure”, whose principal reference is given by the concept of greenway (from the combination of green belt and parkway), appeared for the first time at the end of the 1950s in the urban plan for the city of Philadelphia. It indicated a system of green paths and parks aimed at integrating recreation with ecology, and naturally carries with it themes of “connection” and “multi-functionality” and the concept of “open space” [9].

Environmental continuity is revealed as an articulated, connected system including the ecological and landscape paradigm and involving numerous private and/or public open spaces, which are in turn marked by a wide range of functions. The multiple diverse functions that environmental continuity can undertake can be brought back within a wider definition, that of a dual function.

Environmental continuity can, in fact, undertake the role of maintaining a good degree of naturalness and therefore work as an ecological network and at the same time allow good use to be made of open spaces, especially green ones (in their relationship with urbanized spaces), functioning like a greenway network for recreational pedestrian and bicycle access. Within the dual sphere indicated

above, the different means through which environmental continuity can be expressed are synthesized in the image and meaning of multi-functionality.

Multi-functionality, in as much as it represents the relationships that are created in a territory between different places and relational networks activated between the different activities, functions, and uses of the territory, can help determine greater potential for the place, and can consequently participate in reaching environmental, economic, and social objectives. Coherent with the concept of multi-functionality and in virtue of the overall network of functions and services that the environmental infrastructure is capable of supplying—ecological, recreational, historical/cultural, and educational services aimed at both improving the quality of life of the community and guaranteeing greater sustainability—the environmental structure constitutes the representation of that connection mentioned before between different landscapes, urban, suburban, rural, and natural places, or rather the composition of a mosaic capable of providing a unitary vision starting from different elements and spaces. Such a mosaic, the expression of a connection network understood as each space acting as part of a wider system and in a functional and integrated way within the green infrastructure, is specified in many different ways according to the context and intervention scale.

The existing reciprocity and link between the theme of connection (the unique distinctive character of each environmental network) and the theme of multi-functionality highlights the “open space” as an area of reference. The environmental network, as described up to now, therefore represents a system of open, green, accessible spaces interconnected with the settlement system: a system that may have different characteristics, but which is always aimed at looking for good practices capable of refreshing and guaranteeing relationships between the natural and historical/cultural components, and increasing the integration with local communities in order to protect, use, and develop activities directed at local sustainable development.

Among the signs of environmental continuity, such as the opportunity to imagine new projects for public spaces, new connections, new relationships, new models of human/environment interaction, new relationships between natural and cultural resources, and new forms of sustainable use, important and illustrative actions appear. These may be, for example, the development of natural corridors, the realization of sustainable transport, planning green spaces that can transform cities, and improving the environmental quality of the territory. It is exactly this theme of use within the environmental network that constitutes the link, the bridge that specifies the existing connection between environmental continuity, cultural itineraries, and tourism [10]. Environmental continuity can and should interact with cultural itineraries and cooperate together to produce sustainable tourism. Cultural itineraries are approached from a natural perspective. The “natural glance” with which Geddes defined his “visual” way of getting close to reality comes to mind.

In particular, considering cultural tourism as the manifestation of attention to territorial and cultural signs as well as cities, places of art, small urban centres scattered throughout the territory, natural parks, and the traditions, gastronomy, craftsmanship, and all the other social/cultural elements that characterize a given territory, environmental continuity becomes the framework for the numerous diverse networks and/or forms of sustainable use, in particular for all those forms that refer to the so-called hereditary patrimony (ecotourism, wilderness tourism, adventure tourism, agritourism...). The concept of “heritage tourism” [11] therefore becomes relevant.

4. Cultural Network for Territorial Governance

Despite the economic crisis, the tourism trend continues to be a characteristic factor of the local economy, and one of the reasons for the resilience of cultural tourism is the fact that the range of cultural motives for travel is broad and rapidly increasing as a result of postmodern fragmentation. Instead of a ‘mass market’ for cultural tourism, one can identify a growing range of cultural tourism niches related to specific facets of culture that appeal to tourists or which are being developed by destinations.

Among the most important of these new market niches are:

- creative tourism;
- educational tourism;
- gastronomic tourism;
- religious tourism;
- spiritual and holistic tourism;
- wellness and spa tourism;
- cultural volunteer tourism;
- roots of migrant tourism.

A specific study has recently been conducted to support this. Entitled “The study on the impact of European Cultural Routes on SMEs’ innovation and competitiveness”, it was financed under the Competitiveness and Innovation Framework Programme (CIP), which aims to encourage the competitiveness of European enterprises.

This study was launched jointly by the European Commission (EC) and the Council of Europe in September 2010. Its objectives were to provide insights into the effects produced by transnational cultural routes—such as those certified by the Council of Europe—on SMEs' performance, innovation capacity, and network and cluster development; to examine the potential of cultural routes for promoting sustainable and quality tourism in Europe; and to analyze to what extent cultural route networks can benefit SMEs, especially in rural areas and lesser known destinations.

The provisional edition of the study shows that cultural tourism is an increasingly important segment of the total tourism market involving visitors and local residents, who also seem to appreciate the potential benefits of cultural tourism as it is a form of quality tourism.

The OECD report on culture and tourism (2009) indicated that the main drivers for developing culture and tourism policies are:

- improving and preserving the heritage;
- economic development and employment;
- physical and economic regeneration;
- strengthening and/or diversifying tourism;
- retaining population;
- developing cultural understanding.

The data seem to confirm that cultural itineraries represent a system and strategy that can nudge local economies and make use of the ever more widespread territory, transferring a strategy of recovery and improvement of an often fragile territorial heritage to the constant care of the territory that is also too often found in a state of fragility.

However, from the planning point of view, cultural itineraries pose new questions that go beyond tourism and local economies strictly linked to tourism. This recalls the need to confront landscape management within new and innovative planning and territorial governance actions and to convey their transformation in a contemporary key and in relation to contemporary phenomena such as reconverting agricultural systems, new production and techniques, demographic trends, and phenomena of contemporary urbanization, etc. Reading landscapes through cultural itineraries is not only an aspect of tourism, but also allows the already noted heritage and its relationships to be recognized, identifying other territorial heritage and environmental resources in relation to the contemporary examples, elaborating new meanings, and experimenting with new governance models. In the perspective of a territorial improvement project, the concept of “territory” and “network” take on new relevance. The territory can be understood as the area of reference in the improvement process for individual goods and the landscape, while the network is the instrument with which the “complexity”, the composition of the structure, and relationships between different elements can be described [12]. Not only this, the network can also become the instrument with which the reciprocal relationships between the natural and anthropic elements can be represented, as well as an instrument for systemically organizing the resources and services linked to it. The cultural itinerary enters into this network among networks, situating itself as a mediator between things and the memory of the territory closed within the traces of history. In such a way, the past can be carried into the present.

If historiography codifies signs of the landscape according to an approach that explores the relationships between heritage and context, it is in planning that the heritage is interpreted and inserted within new scenarios. The cultural itinerary is therefore the planning instrument and contributes to deepening the relationship between heritage and planning, sanctioning the ownership of the first by the second. The heritage is therefore a subject that should be confronted within planning not limited only to the landscape, but within ordinary planning, from the wide scale to municipal planning. In this sense, the ELC is very authoritative in assigning great responsibility to planning in the processes of improving the territorial and landscape heritage.

The cultural itinerary can provide a decisive contribution in the challenge open within planning of how to “make a landscape” [13], i.e., how planning can distribute the landscape to the different levels of territorial government. Very often the landscape is not concretized within activation procedures by the directives and orientations of the regional scale to choose the design of landscape on the local scale. The cultural itinerary, being a linear system, a complex network that holds together different objects, times, objectives, and all their interactions, touches the different territorial planning levels, providing indications and orientations that can be taken to the specific scale of interpretation. The cultural itinerary therefore becomes a tool to renew the planning perspective, which becomes exploratory and develops along the lines of improving the various urban components that feed it in different ways on different scales.

In this sense, the planning ability of the cultural itinerary does not merely look at recovering a historical trail, but is the combination of all the local projects conveyed by the historical and contemporary territorial heritage that the itinerary identifies and reconnects to the territorial networks. The project starts from the cultural itinerary, which becomes the tool to interpreting the complexity of the territory.

The new vision that the itinerary introduces notes that territories do not exist as isolated objects, whose life is undertaken only in the mind and following a selection and abstraction made by the human culture, but they are rather still-recognizable historical systems [14]. The diffusion of the heritage, which at first glance may seem difficult to govern, takes on a positive connotation. The elements that were first seen as dispersed and isolated in a territory it did not seem to belong to are now dispersed by their pervasive character within the decision-making choices that direct the transformation of territories and within territorial networks. They are networks that should not contemporaneously hold all the elements of history together, but be taken up one at a time from the territorial heritage based on their uniqueness, being held within the territory and improving its refreshing relationships.

The itinerary acts by identifying these relationships, which however continue to evolve, transforming the meanings of the heritage and producing additional ones. Moving attention from the object to the context, working on the signs and form of history, it is then possible to confer on the heritage a planning dimension and new role within the organization and reordering of the territory.

Therefore, the improvement of the heritage does not occur only in tourism networks, but also within transformation projects with a landscape approach. This is a vision that, starting from the historical inheritance in memories and evidence of the past, recognizes the modernity of the historical territory in its incessant contemporaneousness with the culture of the society that inhabits and produces it [15].

In such a sense, the cultural itinerary interacts with planning, broadening the concept of participation as well. In fact, by walking and travelling, the cultural itinerary creates moments to meet and talk, where participatory processes are born. The practice of walking offers many points for participatory planning of the places of daily life, in which not only tourists or outsiders, inhabitants, and citizens interact, but also interested populations that take part in choosing to manage the territory as the ELC hopes.

5. Conclusion

A fertile relationship between cultural itinerary, environmental networks, and the heritage can produce territorial development and orient land design. The cultural itinerary characterizes the different landscapes and local settlement contexts, marking the link between goods and territory, and favouring the improvement and increasing endogenous resources through the construction of super-local networks. Environmental networks (and all that comes from nature) interact with cultural paths, providing spatial anchoring or becoming the opportunity to superficially change the compromised and degraded spatial situation. The basic premise however, is to give a planning approach to the system articulated by the network in its complexity. The historical itinerary is not only the custodian and witness of a past to be protected and preserved, but also the nervous system of new sensory worlds that unfold on the territorial level, creating new landscape visions. In this sense, the touristic improvement that development of these slow paths can produce is only the first step in a process of complex and organized territorial reorganization based on a reciprocal mixing between memory and modernity.

Correct use of materials and technologies for a sustainable design: the study of “Acrilica” lamp by Joe and Gianni Colombo.

Francesco TAMBURRINO, Raffaella AVERSA, Antonio APICELLA

⁽¹⁾ Department of Architecture and Industrial Design. Second University of Naples, Aversa, Italy

E-mail: francesco.tamburrino@unina2.it, raffaella.aversa@unina2.it, antonio.apicella@unina2.it

Abstract

The theme developed is the Re-design of a cult object of Italian Design: Joe and Gianni Colombo's “Acrilica”. The initial lamp has been revisited with the aim of creating a product with a lower weight and a greater efficiency, in order to achieve a sustainable design through the method of “Concurrent Design”. At The end of Re-design a comparative environmental assessment with the initial product has been made, using specific software tools. The “Acrilica”, has been subjected to analysis of transversal type.

This has led to a new lamp which provides a redefinition of the form of the convector in PMMA, a decrease of its thickness, a change of the direction of whole lighting apparatus; with the aim to ensure the refraction of light along the curve in PMMA and in the direction of its support plane and therefore reduce the dispersion of the light and the environmental impact. The whole design and the choice of the light source aims to an optimization on multiple levels which gives improvements in terms of use of materials, functioning, processing technologies and duration of the life of the lamp.

Finally for the comparative LCA(Life cycle assessment), we have followed the ISO14040-ISO14043 standards that regulate the same LCA methodology and to communicate the data, the EPD certification scheme(Environmental Product Declaration. ISO14025).

The final product has a higher lighting efficiency with an implementation of the illuminated area of 50% and a weight reduction of 46%.

Keywords: Sustainable Design, Research and Innovation

1. Foreword

This work is the result of an ambitious project of re-design. Through experiments and comparisons, an attempt was made to redesign a cult object of Italian design: the “Acrilica” of Joe and Gianni Colombo. Knowing the progress made by science and technology, we have tried to highlight the limitations that the original design presented and groped, at least in part, by rethinking its physical characteristics, materials and processing technologies to overcome them. The object in question, in fact, although for the time in which it was made, represented a commendable and pioneering design expression designed and built today gives inspiration to many criticisms. In particular, the original insight of using a curved sheet of PMMA to convey light has not been accompanied by a rational use of the same material, aimed at optimizing its characteristics without, instead, to highlight its limits. The basic idea of this work is to re-design, recast, revise the concept of Acrilica, adapting it to new process technologies and new materials, enhance its functionality, improving it without neglecting aspects such as those related to the lighting function, the “gute form” and the proxemics. From a purely technical point of view, the method used for the re-design is articulated through various phases. The work starts from analysis of the shape, from the characterization of the materials, from the discretization of the components and from the study of the lighting function with the main purpose of identifying the “weak points of the object” and to eliminate them for the redesign. Nothing is taken for granted, every aspect is examined and verified by computer simulations. The shape, the thickness, the surfaces of the materials used, the orientation of the lamp, the positioning of the light source are rethought(with a

particular attention to photodegradation of the acrylic polymer). There isn't an idea that precedes experience, but the experience becomes a way to give shape to an idea. Solutions are devised, tested and proven. The work was organized as a design process, as a work in progress that through empirical findings and practical applications ended with a significant study on the life cycle of the product (LCA, life cycle assessment). The "Acrilica" lamp and its redesign are compared from a point of view of environmental impact, in order to generate for the Re-design innovation and improvements also as regards the aspects linked to ecosustainability.

2. Description of "Acrilica" lamp

"Acrilica" is a table lamp giving indirect and diffused light, with a painted steel base and a Perplex diffuser. The lamp, designed by Joe and Gianni Colombo in 1962 and still produced by Oluce, golden medal at the thirteenth triennial of Milan 1964, was honoured with various prizes and rewards and now it is present in many permanent collections of great significance, among which MOMA stands out for its prestige (Museum of Modern Art). The desk lamp "Colombo 281" consists of a convector in PMMA bent into the shape of the letter "C" and a metal base, where is placed a small fluorescent tube (max 6W). The luminous flux rises through the convector, from the base to the top pointing downwards, which allows the enlightenment of the supporting surface. Therefore, a kind of diffused and indirect enlightenment is obtained. The approach to the project perfectly reflects Joe Colombo's poetics turned to technological research and the exploration of material characteristics, inclined to futuristic scenarios.

3. The method to re-design.

The method used for re-designing of "Acrilica" lamp starts from a depth analysis of the same. This analysis is divided into several phases: the study of its form, the discretization of the components, the study of materials and their characterization, the analysis of processing technologies. Each part of the analysis is based on the identification of all the weaknesses of Acrylic lamp pointed out in the previous phase of analysis. After this stage, the re-design of the lamp starts, having an effect on the weaknesses, which are transformed into the strong points of the new project. Finally, after the definition of re-design process thanks to an evolution of design concept and by the means of the tools typical of integrated design (especially those related to verification tests and the validation of the efficiency of the luminous device), re-design is also validated from the environmental point of view, performing a comparative analysis between the life cycles of Acrilica lamp and its re-design.

4. Study of the shape of the lamp and discretization of its components.

The lamp "Colombo 281", or known as "Acrilica", occupies a footprint in space of 250x270x240 mm. The lamp consists of two main components: a bent 30 mm PMMA convector and a metal base. The metal base, which is the lodging of the light source (fluorescent tube max 6Watt), is made up of two parts. The assembly and the fixing of the components occurs by means of only five screws. Three screws are fixed in the lodging of the light source and the remaining two are directly fixed in the PMMA convector.

5. Characterization analysis by RAMAN FLEX400F

Physico-chemical characterization of the convector material was realised by means of two tools: RAMAN FLEX 400F and DSC822 METTLER TOLEDO. The Raman corresponds to a technique used for the identification and the analysis of molecular types; it is an equipment (RAMAN FLEX 400F) similar to FT-IR, but it offers a series of advantages. For example, raman cannot be used for the analysis of samples in the solid, liquid and gaseous state and for the analysis of powders, gels and sludges. Raman spectroscopy is based on the observation of the scattered light. Usually, when the light interacts with a substance, it occurs in three different ways:

- It can be absorbed
- It can be transmitted
- It can be scattered

Raman spectroscopy is the result of the dispersion of the light. The radiation can be resiliently scattered, that is without any variation of its wavelength (Rayleigh scattering), or it can be inelastically scattered, producing the consequent Raman Effect. There are two types of raman transitions: "Stokes radiation" (the photon collides with a molecule and loses some energy) and "anti-Stokes radiation" (the photon collides with a molecule and gains energy). Both "Stokes" and "anti-Stokes" radiations consist of lines that correspond to molecular vibrations of the substance in analysis. Every compound is characterised by its own and unique Raman spectrum, which can be used as a sort of digital fingerprint for the identification. The purpose of the experiments is to trace and identify a series of tracepoints along the body of the curve in PMMA, in order to understand the quality of the compounds found in the sample, through the raman spectra and the Stokes lines, thus succeeding in interpreting the type of photoaging that is observed on the material and the influence of

the light source position. A protocol for raman analysis was created and implemented, including 13 tracepoints and the analysis was repeated 3 times for each of them, in order to guarantee the accuracy of the result. The tracepoints were identified depending on their distance from the light source and every one was associated to a letter from A to O; the letter A corresponds to the closest point and the letter O corresponds to the most distant one. An analysis of 4 seconds (0,5 sec. per 8 esp.) was planned for each point and, before this analysis, the sample (in our case the curve in PMMA) should be cleaned with a special cloth.

The results of the analysis denote that the peak of photodegradation, pointed out by the presence of carboxyl groups ($C=O$, 1730 cm^{-1}), in correspondence with the area identified by the points E, F, G, H and L (F and G with the maximum value). This area corresponds to the area that, in simulations, represents the maximum dispersion related to the light of the lamp. The fact that the N and O zones near the light source, but shielded from external light, do not show a considerable degradation, indicates that the material undergoes a combined effect of natural and artificial light.

6. “Acrilica”: analysis of critical points

The Acrilica lamp is characterised by many criticalities, especially from a functional point of view and from the point of view of environmental impact. The peculiar shape of the convector, with a sharp curve and other curves along it results in a significant dispersion of the light and a poor lighting. For example, observing the Acrylic in a dark room, it is possible to notice that a considerable amount of the light, generated by the light source, is not conveyed, but it illuminates the area behind the lamp. This corresponds to an inefficiency, because the performance of the unit is not close to the maximum attainable. On the basis of this first analysis, the use of a 30mm PMMA convector is a possible solution, because a greater thickness permits a greater capacity to convey light. However, this kind of solution collides with environmental issues and manufacturing technology; actually, the overabundance of material (PMMA) induces an higher environmental impact (it will be showed in one of the next sections). Moreover, from the technological point of view, the use of a material with a high thickness, because it induces many problems in the process of heating and curving the sheet, in the phase of thermoforming.

7. Patent: study of utility model given in 1965

The research of data, informations and details about the brothers Colombo's study and path taken to arrive at the design of the “Acrilica”, corresponds to one of the most important moments in re-design process of this lamp. This research, conducted in a transversal manner, engaging many people, corporations and archives, such as the architect Ignazia Favata, Joe and Gianni Colombo's archive, Biblioteca della triennale di Milano, UIBM (Italian Patent and Trademark Office) and Oluce. The research ended with the finding of the utility model n° 99349 (title: “Luminous component with the body in transparent material and radiant end”) in ACS (Central State Archives), which was granted to Colombo brothers on 9th October 1965. As it is showed in the images, this utility model is not directly referred to the Acrylic, but it is useful in order to recall Joe and Gianni Colombo's experience in the early sixties. The shape of the luminous component designed according to the patent is linear, without any curve; as it was showed in simulation tests, realized through the use of softwares for rendering, this shape improved the functionality and the efficiency of the product. Then, Colombo brothers have gone further on the research and they tried to convey the light through curved components in Polymethylmethacrylate. Although motivated by laudable intentions, the procedure represented a considerable step backwards from the functional point of view and it contrasts with many other logics related to the project (for example, the manufacturing process is more difficult, the production costs become higher, environmental impact rises). After the designing of the Acrylic, designers totally adopted its shape and carried on because of unwillingness, or the lack of means of simulation. In conclusion, Acrylic lamp produces great dispersion of light because of the curves of the convector in PMMA. Stretchings prevail over smart and green choices, nowadays required by development and environmental issues.

8. Design research: evolutionary steps

This paragraph shows the main developmental stages of the lamp. As it can be see from the image on the following page, the re-design process served many design aspects; the developments are not only relate to the the curve of the convector, but they involve, for example, the thickness of the component in PMMA, its curved surface, the direction of the lamp, the location of the light source and the ends of the convector. The evolution visualised in the image is not exclusively formal, but it is also characterised by a technical and functional development. The validation of design choices is done by means of simulations, realised by special softwares.

Fig. 1: Evolutionary steps of design

The stage of design research passed through simulations that allowed to verify and validate step by step the re-design the device from an aesthetical and especially functional point of view. The validation tools were the key, because they indicated what choices were to be made. The rendering softwares were not used for the presentation and the adornment of the project, but in order to verify its functioning and efficiency. In conclusion, thanks to simulations, it was possible to make certain choices, such as the changes of the direction or the declivity of the lamp.

9. Materials and production technologies used for re-design

The base of lamp is made of aluminum and it is produced by means of the curvature processing with numerical control and through the realization of 4 countersunk holes. After this process, the base can be painted with the defined colours.

The support of lamp is made of aluminum and it is produced by means of the curvature processing with numerical control; its shape is that of a box open on the rear side, inside which there is placed an housing by the shape of a "V" for the light source(LED). After this process, the base can be painted with the defined colours.

The coil is made of PMMA and it is produced by means of a sheet, previously realised by pouring; then, the sheet is curved by thermoforming. Later, it is necessary a cutting process with numerical control, in order to produce the component which is to be inserted in the metal base.

10. Life Cycle Assessment

The hypotheses formulated in the LCA study arise from the will of creating the basis for a serious and reliable comparison between the LCA of Acrylic lamp and its re-design. Consequently, the functional unit is defined as "support and shield of the light source during its usage phase", not as the enlightenment during a certain period, in order to exclude the analysis of impact related to the two different light sources, which would have altered the focus of the study concerning the optimization of the design process, creating a considerable gap between the environmental impact of the two lamps. Actually, Acrylic lamp is characterised by a fluorescent light source; on the contrary, re-design lamp involves the use of led lights as luminous source. Although the use of led lights for re-designing is part of the eco-friendly designing choices related to the life cycle of the product, it would have overshadowed the environmental benefits linked to structural re-designing, which is more sustainable. In the present case:

- 1) The consumption of Kwh per lumen of the light source is appreciably lower than the led light.
- 2) The duration of the phase of use of the two lamps is different.

In "Acrilica" lamp, the fluorescent light source produces the degradation of the polymer and, consequently, of the convector in PMMA, whereas in re-designing the degradation of the polymer is slower, because of the minimal dispersion of the heat per lumen, which is produced by the source of

led light. The formulated hypothesis are aimed at creating a comparative LCA between the life cycle of the two lamps, in order to provide to the designer the best eco-design informations. According to this approach, the two cited conditions are omitted.

	ACRILICA LAMP	RE-DESIGN
CML2001, Acidification Potential(AP) [kg SO ₂ -Equiv.]	3,364	0,509
CML2001, Eutrophication Potential(EP) [Kg Phosphate-Equiv.]	0,135	0,025
CML2001, Global Warming Potential(GWP 100 years)[Kg CO ₂ -Equiv.]	388,806	62,809
CML2001, Ozone Layer Depletion Potential(ODP, steady state) [Kg R11-Equiv.]	0,001	2,430
CML2001, Photochem. Ozone Creation Potential(POCP) [Kg Ethene-Equiv.]	0,379	0,056

Fig. 2: Environmental impact of lamps

From the data shown in the table, it is clear that for four categories of environmental impact, the same impact is less than in the case of Re-design of the lamp and especially for the category of Global Warming Potential it is in a clear manner. Only for one category(Ozone Layer Depletion Potential) the environmental impact appears to be greater in the case of Re-design.

	ACRILICA LAMP	RE-DESIGN
CML2001, Acidification Potential(AP) [kg SO ₂ -Equiv.]	0,241	0,114
CML2001, Eutrophication Potential(EP) [Kg Phosphate-Equiv.]	0,020	0,009
CML2001, Global Warming Potential(GWP 100 years)[Kg CO ₂ -Equiv.]	31,145	14,851
CML2001, Ozone Layer Depletion Potential(ODP, steady state) [Kg R11-Equiv.]	0	0
CML2001, Photochem. Ozone Creation Potential(POCP) [Kg Ethene-Equiv.]	0,021	0,009

Fig. 3: Environmental impact related to the convectors of lamps

The data of table on the previous page refer to the impacts generated by the coils in PMMA of two lamps, they include the extraction of the material and its manufacturing(transport and energy are excuded from environmental impacts). It was decided to compare the coils, because the EPD shows that a good part of the gap of impacts between the two lamps is due essentially to the part in PMMA.

11. Concluding remarks

It is necessary to point out some findings of synthesis. The work explained in this paper recounts a design path aimed at the definition of a methodological approach to design. This method is oriented to an evolutionary and adaptive design method. All this is oriented to a kind of design that is not separated in different phases, but the stages are enclosed in a spiral which turns on itself several times, retracing and stopping at different times on the same aspects. It is a design that involves an "holistic" approach, without putting aside the rigor and the scientific aspect. First, the book focuses on the study of the Acrylic lamp: its shape, the discretization of the components, the study of materials and their characterization and the analysis of the technologies of processing. Later, the book focuses on the identification of the weaknesses related to the Acrylic lamp in the previous stage of analysis. In light of the found deficiencies, the re-designing starts and it proposes the transformation of those weaknesses into the strong points of the new project. Finally, after the definition of re-design process thanks to an evolution of design concept and by the means of the tools typical of integrated design(especially those related to verification tests and the validation of the efficiency of the luminous device; the device is also valued from the environmental point of view, performing a comparative analysis between the life cycles of Acrylic lamp and its re-design, by means of a peculiar software (GABI). Although the design so defined is based on premises related to materials and their processing technologies, involves all the aspects of design; actually, as it is showed in the preceding sections and subsections, changes in the re-design of "Acrilica" related both to the physical principles at the basis of the propagation of light and the aesthetic aspect of the device. Every possibility is examined by means of simulation tests, starting from the concept of "Acrilica" and leading to a lamp which is not "Acrilica"; but a luminous device which has changed its direction, uses materials with different thickness, different light sources. Moreover, it is a device based on a sustainable designing, thanks to the correct use of materials and technologies; it is a concrete project, which passes from rendering to a finished product and survives the productive, economical and environmental logics.

Abstract

In order to better preserve a monument, it is important, not only to be fully aware of its state of conservation, but also to be able to recognize any critical phenomena that might cause damage to it. Therefore, specialized studies should focus on rational methods, thus allowing correct interpretations of critical phenomena, the definition of the most suitable actions to take, and the identification and elimination of the causes which, over time, could damage the structure. Background knowledge plays a significant role in boosting the importance of cultural heritage and promoting enhancement actions able to raise the awareness and participation of the community. To this purpose, the study was focused on the analysis of the Castle of Belvedere Marittimo – in the province of Cosenza (Italy), which is currently in a bad state of conservation. The specific analysis method adopted was made up of three interconnected steps: knowledge management, control and representation, which enabled the coordination and execution of many operational steps. A preliminary phase of investigation was carried out focusing on the analysis of the geographical and historical contexts. This was followed by an analysis of the materials and structures together with an overview of the state of conservation of the Castle in order to obtain substantial information which may facilitate effective preservation actions. A preliminary static analysis was also carried out with particular attention to the enclosure wall.

Keywords: Cultural heritage, Conservation management, Masonry construction

1. Introduction

In order to guarantee the conservation and enhancement of a historic ancient building, it is necessary to acquire deep knowledge of all that is related to the monument, so as to be able to have a complete and detailed view, thus allowing the identification of appropriate interventions [1,2]. The study of the Castle of Belvedere Marittimo (CS) was carried out in line with the above mentioned approach. The

rational methodological procedure adopted started from the geographical and historical context of the city of Belvedere Marittimo. This was followed by an analysis of the monument (supported by graphic representations and photographic dossiers) aimed at producing an architectural and structural description of the Castle. Lastly, an analysis of materials and of the Castle's state of preservation was carried out. All of these steps are represented in the diagnostic plan scheme, reported in figure 1 [3,4,5].

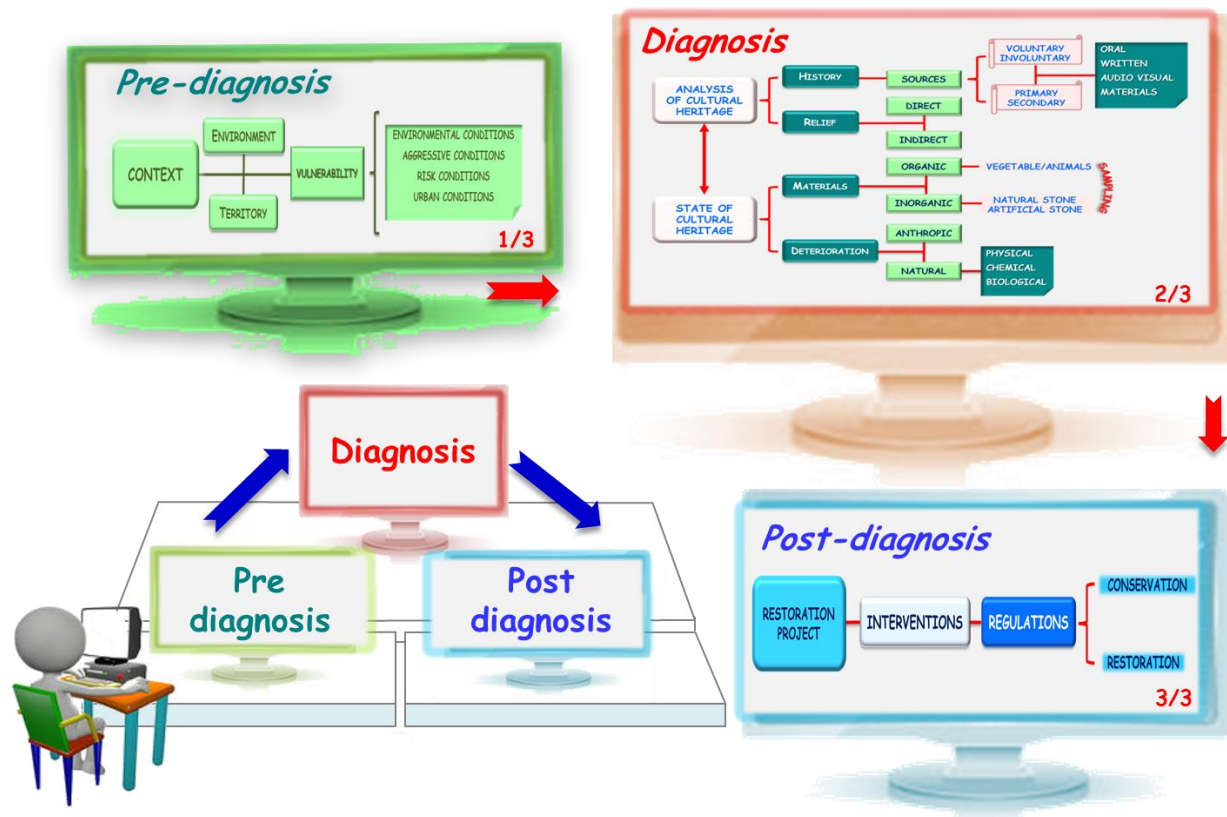

Fig.1: Diagnostic plan scheme

2. Geographical, urban and historical context

The Castle placed in the historic center of Belvedere Marittimo, is located at 300m above sea level, on the foothills of the Pollino massif not far from the Tyrrhenian Sea (Fig. 2). The area is characterized by plains and slopes, behind the Montea mountain, where the highest peak is 1786 m; and it has a rich variety of fauna and mature trees favored by a mild climate.

Fig. 2: Geographical and planimetric location

Sources trace the origins of the historical center of Belvedere Marittimo around the year one thousand, although some findings refer to previous centuries. When the Normans arrived in Calabria, around 1050, the feudal system was introduced and several castles were built to protect the territory; the first fortifications are said to date back from the VII to the X century A.D..

In 1046, after the siege of the Norman Drogo of Hauteville, the Belvedere Marittimo Castle was partially destroyed. It was rebuilt in the XI century on its remnants, thanks to Roger II of Sicily. Subsequently, the Castle underwent a series of restorations by several owners, i.e. Ruggiero Sangineto (in 1287), Ferdinand I of Naples (in 1490), and finally Prince Sanseverino of Salerno and Prince Carafa. The Castle, thus, shows elements amenable to different periods: the portal with the royal shield and the enclosure walls can be traced back to the Aragon Era, while the two cylindrical towers are characterized by architectural ornaments of the Gothic Era. The interior was completely rebuilt for residential use by the Spinelli family. Finally, the Castle, which was completely restored at the expense of the citizens, took on its current appearance (Fig. 3). A plaque with two cherubs and an engraving was placed on the drawbridge to illustrate the reasons for the restoration carried out. Declared a National Monument for its peculiarities, its scale model is exposed in the park of miniatures -Italy in Miniature- in Rimini [6,7].

Fig. 3: Photos of the scale model in Italy in Miniature (Rimini) compared to a current photo of the Castle

In the XVI and XVII centuries, numerous towers were built for the sighting and defense of the town, four of which were located in Belvedere. In the sixteenth century, large noble palaces, which still exist, were built on the walls and defense towers, fulfilling different functions over time. Between the sixteenth and eighteenth century, several families with noble titles took over the Castle, changing its coat of arms. Over the years, Belvedere Marittimo gradually expanded, occupying the surrounding countryside; and, once the area below the town was reclaimed, the town further expanded reaching the coast. Despite its numerous stratification levels, the town still shows its Medieval origins, which characterized the social and political life in the historical center, and later allowed its fortification by creating a real urban plan. The historical center is crossed by a central road - with small shops and houses - and by the Castle from which the remnants of Medieval walls branch off, surrounding the historic center. During the twentieth century, some adaptations were made to the Castle in order to modernize its living conditions. Despite an attempt to maintain its original structure, the latter has been at times modified by restoration activities [8,9].

3. Architectural description of the castle

The Castle is located in the historical center of the city, on a steep rock, not far from the coast. It has a trapezoidal plan characterized by a smaller tower with crenellation on the South-East side, and a thick blind wall on the South-West side protruding from the enclosure walls which have a cylindrical truncated cone shape (Fig. 4). The entire complex is divided into two levels consisting of a slope and an overlapping parapet culminating in a Guelph crenellation. The two orders are characterized by the stringcourse, covering the entire perimeter of the Castle, including the curtains and the towers. On the towers, the stringcourse marks the separation between the cylindrical and the upper part. The main tower is decorated at the top by lancet arches with inclined piers supporting two stringcourse. On the south and west slopes, there are the remains of a moat; while in front of the old entrance are many narrow areas, which were used for the chains that supported the drawbridge. The Eastern walls are made of roughly squared rock made with the same rock the Castle was made of.

Fig. 4: East side of the castle: (A), (B) Two towers; (C) Drawbridge.

The drawbridge, which was built over a small ditch, connected the entrance to the masonry structure, allowing access to the Castle. The courtyard led to the blind walls, where a narrow path led to three central cells. In this narrow canal, there is a stone spiral staircase leading to the top of the flat roof. At the top of the Castle, there is an open space with gardens, surrounded by guarding routes. From the garden, it was possible to reach the rooms and the underground where, it is said, there was a hiding place, connecting the underground to the tower of Paolo Emilio, which was partially destroyed [10,11].

4. Conservation status

Nowadays, the overall structure of the Castle appears to be significantly compromised by the presence of creeping plants, such as moss and weeds, whose roots are the cause of the instability of the original masonry. Unfortunately, this biological degradation is significant, and it affects most parts of the Castle (fig.5).

Fig. 5: East side of the castle: biological degradation

The poor state of conservation of the Castle is evident on the East side of the perimeter wall where electric cables scar the view. In view of the intense erosive action caused by the location and the neglect of the area, the mechanical properties of the Castle have undergone significant alterations. Many cracks on the walls have caused, over time, the fall of parts of the structure, leading to an increase in its seismic vulnerability. This is mainly due to the action of exogenous agents; i.e. water has dissolved the limestone cement rock by transforming the calcium carbonate into calcium bicarbonate, thus creating new cracks which facilitate degradation (fig.5). In the 80s, the head of Fine Arts regional Board carried out strengthening action on the rock supporting the structure. The few timely interventions, carried out by the Castle's current owners, despite being technically inadequate, have prevented more significant collapses.

5. Construction materials, sampling and laboratory analysis

The stone materials used to build the walls of the Castle are mainly of sedimentary origin; the rocks are of irregular shape, many of which were taken from the area where the Castle was built and used for building one of the sides of the Castle.

Sampling of specimens taken from the upper part of the Castle were analyzed in order to formulate a scientific contribution aimed at realistic intervention actions. The sampling of specimens was not

invasive. Many of the samples which were taken had already fallen from the structure due to the cracks on the walls.

In particular, three samples taken from three different positions were taken into account. In addition to the samples of sedimentary rocks, samples of mortar were found (Fig. 6). Before carrying out an analysis of the samples, macroscopic pictures of the external surface of each of them were taken, and technical sheets regarding their macroscopic characteristics were compiled [12,13].

Fig. 6: (A) Sampling of the East side of the castle; (B) camp1, camp2, camp3; (C) thin section

Macroscopic description Camp1 (wall near staircase): The sample is rather tough and gritty, it has a jagged and mostly gray-brown surface; larger white, gray, brown and green minerals are present.

Macroscopic description Camp2 (perimeter wall) The sample is hard and granular with small holes on the surface and areas of different colors; it is not clear, however, if they are due to the presence of different minerals or caused by external factors. The dominant color is gray with black, green, white and brown larger minerals.

Macroscopic description Camp 3 (Eastern wall) The sample is tough and gritty, it has a very rough and jagged surface. It is mostly gray-brown; larger white, black, brown and yellow minerals are present [14,15].

Specifically, the thin sections, observed under an optical microscope, both through parallel Nicol, and crossed Nicol with a zoom of 5x, are characterized by the presence of minerals of quartz, plagioclase, orthoclase, biotite and mica, embedded in a micritic cement matrix [14,15]. In addition to the grains, which have an irregular granulometry, the presence of a benthic fauna in foraminifera was detected. It is characterized by the presence of fusulinid, nummulites and fauna platonic species, belonging to the family of globigerinidi (Fig. 7). Among the foraminifera, species belonging to the family of Bryozoans are also present and only sporadically, in cross section, corals and algae may be found [18,19].

Fig. 7: Thin sections by optical microscope: (A)(B)(C) crossed Nicol (D)(E)(F) parallel Nicol -camp1,2,3

6. SEM analysis

In order to inquire into the composition of the materials, an analysis by SEM (Scanning Electron Microscope) was carried out. The three different samples analyzed have shown a very similar composition. The figures below (Fig. 8a, 8b) show some of the most representative images related to sample C1. In particular, in all the samples there was the presence of calcarenite with large granules inside the sample, mainly quartz and feldspar, embedded in an almost completely calcitic matrix. The matrix is re-crystallized and between the grains there are some crests, caused by the crystallization of cement. It is not very compact and it is highly porous and disgregated [16,17].

Fig. 8a: (A) Sample C1; (B) Disgregated and porous surface; (C) Analysis of the sample C1

Fig. 8b: (A) Granules immersed in the matrix; (B) Matrix; (C) Analysis matrix

7. Diagnostic plan concerning the Procedural protocol for masonry construction with particular attention to the cultural heritage

As it has been said, when historic masonry buildings are analyzed, it is necessary to take into account many factors. Architectural structures belonging to the cultural heritage present major difficulties when compared with ordinary buildings. The former are characterized by a clear typological variety and different construction techniques, due to the changes undergone in the course of time and their conservation state. This variety leads to the lack of a unique and consistent strategy of modeling and analysis. The first step towards an analysis of the structure is based on the comparison between its current state and the project hypothesis, on the one hand, and the definition of the nominal life on the other. The nominal life is the period in which the structure can be considered safe in the sense that it

is able to face the seismic action during a reference period. In accordance with current standards and the classification of interventions, in the case of historic ancient buildings, it is necessary to restrict the choice to seismic improvement interventions, rather than seismic retrofitting. This means accepting a shorter nominal life. [20-21-22-23-24]. For the evaluation of seismic safety and the choice of improvement intervention of historic masonry buildings, in keeping with the standards, [21] the following operational phases must be performed: to achieve adequate knowledge of the structure, to define the mechanical models to apply to the entire structure or to its parts, and to choose the methods of analysis. Moreover, it is important to define a level of seismic safety, evaluate the structure's nominal life in the state of art, design the seismic improvement intervention, assess nominal life in view of the project, and adopt appropriate technical rules during the realization of the interventions.

S. O. n.54 Official Journal

STEPS

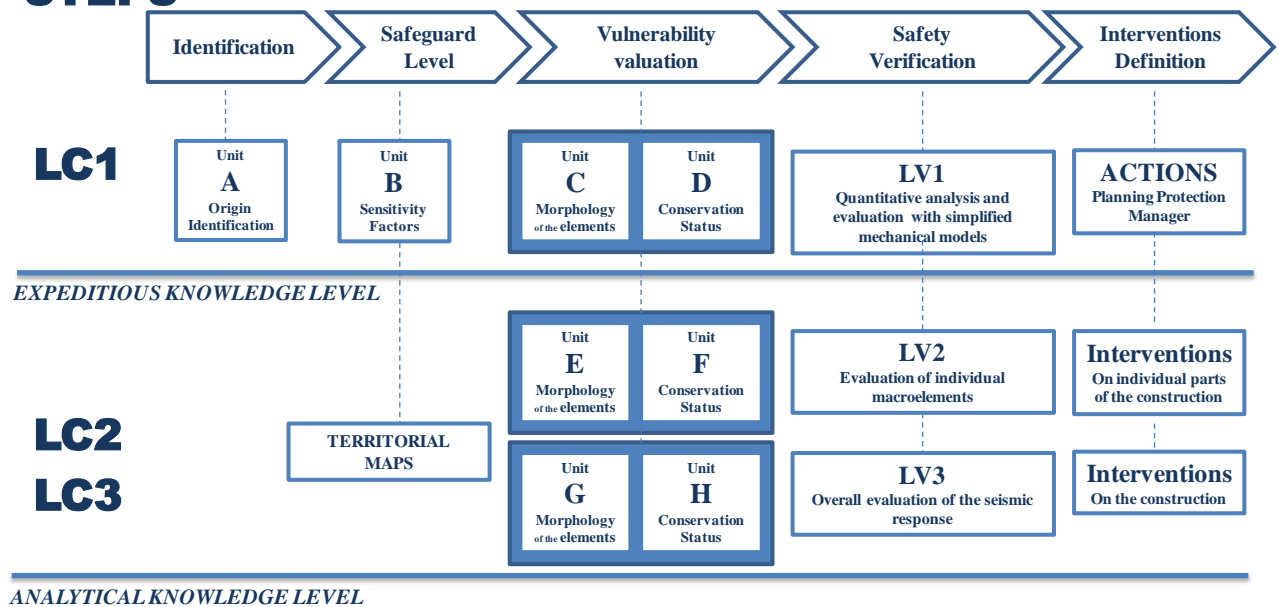

Fig. 9: Schematic representation of the knowledge levels

In accordance with these steps, the standards distinguish two types of knowledge levels: the rapid level, which refers to the direct observation of the construction quality, and an analytical level, which refers to the knowledge of the geometrical and materials construction. Fig. 9 summarizes the methodological process proposed by the current legislation [22], in order to define an interpretative model for the assessment of the state of conservation and seismic safety. Within the restoration project of the Castle of Belvedere Marittimo (CS) the analysis of A-B-C-D has already been carried out (LC1). The procedure for the processing of LC2 and LC3 levels has started, with the static analysis of individual macro-elements, which are to be strengthened in order to reduce the seismic vulnerability.

8. Static analysis of the enclosure wall of the castle

After the historical-cognitive phase of the monumental Castle, the next step is to conduct an analysis and development of the analytical knowledge level, with particular attention to the assessment of individual elements: the enclosure wall of the Castle since, at present, it is the most accessible part of the Castle. The visual and geometric survey allowed to schematize the geometrical and mechanical parameters (Fig. 9) of the examined section (Table 1). The loads acting on the structure and on the upstream ground of the wall were calculated, achieving a distributed load on the upstream ground of the enclosure wall equal to $g = 5280 \text{ kg/m}^2$ and an accidental load equal to $q = 500 \text{ kg/m}^2$. To ensure the safety of the enclosure wall, it is necessary to satisfy the inequality between the stabilizing moment (M_s) and the overturning moment (M_o), where the latter must be smaller than the former.

Table 1

GEOMETRIC PROPERTIES		MECHANICAL PROPERTIES	
Height	14 m	Specific weight	2200 kg/m ³
Thickness on the top	1,2 m	Compressions Stress	40 kg/cm ²
Thickness of the bottom	5,5 m	Internal friction angle ϕ_p	40°
Inclination Angle	15°	Shear strength τ_p	2 Kg/cm ²
Length	1 m		

For the calculation of the overturning thrust, due from the upstream ground of the wall, it was necessary to obtain both the characteristics of the ground itself, in terms of weight of unit volume, $\gamma = 1800 \text{ kg/m}^3$, internal friction angle, $\phi = 30^\circ$, friction angle ground-wall, $\delta = 20^\circ$, and the characteristics of the foundation ground ($\gamma = 2000 \text{ kg/m}^3$, $\phi = 38^\circ$, $\alpha = 25^\circ$). In particular, the thrust was calculated according to two different situations: in the presence of friction between the ground and upstream walls and in the absence of friction (Fig. 10). In the latter case, taking into account the horizontal component of the static thrust, $S_0 = 40948 \text{ kg}$, the increase in seismic thrust, $\Delta S = 3569 \text{ kg}$, of the weight of the wall, $W_t = 110880 \text{ kg}$, of the weight of the wall, $F = 7762 \text{ kg}$, the overturning moment ($M_o = 237115 \text{ Kg}\cdot\text{m}$) was lower than the stabilizing moment ($M_s = 381396 \text{ Kg}\cdot\text{m}$) so as to satisfy the inequality safety. In the case, instead, in which the presence of friction was considered, the static thrust ($S_0 = 34155 \text{ Kg}$) was lower than the increase of seismic thrust ($\Delta S = 4025 \text{ kg}$) so as to produce an overturning moment ($M_o = 395756 \text{ Kg}\cdot\text{m}$) which was greater than the stabilizing moment ($M_s = 208705 \text{ Kg}\cdot\text{m}$). This preliminary static analysis clearly highlights the need for a seismic improvement intervention on the Castle and a detailed seismic analysis, which must not only be localized, but focus on the entire structure.

Fig. 10: (A) Scheme without friction; (B) scheme with the presence of friction

9. Conclusion

The interdisciplinary analysis aimed at gaining a general level of knowledge, necessary to understand the conservation status of a construction of historical and architectural importance, the Castle of Belvedere Marittimo (declared a national monument because of its importance). The articulated study, based on an interdisciplinary methodological procedure in three main phases, contextualized, in the first step of pre-diagnosis, the structure into its territorial and urban dimension also with reference to historical evolutions. In the second part, the architectural and historical aspects related to the conservation status of the Castle were developed. To this end, a sampling plan was prepared and implemented, aimed at characterizing the constituent materials of the Castle. In the present work, the results relating to the characterization of three samples have been reported. Both the optical

microscope analysis and the SEM analysis, allowed the classification of the materials the Castle was built with, such as calcarenite material. To complete the cognitive and material characterization phase, an analytical knowledge phase has been started, performing a static analysis of the enclosure walls of the Castle. From this preliminary analysis, it is clear that the realization of a post-diagnosis project of restoration and seismic strengthening is of great importance, in order to protect and preserve the historical value of the Castle over time.

Abstract

A specific type of rural settlement system in Slovakia, the so-called dispersed settlement, is typical for several regions in this country. They represent a part of the historical landscape's structure of a unique natural and cultural value. Their use reflect both the situation in society and its progress and each change (sudden or gradual), that appears in society, i.e. the way by which the landscape is used. There is a possible threat that dispersed settlements in this region are going to loose the dominant landshaping and eco-stabilizing areas.

The paper focus on the investigation of the current state of dispersed settlements and its evolution in the area of Kysuce region through history and its effect upon their development. Based on the analysis of the problem, we want to show the need for saving the historical landscape structure in this region as it is important to impose the saving of such specific countryside not only through legislation or management but also to promote the pressure of society.

We have analyzed various approaches to investigation of land's evolution together with analysis of natural and demographic characteristics. Natural conditions that created suitable conditions for developing of dispersed settlements from the past till present time were processed, giving reasonable detail.

Keywords: historical landscape structures, dispersed settlements, landscape structure protection, genius loci

1. Introduction

One of the few preserved historical landscape structures in Slovakia is the "kopanice" or dispersed settlement. It represents an autonomous demonstration of social and economic activity as a result of specific natural and historical conditions. It was created as a product of the latest colonisation waves on our territory and its genesis was both territorially and timely significantly differentiated [1]. Such specific elements are usually described in the light of their socio-historical, environmental and visual aspect and in the context of sustainability. There are two main types of specific elements: specific elements with anthropogenic origin and with natural origin. This paper is focused more on the anthropogenic elements.

"Kopanice" is a specific type of soil exploitation and at the same time a specific type of settlement [2]. It was created in a certain historic period when certain part of population due to social poverty cultivated and colonised soil in more favourable mountainous terrains.

The basic function of such settlements was to allow soil cultivation at remote places, mainly in foothills and/or hill zones [3]. Originally, they have been established first as temporary (seasonal) settlements and farm constructions (field barns, stables, chalets, cots) for summer as well as winter cattle stabling. Later these seasonal filial farms became the foundation of permanent settlements. Historical rural settlement structures that have been preserved to these days are a reflection of complicated historical development of Slovak settlement landscape, reflection of human struggle with nature as well as cultural and social changes of our society [4].

What affected “kopanice” the most, was the socialism period and interventions of communist government. Placement of big, mostly engineering factories to cities such as Myjava, Detva, Stará Turá or Čadca that was connected with construction of new housing estates resulted in migration of population from “kopanice” to cities and it was the beginning of their gradual depopulation. Also collectivization of agriculture and mending of lands, that mostly took place around Myjava, had contributed to this. It forced the population to redirect from agriculture to industry and “kopanice” lost their original agricultural function, that was replaced by residential function.

Fig.1: Landscape mosaic structure of Myjava region dispersed settlements (next to the border with Czech Republic)

There are five regions of dispersed settlement in Slovakia. In addition to these five main regions of dispersed settlements several other adjacent regions and islands of dispersed settlements could be identified [1,5].

Historically, they were classified based on multiple features: classification according to origination, according to their size and settlement functions of central village, classification based on affiliation to main regions of dispersed settlements, based on the relationship between dispersed settlement and its core/nucleus, based on number of houses and based on kilometre distances from such settlement to central village [3,6,7]

The only paper focusing on a comprehensive research of dispersed settlements in Slovakia was presented by Nahálka et al. [7]. Nevertheless, even in this paper information were not complete. In Slovak literature there is a tendency to concentrate in more details on one region of dispersed settlement. Great problem of data gathered on dispersed settlement is that within census these has not been presented as elementary settlement units, subsequently they were administratively merged and hence the information on number of inhabitants in each of individual unit within the entire village do not exist [8].

Methodology of research in this field is very broad. Important phenomenon of historic landscape of dispersed settlement is its qualitative value – significance that is the result of perception of landscape and its evaluation by a human being. The importance of identification of visual landscape quality was evaluated in studied community, i.e. its genius loci, landscape identity and characteristics. Landscape therefore represents social value of such type of historical landscape in the light of time changes

having impact on the development of historical landscape, on natural elements of historical landscape (e.g. landscape limits, potential) and socio-cultural or cultural characteristics (e.g. population development, attractiveness, cultural importance).

2. Landscape conditions of study territory

The Kysuce ethnographical region is one of Slovak regions with a relatively untouched nature and a very specific history. The Horné Kysuce region is formed by eleven villages of the Čadca district which are grouped in a microregional association. The region is situated between Javorníky Mountains, Turzovská vrchovina highlands and Moravsko-sliezske Beskydy Mountains. The first look at the map says this is a marginalized area (both from the point of view of its location at the borders of our country as well as concerning the interest of the society). We can observe the marginality within the region of Kysuce itself, as the Southern part between Čadca and Žilina is more developed in terms of tourism and industry, while the Northern part is poorer and less developed.

Dispersed settlement is a specific feature of this area. The villages belong to the Javorníky-Beskydy area of the dispersed settlements and to the Kysuce subdivision. The term "dispersed settlement" is being described as a separately standing dispersed houses or small groups of houses we can find in some mountainous areas. Typical dispersed settlement in the Kysuce region is a hamlet formed by a group of several settlements which are sporadically situated in different shapes of the relief. Dispersed settlement in Slovakia originated in the period of early or very early colonization (16th - 19th century) on the forested hills originally as shepherd's hamlets. Shepherding was later substituted by agricultural activity. This form of settlement was influenced by two important factors. The first one was the effort to gain land. New arable land was acquired by deracination of the existing forests. Another factor was economic and communicational. Using land with low fertility, it was necessary to cultivate large areas in order to obtain the necessary amount of products. Since the deforested areas lied in hilly terrains a long way off the village, to walk all the way every day was very time and effort-consuming. That is why the inhabitants of "kopanice", so called "kopaničiari", used to build their houses at the newly acquired lands.

Area of Čadca town is situated in Kysuce region in the basin of the river Kysuca surrounded by several orographic units: Javorníky, Turzovská vrchovina and Kysucké Beskydy. This study area is well known for its specific historical landscape structures – dispersed settlements, forests, terraced fields, grasslands and non-forest vegetation. The fact that the district town of Čadca with almost 27000 inhabitants is situated in the centre of the region cannot be overlooked, i.e. it is partly urbanised and partly rural landscape. Traditional ways of soil farming have gradually been ceased, nowadays they are really rare. On places of former small strips of arable soil and former extensive as well as intensive grasslands different stages of succession are beginning to appear and elements of a cultural landscape gradually disappear. This type of settlement resulted from three colonisation processes (especially in Slovak mountain area): "wallachian" in 15th century, "goral" in 17th century and "kopanitse" colonisation in 19th century. Several fragments can still be seen – as small settlement units with unique structure of arable land and grassland (Fig.1 and 2).

3. Research methods

The methodology is based on the principles of sustainable development and integrated landscape management where not only the environmental view but also social and economic views are considered. We have inventoried 63 dispersed settlement units around Čadca town and grouped them into five categories depending on their qualitative attributes. There is no universal methodology of mapping and evaluation of this type of settlement to be used in regional development plans and land use plans. Consequently, we have elaborated a methodological plan how to identify and evaluate dispersed settlement units to be able to propose a proper management. Elaboration of environmental assessment is based on the current landscape-environmental research where the methodology is modified for historical landscape structures, and specified for dispersed types of settlements. These analyses will focus on the results of the typical visual characteristic evaluation and results of the analysis of changes in landscape structures in time and spatial context. The result is an identification of the most valuable localities and a proposal of management measures for their preservation in the context of using the entire landscape space. The management measures based on needs of local people with an objective to allow full-value life in the locality are set based on the analysis of social economic relationships that include participation of local inhabitants.

Fig.1: Aerial picture of typical dispersed settlement around Čadca town in Kysuce region, Slovakia

Fig.2: Typical folk architecture of study area

The final result of the entire methodological process will be the complex proposal of management measures and regulations aimed at preserving dispersed type of settlement and a landscape value on the model territory in the context of sustainable development of the territory and clear understandable and concrete guidelines for planning praxis, mainly for landscape planning and also for other planning activities of spatial planning: socio-economic planning, planning of transport infrastructure, spatial management and a system of territorial monitoring and information. Guidelines will be articulated in a way to be applicable within creation of land use plans (as an autonomous land use planning background materials or as a part of landscape plan), plans of social and economic development, land consolidation plans, territorial systems of ecological stability and during environmental impact assessment (EIA).

We have proposed several steps that are not legally binding but they can help to find a proper way of management. The proposed methodology will be modified during a further research and the final results will be presented then.

1. Preparation of background material
2. Field (terrain) research
3. Elaboration of thematic maps and their interpretation in text
4. Historical and development characteristics of specific settlement forms – elaboration of a map of changes of landscape structures in time and spatial context with calculation of ecological stability and quotient of landscape diversity for every time layer and interpretation in texts.
5. Identification and evaluation of characteristic landscape appearance according to the methodology
6. Elaboration of background study for determination of wood succession of study area
7. Elaboration of maps of positive and negative landscape elements, that take into account also the legally binding land use planning documentation and elaboration of maps of conflict of interests and interpretation in texts.
8. The forecasted changes of selected landscape structures and their interpretation in the text (comparison of present status with land use planning documentation)
9. The complex graphical output with classification of historical landscape structures, their evaluation and interpretation resulted in identification of the most valued dispersed settlement locations. The following evaluation criteria will be used:
 - Origin and development
 - Settlement structure
 - The importance of visual impact
 - The typical architecture surrounded by landscape
 - Appearance of constructions
 - Landscape management practise
 - Characteristics of the local society
 - Preserved folk architecture, traditional handicraft
10. Comparison of most valuable localities with dispersed type of settlement with maps of positive and negative landscape elements and the map of conflict of interests – interpretation in texts.
11. Proposition of management measures and regulations necessary to preserve and sustainably develop dispersed type of settlements on the given study territory from an environmental perspective.
12. Socio-economical characteristics of a territory focusing on dispersed type of settlement: history of the territory, trends in number of inhabitants, dynamics of population, age and sex structures, nationality, religion and education structures, housing structure, economy: agriculture, forest economy (industry, unemployment, transport, tourism),
13. Historic development, current status and prognosis of settlement and economic development.
14. Sociological research (to be done mainly in the given most valuable localities) in a form of questionnaires with prevalingly closed questions and directed interviews.
15. Proposal to use construction objects built in settlements of dispersed type.
16. Socio-economic benefits of maintaining dispersed settlements.
17. Proposal of management measures resulting from needs of local inhabitants and from economical perspective.
18. Complex proposal of management measures and regulations aimed at maintaining and developing of scattered settlement type at the study territory in the context of sustainable development and clear directions for landscape planning.
19. Proposal of a monitoring process.
Result will be presented in both visual (maps and drawings) and textual forms (reports), with interpretation of the acquired information from individual steps.

Table 1: Description of the individual methodological steps

4. Proposed measures

Specific settlement forms, including e.g. also the dispersed type of settlement on the study territory represent according to the Swedish rural development plan its advantage, property or asset“ and take into account also the development potential of individual preserved farms as parts of landscape values and so emphasize the connection with tourism and recreation. It is an amazing knowledge if we

imagine that such statement is not present in landscape or scientific studies but in a regular national-level planning document. Examples from abroad, as available in the overview, confirm that the area of dispersed type of settlement is actual all over Europe and in many countries (e.g. Ireland, England,

Fig.3: An example of location of dispersed settlements around Čadca town (indicated by numbers)

Sweden, Alpine region) there are studies for their preservation and development that are then implemented into planning document and in some cases they even achieve positive results.

From actual management trends in solving the given area we can mention that especially sustainability of these structures is getting to the spotlight because in the present their primary function loses justification. The most frequently mentioned ways of utilization is recreation and tourism, specifically agro-tourism and traditional crafts.

Another undeniable trend is the effort to keep the local people in their individual locations. It is the key requirement for preserving as well as for developing not only the dispersed type of settlements but also for other elements of landscape structure that are linked to it – as for example small agriculture farm, grasslands and overall care for cultural landscape, preservation of landscape diversity and characteristic landscape appearance related to them.

For keeping the inhabitants it is necessary to know their present way of life, their opinion on local landscape, know their requirements and show them the ways how to maintain their landscape

valuable. The best way to achieve it is a sociological survey that is a part of the proposed methodology. Based on its results and social economic forecast it is possible to suggest measures for a full-value life of people in specific forms of settlement.

Landscape, naturally, evolves, changes according to the needs of a society and that unsubstantiated and functionless structures fade out. It is important to realize if the newly risen elements are valuable and the vanishing elements lost their value. Fortunately today in Slovakia we have also legally binding methodology for an objective assessment what is valuable in landscape. It is the Methodology of identification and evaluation of characteristic landscape appearance. With its assistance and with other additional criteria it is possible to determine the most valuable locations of the aforementioned type of settlements preservation of which is also in present days legitimate.

The final products of the literal overview, with regard to the Slovak environment are the proposed sequential steps for evaluation and management of dispersed type of settlement in landscape. Concrete management measures for preserving and developing dispersed types of settlement and guidelines for territorial, landscape and spatial planning documents will be the results of this evaluation.

5. Conclusions

The essential prerequisite for a successful implementation of the strategy of sustainable development of Kysuce dispersed settlements and their surrounding will be not the contradictory but the mutually supporting resolution of accumulated problems. The development should change from an extensive and prevaillingly quantitative to a goal-directed, adequate, qualitative, harmonic and sustainable one. Protection of nature, landscape, sights, historical landscape structures and landscape character (*genius loci*) should be regarded as a stimulus and not as a restriction factor limiting prosperity of the territory. As a stimulus that will not be at the expense of the scale, degree, efficiency, quality and regime of nature and landscape protection as well as smart and sensible administration of the entire region. Numerous experiences from abroad from Scandinavia, USA, Great Britain and some alpine countries have proved that it is not impossible, that a consistent protection of landscape, *genius loci* and growth of prosperity are two sides of the same coin. Consistent implementation of such development scenario is not a short-term issue and ultimately it requires modification of the in our country still prevailing industrially yielding, quantitative paradigm driven by major part of responsible executives for a post-industrial, qualitative, that fortunately is in line with opinion of still greater part of both professional and non-professional public.

The key strategic middle-term objective is to achieve an effective protection and sensible interpretation of natural and cultural values as well as sustainable development of dispersed settlement. It is evident that there is a need for mutual understanding that these types of rural landscape represent one of the key territorial entities of Slovakia from the viewpoint of natural and culturally historical values, their protection, proper integration and interpretation is therefore urgent. Prerequisite of success is the existence of multiple protected areas, existence of a range of significant natural sites, several historically valuable complexes, solitaire sights and historical structures of rural landscape preserved in several areas. All these as well as other partial values together create non-recurring character of the Kysuce landscape.

Another strategic objective is to break the de-population trends in parts of rural settlements, improve the demographic structure of inhabitants in the given area and subsequently end the process of demographic structure deterioration and desolation of settlements and rural landscape. This is linked to creation of suitable job opportunities, increase the quality of social and technical infrastructure, extension of possibilities for cultural, social and sport activities, etc. It means an overall increase of life quality and an adequate level of prosperity coupled with protected and mostly attractive natural and cultural values as well as coupled with expected trends (trends ranging from management of raw materials, energy and waste to trends of spending leisure time).

Abstract

The research has as its objective the development of a survey methodology to be developed in a GIS environment designed to spatially analyze the archaeological and natural heritage of the stretch of the Appian Way from Rome to Capua. The analytical method is aimed at supporting actions for the protection of cultural and environmental heritage. With regard to *Appia Antica* further insights are necessary pertaining not only to the exact path but also to the cultural and botanical landscape which although being modified it is still recognizable in some traces; you may think of the row of pine trees that still characterizes some sections of the road. The more detailed study of the settlement structure of Roman society present in Upper Campania together with the study of settlement structures of pre-Roman societies, was a first step for the development of the mapping of archaeological evidences relating to *Appia Antica* in Northern Campania and Southern Lazio.

Keywords: Ancient toponymy, Appian way, Lazio landscapes, Campania landscapes, GIS mapping.

1. A research for the Appian Way between culture and nature

For *Appia Antica* there is the need to carry out further investigations relating not only to the exact path but also to the reconstruction of its landscape; to this aim a comparative reading of historical maps was made within investigations into specific districts. In particular, we analyzed the section of *Via Appia*, which crossed Campania, being abandoned during the early Middle Ages and restored only as of the end of the eighteenth century; studying the eighteenth-century maps we were able to identify useful information for the reconstruction of these places. The route of the Appian Way between Sinuessa and Capua has long been among the most problematic parts of *Appia Antica* despite being the most described stretch by ancient literature; throughout history various studies have been performed to reconstruct this stretch of the Appian Way but only in the second half of the twentieth century, thanks to the topographical studies made by Antonio Sementini, the correct reconstruction of the whole route of the Appian Way between Sinuessa and Capua is realized. The landscape of Lazio and Campania was strongly characterized by the Appian Way, as evidenced by the archaeological remains found along its path; traces of rows of trees lining the street are still recognizable in some stretches. The main purpose of this research is to integrate the restoration of the archaeological sites with the enhancement of the landscape including *Appia Antica*.

The scientific activities provided by the research are intended to further integrate the information, documentation, mapping and modeling of the interested territories affected by the consolidation and development of a Open Data GIS platform aiming at making data accessible and usable by users with specific rules. The realization of a GIS information system for archaeological sites and landscapes of *Appia Antica*, is intended to contribute to the creation of a body of knowledge which can also be used for the purposes of scientific and archaeological investigation and to support the setting up of a coordinated and homogeneous data system (DSS) to help achieving better enhancement, dissemination and teaching projects based on contents of recognized scientific validity.

Among the main GIS applications in archaeological studies we may include mapping and integrated management of recognition data, geophysical and geognostic projections, analyses and simulations of the natural landscape, reconstructions and views of the landscapes themselves. The knowledge and information coming from different disciplines can be incorporated into GIS systems and analyzed in an integrated manner with the purely archaeological data based on the fact that the data vary in type (collection and storage of data), use (processing and analysis) and in the presentation and visualization (data presentation). Hence, data produced by specialists from other disciplines can be introduced into the GIS system so as to include typical analyzes of Earth Sciences, such as the creation of soil digital models, the determination of slopes and exposures of the slopes, hydrogeological modeling. GIS ability to integrate different levels of information on the landscape allows to use them as tools with which to test and evaluate the correlation among archaeological, archaeobotanical data and the physical landscape .

Fig. 1: The V mile of the Appia Antica with the Nymphaeum and Villa dei Quintili (archive Fratelli Alinari 1920 - 1930 ca.)

1.2 In-depth topographic studies

The Appian Way was realized as a result of a specific military strategy project aimed at creating the conditions for the conquest of Southern Italy, the territory controlled by the Samnite confederation. From the sources it results that the construction of the Appian Way is fixed, by work of Appius Claudius Caecus, in 312 B.C. In his censure of the same year, the magistrate started and finished the construction of the *regina viarum* from Rome (port Capena) to reach Capua. As a matter of fact, many saw in this tradition an excessive schematization noticing some inconsistencies that would suggest the implementation of the road into several lots and in a longer period. Nor should we believe that it has been paved in stone at the same time of its realization as this happened much later and in different steps. Just think that to pave the first section from Porta Capena to the Temple of Mars, that is only the first mile, it was not until 296 BC when *Ogulni* covered the office of *aediles curules*. The additional length of up to 11 miles Bovillae was paved in 292 BC. With the exception of these tranches and the urban areas, the Appian Way in 174 BC was in the best case only graveled as Livius witnesses: « (Q. Fulvius Flaccus and A. Postumius Albinus) Censores vias sternendas silica in urbe, glarea extra urbem substruendas marginandaque first omnium locaverunt ... ». The milestones, then, do not tell us much more than just that tiling were made by Caracalla and then by Nerva and Trajan. Besides Formia, however, there is no notice of stone paving although recent excavations show that even

outside urban centers there could be found, however, paved stretches realized in times very distant from 312 BC. In 312 BC, however, it certainly began the construction of the Appian Way that from Porta Capena after *Ad Nonum*, *Bovillae*, *Aricia*, *Sublanuvio* (*Ad Sponsas*, *Tres Tabernae*, *Forum Appi*, *Ad medias*, *Terracina* came to *Fundi*. It passed, after getting wedged in the narrow valley of St. Andrew, through Itri, and continues towards Formia. Beyond Formia the construction of the road would be started in 307 BC (the year of the consulship of Appius Claudius) or in conjunction with the construction in 296 BC of *Sinuessa* and *Minturnae* colonies. Once bypassed *Minturno castrum* and the bridge over the river Garigliano, the Appian Way wedged in the narrow strip of land between the sea and the latest offshoot of the chain of Massico Mount (Cicoli Mount) where *Sinuessa*, a coeval colony of *Minturnae*, is localized being placed as a guard of this obliged coastal passage that gave access to the fertile plains of Campania. Unlikely, the Domitian Way which was built in 94 AC, crossed a little over *Sinuessa* the Appian Way, along the coast, and reached the important port of Pozzuoli, while the *regina viarum* turned sharply to the inside through the *Ager Falernus*. From there the road headed towards the *mansio* of pons Campanus being famous because nearby, in a small tavern, Horace stopped there. Today this place is localized close to S. Janni farmhouse on the river Savone. Once gone ahead pons Campanus, after having crossed Urbana colony during the age of Silla, which is localized under the management of the Municipality of Francolise, headed towards *Casilinum* (today Capua), meeting point of the *Appian Way* and the *Latin Way* and reached Capua (today S. Maria CV). Little remains today of the *Appian Way*. Often placed several meters below the present ground level, it is covered by a thick layer of *humus*; trace of it remains in many cases only in aerial photos: thin white lines betray the stone paving placed below the ground level. Badge of honor and pride of engineering and of the Italic lineage, there is not a wise legislation that has sensibly taken in charge its preservation seriously promoting its enhancement. The excavation of the first part of the Ancient Appian Way is due to the foresight, economic availability and cultural sensitivity of the papacy. The first kilometer is one of the most picturesque routes that the human being can walk on the earth. Since then nothing or almost nothing: no excavation planned, no attempt to recover even the minimum stretches of *Appia Antica*. Neither neglect nor insensibility, only lack of programmatic and cultural horizons. The cultural asset is certainly a public good that should be protected, but it can and must be a flying wheel for the economic development. This is what has been done in other places, such as Santiago de Compostela or, to remain within our boundaries, for Via Francigena: the project is already fully realized, and it is a very good representation of the synergy between Culture and Tourism. Via Francigena is a way to create employment and opportunities for small businesses and, at the same time, a way to connect various parts of Europe highlighting a common identity. A project that looks away, and that aims to enhance the whole environment: food and wine, art and architecture, traditions and breathtaking landscapes. All priceless Italian values. After the first mile of the Appian Way to find stone paving we need to get to the Natural Park of Monti Auruncis and in Campania to the *ager Sinuessanus* (territory of Mondragone, near the municipal cemetery). Other sections of the *Appian Way* have been excavated but then covered for security reasons. The latest architectural emergency in Campania is the triple arch which represents the entrance of the *Appian Way* in the city of Capua. Then only traces here and there of the stone paving, the *itineraria picta et adnotata* and some news from archives. In spite of this we are able to define its path up to Benevento. A mystery is the *ancient Appian Way* after Benevento: The reconstructions are exclusively based on the few strongholds offered up by the Roman names transmitted to us through the *itineraria*.

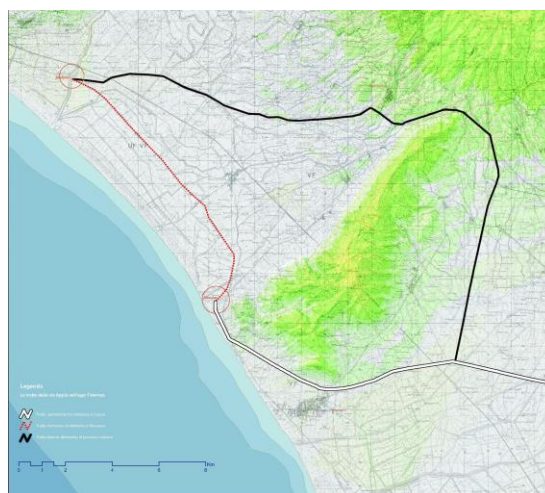

Fig. 2: The route of the Appian Way between Lazio and Campania and the internal road alternative to the coastal path.

1.3 Landscape crossed by the Appian Way

To support actions for the protection and enhancement of *Appia Antica* cultural resources, the archives to be prepared and implemented in the GIS system should also include storing of useful data for the exploitation of natural resources. With reference to the transformation processes that have occurred over time, a reading was made of the interested landscapes affected by the passage of the first stretch of the Appian Way (312 BC) that linked Rome to Capua. The Appian Way started from Porta Capena (378-352 BC) and allowed to continue in the valley of Almone river. The landscape of the valley is characterized by a vegetation consisting of a residue of evergreen maquis in which the dominant species are *holm oak* and *broom*; the valley floor is covered with a wet wood composed of oaks, dogwoods, elms and white willows. A deciduous bush with mostly oaks, downy oaks and periwinkles covers tufa outcrops while the vegetation cover of the alluvial valley consists of willows, poplars, arum, horsetails and riparian vegetation where the dominant species is the reed marsh. In this landscape, where the road retains significant remains of the original calcareous stone paving, the arches of the Aqueduct of Quintiles run parallel to the course of the road.

Once crossed the valley, the Appian Way went back toward the Alban Hills exploiting the summit of a hill overlooking the Roman countryside where the landscape is characterized by the presence of volcanic lakes and a dense woody vegetation: as a testimony of the original forests, largely replaced by chestnut, oak and beech trees, remain holly, linden, hazel, field maple, hornbeam and clematis. The vegetation cover of Colli Albani is also composed of Mediterranean shrub species among which we find viburnum, privet, laurel and hawthorn. The Appian Way crossing olive groves, vineyards and chestnut woods and along the Pons Aricius descended into the valley of Ariccia, a volcanic crater with the bottom covered with cultivated fields and slopes covered with residual forest formations composed of holm and downy oaks. In the valley the road reached Ariccia and then crossed the southern end of Colli ALbani through the Pontine marshes with a long straight and reached Terracina on the Tyrrhenian coast. The pontine section that was the object of powerful interventions of consolidation because of the swamps, today shows the typical reclaimed landscape, characterized by canals, embankments, fenced ditches, vast areas of arable land and rural homes. After reaching the maritime colony of Terracina, the Appian Way continuing towards Capua, following a difficult hilly course, crossed Monte Sant'Angelo, the last offshoot of Ausoni Mounts; on top of this outcrop overlooking the sea there was the Temple of Jupiter Anxur whose archaeological site, declared a Natural Monument, can be reached by traveling part of the Ancient Way that once ascended, it slope down the opposite side of the plain of Fondi one of the many marshy plains that follow each other along the Tyrrhenian coast; among the ponds that persist in this landscape there is the lake of Fondi, near which the road passed. The lake being rich in springs, is seat of a rich plant population of aquatic flora consisting of marsh hibiscus, marsh marigold, penta carpus hibiscus, and bell marsh; once crossed the plain of Fondi with a long straight, the Appian Way reached the town of Fondi situated at the foot of Aurunci Mounts and continued his path beyond the mountains of Fondi and the rugged gorges of Itri: of this stretch, perfectly fitted into the natural landscape, the ancient terraces, the large cisterns to collect water and the volcanic basalt polygonal paving remain. The crossed landscape is typical of Aurunci Mounts, characterized by hills surrounded by forests of carob trees, holm oaks, oaks and beeches alternating with typical plants of the Mediterranean maquis. After passing the mountains of Fondi and Itri gorges, the road descended towards Formia, on the Tyrrhenian coast, where the sandy beaches alternate with stretches of rocky coast covered with Mediterranean maquis composed of mastic trees, holm oaks, cork oaks and maritime pine trees. After crossing Formia area, landscape showing simultaneously the rural character of the countryside and the maritime character of the coast, the Appian Way, following the coast line, crossed the maritime colony of Minturno, Ausone city located at the mouth of the River Liri-Garigliano and conquered the plain of the Liri-Garigliano, which today features the typical reclaimed landscape, being mainly cultivated with wheat. The last coast step of the Appian Way was Sinuessa, a maritime colony situated at the southern edge of the plain, after which the road was diverted to the slopes of Massico Mount towards the interior of Campania; this deviation is documented by the calcareous stone paving found in Mondragone, the stretch of road was that connecting Sinuessa to Ager Falernus, an important agricultural land of the ancient Roman world among Volturno River, Massico Mount, the Tyrrhenian coast and the river Savone. Ager Falernus was and continues to be a lush countryside where fruit orchards, vineyards, olive groves, wheat fields and woods preserve archaeological sites related to rustic villas and rural settlements; the landscape is characterized by the design of the organization of agricultural soils made by the cadaster registration of the Roman civilization. Even today this organization of the countryside, based on large square divided into parcels, persists in the agricultural tradition of the area; in fact in the countryside an intensive agriculture is practiced based on cereal fields alternating with rows of vineyards and fruit orchards. The fertile plain of the Lower Volturno river, characterized by horizontality and leafy crops, is the ultimate landscape traversed by the first section of the Appian Way that after meeting in a bend of Volturno river the Via Latina in the river port of Ancient Capua, after having crossed the river by a bridge, ended his path straight focusing on the western gate of Capua, a town sheltered by Tifata

Mount and placed near a wide bend of the Volturno river. In a second phase the Appian Way continued towards Brindisi , but that's another story.

Fig. 3: Some botanical species of the Appia Antica illustrated by Marina Russo

1.4 Data management with GIS technology

GIS technology and methodology is an important resource for any activity that pertains to the territory and in any case to phenomena that have a spatial distribution. The quantitative geography has contributed in a decisive manner, in recent decades, to greatly amplify the possibilities of spatial analysis and to put in relation to each other gradually increasing quantities and types of data. As we have seen, the space of the Appian Way is not only constituted by material places, but by a set of references and images that only through the power of multimedia can find a suitable space to be properly read and understood. In recent years we have tried to integrate a series of researches, and in particular researchers and methodologies, on the territories involved with the path of *regina viarum*, researches that led to the definition and construction of a first structure of GIS database. The basic structure of the GeoDB is constituted by the chorographic structural territorial model. A physical model and an administrative model through which it is possible to pursue the systematic storage of a wide and heterogeneous set of data and models. The current debate about the cultural heritage identifies in the ICT fundamental and irreplaceable tools for knowledge and enhancement, with a very significant progression of solutions and developments. In parallel to the diffusion of technology, however, the availability of data structures related to the territory still remains marginal, completely lacking a proper policy of sharing and reuse of geographic data. This implies an extra effort, being not marginal, to start building over again structures and models that could be easily shared. The current physical model of the territories crossed by the Appian Way has been achieved with the use of DTM realized by the National Institute of Geophysics and Volcanology through the project TiniItaly; the model is based on a grid resolution of 10 m. For a chorographic study a DTM based on a 75m ISPRA grid was also realized. For the more detailed topographical components, we think to be able to utilize, when available, the model with 1m resolution being tested by the Ministry of Environment. For the analysis, the open data from project DBprior10K of CISIS relating to information layers result to be of particular interest: linear and polygonal hydrography, road and railway networks, administrative boundaries,

urban areas, very useful to chorographically define the current urbanization on the territory is constituted by ISTAT open dataset concerned with census variables. The structural administrative model is certainly more complex, because it refers to a heterogeneous public Subjects. The route of the Appian Way crosses four regions and more than one hundred municipalities. In the current state of the work it was only used a raster cartography, being homogeneous for the whole area, consisting of IGM sections; and only afterwards vector CTR of the different Subjects will be able to be integrated with more detailed scales. The reconstruction of the road network of *Appia Antica* was carried out for different sections according to the different origin and type of data. The road layout, although being presently organized into a single dataset, keeps the information of the different sources being utilized. The most detailed stretch is that between Sinuessa and Capua. A section that was investigated directly by the work group, with specific studies at a topographical scale, including the use of aerial photo interpretation. All the other derived information of the study were organized in datasets, such as: the location of the milestones and their characteristics, the classification of road sections on the basis of their recognition, exploratory essays and planning assumptions, the existing and potential archaeological sites; georeferencing and classification of bibliographic records related to the findings in the areas, etc.. Particular attention should be given to the studies on *fora* along the Appian Way and the role they have played in the economy of the ancient territory, including the agrarian structure of the same land and its definition through centuriation. The traces and the assumptions of the centuriation structure will be similarly structured in vector datasets. The two additional sections, towards Rome to the north and towards Benevento and Brindisi to the south, are currently less detailed and heterogeneous between them. Based on studies of other authors they are consistent with the scale of the more detailed documentation that it was possible to find for them. In the northern section there were also recognized some variant stretches due to special reasons, such as weather that even in ancient times, as it is known, have profoundly altered the economic habits and determined significant changes in the infrastructure in the area. Of particular importance is the internal variant that from Minturno deviated towards the inner area on the volcanic terraces of Roccamonfina through the pass of the current Cascano overcoming Massico Mount reaching the plain linking up to the previous road path near the crossing over the river Savone. A fixed course from the swamping of the coastline excluded completely the colony of Sinuessa. The goal is to reconstruct the idea and the image of the ancient territory through the layering and interrelationship between all the physical and cultural elements of the territory. A certainly incremental path that is progressively integrating more and more complex research profiles being necessary to continue the work. A GPS survey of Campania sections will be shortly carried out also in order to quickly produce traces of routes and POI facilities in formats suitable for the tools of hikers to start data dissemination to a wider audience of users. An appropriate policy to promote the understanding and use of the area linked to a new and integrated fruition of cultural heritage.

Abstract

We established how laser scanning has given reliability to the work in Pompeii. Ordinary measuring with tapes or a total-station does not accommodate effectively the strong connections between geographical features and structure of buildings, in design or in urban configurations, essential to a definition of the whole geographical contexts. In practices from 2012, we introduced a middle-range laser scanner. The long-range laser scanner was applied particularly to land surveying, while a middle-range laser scanner worked for measuring houses and town blocks in scale. With Faro Focus 3D, we explored several selected buildings; the insulae 7 and 15 of Regio VII and the streets along the south-west edge of Pompeii. As the result, we created orthographic photos of plans, elevations, cross-sections and various mosaics in the House of Trittolemo (VII 7.5) and the House of Gallo (VII 15.2). The mosaics can be set into the plans in the orthographic views of point clouds. And in detail, the each piece of tesserae can be identifiable. We have to develop the measurement using up-to-date technology, such as GPS, Photogrammetry and laser scanning. As the work of surveying engineer using optical transits undoubtedly contributed to the spread of a new knowledge of urbanization in the ancient world in the first half of 20th century, the new technology in 21st century could provide new evidence.

Keywords: Pompeii, mosaic, laser scanning, orthographic image

1. About laser scanner

The development of the measuring method is exemplary for technical change in archaeology: equipment that as important for production of the drawings; new mechanism, such as ranging technology of triangulation, time of flight or phase comparison, was introduced on the field survey. The laser scanner provides a technology, which accurately and repeatedly measures distance, based on a precise measurement of time, and aggregates these measurements into a collection of 3D coordinates, called as point clouds. Terrestrial scanners are best suited to recording complex objects, such as buildings, city blocks and streets, as they can record the largest number of measurements. Whatever type of terrestrial scanners we use, the basic premise remains the same: the distance to numerous points on the surface of an object are recorded by a laser scanner which is fixed to the floor, after which the inbuilt ranging system, which is key to all these scanners, calculates the horizontal and vertical angles of the individual points. Having been assigned these 3 values each point now has a set angular coordinates which can be used to locate them within 3D space. In the case of the Faro Focus, the maximum distance a point can be from the scanner to acquire the optimum reading is 20m (Fig.1).

Fig.1 Scanning system of Laser scanner

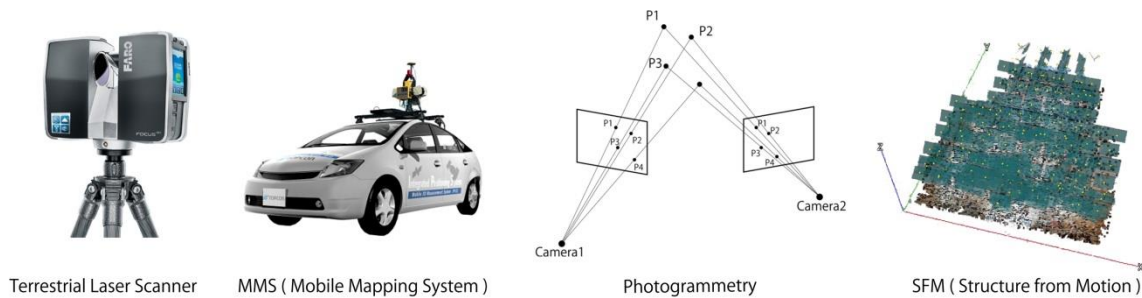

Fig. 2 Various techniques of capturing for three dimensional information

Many types of terrestrial laser scanners have an in-built or externally mounted camera, which can collect high-resolution digital images. These images are assembled into a multi-image mosaic and the RGB data extracted from the images is applied to the point cloud; RGB data can be used as an aid in classification and identification of objects within the scan, and facilitates the development of realistic visualizations. Originally photographic techniques, most obviously digital cameras, has been used to record the surface of the object without losing any nuances of detail and the laser scanner with digital camera can take over their role of recording in the near future. In some ways they are quite similar to digital cameras, allowing us to take a picture by releasing the shutter, although in the case of laser scanning this picture is a 360 degree panoramic view.

As Fig.2 demonstrates, there are a variety of techniques available to capture information for a three dimensional survey, and it is important that the method chosen corresponds adequately to the scale of the project. This is determined by the size of the object and how many points one wishes to record; the more complex an object, the more measurements that are required.

2. Laser scanning in Pompeii

The laser scanning market is becoming increasingly crowded with a range of vendors and products to choose from, with equipments produced by Leica and FARO tending to be the most popular on archaeological sites. Each company offers a variety of formats for storing 3D data, as one of the key elements to be considered is data compression. PTX, which is written in a text format (point text format; X, Y, Z, intensity, RGB), by Leica is a common format and is supported by all vendors. However, Cyclone, which is Leica's software for data processing, uses Leica's system file format (binary format), which is incompatible with other companies' products or third-party software. Currently, we use the FARO Focus 3D scanner, which was produced in 2011 by a German manufacturer. Prior to this, we mainly used Ilris and the Faro Photon 120. Optec producing Ilris scanner is a company which produces long range scanners that are useful for geographical and urban scale measuring. In Fig.3, a reconstruction of the streets of Pompeii, which consists of over 200 million 3D points, grouped together in what we call point clouds, has been recorded in black and white during three week periods in both 2005 and 2006.

Fig.3 Laser point cloud of Pompeii street

In Pompeii, the most advanced 3D scanning system available at the time, Ilris, which could emit more than 2,000 laser beams per second has been applied. Optec in Canada is a company which produces long range scanners, such as Ilris, that are useful for geographical and urban scale measuring. We recorded the entire Pompeian city wall, which equated to over 200 point clouds consisting of more than a million 3D points. Consequently the whole structures of the town walls in the visible area were separately measured into more than 300 points clouds consisting more than million dots having independent local coordinates (the places of machine is the original point of those local coordinates), and thus we have to align, merge and compose them into one three-dimensional model on the united coordinates, which can provide a new general map in 2006 as a by-product of our works (see a map in above in 2006). The result was published in the final report of Japanese excavation of in-existing Porta Capua in 2010 and the point clouds data provided the useful data for analysing the drainage system of Pompeii, which was published in 2012. As a long-range scanner, Ilris can record objects over 500m away, but the resulting image for such a distance is produced in a low resolution, and is thus not suitable for the investigation of buildings or city blocks, but can still be used for geographical surveys, such as the work we undertook at Akoris, Egypt, in 2011.

We introduced an up-to-date laser scanner in 2012: a middle-range scanner; Focus 3D by which more than 900,000 scanning laser beams emitted in one second can be reached to the object in spherical area with a radius of 20 m (less than 1mm error) and those objects can be described as the aggregation of dots having 3D coordinates. In 2012, we launched a new project of laser-scanning in Pompeii, in which the materials including walls, paintings and mosaics of the whole insula can be visualised. And by clipping the points cloud data, the elevations, which are quite helpful for geographical studies, can be created as seen in figure. Furthermore we applied object-scanning in high-resolution mode built in the Focus 3D to the mosaics, that have been well preserved in the House of Trittolemo (VII 7, 5). The dimension of each piece of tesserae could be measured as seen in figure. The visualization of the point cloud data, which can be used in the report, should usually be produced as a JPG or TIFF files, although it is now also possible to have them in a 3D PDF, PDS or true vision file in html format, or as a OBJ file. Pointools, which was recently acquired by Bentley, who are one of the largest vendors of CAD and CAM software worldwide, is an effective tool for rendering images.

3. Works in Pompeii from 2006

During two seasons (from 26th August to 9th September in 2006 and from 22th December in 2006 to 11th January in 2007), the investigation of town wall applying a long-range laser scanner has been carried out at Pompeii by Japan Institute of Paleological Studies (JIPS), a member of which we were. In the resulting model, the object has a set of local coordinates. To place them on a global model, we must convert their coordinates into latitude and longitude. Certain markers, which had their longitude and latitude coordinates recorded in a survey by Rispoli in 2006, were included in our data in order to provide fixed GPS (Geographical Positioning System) points. With this completed, we produced the first 3D model of the Pompeian streets. Although there were errors in some of the merged clouds, resulting from dimensional inaccuracy in the scanning process, these all fell within the accepted 0.05% error percentage.

In that investigation, Japanese team established how laser scanning has given reliability to the work on the Archaeological sites contains large-scale structure of the town.

In 2012 it is a merit of our investigation to show three-dimensional data can bring the elevations of structures. Furthermore, measuring with tapes as orderly method, with its attractive, is still a useful way to record archaeological sites, but it does not accommodate effectively the strong connections between geographical features and varied structures of buildings; such as the rubble, brick and mixed works in Pompeii, widely spreading over this town, which has been recorded by photos and not measured, in design or in urban configurations, essential to a definition of the whole geographical contexts; laser scanning is somewhat like an useful tool that can collect point clouds with three dimensional coordinates and RGB data.

On the other hand, we faced the problem of occlusion behind the structures in the work with the long-range laser scanner. In the case that stations of the laser scanner were set on high-raised places, from which the lower parts of structure could be visible, it was possible to draw a general map tracing the 3D model of points clouds. However those scanned areas were often larger and more widespread than other stations, yet the radiating laser-rays were sparse and often occluded by walls so that the 3D models could not be created.

However, since the measured area has been limited along the streets in two years of 2005 and 6, we should move to inside of the city block in this stage. Our re-examination with Focus 3D is producing valuable new data in three dimensions in the insulae 7 and 15 of Regio VII. By merging the new data into those in 2005 and 06, studies in the 3rd year will be greatly enhanced by a collection of three-dimensionally measured surveys of the principal structures in the final report, as detailed analysis will doubtless provide much telling information on the methods and modes of construction, and, it may be hoped, will clarify an often sketchy chronology.(Fig.4,5,6,7)

Fig.4 Plan of th House of Trittolemo(VII 7.5) and the Houseof Gallo(VII 15,2)

↑Via Soprastanti

Via Marina↑

Fig.7 North-South Section of the House of Trittolema (on 5m by 5m grid, North left)

At last, we tried to create orthographic photos of various mosaics in the House of Trittolema (VII 7.5) and the House of Gallo (VII 15.2), but, unfortunately, the 3D data of the House of Gallo does not be analysed yet(Fig.8,9). This point cloud offers the possibility of providing geographical information about the streets of Pompeii that archaeologists could never achieve by using a total station, for the simple reason that it would take far too long to use a total station to record anywhere near the required number of points.

Fig.8 Mosaic in the House of Trittolema (central tablinum, on 50 cm by 50 cm grid)

Fig.9 Mosaic in the House of Trittolemo (west ante-room of the central tablinum, 50 cm by 50 cm grid)

4. Conclusion

We provide 3D point cloud data covering the parts of Insulae 7 and 15. And a major part of this paper is devoted to the brief summary of laser-scanning applied in two weeks (from 11/09/2012 to 21/09/2012).

Why is laser scanning becoming increasingly important in archaeological recording? One of the main reasons is that by capturing the data in this way we can avoid the high cost and numerous working days necessitated in the construction of scaffolding in order to record the objects and surfaces that are out of our reach. Furthermore, the point cloud data captured by a laser scanner can allow us to alter the angle at which we view an image and enables us to zoom in on specific elements and view them in both two and three dimensions, thus allowing us to scrutinize an object up close and in high detail, something that we previously would only have been able to do with the construction of scaffolding.

As mentioned above, we established how laser scanning has given reliability to the work in Pompeii, contains well-preserved mosaics of the House of Trittolemo and the high raised walls of the House of VII 15. 2; it was a merit of our investigation to show three-dimensional data can bring the elevations and sections of structures.

One of our main purposes in the work of re-measuring the streets and buildings in the map of Pompeii by Eschbach from 2005 to 2006, which is still general but unreliable in detail was the revise by applying up-to-date technology; laser-scanning. On the new investigation of 2012, the smaller-scale structure of the town, such as insulae, could be revised by that technology. In insulae 7 and 15 have many curving walls and winding streets, of which the three-dimensional data collected in 2012 will be analyzed in detail in the near future. In the field surveys in 2012, an unusually dense concentration of point clouds happens along the streets and on the other hand, less conspicuously by going farther from the streets, the structures can be described from the point clouds. To provide a completely revised map of those insulae, the work will be continued inside of city blocks and we will be helped by at least point clouds of what the finished work should like room by room rather than along the streets. On the other hand, mosaics can be set into the plans in the orthographic views of point clouds (Fig. 5). And in detail, the each piece of tesserae can be identifiable. Repaired area including the damage of bombing in the Second World War II, could be detected in future analysis.

The laser-scanning created among archaeologists a new confidence in the possibility of identifying and drawing the whole structure of buildings including features such as mosaics and wall paintings, which are more abundant in larger structures. Our re-examination with Focus 3D is producing valuable new data in three dimensions in the Insulae 7 and 15. By merging the new data into those in 2005 and 06, studies in the 3rd year could be greatly enhanced by a collection of three-dimensionally measured surveys of the principal structures, as detailed analysis will doubtless provide much telling information on the methods and modes of construction, and, it may be hoped, will clarify an often sketchy chronology.

We have to develop the measurement using up-to-date technology, such as GPS, Photogrammetry and laser scanning. As the work of surveying engineer using optical transits undoubtedly contributed to the spread of a new knowledge of urbanization in the ancient world in the first half of 20th century, the new technology in 21st century could provide new evidence.

Acknowledgements

The fieldwork in 2005 and 06 was financed by KAJIMA FOUNDATION and NISSEI FOUNDATION grants. Thanks are due to Dr. P. G. Guzzo and Dr. T. E. Cinquantaquattro, the Superintendents, who granted the permission to work at Pompeii, to Dr. P. Rispoli, who provided useful data of GPS in Pompeii, and to Dr. S. Sakai and Dr. V. Iorio, the Supervisors of the survey in 2005 and 06. I would also like to thank Dr. G. Stefani for her advice and help in 2012 and 13. I am grateful to engineers in KEISOKU RESEARCH Corp. in Japan, who lent their cheerful collaboration to the task and offered many useful technological comments. This report is a part of the result of a research project, "Architectural History as Reverse Engineering, reading the structural process of ancient Roman architecture and cities", (director Prof. Yoshiki HORI in Kyushu University), which is financed by J.S.P.S. (Japan Society of Promotion of Science).

Abstract

The tools of representation, related to the way of knowledge of architectural survey, allow a series of analysis of the built, such that they can deal with complex themes and often not clearly tangible in the stratifications of historical events. The theme of “young archeology” is particularly fascinating because it regards architectural and urban landscapes which, in sudden and irreversible events, caused an abandonment of the places that were vital and productive until shortly before. In fact, even though these sites can be perceived as archaeological excavations, in reality they are coeval to the many towns of our sites. For this reason, although there is the possibility to hypothesize the old reuse, the study of these places is very important because it allows us to understand the building tradition in relation to the place and to the historical periods that characterize the temporal stratification. Within the research, we focused in particular on the definition of a system based on different methods and tools used in the survey, which are involved in different professions and skills, not only in purchasing and returning three-dimensional, but also in those of use and cataloging of cultural heritage.

Keywords: documentation, storage, survey, abandoned heritages

1. Introduction: the method [1]

Memory and measurement represent, by now, an inseparable union in the field of conservation and protection of the heritage inherited from the past. The path of knowledge is, and always will be, the starting point for any kind of “action” to be taken in the field of valuation, recovery and restoration, a huge responsibility that sees students and operators of the sector such as guarantors of the continuity between past and future. This responsibility requires a strong methodological rigor that brings together all of those elements of analysis that affect the future “project” of an architectural and/or monumental asset. Memory is therefore the key element for the understanding of an asset, the principle that enables the stratigraphic temporal reading of our heritage and that defines the history and the events that led to the current situation. There is no future design without memory, there is no continuity in the life of an asset without a conscious inheritance of the past. The historical and critical analysis is, therefore, a vital step in the definition of the “identity card” of an asset, is that part of the learning process that uses the “spent” not merely for the documentation and disclosure of the knowledge, but to put the groundwork to a project of revitalization and of temporal extension. Sometimes it is easy to trivialize this stage of “approach” to the asset as a “necessary act”, as if you want to shape a foregone process. Instead, those who work for the historical and critical analysis of a heritage know that they

are faced with something that does not belong to them, because they have to do with a "bridge" that crosses the river of time and that connects also very far away generations and temporal contexts. The heritage of the built is, in fact, the only tactile reality that pierces the temporal space and which requires, on our part, a sense of duty which on one hand makes honesty to the past and, on the other hand, ensures continuity with the future. If the memory is that part of knowledge that ensures immortality to the heritage, the measure will take a snapshot, a detailed survey of the objective conditions (geometric-formals, materials, etc.) and of support for the critical evaluations related to memory. The surveying techniques, which support and complement the knowledge of an asset, allow a process of analysis and evaluation of the tangible evidences, that put the bases, together with the memory, to the strategies to be adopted to invigorate and to prolong the life of our built heritage .

On these simple but fundamental concepts is based the method of study and research adopted by the Working Group ICAR/17 of the University of Basilicata, which operates on different local realities which range from the study of the ancient [2] to the modern [3], from the architecture to the city [4], from the territory to the landscape. Minor fortifications, monasteries, religious architectures, historical sites, underground constructions, etc., are themes that have found, in the researching method adopted, exciting results that represent the experiences to pass on to the young researchers, to the students whom, with passion, continue the training in the PhD and/or in the personal studies.

In the following paragraphs, in fact, we go to document the study that Giuseppe Damone plays in his PhD [5], where the searching experience, that is an integral part of the "young archeology", becomes the reference model to be followed in his studies on the disappeared centers in Basilicata. The continuous and progressive abandonment of centers, of architectural assets, is now, in Basilicata such as in other national and European realities, a strong emergency that calls us, researchers and students, to a sense of "duty" with respect to our human existence.

In the procedural application of the method of research, the "measure" makes use of advanced technologies for the survey and the representation, trying to govern and to control the computer applications on the market in the best way suited to the importance of the issues discussed in the specific studies. In this critical logic with respect to the use of software for the survey and the representation, we can also catch the possibilities offered, on the open market, from the open source applications, to encourage a more widely spread of the potential offered today by technology, and to interact, in a "constructive" way, on the refinement of the software themselves.

Without getting into specifics of the instruments, not to deviate from the specific topic of this paper, we include now the applications where the technological experimentation is underway, with particular reference to the instruments for survey and for communication and disclosure.

The survey system with 3D Laser Scanner allows, for example, to operate in particularly complex conditions both in terms of geometric shapes, both with respect to the state of conservation of a monument. Even the modern photogrammetry facilitates a series of operations that postpone the analysis phase to the study of a model manageable in virtual. In fact, specific software, including the open source ones, digital cameras on the market today, make accessible to everyone the operations of an architectural photo-survey, which once were made possible with expensive and hardly manageable equipments. In a way, with the help of modern tools, we try to establish a cognitive apparatus that can serve as a valuable support to the whole technician process using different instrumentation, traditional or innovative. The choice of which technology-instrumentations use for data acquisition is related to several factors such as the size and the geometry of the survey, the material nature itself, the purpose of the survey, and the conditions in which one operates.

From survey Laser Scanner 3D to the Fotomodellation 3D, from virtual modeling to the implementation of the pano virtual tour, the traditional survey methods (direct and instrumental) integrate with the possibility of managing digital models that can be explored and manipulated for the creation of multimedia products useful to the analysis of the heritage and to the disclosure of knowledge.

The invention relates, therefore, the operational phases of the documentary production and of the graphic rendering of the data collected. In fact, to the survey's irreplaceable paper representations approach three-dimensional models that allow you to thematize, in a more intuitive way, the data coming from the process of knowledge. The ability to model reality to communicate it also allows you to create digital models representative of a reality in times forgotten, or never existed.

Citing the above said to the historical-critical survey, namely to that study conducted by comparing in field-acquired data with information obtained by an archival study, it is possible to clarify the concept of "historical-critical" thinking of two possible applications: the reconstruction of the three-dimensional models for the projects documented by original archival sources, or the reconstruction of the evolutionary phases of the object of the survey. The techniques and the innovative tools of survey and representation play a fundamental role in the study of architectural and cultural contexts to discover and recompose, namely in that realities of abandoned centers whose degradation is such that it requires a complex process of analysis of archaeological type . Furthermore, the study of these places is very important because it allows us to understand the building tradition tied to the place and to the historical periods that characterize the temporal stratification.

2. The ghost towns: problems of documentation and protection [6]

2.1 The value of the documentation for the protection of memory

Always the problem of the documentation for the knowledge and the valorization has assumed a pivotal role in the academic world and not only. In fact there are numerous architectural evidences, or human in the broadest sense of the term, that have come down to us from the past, and of which we want to give knowledge to the future generations.

The possibility of "snapping" the condition of the places at any given time in the history of an artifact offers the possibility to block a concrete image of the same in that place, and therefore is an excellent base for study and research.

To a more traditional survey, are now related multi-disciplinary knowledges in order to break down, and then analyze, individually and as a whole, the building blocks of an architectural artefact.

Through the development of informations obtained from the examination of archival documents and of data acquired from campaigns of directed, instrumental and photographic survey it is possible to conduct historical-critical studies that also allow you to fill any eventual archival gaps.

The man-made material has a limited duration in time, and therefore is destined to disappear. It is for this reason that comes the need to document, analyze, and then, store the data related to architectures, or, more generally, in structures built by man.

Of course, the analysis of an artifact cannot be separated from the operation of the survey itself. It is indeed only by the survey that a building is described in its simplicity or complexity.

Investigate the building lexicon allows then to determine the value of an architecture, a key element in the study especially of the minor construction where it must be recognize the formal value of structures in which the form is not born as a product of the designer's artistic intentionality, as it happens in monumental buildings, but is the consequence of the specific needs of everyday life for those who live there, as well as being subject to continuous changes during its lifetime in response to the changing human needs [7].

The union of "memory" and "measure" in this context is linked inseparably, where the first term is intended to indicate the importance of documentation for future generations, while the second

summarizes all transactions involving the acquisition, analysis and interpretation of data related to a constructed object. We do not want to intend therefore a mere exercise of data collection.

2.2 Abandoned centers: from the causes of the abandonment to the problems for their protection

Today, more and more often, we hear about abandoned village, better known as a 'ghost town', wanting to use an English expression. They are crystallized realities, no more inhabited due to an instantaneous and no longer reversible event, or simply as a result of a slow depopulation.

There are hundreds of abandoned centers in our region today left to the slow decay. But Italy is not the only nation to host ghost town; it is in fact a widespread phenomenon that is having exponential development in other countries. We can think, for example, to Spain where many internal realities are empty because of a migration to the cities due to social and economic changes.

Visiting one of these centers is to take a trip back in time and immerse yourself in urban contexts stopped at the time of the abandonment. Some examples are, to name a few, the countries abandoned after the Irpinia earthquake in 1980 where, along ancient roads, among collapsed buildings, it seems to relive the moment of the earthquake, as well as to bump into objects of everyday life of the time. But the most important characteristic is given by the possibility of being able to analyze the construction techniques of the past, since these buildings have not undergone alterations related to partial or total reconstruction with the use of different materials from those of the constructive tradition of the place, or even technological adjustments that usually have affected the structures of our city centers.

Of course the state of conservation of the centers is closely related to the period of the abandonment and the materials used in the buildings. We can speak of archaeological evidences with regard to abandoned centers in the times of which we have been forgotten, and of "young archeology" for all those realities fairly recently abandoned, and that now you have to study in ruins of Ruskin memory. In this latter case, they are centers that have a history of construction comparable to that of the many historic centers still inhabited.

The abundance of stone quarries has made possible the construction of our Italian realities, and therefore also of those which were subsequently abandoned, done in masonry with building panels of ashlar more or less worked. This constructive peculiarity has meant that came to us the ruins also of all the towns that were abandoned in the course of centuries and that now is possible to investigate. An exception is the lesser buildings made especially in the Middle Ages that was, instead, made of wood and of other degradable materials. Of this, having been abandoned before it was replaced by masonry structures in the later centuries of the structuring of the territory, it is often impossible to trace even simple archaeological traces, and the only feedback on their actual existence can be inferred from the old tax records, or from the ecclesiastical ones, or from the names of the areas that allude to towns with churches or monasteries. What has been described is still happening to many abandoned centers in Spain and made of adobe. In the media and bottom valley, the lack of stone quarries, resulted the construction of the same in raw land, an extremely friable material and intended to degrade in just a few years, as soon as fails the constant maintenance required. Only the main architectural emergencies were made by stones. Therefore, a few decades from the abandonment, of the all of the inhabited realities there are only the ruins of churches and military architectures to testify the existence of a settlement in that site.

Another problem related to the conservation of the ghost towns is the phenomenon of looting, first for the recovery of material, in the aftermath of natural disasters, to use for the delocalized re-reconstructions, and then to the recovery of structural elements of the tradition to address to the market. For what just described the survey for the documentation is a key to ensure the memory of these centers with their history sedimented in the built. The impossibility, in fact, to be able to retrieve all the sites will result in the destruction of many of these.

2.3 The case study of Campomaggiore in Basilicata: the definition of a methodology for the reading

The method of analysis has been applied to various lucan abandoned centers and not in order to capture all the peculiarities of each individual situation analyzed. Being smaller towns, it is difficult to find traces of their urban and architectural history in documents or in literature sources.

A very interesting result is achieved by analyzing the abandoned center of Campomaggiore, in Basilicata. It is a reality of foundation built between the eighteenth and nineteenth centuries, and whose life ends in 1885 following a landslide that destroyed part of the town. Passed the state of emergency, in fact, was made the decision to make a delocalized reconstruction [8].

Since the beginning of the study conducted for the documentation of the center we realized the oneness of the same for its history and its urban layout so different from the other Lucan countries.

Today, of the whole center built according to a rational scheme with a public central area, and houses located checkerboard all of the same size, as required by the act of foundation of 30 December 1741, remains only a small amount of ruins because of the collapses, and especially the stripping of which has been the subject, at first for the recovery of materials for the re-reconstruction, and subsequently for the removal of architectural elements. At the same time of the analysis *in situ* was carried out the

study of archival and bibliographic sources, in order to capture all the changes of the center and place them in a precise space-time context.

Particular attention has been given to the analysis of the smaller building, of which was not find any trace in the examination of archival sources. It was clear, indeed, that although it is a center of foundation, its growth and expansion was not immediate, but is distributed over a period of one or two centuries. To a first group arose immediately after the purchase of the feud by Rendina in 1673, it will be gradually added portions of the urban fabric. Through the survey, the cataloging and analysis of the masonry pannels has been possible to define this trend, also catching in what stage of the urban development is part the intervention of the architect Giovanni Patturelli, a Collecini's student, which probably draws the diagram of the center as it is perceived today by visiting the ruins, as well as some important buildings such as the Palace Cutinelli - Rendina. As already said, the city is divided according to a rational scheme gravitating around 'Piazza dei Voti' and 'Piazza Rendina' on which face the main important buildings such as the Palace said, the parish church, the town hall, the barracks of the royal Carabinieri, and a series of buildings housing services for the community. Just outside the village find their place, instead, The Casino of the Countess, the summer residence of the Counts, the farm, the Laboratory of Wine and a public source. Also all of the major architectural emergences, also in ruin, were recorded and broken down into their components for a reading of the individual parts. It was possible to reconstruct the entire urban and architectural project wanted by Rendina Counts, and of which there are some documentary evidences. The traditional surveying techniques, was accompanied by an analysis of multidisciplinary data, in addition to the return of the three-dimensional objects of the survey.

The returned documents, in addition to being a valuable documentation of the main buildings, and of the whole center, also allow you to read the state of preservation, and thus provide a basis for the study of failures and pathologies of the same. Virtual reconstructions of the individual buildings and of the entire center also allow you to admire the entire complex as it must appeared before the landslide of the nineteenth century and the subsequent abandonment.

Fig. 4: Analysis of masonry panels of the Casino of the Countess in Campomaggiore.

3. Ghost town and landscape: ideas of searching [9]

An important element in the study of the documentation for the abandoned centers is definitely the reading of the ghost towns within the natural context in which they are located. Since these are actually blocked at the time of abandonment, nature slowly reclaims its space because there is no longer a regular input of man who, with his human activities, changes the natural environment. The landscape, in fact, is

the tangible manifestation of the relationship between man and environment, it is not only an expression of nature, but is an economic and social operative space in which we find objectified signs and works that man realizes. The landscape exists because man builds it, sees it and turns out it, is a matter of the senses but also a matter of culture that, to be understood, must be viewed as a concrete set of forms and phenomena related to each other and in constantly evolution. The concept itself of landscape is related to the ways of human perception and the moment of perception can, by design, result in interpretation. In the survey of the landscape is not too much important the collection of geometric data but rather the ability to observe and understand the geographical, natural, historical and cultural factors that define it. In this sense, the design is a real process of knowledge, because as the painting and photography it represents the landscape and allows the reproduction and the dissemination of his image but also because it allows the interpretation.

There is no landscape if there is no a man who observes it and lives it, to detect the landscape means to process a refund that is able to summarize the constituent and connoting elements. Naturalistic area, architecture, weather, seasons, colors, are all elements that need to find their place in the survey intended as a method of study of a system of relations. In particular, in the relationship between architecture and landscape, the color theme can be central in the search for the common thread that binds the system of relations in the unit of the landscape studied. The color of the architectural elements: houses, factories, historical, infrastructure, small towns, contributes significantly to the impact of the perception of a landscaped area. Deepening the relationship between natural environment and color artifacts helps to understand the building dynamics of a center. You can, in fact, identify the nature of stone materials with which the individual buildings have been made and, therefore, identify the quarries where individual segments were cut. Coming less the constant maintenance of the housing units, as well as of the historical architectures, vestments lose any layers of plaster and, by the action of atmospheric agents resume their natural color. What above said makes the abandoned centers of mountain almost invisible from great distances. Being the slots made in the same bedrock on which the center stands, from large distances the mountain seems almost imperceptibly shaped.

In the methodology of reading of the area, experienced in recent years in the researches, the description of the landscape, it was not only based on planimetric references. The term landscape, in fact, also implies a volume, a thickness in which the man himself lives and is immersed, and this space needs to be explored and represented through systems that enable the analysis of perceptual parameters or spatial relationship between the parties. For this reason, the boundaries of the section of the landscape to be analyzed are identified starting from the possibility that the landscape has to be looked at, resulting in the same geographical area more sections or scopes of investigation. For each section of landscape the margins are defined and identified, on the basis of direct observation, the benchmarks or baselines of the survey.

Using all the bases, the landscape is analyzed from several points of view. In every area, defined according to the visibility and no with geographic criteria, naturalistic or geomorphological, are then identified homogeneous areas that may be subject to specific analysis or to zooms to focus the details and connotative data. These areas may be more or less extensive, in a first phase of the observation one can proceed, for example, beginning to separate the natural scope from the settlement one, and then below, proceeding in the survey, it is possible to make insights that help us to identify the shapes that arise in the various areas the spatial pattern of the landscape and define its structure. Then we will get a series of graphs that will propose a reading of the place and of the elements that characterize, from perceptual and morphological data until the realization of a graphical depiction of the landscape observed. The proposed graphical analysis can not, however, be apart from more general considerations on the landscape, considered not as stable and defined perceptive datum, but as an expression of the environment in which man acts, a concrete witness of the relationship between culture and nature. In this sense it is important to extend the analysis to the system of relations that takes place between the different fields that characterize the landscape analyzed, starting from considerations relating to the nature and use of soil: the topography, vegetation, crops, the road system and the hydrografic one must be considered and analyzed in the general context that inevitably will include the works of man in the area (houses, industrial settlements, castles, monasteries, fortresses, etc.) and infrastructures (bridges, dams, viaducts, installations for the production of energy etc.) views always in relation to the landscape in which they are inserted .

In the schematic chart the coexistence of different elements and partly conflicting may suggest the type of ongoing dynamic and the evolution of the spatial order, since in the landscape there are no elements of stability and permanence and therefore it is important to be able to capture also the ongoing transformative processes. In the survey of the landscape, then, everything is incorporated and elaborated from the vision, the ability to look is at the basis of a method that leads to work establishing a direct relationship between the observer and the observed objects. The eye detects and the design revises and summarizes the elements of nature: mountains, trees, hedges, rivers, lakes, and those of architecture: towers, castles, monasteries and towns, but also dams, bridges, viaducts and, in many cases reduced to a state of ruin. The final product will allow us to create a pattern of

perception of the landscape: setting margins, nodes or references, will allow us to read the mutual relations between the parties and to highlight the figural and recognizable qualities, depending on the presence of signs useful to the guidance - architectural artifact, natural emergencies - or widespread signs that give identity to places, whether they are deemed to be positive or negative. In this sense we examined different elements that are evaluated not for their intrinsic value but for their readability.

The museums' world tries to safeguard and communicate the intangible dimension of heritage

Abstract

The UNESCO Convention for the Safeguarding of Intangible Cultural Heritage signed in 2003 deeply questioned the museum world. It is necessary for the museum to modify certain among its essential functions and its ways of working, since a new challenge urges it. It's not an easy task, since the most spread museum model in the world is the Western one, which is conceived and lived as the reign of of tangibleness: it's not adequate for an intangible collection. In this respect the failure of museum in the colonial era is well known. A deep change in museum structure is required, and a "comparative museology" can help for this aim; the museological attitude is not exclusive of the Western world, and examples of it gathered throughout the world by anthropologists can provide a good model to face difficulties that arise when the museum meets the intangible.

The biggest risk the museum encounters is the one of freezing intangible heritage in fixed forms, thus letting it die. For this reason, a good practice of heritage conservation and management should be based on the engagement of the cultural community linked to a landscape or to a cultural expression. Firstly it should be aimed at making the cultural bearers continue to practice and produce their cultural expressions; secondly, the local cultural community should be involved in the process of communication of its heritage. Its correct communication is indeed a fundamental way to permit a right conservation of our heritage's memory and collective identity. Many different good example of it are rising in Italy, as the artistic interventions of Studio Azzurro, among the others, show.

International policies about intangible cultural heritage

The 2003 UNESCO Convention for the Safeguarding of Intangible Cultural Heritage has been a turning point in the lively debate that has occurred particularly in the last forty years.

As a matter of fact, starting in the 1960s and 1970s the conception itself of cultural heritage has been widely debated by means of a confrontation among different cultural perspectives endorsed by various geographical areas of the world. The traditional normative references that had been enacted until 2003 were namely focused on the tangible aspects of cultural heritage, and the legislative tool that best represents this trend is the well-known 1972 UNESCO Convention for the Protection of Cultural and Natural Heritage, which has met extraordinary consensus worldwide. However, this convention has strongly disadvantaged vast areas of the planet whose culture is mainly represented by intangible forms of art, namely the native populations settled in Africa, the Americas, Asia and the Pacific region. On the contrary, the 2003 UNESCO Convention has drawn the attention over many cultural contexts that had never been considered at an international policy level, this way being excluded from the benefits of preserving interventions. It is precisely these contexts whose existence is nowadays threatened by several factors such as globalization, which has spread cultural models worldwide: it contributes to the detachment of communities and groups from their know-how, traditional values, usages and activities such as craftsmanship. As a consequence, today several actions are being

taken into consideration from the State parties in order to guarantee the safeguard of intangible cultural heritage. With regard to this aspect, article 2.3 of the Convention provides a list of the necessary measures in order to ensure the viability of the intangible cultural heritage such as «identification, documentation, research, preservation, protection, promotion, enhancement transmission, particularly through formal and non-formal education, as well as the revitalization of the various aspects of such heritage».

Despite the lack of express mention by the Convention, museums can play a pivotal role in the enhancement as well as in the transmission and revitalization of the intangible cultural heritage. As a matter of fact, museums have always performed a role of collection and protection of the cultural heritage, and they can no longer avoid considering that also intangible aspects represent an essential part of mankind's cultural heritage. Such improvement derives from the official recognition of the concept of intangible cultural heritage by the 2003 Convention. With regard to these developments, ICOM has been encouraged to re-conceptualize the form of museum shaping it over intangible collections. Already in October 2002 ICOM had officially taken into consideration this subject for the first time in the Shanghai Charter: Museums, Intangible Heritage and Globalization, following the workshop on Museums and Intangible Heritage (7th Regional Assembly of ICOM Asia-Pacific Regional Alliance). This charter encourages the adoption of "interdisciplinary and cross-sectorial approaches that bring together movable and immovable, tangible and intangible, natural and cultural heritage" and recommends "to develop documentation tools and standards in establishing holistic museum and heritage practices".

The most significant step towards a full endorsement of this perspective is represented by the XX1st ICOM General Assembly held in Seoul in October 2004 on the theme of 'Museums and Intangible Heritage'. During this conference, the member States have agreed to support the 2003 UNESCO Convention by promoting policies of enhancement of the cultural traditions, thus shedding new light on the definition itself of 'museum'. The motto that had been universally embraced by the national delegations gathered in Seoul was the well-known sentence by the Malian writer Amadou Hampaté Bâ: "In Africa, when an old person dies, a library burns down". The underlying reasoning of this sentence is crucial: the museums must first of all consider the human beings together with their knowledge, values and way of life as essential cultural resources.

However, a simple change in the definition of 'museum' is not sufficient in order to bring about substantial change to the present condition: it is necessary for the museum to modify certain among its essential functions and its ways of working. Today museums are facing a new challenge: safeguarding intangible cultural heritage. This task is not always a simple one to accomplish, since the museum can easily slip into the risky attitude of freezing the living intangible heritage into fixed forms and images. By acting this way, museums risk to misunderstand the true sense of their collections, to inaccurately hand them down, and, consequently, to disrespect them, thus betraying their main mission.

The materialistic gaze in the traditional Western museum

The most commonly spread model of museum worldwide is the Western one, which is deeply dependent on the "culture of the object". Such model is intertwined with the concept of material conservation and with the enhancement of the tangible aspect of heritage. Even though the history of the first proto-museums traces back very far in time in the Mediterranean culture, we can consider the current form of Western museum a direct heir of studioli, cabinets and galleries which began to rise in the courts of European and namely Italian Renaissance. The nobles used to collect mainly paintings and sculptures (and later any sort of natural or artificial curiosities), in search for personal prestige and inspired by an aesthetic attitude, and gathered them in specific architectural spaces within their palaces. Hence, since its origins, the museum emerged as a shrine of the most precious, extraordinary and rare objects of art and culture. Its specific task was the one of preserving its marvellous collection from anything that could damage it, first of all the passing of time. For this reason the museum spaces began to be commonly considered a sort of temple, a sacred space dedicated to the divinities of Muses, where the concept of time and history disappeared into the value of eternity. Clearly, this specific attitude was namely directed to the conservation of the material quality of objects and to the appreciation of their visual and tangible aspect. As a result, the idea of museum as an incorruptible and sacred space, deeply detached from the on-going reality, was handed down from generation to generation throughout the centuries in the Western European society.

Given the historical events that have taken place especially in the 19th and 20th centuries, the above mentioned model of museum has spread over a large part of the globe. Even in the Americas, in Africa, in Asia and in the Pacific region many museums have been conceived through a Western

museological discourse. Specifically, there was a particular moment in history when European people started considering and meeting the culture of native societies and groups in other continents: the colonial era. In that context, even museums became a tool of the foreign cultural domination. For the first time since its origins, such Western institution had to face a serious confrontation with an intangible collection, due to the fact that native cultural heritage was mainly characterized by intangible forms of culture. However, a large amount of customs, oral traditions, practices and representations obviously implied the use of various materials such as tools, images, masks and objects.

It was actually this tangible aspect of the culture of native peoples met by European conquerors that induced a significant misunderstanding. The museums that were settled in such new areas functioned exactly as they were used to do in their countries of origin: as collectors of objects. As a consequence, intangible cultural heritage was studied, collected and treated as if it was just tangible, being very often detached from its frame of life and from the symbols that gave sense to it. Many objects were considered and appreciated as mere curiosities or, at best, as works of art, whereas they were just tools and objects that should have rather been appreciated for their long history of traditions and know-how that they echoed. In addition, scientific and ethnographic interests often inspired the construction of new museums in the occupied areas. While native people safeguarded their traditional objects across generations in order to respond to their material and spiritual needs, Western collectors were rather animated by a scientific interest, which mainly focused on the tangible side of cultural expressions. This attitude led Europeans to build object-centred museums whereas today it seems more and more urgent to develop person-centred museums. Indeed, today we can say that this traditional approach to heritage's preservation has not brought about very effective results since it hasn't contributed enough to the survival of those cultural expressions. In other words, in the colonial era curatorial methods have been exclusively applied to objects, without considering the people who were using them, their lives, their intentions, their symbolic and empathic participation, not even the meaning they socially conferred to those same objects. As a consequence, collected artefacts were totally detached from their living context, therefore losing their main sense.

Furthermore, it should be mentioned that scientific research was unfortunately too often conditioned by cultural and political interests. As a matter of fact, museums were crucial vehicles either for the demonstration of the European culture's superiority, or for the attribution of meaning to native cultural expressions filtered through Western cultural, scientific and even aesthetic standards. Colonizers took control of the interpretative process of indigenous cultures: museums mainly focused their attention on the visual and aesthetic quality of the objects, without taking into consideration the wider intangible aspect, which, on the contrary, gave a more comprehensive meaning to that same heritage. This situation often brought about a misinterpretation of indigenous cultural heritage, and, more importantly, a total lack of respect of the very essence of their culture. In the absence of due consideration of native customs and artefacts, several detrimental events took place, such as the profanation of sacred objects and human remains (Simpson 1996). Such a difficult and thorny issue cannot be treated within the scope and possibilities of this essay: reference should be made to the contributions that have specifically treated this subject.

Nonetheless, even though the era of colonial museums is over, it must be considered that some bad practices have continued up to the present and that a strong and shared knowledge about how to preserve, enhance and transmit intangible cultural heritage through museum is still missing in various contexts. As M. Simpson effectively shows (Simpson 1996), postcolonial museums keep interpreting intangible cultural heritage of native peoples using inadequate instruments: in some cases museums still display their collection through Western cultural lenses, and it isn't until a very recent past that they began to involve indigenous people as partners or consultants in the management of their own objects of art and culture. Even though nowadays colonial and post-colonial museums are no more a current reality, and European museums are no more built as symbols of the Western superiority, the same "materialistic" gaze that inspired the past seems often to persist up to the present. Objects collected and displayed generally bear a large amount of symbols, cultural, spiritual and social information, beliefs, customs and know-how, but, unfortunately, they are in some cases welcomed by mere appreciation of their own shape and material quality. This behaviour can contribute to kill the fragile existence of some essential immaterial cultural expressions, consequently a museum can even become an element that helps to destroy a culture instead of preserving it. By contrast, museums dedicated to host intangible heritage should get involved towards the following aim: make an object speak and tell its stories, which go beyond its visual appearance.

A prompt response to this issue is even more urgent since 2003, when the UNESCO Convention drew the international attention on the safeguarding of intangible cultural heritage together with the 2004 ICOM General Assembly, dedicated to the theme of museums and intangible heritage. In addition to

this, in the last years “museums of the intangible” are increasingly arising throughout the world, and they are not exclusively ethnographic museums. As a matter of fact, many current collections in newborn museums concern historic memories, concepts, aspects of human life and ideas: therefore they display totally immaterial elements, which require appropriate policies of communication and safeguarding. Given this current trend, it is vital for museologists to reflect upon new systems and methodologies for preserving and transmitting intangible cultural heritage.

A different conception of museum experience

Nowadays a museum dedicated to intangible heritage is, first of all, solicited to welcome the idea of safeguarding its collection rather than merely protecting it, as the most commonly spread tendency would suggest. As a matter of fact, the major risk museums encounter when they relate to an intangible collection is the one of freezing it into fixed forms in order to protect it. Generally, it is not easy for the Western conceived museum to safeguard intangible heritage without giving to it a specific and durable form: as mentioned before, the very essence of the European museological model is indeed to guarantee enduring cultural and artistic forms despite the passing of time. For this reason, museums should favour the crucial passage from the concept of conservation to the one of safeguard as advocated by recent international policies. As the titles of the two UNESCO conventions of 1972 (Convention for the Conservation) and of 2003 (Convention for the Safeguarding) effectively remind us, the time has come to enlarge the very concept of cultural preservation: it does not refer just to the material structure of artefacts, but it affects a wider scope. The aim of museums is nowadays the contribution to intangible cultural heritage's viability. Consequently, they cannot simply gather documents, objects and evidences, but they will hopefully encourage the constant living and sharing of the preserved cultural forms among their community.

This radical change in conceiving the approach to cultural heritage preservation takes part in the recent comprehensive reflection over the concept of cultural heritage, which obviously has many consequences with regard to museums' ethos. As a matter of fact, the conceptualization of intangible heritage in the last years has thrown new light on some standards and qualities that have always been considered fundamental characteristic of cultural heritage in the Western intellectual milieu. The growing awareness of the existence and of the value of the intangible cultural heritage prompted the international community to re-examine some traditional axioms about the very nature of cultural heritage. If an essential feature of cultural heritage has traditionally been the outstanding universal value of objects, this is no longer a requisite for its identification: intangible cultural practices and expressions, together with their related instruments and objects, are not necessarily the fruit of a precious and elaborated art. Their value is not merely due to their superb, original and unique visual quality, or to the rich material utilized, whereas they are considered significant because groups and communities identify themselves with it. This is the very reason why the 2003 UNESCO Convention revisited the method of the lists adopted by the 1972 Convention; charged with elitism, they were abandoned for the creation of a Representative List of Intangible Cultural Heritage of Humanity, of a List of Intangible cultural Heritage in need of Urgent Safeguarding and for the national inventories. This new trend reflects the current museological *modus operandi*, which diverges from the former widespread model of museum as a “temple”, where sacred objects are guarded as exceptional and unique artefacts. Museum is rather a place of cultural identification, its collection is not “out-standing” but, on the contrary, it is “standing” in the midst of people and belongs to them.

Besides, the idea of cultural heritage has always gone along with the principle of authenticity, which, in the Western cultural context, is interpreted as material authenticity. A displayed object must be the original one, and its material existence should be as much preserved as possible: reproductions are not admitted. Therefore European museums have always been trying to keep their collections safe from the passing of time and from other potential damages; objects in museums have been guarded as relics, and, as a result, the main attention and care has been focused on their material existence and visual appearance. With the introduction of new parameters connected to the conception of intangible cultural heritage, also the cardinal value of material authenticity has been deeply called into question. Museums can no longer function as shrines for objects handled as relics, thus supporting and promoting the preservation of fixed and frozen cultural forms. At the present time authenticity, when referring to intangible heritage, redefines its scope; as very well the Nara Conference highlighted in 1994, authenticity is not exclusively linked to the tangible evidence of objects:

Depending on the nature of the cultural heritage, its cultural context, and its evolution through time, authenticity judgements may be linked to the worth of a great variety of sources of information. Aspects of the sources may include form and design, materials and substance, use and function, traditions and techniques, location and setting, and spirit and feeling, and other internal and external factors .

Ten years later, in October 2004, the Yamato Declaration corroborated such concepts and suggested to eliminate the notion of authenticity as a selective criterion for the denotation of intangible cultural expressions; since they are constantly recreated, authenticity is not relevant to their identification and safeguard. The museum world welcomes this principle and, consequently, it is encouraged to revise one of its traditional functions: guaranteeing the display of unique and original items. Rather, the museum space will hopefully come to be the place where the authenticity of the cultural context and of the human and social background, which gives life to cultural expressions, is maintained and safeguarded. As a consequence, museum's activities of preservation should aim at the larger scope in which testimonies of intangible heritage are inserted.

In order to conform to these renovated concepts regarding the very essence of cultural heritage, it can be very advantageous to consider other museum-like spaces developed throughout the world in many different cultural contexts and in a large number of geographical areas. Even though we generally speak about museum and use such term by referring to what was born and developed in the European culture, we can't avoid considering that the "museological attitude" is trans-cultural: the need of gathering objects with a special value in a devoted space belongs to the very nature of human beings. Anthropologists show us how many ways of creating museum-like structures human beings have elaborated in different cultures. Studying these models and forms is crucial, especially to the contemporary museologist: they represent indeed a very successful example of how intangible cultural heritage can be optimally safeguarded and transmitted from generation to generation across the years. Nowadays the debate over the museum and the intangible cultural heritage can greatly benefit from what we could call a "comparative museology" (Kreps 2003: 4). Non-Western examples of "museums" show advantageous methodologies that are meant to keep the heritage alive. In some cases, those indigenous models can be easily identified due to their very explicit nature, such as –for instance– the meeting house in the Pacific Islands; in some other cases they must be traced within their larger cultural context: religious practices, social systems, popular knowledge or artistic traditions. We can nonetheless learn from what these peoples have been creating in order to make their culture live across the generations, as well as to help intangible cultural heritage survive in our menacing world, where it risks to shortly disappear. Indigenous models of museums and curatorial methods are so precious that they can be considered themselves as part of cultural heritage worth of preservation, as C. Kreps suggests (Kreps 2003, 2009).

The native museological attitude has always been focused on people, since museum-like spaces and activities have been meant to keep their culture alive, and culture can survive as long as people live. Objects arranged in a special place for their preservation either have an artistic and religious character, or they are tools that take part in the community life, both for specific rituals or simply in everyday life. Museums and items are intertwined with people's life: they are touched, utilized, consumed, visited, lived. A completely different museum behaviour emerges in comparison with the Western conception: in the "sacred temple of the Muses" (this is the origin of the term "museum"), objects must be kept incorruptible, they are not part of people's life unless considered under an intellectual point of view. This is quite a paradox: the heritage that is usually considered as the "material" one requires a very immaterial fruition, whereas the so-called intangible heritage needs a real and concrete involvement of the people in order to stay alive. This is true for the cultural transmission too: native people keep their cultural objects living because their uses and symbols are constantly communicated to the community (with specific restrictions changing with the context) across the generations through non-formal education: oral traditions such as storytelling, songs, dances, rituals and ceremonies.

Museums that nowadays face the issue of how to correctly and fruitfully safeguard intangible heritage, can be concretely inspired by the indigenous curatorial methods. Under their influence, the museum can aim at becoming a place charged with a deep meaning for the community: from this perspective it can't be considered something detached from the context of which it is part, a mere place of scientific research or of aesthetic and intellectual pleasure. Besides, another important suggestion from native museology is about local people, it is essential to safeguard intangible heritage through people: by means of their lives, their thoughts, and their experiences. Intangible heritage is a living heritage, and for this reason it can be in no way separated from life, i.e., from people. People are also essential to the cultural transmission in the museum environments, which will hopefully become a place where culture is produced and shared with others in a sort of workshop.

It could be said that intangible heritage's museums today challenge the pervasive and hegemonic curatorial model that is spread in our transforming world. The roles are switched: if for a very long time the Western culture has been exporting its idea of museum to other contexts, nowadays a change of

direction is occurring. As a matter of fact, non-Western models of museum can help national and international policies of cultural preservation find effective strategies aimed at the viability of mankind's heritage. For that reason, Western museology should become very receptive to different methodologies of safeguarding, diverting its historical role. Western approaches to cultural heritage preservation have developed through time museums that are still today similar to temples or shrines, which keep objects intact and almost mute. Nevertheless, such an attitude can no longer contribute to the actual safeguarding of a large part of our heritage.

The museum as a vital space for cultural production and transmission

Nowadays it is quite recommendable for a museum with an intangible collection to be structured as a vital space where cultures keep living through the participation of the groups and the communities involved. As a matter of fact, in the current proliferation of intangible heritage's museums, it is essential for them to become useful and efficacious for local people, in order to help them practice their cultural activities and to transmit their knowledge to others. The museum should become progressively an experiential space, in other words, a place of cultural life and cultural production, where cultural expressions, customs and know-how, can be practised and shared with other people. Thus, considering museums as the guardians of mankind's cultural heritage, the concept of preservation traditionally endorsed by Western museology has to be completely revised. Preservation is not to be interpreted in terms of absence of use, whereas, on the contrary, it is bound to human practice and exercise. The care for a cultural object obviously implies the material conservation of its physical structure, but it is also essential to safeguard its original function, its narratives, its relationship with people who created it and use it. Otherwise the result is the one of assembling and exhibiting died and mute artefacts.

With regard to these aspects, it could be said that the true turning point in museum's policies is the participatory approach. Only if tradition bearers are involved as partners, consultants, actors and public, the museum turns out to be a space of safeguarding a dynamic, immaterial and living culture. Since the major characteristic of intangible heritage is the one of being a lived and a living heritage, it is necessary to consider that people's involvement in the museum's projects and activities is essential to guarantee heritage's preservation and transmission. As pointed out earlier, the direct participation of the people to the project, to the development and to the management of museum's space and collection evokes to a great extent the indigenous curatorial models.

Considering the participatory approach, it must be recognized that some museums around the world are already working very well, interpreting preservation of the intangible cultural heritage as a dynamic practice and as a living process. The Museum of Anthropology of Vancouver, for example, is one of the museums leading a new approach to the policies about the management and the communication of a living heritage. Built on the Natives' territories, this is first of all a place conceived for them: in the museum's rooms, objects are not just displayed for an external visitor or for a tourist, as the traditional approach would suggest; their exhibition is expressly developed for the indigenous community. This is the very reason why, for example, some objects are put on display but are not visible, they are covered because they are sensitive objects for the Natives' culture: they can be seen with restrictions, i.e. only by strictly determined categories of individuals and/or in particular occasions. Therefore, since the museum is a place primarily oriented to the local community, it becomes a very important instrument in order to facilitate the practice and the transmission of intangible cultural expressions. For the Native people, the MOA is, for example, a place where adults can teach the young generations traditional skills and craftsmanship, such as weaving baskets; in other words, it is a place where the youngest ones contribute to the perpetuation of their intangible heritage in our contemporary society. A similar process occurs in the Ned Hatathli Cultural Center Museum, within a Navajo reservation in Arizona: its main aim is to educate the young Navajo people, teaching them the oral history, the traditions and the language of their community. As a result, the museum is the place where they can attend classes and participate to workshops of traditional weaving, and of wicker or ceramic craftsmanship. In addition to this aspect, the museum with an intangible collection can turn to be a place hosting living performances too, namely dance or music performances, and this is not made with the intention of creating a touristic attraction. The MOA, for instance, allows the Natives to use a part of its environments for their rituals, a space on the contrary hard to find in the modern city of Vancouver. Similarly, another important function of the "museum of the intangible" is to collect oral histories, which are the most immaterial and fragile heritage to preserve. Since oral histories are bound to people's life, it is very important to record and collect them: a museum's archive of the oral history and of the language of a community is a treasure, as the MOA's archival collections show.

A similar approach to the Native community is endorsed by the National Museum of the American Indian (NMAI) in Washington and New York, where the collection is displayed and managed giving

importance to the “Native voice”. For this reason, this is not a traditional object-based museum, objects are not considered as mere things, since their meanings are deeply intertwined with people who use them and animate them. Rather, it is a people-based museum, where the Native community can participate in the process of cultural interpretation. As Richard Kurin maintains, “cultural heritage for that museum is not something dead, frozen, stored away for the voyeuristic gaze of tourists or the idiosyncratic interest of scholars, but rather something living, vital and connected to the identity and spirit of contemporary people trying to make their way in a complicated world today” (Kurin 2004A: 9).

Beyond that, an efficient way to preserve intangible heritage should engage the generic public too. If visitors are invited to take part to workshops where they can learn particular skills or specific know-how, and to participate to performances where they discover traditional dance, music, food preparation, craftsmanship, etc, these practices contribute to maintain intangible heritage as a living process in our present time. Nowadays many museums hosting various kind of collection employ workshops as a tool to communicate their scientific, artistic or ethnographic heritage to the public; similarly the “museums of the intangible” are strongly encouraged to offer workshops not only addressed to local communities, but conceived for visitors too. A particular example of workshop is offered by the Lusaka National Museum in Zambia that has developed in the last years a programme called “Catching the Culture of Food”, in order to teach to the young urban generations traditional dishes belonging to the Zambian folklore. The aim of the project is not only documenting traditional food, but it is especially to educate children to the value systems around them, such as the importance of sharing and of hospitality, or even particular rituals and celebrations. The young public is not only engaged in performances of cookery, since tours to rural markets and villages are conducted too (Mudenda 2008).

Furthermore, it should be considered that even a right and efficacious mediation of the museum's collection to the public can contribute to its own safeguarding; for this reason, Western-oriented museums must look at ways of communication different from the traditional ones: they are solicited to involve either real or virtual people in the process of mediation, because objects won't remain voiceless if someone or something makes them speak. Panels, labels and written texts in general are—for example—significantly spread in the Western museums, but they are not always so stimulating and so communicative as other means could be. They often contribute to provoke the so-called “museum fatigue” among visitors, and for this reason they are just partially read, thus losing their usefulness. Consequently panels and captions in museums' rooms are often lifeless and ineffective media, which only partially succeed in their attempt to communicate and mediate the true meaning of the heritage that they denote. Conversely, it is important for the museum not to offer itself as a book to read or as a traditional frontal lesson: it should rather communicate as a storyteller.

Storytelling is indeed one of the traditional and most powerful means of cultural transmission across generations used throughout our planet. Thoughts, emotions, symbols, cultural and social constructions, cosmogonies, rituals, habits, customs, traditions, legends and know-how have been shared through time by many individuals with the help of storytelling. This narrative performance has been ensuring their survival because it is bound to human being and, consequently, to life: there is no storytelling without human beings. This is the same suggestion we can take from the observation of indigenous museum-like structures too: in such contexts the cultural objects, artefacts, practices, representations, and expressions are kept alive not only because they are used and performed, but also because their stories are told. Therefore, the current challenge for the museums hosting the intangible heritage is not only to create a chance for living and experiencing the collection, but it is also to give life to a place where collected things can reveal their narratives through the persons who are their own protagonists: in other words, a place where objects are no longer mute. As a result, it could be said that at the present time the “museums of the intangible” are both solicited to be museums of storytelling and expected to be spaces for the actual making of culture. In such a situation the presence of the human being is essential to both aims, but it cannot be always guaranteed in the museum's rooms, especially for the mediation of the collection.

However, luckily, today this is possible, thanks to new media that are able to virtually reproduce the living presence and the interaction of individuals in the museum, as well as their voice, their experience, their activities and thoughts. Despite being a fascinating possibility, this is a quite delicate option, since a good use of technological devices is not always ensured, with the consequent risk of misinterpreting and mistreating the cultural manifestations that the museum hosts. It is not rare to find museums that try to avoid the temptation of freezing their collection through the employment of new media, especially videos and interactive devices. It is true that audio-visual technologies allow us to go through extraordinary experiences, even specifically related to the appreciation of heritage; it must be said, however, that they can turn out to be very insidious and misleading tools. Especially with regard

to the intangible cultural heritage, the utilization of videos can appear very advantageous at first blush, because the video is able to immediately do what museums generally fail to achieve: catching life. As a matter of fact, it maintains and shows the movements, the sounds, the lapse of time and sometimes even an emotive side of the cultural manifestation that it represents. In addition, if videos are enriched with interactive devices, the illusion of taking part to a living cultural experience is very strong for the visitors, as well as the idea that the museum is truly safeguarding that heritage.

On the contrary, it is not as simple as it could appear. When we employ visual technologies in museum, we risk merely offering to the public a documentary of a specific cultural expression or activity. But documenting is not equivalent to safeguarding, a documentary can indeed be produced also in many other different places that are not specifically museums. Which is then the specific task of museums hosting the intangible heritage? It could be identified in the effort to make it keep living and be known and shared by the public. With regard to the latter aspect, videos are often intended as means of communication aimed at presenting and showing cultural heritage, but, for this same reason, they don't significantly contribute to the safeguard of its existence. Vice versa, they can actually have a very detrimental effect, because they freeze one form of cultural expression and reproduce it always in the same way. If intangible cultural heritage is subject to continuous reshaping, instruments to safeguard and transmit it must evolve into dialogue with the cultural community too. If a museum, for example, chooses to use videos, they have to be constantly connected with the cultural and social framework to which they refer. In other words, museum's media should be interacting with the cultural substratum of their collection as well as encouraging it to dialogue with the visitors, who do not necessarily come from the same background.

An Italian contribution to the safeguarding of intangible cultural heritage

In Italy, as well as in several other European countries, the issue of the preservation of intangible heritage is a recent one; it does not have an historic and solid tradition, except for the reality of ecomuseum conceived by Hugues de Varine in the 1970s. Relying on its excellent and rich artistic tradition, Western Europe in the centuries devoted itself to the study and improvement of methodologies for conserving and restoring paintings, sculptures and architectures in the best possible way. This does not, however, imply a lack of intangible cultural heritage in Western Europe, yet it has been overlooked for a long time by scholars and cultural policies. Particularly, until a very recent past, the museum institution has never been considered as a place where the immaterial essence of cultural expressions can be lived and experienced by people. The traditional Western museological model is indeed strongly entrenched in Europe, and mainly in Italy, which was its country of origin: the museum is first of all an object collector. This being the case, nowadays many initiatives about safeguarding intangible heritage occur far from the museum world; groups of artisans, schools of art, cultural associations are engaged in the effort of keeping alive the know-how, the skills and craftsmanship. They indeed sustain the activity by supporting who runs it and by teaching youths.

However, even if it is not frequent to find a museum hosting workshops addressed to the local community or to the generic public for the transmission of traditional skills, the Italian museum world can offer a valuable contribution to the field of the heritage communication and of the mediation with the visitors. A right communication is a very important step in the process of safeguarding intangible heritage, because only the true comprehension of a cultural expression allows it to keep living through people's mind. Thus the survival of intangible heritage in our world is highly dependent on its same knowledge, which is the first way to preserve it. Many interesting experiments are nowadays being made to this aim, especially through the use of modern and interactive technologies in museum.

Some good examples can be found in Italy over how new media could really help intangible heritage to be enhanced and transmitted in the respect of its very essence. If rightly employed, videos are not mere documentaries, but they can on the contrary offer themselves as instruments able to keep intangible cultural practices, know-how, and experiences alive. Considering this aspect, the artistic group named "Studio Azzurro" should be mentioned, since it is working very well with regard to the enhancement and transmission of the material culture in Italian regions. In the last years, this group has been creating numerous museum-like experiences in geographical and cultural areas where oral traditions, material culture, craftsmanship, know-how and historic memories are vanishing, owing especially to the fragility of intangible heritage in our contemporary society.

As we can see, for instance, in the case of La Fabbrica della Ruota in Biella, Studio Azzurro aims at making objects tell their histories and stories through the immersion in people's lives. New media in this occurrence are means intended to allow things to narrate, things that would otherwise remain mute. Sounds, videos, interviews, interactive devices are all meant to bring to life a particular kind of

heritage, which is now disappearing. The museum is indeed located in a traditional industrial working area, which is very famous for the production of wool yarns. The ancient art and know-how of carding and spinning wool, its mechanization in the modern era, as well as life's histories of people involved in these activities, are the subject of the display. The museological intervention is not limited to the exhibition of tools, documents and products: starting from the presented objects, the museum succeeds in giving life and in conveying to the public a heritage composed of know-how, art, experience, activities, human memories, thanks to technological interactive devices. It is a matter of recovering memories of spaces and objects through the mediation of human experience. In that case, new media aren't simple videos good at recording a collective heritage, but they are true means able to keep it living; storytelling is indeed a very powerful instrument, which is able to bring objects to life.

A further example of what can be a positive union between the new communication's technologies and an intangible cultural collection is the quite recent (2006) Museum of the Alps near Aosta, located in the beautiful landscape of the Western Italian Alps. The museum's collection deals with topics of both natural sciences and anthropology. The main theme of the anthropological display is about how local people during the centuries have managed to live in a quite inhospitable habitat: the cultural forms they've produced, their knowledge system, their tools for their activities and everyday life, their legends, their symbolism, their arts and craftsmanship. The exhibited objects and the museum's environment aim at immersing the visitor in the animating principle which originated such a rich culture.

For example, the stall is not simply reproduced as it can be found on the ground of the Alpine houses; in the museum's room there is a place where, thanks to technologies, visitors can hear and look at virtual local people telling about the real meaning of that environment, as well as their histories about moments lived in there. Within the Alpine tradition, the stall has always been the warmest place of the house, given to the animals' presence. For this reason, during the long lasting winter, families slept there: the breath and the warmth of the bodies of both animals and people made this place very comfortable. But it was a special place for other reasons too: after a hard working day, in the evening the family gathered there in order to tell tales and histories about the happenings of the day or more generally about life. The elderly used to teach to the youths the mountaineers' wisdom as well as their know-how and craftsmanship. It was a place of education and apprenticeship for the youngest ones, they learned the Alpine life's rules: it was there that they grew up. Therefore the stall was not simply a place hosting animal's manger, a table and some beds, but rather the favourite place for the transmission of the knowledge, for living oral traditions and for storytelling. How many stories, legends, customs, know-how have been handed down through generations in the stalls! It was a space where intangible cultural heritage truly lived. Today this use of stalls has nearly disappeared, there is no point in gathering in such a place, and consequently that background of intangible cultural heritage has been partially lost. The Museum of the Alps can contribute to the preservation of this heritage that is so fragile because of its bound to human beings. Its aim is to present to visitors a stall lived by histories of people who really were the actors of intangible cultural expressions that originated there.

In such an environment, videos, sounds, and interactive devices can work very well, because they are intended to give life to objects and to environments that would otherwise remain partially mute. If the museum didn't operate this way, its way of acting would be very misleading, because it would concentrate the attention mainly on the tangible and visual forms displayed. This being the case, it could be said that new media's application is successful and desirable when it becomes a way of giving life to the human presence who carries an intangible culture; in this case collected objects receive a new and wider meaning. Differently, videos, as pointed out earlier, can just be employed as a simple way to record a cultural expression but not as a way of real preservation of it. Comprehensively speaking, these considerations can be easily addressed to the museum in general.

Conclusion

In conclusion, it could be maintained that only by becoming a people-centred museum will the intangible cultural heritage's museum be successful in its aim to contribute to the safeguard and transmission of its collection. It is vital for the museum to dismiss the Western traditional attitude of an object-centred museum: it is urged to renew itself by putting the human being, his culture and his life, as its core. The human being's presence in the "museum of the intangible" is both the key actor and the subject of the museum, as well as a vital element for its safeguard: it is the nucleus on which new museum reality shapes itself. As indeed the 2003 UNESCO Convention recalls us, the intangible cultural heritage is a living one, and, as a consequence, it has to be safeguarded rather than being protected. Among the various available means of safeguarding, the museum can be chosen as an effective opportunity to preserve the living character of intangible cultural expressions. This is obviously possible provided that it redefines its traditional structure and its way of functioning –by

becoming a storyteller and a place of workshops and experiential learning-, as this essay has tried to illustrate.

Abstract

French archaeological heritage of the classic age has been subject, over the centuries, to phenomena that have caused either its abandonment or the continuation of its use, its transformation or the loss of its integrity. In particular, the sites for entertainment such as theaters, amphitheaters, circuses, stadiums and hippodromes are now often in ruins (as a result of either destructive events or the interruption of their use) after knowing seasons of transformation, conversion to new uses, repairing of damage of various kinds, restoration, adaptation to new stylistic canons: processes that have ensured the survival of these buildings through a continuous integration in urban activities. Today, these goods, mostly located in relevant urban contexts, are part of a landscape whose transformations guided by illusions aimed to make them attractive for tourists, are creating sharp separations between these monuments and the context in which they are. Based on these premises, the paper presents the results of a research aimed the preservation of this heritage, suggesting strategies for its valorization that, in accordance with the requirements of the contemporary world, propose a project for tourist fruition which must be compatible with such goods that are architectural and parts of a landscape. In particular, the paper analyzes some interventions of enhancement on the archaeological heritage in comparison with those cases in which development strategies have proved compatible effects with the demands of conservation.

Keywords: conservation, enhancement, archaeological heritage, theater, amphitheater

1. Memory values and current French archaeological heritage*

In France, the interest in archaeological remains dates back to early years after the Revolution. At the time, within the first activities for the protection of monuments considered as national treasures, Vitet, Merimee, Hugo and Viollet-le-Duc exalted the heritage's documentary value, studied its processes of transformation and took over the architectural consistency proposing, in some cases, restoration projects. In particular, the young Viollet-le-Duc, during his training years, drew few archaeological ruins and some proposals for intervention which are considered as interesting documents about their state of preservation: the aqueduct of Gard, the theater of Orange, the amphitheater of Narbonne, the main Roman buildings of Arles and Nimes

This attention and the following measures of restoration and protection especially, have ensured the survival of monuments such as evidence of a rich historical and architectural heritage. The above-mentioned scholars, considered the Roman monuments with an original and revolutionary point of view: not only for their aesthetic value, but also for their material consistency and their specific qualities, their successive layers, their relationship with the town and landscape. This idea resulted out of the Victor Hugo's letter, sent in 1883 to the President of the Municipal Council of the arena in defense of Lutèce in Paris: "*Il n'est pas possible que Paris, la ville de l'avenir, renonce à la preuve vivante qu'elle a été la ville du passé. Le passé amène l'avenir. Les arènes sont l'antique marque de*

la grande ville. Elles sont un monument unique. Le conseil municipal qui les détruirait se détruirait en quelque sorte lui-même. Conservez les arènes de Lutèce. Conservez-les à tout prix. Vous ferez une action utile, et, ce qui vaut mieux, vous donnerez un grand exemple" [1].

With these words, Hugo emphasizes the importance of amphitheater in Paris as a document that ideally connects the city of the future with the one of the past, giving to the monument a significant historical value, as an example of gallo-roman architecture. According to the writer, in fact, its preservation would have been an example for future actions of protection of the archaeological heritage of France. The arena in Paris became, therefore, the symbol of the past in the contemporary city, assuming a focal role about the social neighborhood and the cultural activities.

The "obligatory" protection of the archaeological heritage also characterizes the choices made in previous years when Mèrimè and his staff visiting Nîmes and Arles. For those cities, regardless of the work already undertaken for the liberation of the amphitheaters in the both cities, he expressed interest to all the ruins, even the smallest ones, which can be related with a more complex and articulated classical ruins web. From these ideas, took place the first excavations and early restorations of the *Maison Carrée*, the temple of Diana at Nîmes and the *Castellum Aquae*, the *forum*, the *cryptoporticus*, the theater, the city walls and the *Champs Elysées* in Arles [2].

The will to place each fragment in a broader context, in fact, is not limited to the urban fabric but it includes the surrounding territory involving, in these specific cases, the infrastructure system such as aqueducts. In particular that case of Gard which, with its numerous branches, supplied the major hinterland cities and coast. A network of classical buildings then that lies ahead, in the early decades of the 19th century, as a base from which extended protection that would cover both major centers and the less important gallo-roman urban realities.

Viollet-le-Duc drawings represent restorer attention to landscape and cultural heritage. In these paintings is possible to see how the architect, starting from surrounding contexts and ruins description, lingers later in relation of ruins with respect to urban fabric, and then describes accurately monument and its construction and decorative details. An interest, therefore, that suggests a love for an *ante litteram* modernity because the documentary value of the archaeological heritage is enhanced, thanks to its surroundings, and in some cases, thanks to what hides it. In this sense the different architectural and urban transformation are perceived as added value [4].

However, some drawings in which Viollet-le-Duc does not only show the real size but also "the hypothetical original monument condition", give rise to the subsequent proposals for liberation and integration, which, during the 19th and 20th centuries, deprived the archaeological heritage of any character of authenticity. The categories most affected by these interventions, result of a misinterpretation of the early spirit of preservation of the archaeological heritage, are: the triumphal arches and the city gates, the temple buildings, the theaters and amphitheaters. For examples: the arches of Orange, Saint Remy de Provence, Saintes; the city gate of Saint Andre in Autun, and the martial one in Reims; the *Maison Carrée* in Nimes and the Temple of Augustus and Livia in Vienne; the theaters of Orange, Autun, Lyon, Arles and Vienne; the amphitheaters of Saintes, Bordeaux, Arles and Nîmes.

Fig. 1: the Lutèce arena, Paris

However, the enormity and declared importance of the French archaeological heritage of Gallo-Roman period suggest a discussion limited to a specific geographic context and to a specific group of

ruins. This, in the belief to simplify reflections on the protection, preservation and enhancement of the entire heritage of the classical era present in France, is limiting the research to a selected territory. The choice fell on those southern territories, bordering the Mediterranean Sea, corresponding to the historic region of the Roman Empire called *Gallia Narbonensis*. This territory, which extends from the Italian border to the Spanish one, still retain considerable traces of monuments of ancient urban infrastructure that are still an integral part of a landscape full of cultural ruins.

Entertainment buildings in particular (theatres, amphitheatres, *odeia*, circuses, stadiums and hippodromes), due to destructive events or simply because of the discontinuation of their use, have lead us to a state of ruin often through transformations (conversions to new uses, reparations of various kinds of damage, restoration or consolidation interventions, adaptations to new stylistic standards) processes which on one hand delay the recognition of classical architecture characters, but on the other, have guaranteed the survival of these buildings through continuous integration.

Nowadays, these monuments, mostly located in natural or urban environments, are particularly an important part of landscape. Their continuous changes, dictated by those illusions designed to make it attractive for tourists, are relentlessly creating clear separation between these buildings and the landscape mosaic in which they are inserted. The context/architecture relationship, in fact, persevered for centuries while with the change of use entertainment buildings became a reference point for agricultural activities or points for the territory defense.

This function, although with subsequent transformations due to the well-known urban and regional organizations of the modern age, remained mostly unchanged, with the rediscovery of classical antiquity, until the archaeological excavations and subsequent restoration, undermined that existing *symbiosis* between human life and the ongoing regeneration of nature.

For example, the substantial “liberations” that have affected the amphitheaters of Nîmes and Arles during the 19th century, caused the consequent loss of historical-documentary data: the Middle Ages residential buildings, living accommodations arose in the stands. Moreover the system of small squares formed within the arenas; inputs fortified and equipped with towers, born in correspondence of the *vomitoria*; commercial and rural agglomerations that near the arches of the ancient Roman gave to the ancient cities a new life, in the centuries following the fall of the Roman Empire, defining the current plan metric patterns and urban settings. For another example, the “liberation” took place in the theater of Orange showed, even up to the mid-19th century, the houses and shops of those who had used the building as a fortress during the wars of religion, during the middle Ages.

The paper presents, therefore, the results of a research that aims to conserve this heritage suggesting enhancement strategies which (although in compliance with the requirements of the contemporary world) propose a project of compatible tourism with such buildings. This is achieved through strict observance of the dynamics of transformation that have always ensured a close relationship between building and environment. The research on this topic, therefore, proposes some thoughts about the consistency of archaeological heritage by analyzing current state of conservation, suggesting advanced techniques of investigation and finally proposing new tools for development.

Ancient entertainment buildings can be found today in many cities of *Gallia Narbonensis* but also throughout the territory and can be, in our opinion, divided in four categories at least based on not only the historical events that have determined their conservation, but also on their use throughout history, and on the degree of interest that they have raised in the past, especially in the decades between the 20th and 21st centuries: in the first group are those structures found in locations or archaeological sites well known to critics; to the second group belong those buildings that can be formally recognized in urban areas boasting Roman or Greek foundations; in the third group are entertainment buildings still present (in urban areas but also other contexts) but only recognizable through traces or whose structure corresponds to current building or urban systems; the fourth group, finally, gathers those structures (mostly not adequately researched) which are located throughout the landscape: these are more or less preserved, frequently prove to be abandoned, and are almost never the object of valorisation strategies [4].

Furthermore, these buildings show subsequent stratifications that on one hand have guaranteed their survival, but on the other, by not showing the typical classical architectural characters, haven't raised enough interest even while representing a potential cultural resource as much as the other categories. Up to now valorisation practices have in fact favoured structures located in traditionally acknowledged archaeological areas which have maintained, even though in ruins, an authentic “classical” character by not showing stratifications owing to reuse.

The same cultural influences have also too often suggested restorations and operations of “liberation” from stratifications on theatres and amphitheatres (both in archaeological sites and in urban contexts of roman foundation) in order to recover the original image of the monument, thus endorsing the loss of valuable layers of history which had been collected on these structures. On the other hand, those complex elements resulting from successive stratifications haven't yet been through a recognition process, mostly because of the lack of understanding for these same centuries-old processes.

Considering then the growing interest for cultural heritage conservation in Europe and in extra European countries, and the new initiatives in the field of archaeological heritage conservation, there follows a need for improved instruments for its study and valorisation. This includes, after the identification of the structures inside urban aggregates and the analysis of their transformation processes, the development of instruments for the interpretation of these classical testimonies in the landscape, and the creation of befitting promotion strategies.

2. Consistency and state of preservation of the Gallo-Roman entertainment buildings**

The past studies [5] researching the French archaeological heritage are certainly useful as a starting point to define correct conservation strategies and enhancement programs. Plus, precisely because of the high reputation of these monuments, they appear as less vulnerable ones, in fact these buildings are often protected by national and international committees, such as UNESCO.

However, it is necessary to include, within those programs, a safety measure that should also be extended to those ancient entertainment buildings lesser known. Especially for them, in fact, when it was done, the researchers used to apply knowledge tools related to traditional detection systems and graphic rendering ill-suited to highlight those aspects that most easily make this vast and interesting heritage understandable. Moreover, in almost every case, among those investigated, it was found a particular interest in urban or landscape in which the facilities are located, but often the program strategies for tourism led to the devastation of the landscape as well as the isolation of the monument and its consequent desertification. In fact the study of the ancient entertainment buildings requires a very complex knowledge process from the origins of the monument shall consider all stages of the history including the most recent ones.

So, firstly it is necessary to identify, through topographic maps, all the known buildings within urban context, including also those which show later stratifications. It is necessary to verify the state of the legislation and the existence of conservation policies extending to the archaeological structures, their context and especially to their stratifications. The existing graphic documentation must also be verified and, if inadequate, integrated with new surveys carried out with current systems and technologies.

The identification of classical permanence in historical cities is also essential, together with the study of their later uses and integration with political, economic, social dynamics. A historical register of buildings must be compiled identifying the transformations owing to functional adaptations, and exposing the more recent incongruous elements. There follows, unavoidably, the study of architectural elements and technological solutions pertaining to later additions, and a verification of their efficiency. Furthermore, for those theatres and amphitheatres which are still in use, an analysis of current functions and urban context is essential, and must focus on the compatibility between conservation of the structures, landscape preservation, and fruition.

Another determining factor is the creation of thematic tables related to the state of conservation of the structures and, in order to facilitate their study, the identification and cataloguing of possible finds kept in museums and ascribable to these urban systems and architectures. Finally, for the development of a correct conservation policy, it is necessary to consider the drafting of a Charter with both methodological guidelines (in order to define a reference point of typologies, requirements and priorities for analysis procedures), and conservation and valorisation procedures. The Charter will contain recommendations on conservation – including restoration, consolidation and maintenance projects – but also programmes for urban and territorial redevelopment and proposals for compatible reuse.

This document, with reference to the indications contained in the more recent national and international Charters on archaeological and urban heritage restoration (in particular the international Siracusa Charter for the *conservation, fruition and management of the ancient theatrical architectures* of 2004), will focus on different specific questions, as for example the recognition of the cultural value of these structures, operating procedures on materials and architectural elements, permanence of formal and functional characters, relationships with the urban and territorial context, connections with the current socio-economic realities.

Following the division suggested in the previous paragraph, the study will analyze for first the theater and recreational facilities found in archaeological areas, well-defined and known to the experts, starting geographically from the eastern border of *Gallia Narbonensis*. The paper will describe the state of preservation and architectural consistency, referring to the next paragraph any proposals for enhancement and management.

Firstly substantial traces remain of the amphitheater of *Cemelenum*, within the archaeological area of Cimiez, in the town of Nice, though, after the disposal, in the Middle Ages, it was partially destroyed by the construction of a road. However, it is precisely the interventions of urban enlargement on the hilly area of the city of Nice, in the late 19th and 20th century, that stress a new interest in the structure

through the first systematic archaeological excavations and the first restoration. These focus on a portion of the outer north-east with the restoration of some parts dismembered and reconstruction of several arches. These measures have not altered the authenticity of the monument that still looks like an interesting ruin that characterizes the entire archaeological area.

The additional archaeological excavations, dated on the threshold of the third millennium (2007-2009), have added helpful information to the monument comprehension, while strengthening interventions and maintenance have affected the amphitheater since 2008. Such actions have ensured a favorable conservation status, although it is found the need to date tools both monitoring of development that may affect the entire archaeological area. But the largest concentration of entertainment buildings can be identified within the existing urban context of what were the most important Roman cities of *Gallia Narbonensis*.

Fig. 2-3: Cimiez archaeological site and part of the amphitheater of *Cemelenum*.

Forum Julii, now Frejus, has both a theater and an amphitheater, studied since the early years of the 20th century. In particular, the theater is easily recognizable thanks to the presence of the substructure of massive walls that once supported the *cavea* and the stage building is perceptible through the lower parts of the proscenium. Nevertheless, the size of the ruin is strongly affected by the presence of intrusive structures deemed necessary for use as a theater for cultural events and performances of various kinds. These structures insist on the archaeological sediments and prevent the perception of the ruins in respect of which there is not a special interest aiming at improving the state of conservation. The only action concerned to the structures monitoring and maintenance, are carried out rarely only for specific events and are closely linked to the latter.

In addition, the constant presence (almost throughout the year) of temporary structures invades the entire area, which, on the contrary, would have rich cultural potential. It is, in fact, inserted in an urban environment with buildings of architectural quality, it is rich in typical Mediterranean vegetation and it is walled by structures minimally that prevent man-made invasive actions and damages.

It seems more problematic the question related to the amphitheater whose history is linked to age-old collapses and looting, most recent damage caused by natural events (Malpasset-Reyran flooding dated 1959) and recent work of "restoration". These actions have irreparably destroyed the ruins trapping it in heavy reinforced concrete structures. The concrete structure spanning and invading the entire building, has been designed to allow new functions such as shows and bullfights, and affects the outer perimeter, the ambulatory, the stands and the arena.

Inaugurated in June 2012, the "new" amphitheater has, ironically, a bad state of conservation that mostly affects the few authentic structures still visible. These are attacked by weeds and show, in several places, signs of structural failure caused, of course, to the concrete structures that rely heavily on the ancient ruins. The amphitheater of Frejus no longer presents today any historical value or antiquity, accounting rather only an example of myopia in the management of the French archaeological heritage.

The management of the amphitheater of *Nemausus*, better known as the Arena of Nîmes seems unattractive too. The touristic reasons and the needs related to various events have now the upper hand on the value of authenticity that the building had preserved for centuries. In this case we find that the choices aimed at the preservation and enhancement have not always respond to the international directions especially for what concerns the sustainability between new function and ancient monument: the latter, in order to satisfy the pressing touristic demands, allow new functional adaptation interventions hardly compatible.

For example, the structures (present almost all year) covering the arena's lower part to allow many viewers to attend bullfights: they block the view of the steps (both the original and the ones result to

the 19th-century restoration); of the annular corridors; of the separation barriers between the stands and the arena and of the original functional elements of the latter.

But the damage is not only aesthetic and formal as the need to accommodate, during these events, a large number of viewers has led not only the safety of the ancient structures, but the complete replacement of those items that would be able to survive only if it was respected a less consistent load of users. To all this it must be added the creation (between the arches of the ambulatory outside the ground floor) of new functional spaces for the accommodation of spectators and visitors: ticket office for sightseeing, book shop, box office for events related to shows, toilets, information points.

Ultimately the amphitheater of Nîmes is only felt from the outside, while the interior is now an "amusement park" where everything is placed in the foreground (bullfights, the fantastic tales of the fights between gladiators and wild beasts, gadgets, audio guides unnecessary for the purposes of historical knowledge of the archaeological heritage) except for the documentary value of the monument. Farther the building along with the entire town is UNESCO, an organization should not only ensure the enhancement but especially the preservation of the values of uniqueness, authenticity and integrity.

A similar situation, although with less devastating results, can be found in the amphitheater of **Arelate**, the current Arles. The questionable restorations (done several times) that have now almost entirely replaced the remaining original elements and not result of 19th-century additions, are alongside to enhancement measures that disfigure and make it difficult to see the outer ring of the structure such as the great platform that collects information from a number of devices on the one hand, the functional elements, almost identical to those for consistency and number of Nîmes, on the other.

Even within the arena and stairways are hidden by the necessary facilities for the performance of the shows entertaining. Finally it appears as chilling the inclusion of toilets (still under construction) between the arches of the lower ring: these new toilets in brick masonry area related to the ancient walls, hinder the readability and affect the value of antiquity; enhancing only a misunderstood and vulgar value in use or topical.

On the contrary, still in Arles, the conservation and renovation of the theater are compatible and sustainable: these are constituted by lightweight structures, which are necessary for today's theater but they do not invade or hide the structures of the original building. They fit in a but evoke distinguishable, admittedly in a modern key, the structural elements of theater: they are the service spaces (constructed entirely of laminated wood) placed between the radial septa of the auditorium where they have lost the vaulted structures of coverage. The new architectural elements are detached from the original structures and follow the trend oblique to the ancient times of substructure.

Fig. 4-5: Forum Julii theater e a view of the Arelate one.

Renovation of *Arausio* Theater, the current Orange, also in Gallia Narbonensis, deserves attention as compatible with the old building. Here the necessary facilities for the manifestations performance are minimally invasive: they exploit modern coverage (which is essential in its sole function) which protects the original front stage, do not hide the original fragments of decoration; do not overlap the old architectural setting used indiscriminately as a scenic backdrop for any event. This decision shows respect for the original monument as it places at the same scenic backdrop a value that cannot be compared to any contemporary setting. In addition, maintenance and structural health monitoring are constant and the structure presents an excellent state of preservation. However it might regret, in this as in previous contexts of Nîmes and Arles, the loss of stratification occurred with the releases dating back to the 19th and 20th centuries.

The roman entertainment buildings of the ancient *Colonia Julia Viennensis*, current Vienne are fully in the middle of today's cultural city activities, although preserved in ruins. The theater, for example, was

discovered in 1909 and the restoration work begun in 1922 and were completed in 1938, the works concerned mainly the area of the auditorium where they were rebuilt much of the bleachers. The theater today presents a balance between conservation and upgrading work to ensure the performance of cultural activities within the building. Much like the Roman theater in Lyon by type and especially for the restoration work carried out, it will keep track of the stage and the orchestra and almost the entire auditorium. In it, the temporary structures allow the execution of events without completely hide the original plan metric shape of the ancient theater.

The same cannot be said referring to the odeon. It is in a state of abandonment although it is located in the neighborhood of the theater and may help to define, with the circus, a "system" of entertainment and recreational buildings of ancient *Colonia Julia Viennensis*. The circus remains in fact are represented only by one of the elements that decorated the central spine, while the rest could be traced, in the urban fabric where it is clear the mark left from the classical building, like the one found in Arles.

The presence, only as urban trace, left by the two circuses just mentioned, is also manifest in the city of *Baeterrae*, current Béziers, where the amphitheater is still an integral part of the fabric of the medieval city. The building, on which stands was built in the Middle Ages a neighborhood and the church of St. James, is now recognizable paragraph in curvilinear facades of the houses and the radial shape of the land parcels. In addition, a series of excavations and interventions of consolidation of the ancient structures still evident today, allow to better perceive the shape and size of the original.

However the authenticity of the monument (found only in a few other cases such as the amphitheater of Tours and Paris) is guaranteed by the functions attributed to the arena today: a public garden where the ruins of stands, *vomitoria*, columns and other elements that became apparent during the excavations of recent decades.

Fig. 6-7: *Baeterrae* amphitheater, e a view of present Tours where the Roman amphitheater it was located.

Finally, it's important to mention those buildings less known by the scientific community need further studies and investigations or additional conservation actions. Among these it seems important to mention the amphitheater located today in the neighborhood of Toulouse Purpan between the city of Blagnac and Toulouse. The first excavations were carried out between 1837 and 1899, while the first restoration dates back to the sixties of the twentieth century. Unfortunately, until 1983, the building (abandoned) becomes a city dump and the structures previously restored were irreparably compromised. Currently, it is the easily identifiable in its floor plan, but the facilities need further routine maintenance and consolidation. However, it retains the charm of a ruin set in an urban setting. Nowadays, no visible trace remains of the amphitheater of *Narbo Martium*, the current Narbonne, although they were visible at least until the mid-19th century, the years in which Viollet-le-Duc detects the significant tracks along the road that leads to Narbonne Gruissan modeled on the ancient Via Domitia. Today the building remains in memory only the topography of the area and thanks to some buildings and urban projects that are modeled in part on the track.

Similarly for the roman buildings as the theater of *Massilia*, the present Marseilles: discovered in the early decades of the twentieth century was partly destroyed and covered up until 2005, the year in which it began a campaign of excavations for the purpose of recovering the few tracks. Currently some steps and part of the orchestra can be seen in the courtyard of the Vieux Port. The theater, the amphitheater and the circus present at *Valentia*, the current Valence, whose historical and literary sources testify to the presence.

Fig. 8-9: Tolosa amphitheater and part of the Roman theater of *Massilia* ruins.

3. Enhancement tools: the approach to the systemic episodic***

A last objective, in terms of valorisation and promotion, for the paper could be that of creating a series of guidelines (scientifically correct but accessible to everyone) to support the interpretation of this widespread heritage, with strategies that can be relevant on a national (for each single country) and international (for the whole Mediterranean basin) level. Particularly it would be useful to: plan themed itineraries for the fruition of archaeological remains; publish maps, historical data, virtual reconstructions of theatres and amphitheatres that can highlight the different transformations and an abacus of reemployed elements found in the structures or in the wider urban context; create interactive cartographies connecting the diverse fields of study and promoting the accessibility of data and information at different scales.

Thus, the use of technologically advanced instruments, combining ease of use with scientific precision, seems unavoidable: a useful medium could be the GIS systems which, by mapping a remarkable quantity of data and proving to be easily consulted through the internet, would enable every kind of user to access historical and territorial information.

From this statement we understand how important it is to suggest a not-so-much as episodic but systemic approach regarding the inclusion of such goods within specific contexts of reference: among the different entertainment architectures, among the different urban realities, inside an area strongly influenced by infrastructures (roads, ports, water, etc.) to serve different individual monuments.

In fact this approach, which was characterized, as seen above, the first studies on the archaeological heritage of *Gallia Narbonensis*, is based, first of all, on a series of spatial references through which the playful and entertainment buildings are born, have been used originally and during the period of their disposal and reutilization focused on urban or residential use. The Roman road network represents the major point of reference, which connected along the coasts of the Mediterranean and inland the urban centers, united by an osmotic system of military and commercial connections as well as socio-cultural exchanges. This road network, for example, linked the major cities to the minor realities and all were connected with the capital of the empire.

In this sense, the greatest role was delegated to the *Via Julia Augusta* (built from 13 BC) starting directly from the Aurelia one, joined, along the coast, the cities of *Cemenelum*, *Forum Julii*, *Aquae Sexstiae* and *Arelate*. In it hooked the *Via Domitia*: built in 118 BC connected the *Cisalpinia Gaul* with the *Hispania Tarraconensis* across the entire province of Narbonne connecting *Arelate*, *Nemausus*, *Baeterrae*, *Narbo Martium*, the capital of the province. From *Arelate* departed, heading north, the *Via Agrippa* that after going through *Avenio* (Avignon), *Arausio*, *Valentia Julia*, *Julia Viennensis* *Cologne*, reached *Lugdunum* (Lyon). Finally, the *Via Aquitania*, built around 14 BC, starting from *Narbo Martium* through *Toulouse* reached *Burdigalia* (Bordeaux) [6].

Even nowadays, the main playful and theatrical buildings insist along these roads and could be the starting point for a systemic enhancement that not prefers the most important and most well-known buildings only, but also the smallest one, poorly studied and currently less promoted by the tourism systems. In fact, the success of these buildings is also due to the capacity of the road network to transfer the population of the surrounding countryside in the big cities where they organized games and theatrical performances, as well as the same elements of communication played a vital role when, during the final years of Roman Empire, especially the amphitheater became a fortified collection point for the inhabitants of the rural districts.

Another infrastructural system that now deserves to be related to the preservation and enhancement of theaters and amphitheatres are port facilities: in particular, *Forum Julii*, whose playful buildings were

built on the edge of the great commercial port, as well as in the case of *Narbo Martius* amphitheater, built at the marina, or the theater of *Massilia*: nowadays the few ruins are incorporated in the buildings along the old wharf. Finally, a fundamental role for the functioning of these buildings was covered by the network of aqueducts as shown by the water systems of Gard, Nîmes, Arles and Frejus .

A series of actions aimed at the enhancement and a more integrated management of these archaeological sites could further consider the coexistence of several buildings (and not only the playful and entertainment one) in the same urban reality. If in Nîmes, the amphitheater and the *Maison Carrée* are worth a visit, they could be put in relation with the traces of the urban fabric of the Roman city (in some places very evident, though little known) and other monuments such as the temple-nymph of Diana, the Roman tower (probably a *castellum aquae*), the ruins of the fortifications, the city gate. Similarly in Arles, where the acts of exploitation may create two thematic itineraries.

The first could create a system of the Roman buildings still existing: such as the traces of the *forum* with the underground structures of the *cryptoporticus* (whose careful visit would let to understand the real extent of the area at the *cryptoporticus* delimiting the boundaries) and the exedra annexed to the forum and visible inside the Hôtel Lavan-Castellane, the Baths of Constantine, and the city walls and towers are still visible and partially embedded in the urban present, the burial area of the Elysian Fields. The second should correlate with the amphitheater near the theater (generally excluded from sightseeing), emphasizing formal characteristics and similar decorative, but especially the common fate tied to abandonment, reuse as medieval fortresses, the rediscovery and restoration eight - twentieth century.

Most interesting would be to relate these buildings to the circus, whose ruins are barely perceptible. However, traces of it remain in the south-western urban fabric on the banks of the Rhone. Recent studies and excavations carried out between 1974 and 1989 showed some portions of the substructures and a good part of the arena also in those years it was finally determined that the obelisk at the center of Place de la Republic, originally decorated the plug of the Roman circus [7].

The simultaneous presence of three entertainment buildings may also be seen in Vienne, where, however, only the theater is advertised and is subject of constant maintenance works. It is in contrast to the nearby *odeon* which is little known and looks abandoned, virtually unknown, finally, the circus which is apparently only the obelisk that decorated the monument. However, further excavations may trace the structures embedded in the urban fabric.

Fig. 10: *Colonia Julia Viennensis*: Roman theater and odeon

Even in this case, a systematic approach could be related the playful and theatrical buildings with the other monuments of the Gallo-Roman town (Temple of Augustus and Livia, the Sanctuary Pipet, the sanctuary of Cybele, the remains of the city walls) and with the extensive archaeological site of Saint-romain-en-Gal which contains some ancient Vienne residential and commercial districts. Interesting, would be ideally reconstruct the monuments and the city of *Valentia* based on available literary and documentary sources: from them we learn that the Roman city had a theater, an amphitheater, a circus, an *odeon* in addition to a large forum and a basilica.

More attention deserves the amphitheater of Toulouse, while in-depth studies and excavations would put out the ruins of the amphitheaters of Narbonne and Orange. The latter, in particular, might merit the same attention given to the theater and the arc de triumphed in honor of Tiberius if only actions for the protection and conservation (such as to prevent the complete cancellation as archaeological and historical evidence) would be encouraged. It, situated near to the edge of town (across the street from

Caderousse) occurs below a large car park and it has neither studies nor tourist signs, although the place names (avenue des Arenes) are mindful of the existence and location.

Finally, it needs to be put in direct relationship (network) as it is reported in the literature or documentary sources relating to these playful and theatrical buildings, and especially that there are real connections and virtual museum institutions (local and national) that contain fragments belonging to these monuments.

Concerning the virtual reconstructions, they must always be guided by the severity of the disciplinary restoration (the so-called Virtual Restoration, which in the field of archeology, it called the *Virtual Archaeology*), so it will not have to incur in the pre-eminence of a suggestive impact of a virtual reconstruction more than to their accuracy, or even in an excess of technicality at the expense of the content (the so-called “Cinecittà” and “Star Wars” syndromes). Is it clear how the digital recreations have an inherent educational and informative role, which allows the reconstruction of monuments, cities and territories with the aim of communicating the ancient cultural heritage in an effective, fast and repeatable way, but also to be an instrument of verification and synthesis of analytical data (derived from the findings, or the analysis of erratic fragments of the architecture, for example) [8].

Whenever the wishes to follow a correct preservation, it is therefore necessary that the aspect of advertising will parallel the stringency historical-scientific and, consequently, the tools to support the knowledge are also the basis for the enhancement: in this sense, applications and virtual restoration of the Virtual Archaeology is the right balance between fairness and potential disciplinary layman.

In conclusion, the old buildings for the show, thanks to their transformations and reconfigurations, following these strategies, can renew and strengthen the interrelationship between the land and the landscape, becoming accumulation points of the memory of centuries of historical events, economic processes and social structures of people and society as a whole.

Archaeology and Architecture, the Stagnum Neronis of Baia

Marco RUSSO,

Ph.D. candidate at Department of Architecture and Industrial Design "Luigi Vanvitelli", Aversa – Italy

archmarcorusso@gmail.com

Abstract

The area of Campi Flegrei presents an overabundance of geological resources as Fondi of Baia, unique union of two craters in the world; cultural resources as Campi Flegrei's museum in the castle of Baia; archeological resources as the underwater site of the Stagnum Neronis and other important sites along the coast. The area is under the Aragonese Castle of Baia, 4 meters underwater. It is an important ROMAN FISHPOND of the 1 sec. A.D., built on the ancient road called "via Herculanea" that linked Pozzuoli and Miseno. Due to *bradyseism* the coastline reduces of 40 meters, so all buildings are underwater but in the same time we can assist to the birth of the underwater archeology culture. Thanks to new and unpublished multibeam images, we can understand the real situation of the ruins and propose a method to preserve and develop the area. This research on the Stagnum Neronis tries to trace a scheme adaptable to other sites along coastline with structures fused with the landscape and with the underwater ruins, a method to restore the area with a sustainable approach choosing functions adaptable to various sites. The architecture could be the starting key of a development process in the area to give new life to this great and abandoned underwater heritage.

Keywords: underwater archaeology_stagnum neronis_Baia_center of underwater archaeology

1. Underwater heritage of Baia

The area of the phlegrean fields is one of the areas with greater presence of archaeological ruins and natural resources, Baia in ancient Rome was the place where the wealthy romans were staying and spent their free time at the thermal bath which were numerous due to the presence of volcanic springs. The volcanic nature of the area meant his ruin with the phenomenon of bradyseism buildings constructed along the coast ended underwater, today the coastline is retreated to 40 meters compared with the Roman shoreline. Underwater Roman buildings have been rediscovered only in the mid 900's, before then the landscape painters put the focus on small parts of the ruins emerges from the sea as the views of Brambilla (1586), Francesco VillaMena (XVII century), Van Aeslt and Quenquelair (1696). The oldest map of the area is represented by glassy flasks from Odemira, Prague and Pilkington, on the glass surface there was the topographic image of Puteoli and Baiae with the main monuments arranged on several levels.

After the renewed interest at the beginning of the '900 resumes since 1984 the relief program by Maiuri^[1] and Lamboglia^[2]. Based on surveys and direct observations of the archaeologists have played a submerged archaeological map of the bay including the most famous areas as the site of the Baianus lacus, the nymph of Claudio and the less famous site as the roman fishpond under the Aragonese castle of Baia. The area was densely built erased by shipyards that are implanted on a giant concrete slab operated in the early '900. Fortunately, as recent investigations have established, the rests are not totally lost, we can see a small group of *pilae* (breakwater) that represent the extreme limit reached on this point by the ancient coast.

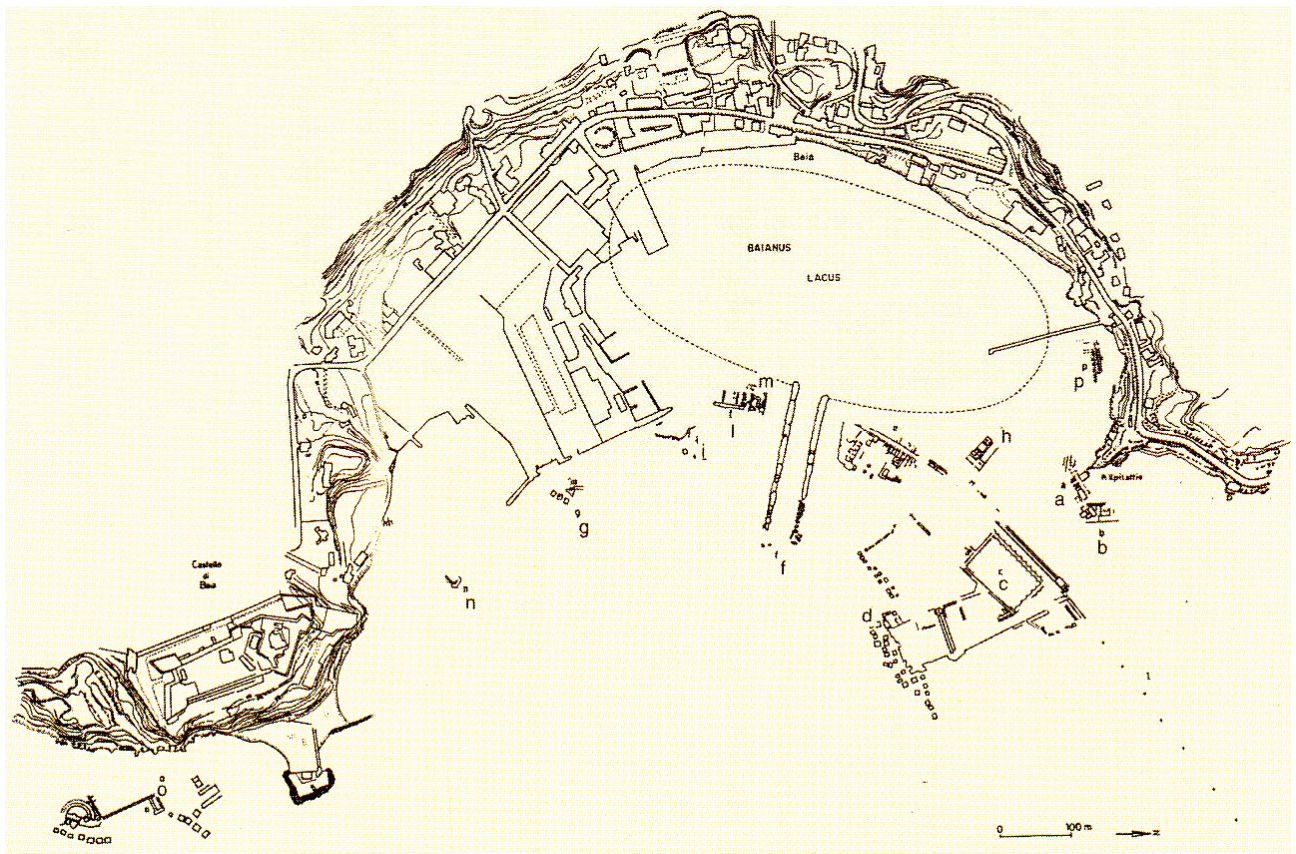

Fig. 1: Tav.A – Archaeological map of the phlegrean fields; a_nymphaeum of emperor Claudio; b_thermal bath; c_palace of Adriano; d_fishpond and breakwater (relief: E.Scognamiglio ^[3])

2. The site of the Stagnum Neronis

The project area is under the Aragonese Castle of Baia, 4 meters underwater. It is an important roman fishpond of the 1st century AD , built on the ancient road called "Via Herculanea" that linked Puteoli and Miseno, in the 1579 Mario Cartaro shows in a map a "*via selicibus strata sub aquis*" (underwater road). This stretch of road is identified as an extreme offshoot of a seaside villa and shows an elaborate succession of ponds, porches and scenic pavilions occupying an area of approximately 300m x 80m, 300m represent 1.000 roman feet (1 roman feet = 29,65 cm), a measure that in Baia not even billionaires could afford at the time.

The monumental area and the great deal for the realization, the desire to impress at all costs was an exeption, the palatium built over the stagnum was the residence of Nerone, as shown by excavations recently conducted by Dr. Paola Miniero^[4].

The villa occupied the best position from which it was possible to observe all the Phlegraean area, a monumental building that had a direct connection with the sea, yet the tunnels dug into the tuff and pozzolana has been partially destroyed with the construction of the Aragonese castle in 1493-1495.

The term *stagnum* indicates an artificial lake surrounded by arcades, may also designate a stretch of sea sheltered and enclosed by quays^[5].

The big structure in the sea to the south has a nucleus with a large semi-circular tanks having 55 meters in diameter and protected by a pier of 85 meters, today remain only seven *pilae* (breakwater) erected in *opus reticulatum*. The great oyster fishpond had multiple compartment with a scenographic porch in the background, a structure in pillars and roof tiles. There was first an external protection, the pier long 85 meters, then a concrete protection crossed by four channels for the water exchange, finally the fishponds a series of big oyster tanks built directly into the sea, *in litore constructa*.

The semi-circular area is connected to a huge rectangular body divided into different adjoining oyster tanks, to which are added porches and indoor spaces identified from elevated platforms facing in front of the sea.

In the rectangular body there was the *suspensurae*, the architectural term given by Vitruvius to piers of square bricks (about 20 cm X 20 cm) that supported a suspended floor of a roman bath covering a hypocaust cavity through which the hot air would flow.

The channel leading into the basins is protected by seven external breakwaters. Everything is on big scale as the concrete wall border that has a thick of 6.5 meters.

Fig. 2: Plan of the site with ancient shoreline

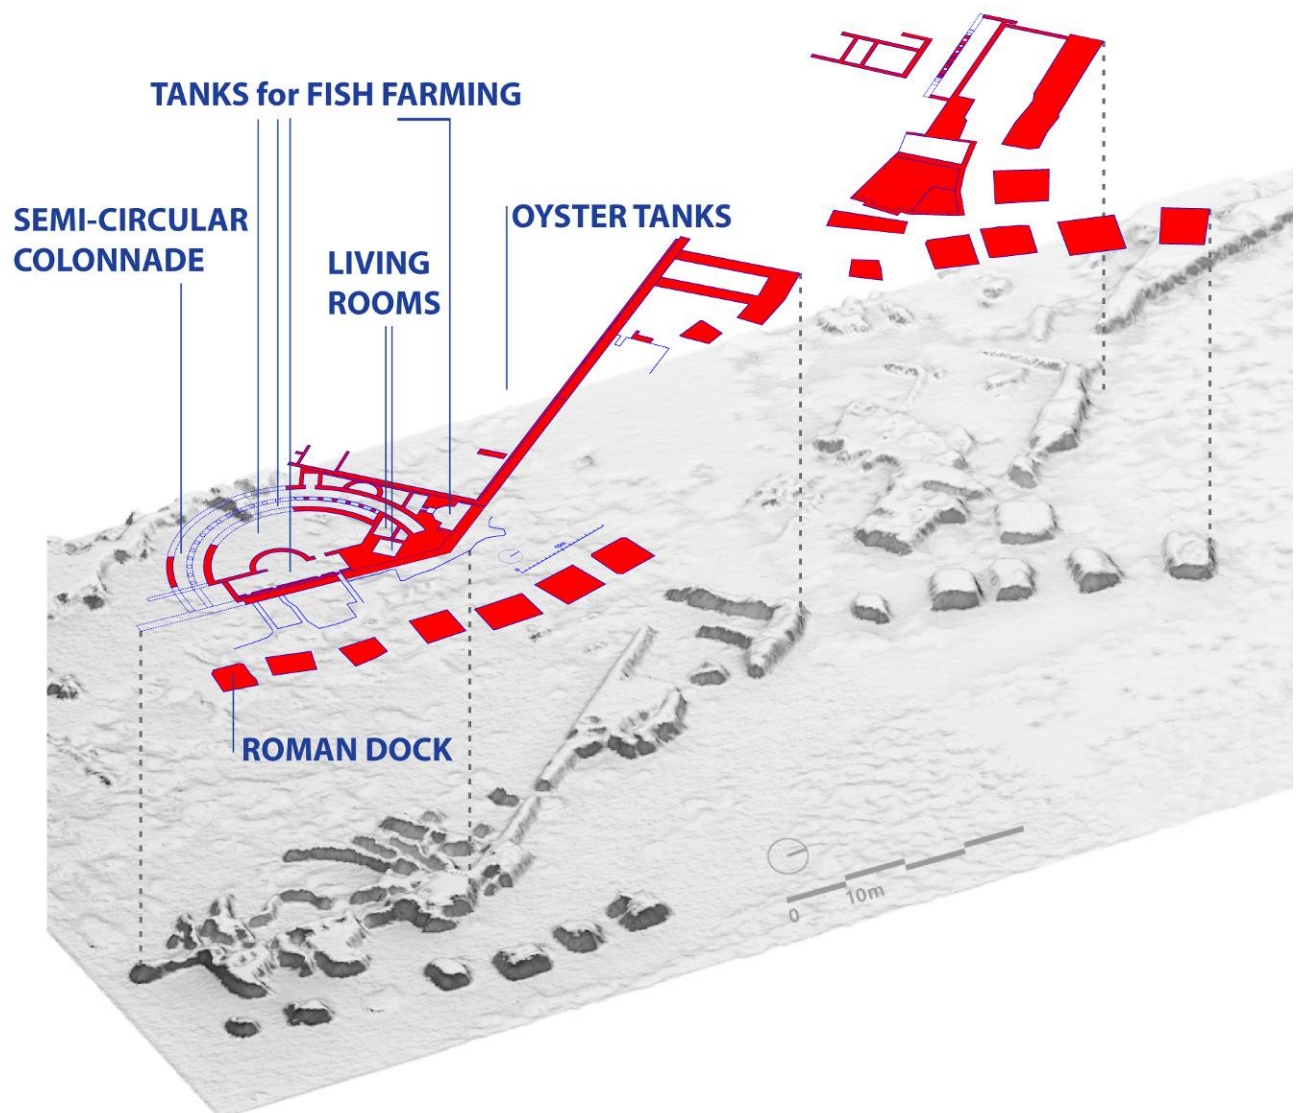

Fig. 3: Virtual reconstruction of the roman fishpond – *Stagnum Neronis*

Through the *multi-beam* image, recreated with computer graphic, it has been possible to take a careful look to the real situation of underwater rests, this is unpublished images important also for the underwater archeologist for an immediate and clearly view of the site.

This technology is very important for this research because all the reliefs and historical maps were produced with the traditional techniques of relief in the years 1980-1990, the samplers hadn't satellite images or 3D reconstructions, they have not been able to benefit of many other information that these technologies offer us.

The first job was to redraw the building plans crossing the information from the old reliefs and new 3d images and satellite images, the fig. 3 synthesizes the work on the area, have been important the written sources describing very well the internal organization of the spaces and in some cases even the patterns and materials used.

It would have been interesting with the help of an archaeologist reconstruct the ancient structure to have a 3d image and a 3d model of stagnum Neronis not to understand what remains today what it was in the past.

How many underwater archaeological sites have been looted statues and decorations, this structure had to be full of ornaments as the area of the semi-circular colonnade had to be quite a sight.

3. The project

The theme of the project derives from the desire of people to *rebuild* the ancient bond with the sea, which was destroyed by the neglect and constructions in breach of planning control.

The area presents an overabundance of *geological resources* ("Fondi of Baia", unique world union of two craters); *cultural resources* (the castle of Baia is the museum of the phlegrean fields with over 2000 years of history); *archeological resources* (the site has important buildings along all the coast).

Due to *bradyseism* the coastline reduces of 40 meters so all buildings are underwater but in the same time we can assist to the birth of the culture of the underwater archeology.

It's unbelievable that the Museum of Campi Flegrei is of the last museum in Campania forasmuch as its amazing heritage.

The museum contains exceptional evidences with over 2000 years of history, the art installations are dated and do not promote the interest of visitors, a museum that is not in line with the times, very interesting and educational is the reconstruction of nymphaeum of Claudio which is almost always closed to the public.

The idea is to insert in the territory a function that can be integrated with the economic and social fabric of the area, were important talks with the local people to understand the needs and requirements of a place that has suffered the economic crisis in recent years. Speaking with some of underwater archaeologists in Baia and with the various associations concerned the exploration of the sea and archaeological sites was clear the need for a structure able to satisfy the growing demand for courses on the topic, this debate has been going on for 10 years and for economic reasons it has not been possible to realize a similar structure.

Important was the decision to include the museum function, most of the building is destinate in virtual exhibitions and sculptures installations to offer a unique experience to visitors.

From these considerations and numerous visits to the museum of the phlegrean fields was born the idea to reconnect the area of the museum with the sea, providing an exhibition inspired by new ways of museumification, by providing in the first section of the building a large hall of statues where it will be exhibited in glass cases many artifacts stored in the warehouse of the museum while in the heart of the building is situated the center of underwater archeology.

The area is perfect to accommodate an *Off-Shore building* (we are in a bay in the gulf of Naples). The weak sea currents and low deep (4 mt) make possible the study of the site. The building will not face strong water pressure on its walls, something that makes this idea more possible.

The project involves a floating building completely overlapped on the underwater rests, so as not to alter the roman monument, the choice was to design a building according to the 2001 UNESCO convention for the protection of the underwater cultural heritage^[11], the convention decided that submerged artifacts should ideally remain on the seabed out of respect for their historical context and, in some cases, because water actually preserves rests.

An "*Architectural Shell*"^[6] with some spaces opened on the landscape and other underwater spaces where the inside pressure is constant (completely immersed to allow the watching of the rests).

The principal references are "*Floating Archaeological Center*"^[7] (golf of Giens_1976/77) and "*Underwater Archaeological Museum*"^[8] (Alexandria, Egypt_2008) designed by the French Architect Jacques Rougerie^[10]. Some ideas comes from the art installation "*Liquid Door*"^[9] (a threshold between the indoor environment and the sea produced simply by air pressure) inspired by Jacques Cousteau's dream of living underwater.

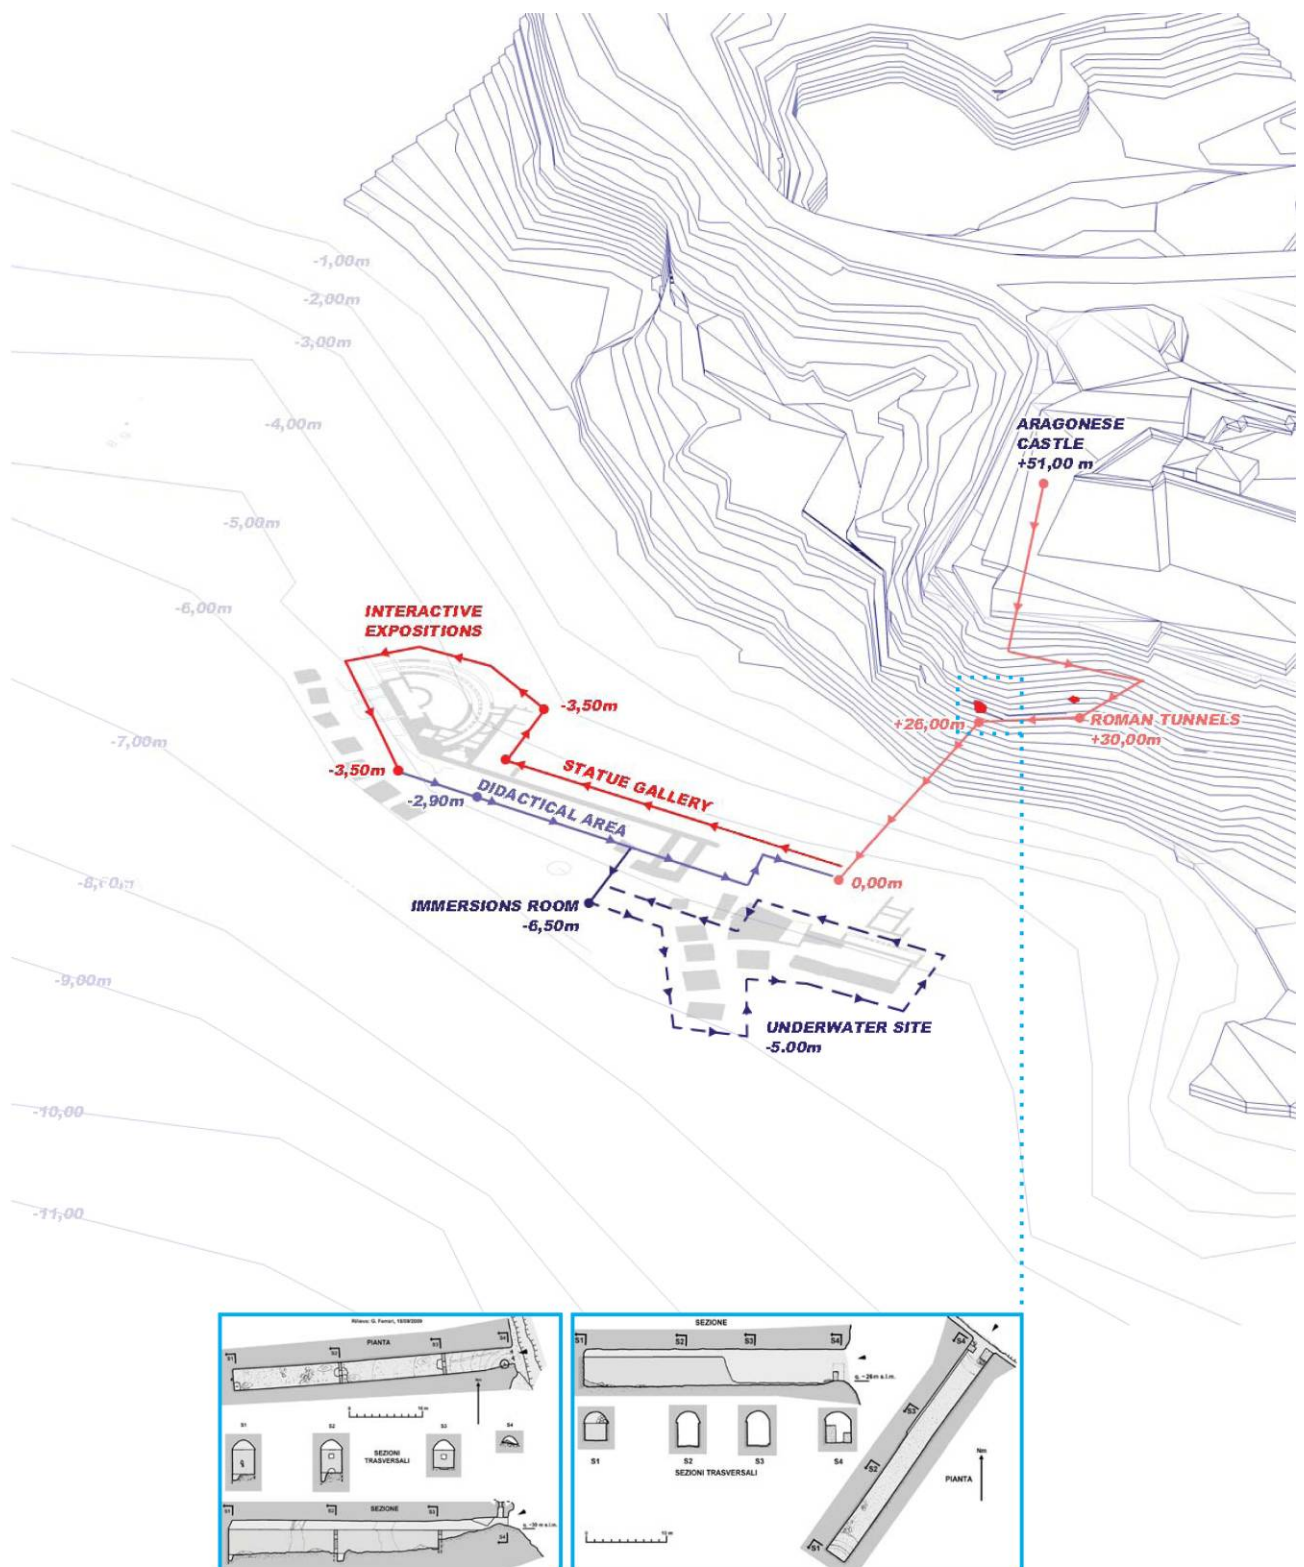

Fig. 4: Diagram of the functions with path and draw of the roman tunnels under the aragonese castle

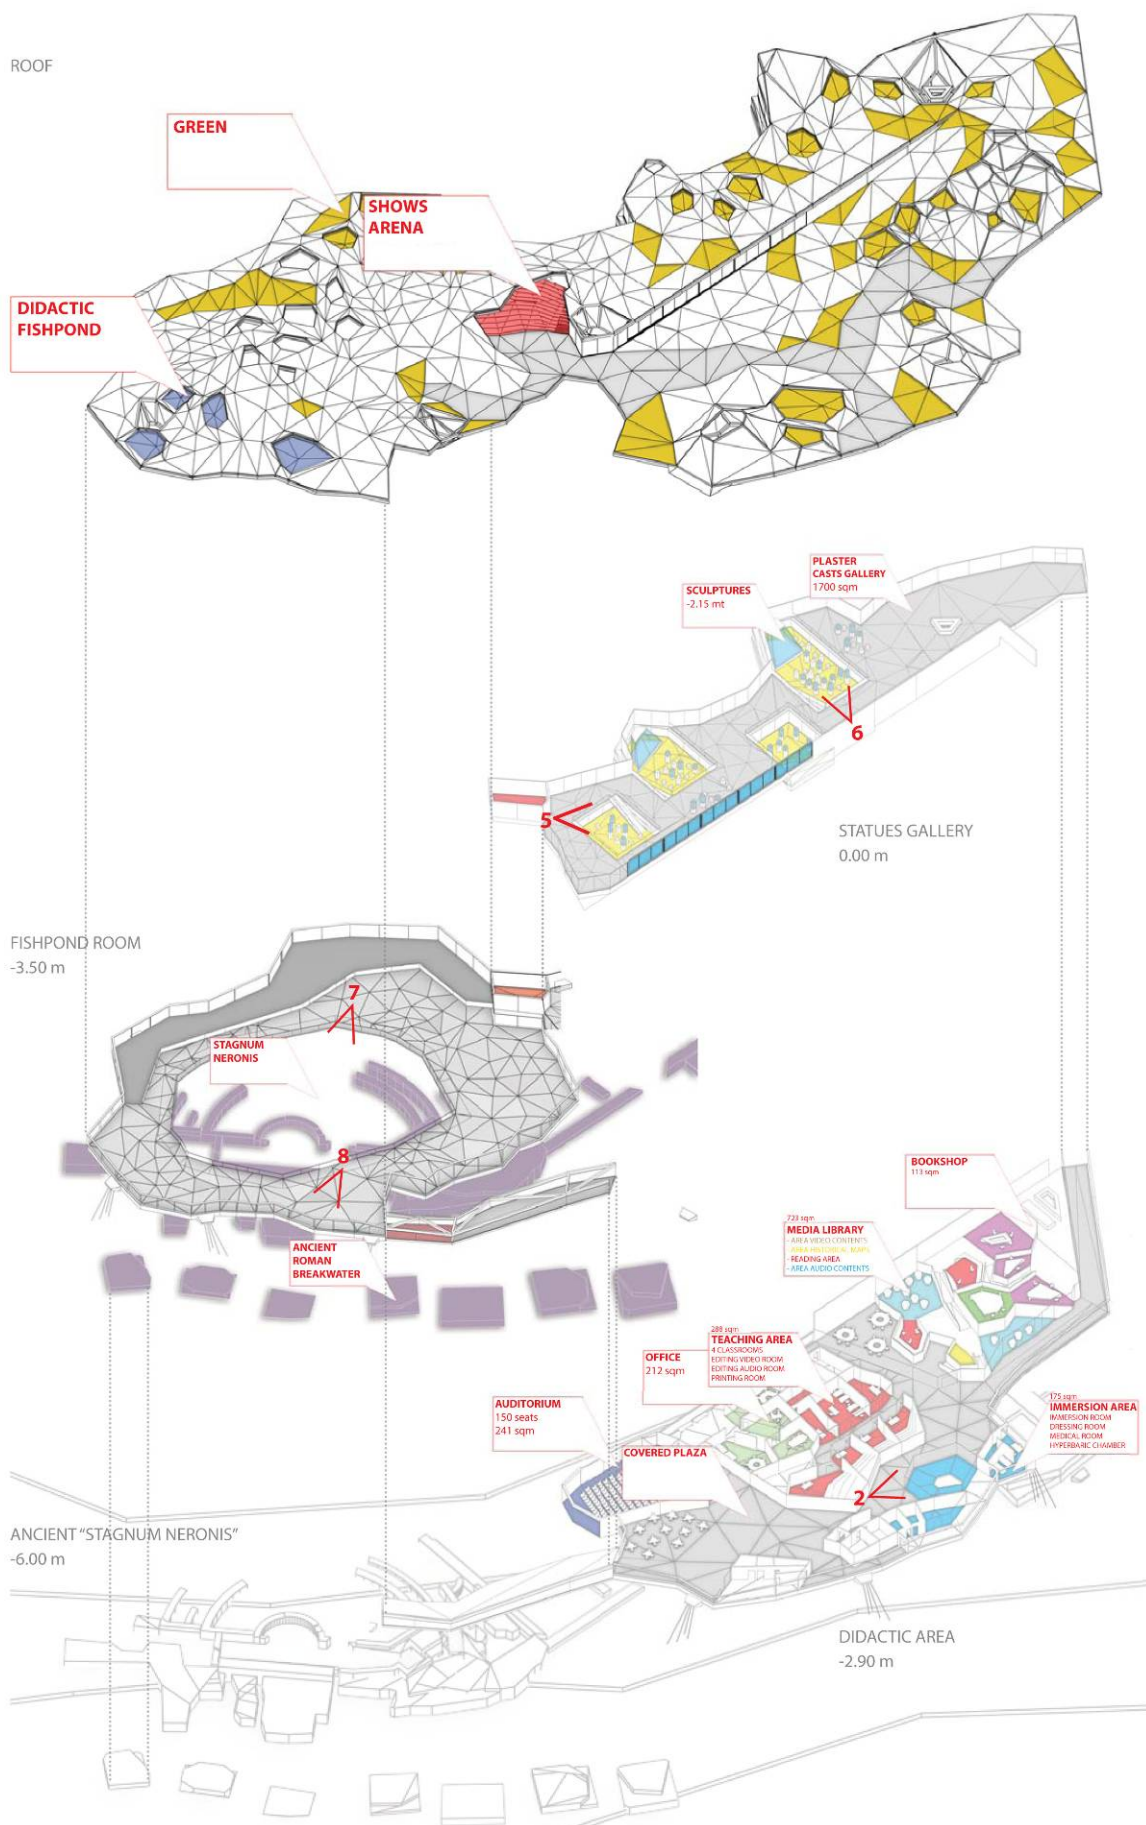

Fig. 5: Exploded axonometric view of the building

The project is based on a modular structure. The scheme chosen is not anonymous but is a scheme in relation with the roman building. It's the *Voronoy scheme*, starting from noted points of the ancient fishpond is possible obtain a series of "cells" in relationship among them. Note that the final scheme is fused with the ancient structure and not adapted to it. Modular scheme is used to design the spaces, tracing the shape of the roman fishpond.

After a first dimensioning of the structure has been necessary calculate the *Archimede's principle* to know the effect as a result of the immersion of the volume in the sea. It has been necessary to provide a ballast tank to increase the weight force of structure to stabilize the building. This ballast volume is located under the pavement. The building position is ensured by steel cables.

Indoor spaces have various heights, the roof is designed to join all this different levels. The final configuration of roof derives from the modular scheme. Some "cells" go up to let in the natural light and ventilation, another "cells" that go down are the vertical supports. The work on the roof allows having a lightweight component that permits to reduce the visual impact on the landscape.

Fig. 7: View from the beach of Baia under the Aragonese castle

Fig. 8: View of the gallery of statues with the glass cases inspired by roman *suspensurae*

Fig. 8: Plan of the *Stagnum Neronis*

4. Conclusion

The project proposes an experimental architectural language that doesn't conflict with the landscape or with the ruins, also the building remains in contact with the preexistences and tries to integrate them, such as the coastal path that leads to inside of the center of underwater archaeology, a lightweight element that intersect all historical elements of the area as the roman tunnels^[12] on the rock face.

This study tries to trace a scheme adaptable to other sites along coastline to design structures fused with the landscape in order to give new life to this great and abandoned underwater heritage.

The architecture could be the starting key of a development process in the area as in other parts of the world such buildings are made with great response from the public.

Start to protect and use the historical-artistic patrimony as an economic and social engine, in this precarious and variable economic situation find the funds for this type of intervention is very difficult but would ensure a better future.

The subtraction architecture

Stefania DI DONATO

Ph.D. candidate at Department of Architecture and Industrial Design "Luigi Vanvitelli", Aversa – Italy

Sant'Antimo (Naples), Italy

didonato.stefania@hotmail.it

Abstract

The hypogeal aspect of the architectural project has not to be interpreted as the evasive folding into the nostalgic and symbolic dimension that has crossed the civility and culture of the human history, not even as trying to deprive the architecture of his alter and different presence inside its natural setting. The subtraction architecture consists of the way of the environmental transformation that does not look at the architecture as independent object, but it works on the elements complexity and relations that enclose itself. Choosing to talk about the subtraction architecture instead of “passive architecture” or “negative architecture”, it underlines the intent of the subtractive act in the same way as building out of the soil becomes the additional act that is assembly work and the addition of hand - made materials. The first is born from sculpting the natural landscape, and in the landscape it blurs because it is an essential part of that landscape, so it is not a different universe relegated to the depth, but it talks with the superficial life of which it is the natural extension ; the second is identified with the environmental contest as additional object and so recognizable.

The subtraction architecture then brings us back to the archetype of the crypt, the excavation of the cave: the return to the womb.

Keywords: subtraction, hypogeal, passive architecture.

1. Le Corbusier and Utzon, architecture comparison.

“Ognuno di noi, pensando ad una prima forma di costruire, pensa allo scavare.” **Francesco Venezia**

Conceiving a building as a cave is a highly unusual attitude in modern architecture. The massive, opaque condition involved in the construction of an underground building seems to directly contradict the principles that the Modern Movement had defended most strongly. The cave archetype as the presumed origin of the earliest human shelters had previously been replaced as a model by the Enlightenment's treatise writers, for whom another metaphor, the primitive hut, was a much more precise representation of the fundamentals of the art of building. Abate Laugier's canonical image was an optimistic substitution for the dark myth of the cave, and heralded, two centuries early, Dom-ino structural icon which for Le Corbusier had to synthesise the new way approach to architecture which was to mark the entire 20th century. Paradoxically, Le Corbusier was also the author of the unusual proposal of a building that was the antithesis of almost everything he had defended so strongly: the project of La Sainte Baume.

Sainte Baume conceived as architecture sculpted into the mountain to hold the grotto where the biblical Maria Magdalena was supposed to have come; a succession of hidden spaces linked by corridors that perforate the mountain to open finally to the sea. In this case, the lines which had hitherto defined Le Corbusier's architecture plan almost without exception were transformed into a black corporeal silhouette that revealed the interior section using mechanism of figure-background opposition.

Another project is an example of architecture of the subtraction is Silkeborg Museum of Jorn Utzon. Utzon conceived the project as a buried grotto that would only emerge from ground level to seek light and permit access from the outside from the exterior world. The Silkeborg project is also a sunken building, represented on its plans and sections with expressive density and rotundity. However, in contrast to Le Corbusier, Utzon conceived the large sunken vessels in a sculptural sense rather than as the result of the desire to carve away the ground. Beneath the ground, the orthogonal geometry loses its constructive purpose, and the forms that are used respond freely to the solicitations that are transmitted to the underground building by the surrounding mass of earth.

Fig. 1: Le Corbusier, Le Sainte-Baume Basilica 1948.

Fig. 2: Jorn Utzon, Silkeborg Museum, 1963.

2. Case-Study: International Museum of Volcanoes.

The project, presented as a demonstrative example, is a thesis developed by Stefania Di Donato within the Planning Workshop at the Department of Architecture and Industrial Design Luigi Vanvitelli. It is a "International Museum of Volcanoes" located in Lanzarote (Spain). The project is a particular and dramatic experience :a path inside the earth that then rushes towards the landscape. A portion of the project is cantilevered over the landscape, because the landscape to go inside the museum. Then the observer arrives at a lower altitude through the exhibition halls: the circular room is designed like a mother's womb, the metaphor that indicates the origin return. The Observer does not lose the link with the sky which enters in the room through two large skylights, one of which is completely open and allows water to invade the room.

The steel in historic buildings: concealing vs exposing

Laura CIAMMITTI¹

⁽¹⁾ PhD Student - Department of Civil, Building Architecture and Environmental Engineering University of L'Aquila - Italy
laura.ciammitti@virgilio.it

Abstract

The steel material has changed over time its role in the historic building, passing from the first one linked to the purely technical aspects of consolidation, to the second one, where it is considered a project item with specific intents in the design act. Certainly, these two roles are correlated to different way to use the steel, employed for metallic elements disguised by the existing material or, on the contrary, for components put in view.

On the one hand, the rehabilitation project uses metal components for their high structural performances, placing them in an hidden position; on the other hand, the transformation project uses steel as a material capable of operating the renovation, finding in the Italian tradition an important technical and formal experimentation, which shows the ability to overlay to the historic layers the ones related to the contemporary culture.

The binomial between concealment and exposure of the added elements is the investigation field of this research, which explores the delicate boundary between the visible and invisible sphere as a pretext to understand the dynamics of the Italian design for the built heritage, known for ranging from conservation to transformation: the duality between these two poles gives to different levels of evidence the task of defining the steel role.

Keywords: Steel, Consolidation, Transformation Project, Concealing, Exposing

1. The role of steel in the built heritage

The steel use in the built heritage has ancient origins and has gone through a constant evolution in terms of role, technologies and meanings.

The need of the post-war reconstructions in the Twentieth Century introduces unusual operating scenarios: the extension of the concept of monument from the single architectural object to the ordinary urban plot, requires the experimentation of innovative design strategies, best suited to operate on the common heritage. The search for appropriate functions for older buildings, combined with the need of conservation, makes the metallic material not only the technical tool with which preserve the built, but also the formal mean for make it new, allowing the reuse.

The adoption of a critical distance towards the built heritage is the main prerequisite for the recognition of the values to be preserved [1]: the role of the steel, and of the technique in general, is therefore defined through design choices that, in the Italian tradition, range between the historical instances of preservation and the architectural ones of change.

The historical approach to the built supports the thesis of conservation and the necessary knowledge of the historical processes that have generated the urban plot in different eras. The attitude towards the technique is of cautious distrust: in fact, it consists essentially in the technique of restoration and structural rehabilitation, making the technical act at the service of preservation [2]. The steel, therefore, plays a role exclusively linked to the technical-structural aspect: this added technological component tries to reconcile the needs of the iconic and material preservation of the buildings with the structural safety, without imposing substantial modifications of architectonic elements of which this approach wants to preserve the integrity.

This attitude, which is widespread in common practice, is supported by the same Charters of Restoration: the first one, edited in Athens in 1931, admits the use of all the means of modern technology, provided that the new materials are disguised as not to modify the image of the historic building on which the project operates. The consolidation act is implicitly described as a neutral and indifferent operation, because it is hidden by the ancient structures, considering legitimate any operation placed in the not-visible sphere [3].

After the II World War, the Charter of the Italian Restoration of 1972 represents an important reference for the practical use of modern materials, emphasizing the need to operate in the invisible sphere: the new materials appear qualified "for changes with a static and conservative purpose in the internal structure or in the substrate, provided that any distortion or discoloration of material is not evident on the surface" [4].

Only at the end of the 80's, the previous principle is put beside an attitude of distrust towards the concealed insertions in steel "because of their invasiveness, poor durability, irreversibility and relatively low reliability". Therefore, the means of traditional type for rehabilitation are preferred as verifiable and easily replaceable, even if they have a showy foreignness to the historic building [5].

The principle of dissimulation of modern materials is the leitmotif of the Italian Charters.

The character of visibility, defined as the ability to interact with the existing from the point of view of the figurative forms, is one of the main aspect to be checked in the project on the pre-existence, even when the value of the old material is recognized and the operations for addition, rather than by subtraction, are preferred: next to the direct dissimulation through existing materials, the concealment of the added resistant elements is achieved through the design of their shapes, that carefully minimize the perception of their presence.

The architectonic approach holds up the instances of change, adaptation and revitalization. It is based on the full legitimacy, if not the necessity, for the contemporary project to work in the dialectical between a rooted tradition and an attempt of innovation: simply, in order to place the work in the contemporary natural historical flow [1]. Technological innovations, adapted from the culture of new buildings, are transferred to the historic fabric and adequate to it, assuming the forms of an handcrafted production, which is very close to that of the old building. In this context, the steel is used as a material skilled to interpret the reasons of the project from a structural, technological and formal point of view, becoming an instrument capable of effecting the transformation and define the elements of a different formal configuration.

While the historical approach is substantiated by the suggestions of the Charters, the architectonic one is based on less coded principles, which are not allowed to be systematized: in fact, the resistance of the ancient buildings to any act of conceptual simplification and the shared theory of "case by case", makes any attempt impossible.

Transferring the principle of visibility in this second approach, the concealment of the added resistant elements turns into expressed forms that operate a significant transformation: the steel, along with the ancient material, contributes to a renewed formal configuration, showing itself "in the first person rather than through metaphorical figures" [1].

The combination between concealment and exposure of the metal material is the investigation field of this research, which proposes a new key to the interpretation of the operative dynamics on the Italian built heritage and, in particular, of the role of steel technology that, in some project, becomes the co-star of the architectural scene.

2. The levels of concealment

The character of concealment belongs to the technical operation of consolidation: the concealment denies to the simultaneous production the right to participate in a direct, immediate and visible way to the structural rehabilitating act, allowing the coexistence of the past and the present only through the cancellation and the sacrifice of one for the other [6].

The concealment is justified by considering the rehabilitation moment as a scientific act, independent from the project on the pre-existence, that is turned to take care of the aesthetic of the building: the main goal is identified in giving back the maximum security to the structure, with the minor, or better, with no one impact on the aesthetics of the building [7].

The architectonic form takes, therefore, the value and the function of a decorative finish with no relationship with the reality of the structural body, establishing a distinction between form and structure: the denial of the evidence of the added resistant elements contrasts, however, with a wide freedom of action in turning the invisible, also working for replacement strategies.

The subsequent recognition of the value of the existing material as document and deposition of civilization, introduces new principles for planning the rehabilitation, defined as a "culturally conscious act" [8]: the respect for the old matter and the principle of reversibility introduce the possibility of working for additions, through visible prosthesis, aimed to the integral conservation of the building.

The design strategies for consolidation, whether they operate by subtraction or by addition, prefer in each case the size of concealment, allowing the identification of different levels of not-visibility, aimed

to investigate the multiplicity of relations that the steel technology is able to establish with the historic heritage and its materials.

2.1 Total concealment

The total concealment of the added resistant elements subtends to a definitely irreversible subtraction of matter. The image of the building is kept intact from the point of view of the formal configuration; constructive elements, however, are deprived of their structural function, so as to cause a split between the form and the structure of the architectural organism.

Repeated subtractions of the stone material from the perimeter walls, make possible to insert a new metal structure frame in Rione di Capodimonte in Ancona, damaged by the earthquake of 1972. The load-bearing function is transferred from the perimeter wall, reduced only to a casing, to the new structure of steel columns (HEA or pairs of C-profile), that are connected to the horizontal elements, also in metallic carpentry. [9]

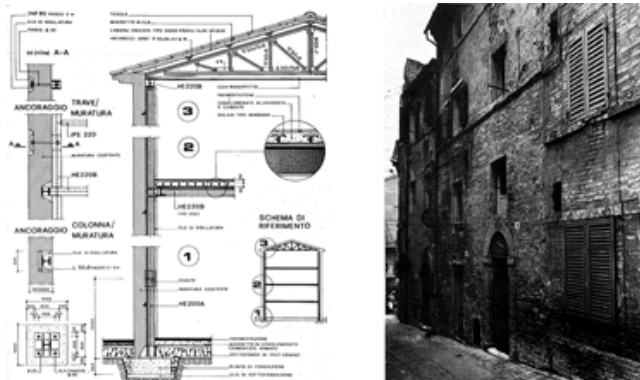

Fig. 1: Rione di Capodimonte, Ancona (Project: Vittorio Mosco, 1973)

The total concealment of the added elements is reached not only by the subtraction of matter but also through the use of the existing constructive elements as a mean for obscure the new steel work. Therefore, this strategy doesn't entrust to the ancient material the task to conceal the presence of the addition, but it justifies the new metallic elements because they are covered by another part of the building, which prevents their participation in terms of formal configuration.

The decision to replace the existing roof with metal structures put in view coincides, therefore, with the presence of an attic floor that conceals its presence: the replacement of the wooden roof of the apse of Naples Cathedral, with a metal structure consisting of a dome with ribs of 70 mm rectangular section of 5 mm welded sheet, fixed to the base to a concrete curb and joint in a drum on the key dome, is justified by the fact that, for the presence of the ceiling, it is not visible from the inside of the Cathedral. Similarly the project proceeds to the replacement of the nave roof with a metal structure, whose presence is justified by the coffered wooden ceiling that denies its visibility [10].

Fig. 2: Apse of Naples Cathedral (Project: Roberto Di Stefano, 1972)

2.2 Partial concealment

If the new resistant elements are exposed, the reasons for the revelation must be sought in respect for the integrity of the existing matter and of the principles of reversibility and recognition.

"Apparent, but not flashy, visible but not ostentatious, different but not brash" [11], the new is characterized by its neutrality, so the metallic items can be placed in the visible sphere just because they are in addition to and not because they are fitted of a formal and meaningful autonomy.

The consolidation of the walls of the Castle in Trezzo d'Adda is made according to this strategy: the metallic elements added in support of the vertical wall consist in guyed cables of small thickness, which don't allow to lose a complete sight of the monument. The technology, which employs a double set of diagonal cables, that hold up the wall on both sides, responds to a principle of minimally invasive action and of totally reversibility. According to Lorenzo Jurina, the intervention thus shows itself "to those who want to see" but remains "subdued for those who prefer the previous image": the project is contemporary but it doesn't contrast with the material and the nature of existence. [12]

Fig. 3: Castle in Trezzo d'Adda (Project: Lorenzo Jurina, 2003)

2.3 Denied concealment

Finally, there are uncommon experimentations in which the added metal elements are employed at the same time to rehabilitate and formally renew the existing building: the visible prosthesis denies the concealment of steel, and the rehabilitation actively participates in the transformation process of the building. The advantages of showing the added metal elements are attributable not only to the reversibility of the methods, the ease of controlling the efficiency and economic benefits, but also to the ability to summarize in a single moment every action on the existing, from static recovery to the formal feature.

In the consolidation project of the porch of Villa Casati in Muggiò (1984), the inability to pierce the columns for the excessive brittleness of the stones, determines the testing of a design solution aimed to combining the stone colonnade with a fully exposed steel frame, which, in addition to take the weight of the timber floor, gives to the porch a new formal configuration. The choice to work in this direction is suited to respect the material authenticity: the metallic system, in fact, is entirely readable, but at the same time it is perceived as subordinate to the existing for size, texture and color. In this way, the architecture of the porch is modified through a consolidation act: the steel, no longer disguised, is used by exploiting its structural features, but also the material and perceptive ones [13].

Fig. 4: Villa Casati, Muggiò (Project: Alberto Ferrari, 1984)

3. The levels of exposing

The exposure of metallic elements belongs to the transformation project: the exhibition of added items implies an active participation in the spatial and architectonic construction of the existing. The focus of the project is the research of the properties and the linguistic-syntactic meanings of steel, taken as the first element of the design act, only later substantiated by a technical act: as the protagonist of a detailed project, the steel claims an handcrafted design, very close to the construction methods of the ancient buildings, becoming a qualifying feature of the restoration project.

If in the concealed sphere the reasoning is limited to the quantitative aspect of dissimulation, in the exposed one the question of steel requires an additional level of reflection linked to the formal and technological choices: the figuration of the metal elements lies, in fact, not only in their visual – tactile formal values, such as surface smoothness, structuring, brightness and weight, but also in the discontinuity points of the components (joints and connections), since they are used in composite systems.

The quantitative aspect is then combined with the qualitative form of the addition, not considered as independent and self-sufficient, but an integral part of the architectural object in which it is inserted: the grafting of contemporary design on the historic building takes place more effectively if it's involved in the started speech rather than disengaged from it. The project is proposed as a dialectic dispute in which old and new are compared on equal terms, in the same "perceptual ring" [1], reconciling disparate and multifarious instances and seeking a precise balance point designed to express the dialectic between past and present.

In Italy, the exposure of steel finds its antecedents in the exhibition settings: the premise of temporality constitutes the basis for testing different expressive forms, which operate on the contents of the historic building. The configuration by analogy of the new elements determines the transformation of the spatial content of the Museum of Palazzo Bianco in Genoa, where the art- works support are designed by lightest steel profiles thesis to the neutralization of the space. The technique of suspension is limited to minimal contacts with the building, with which it establishes a dialogue with harmonic and moderates tones [14]. In contrast, the dialectical contrast created in the Museum of Castello Sforzesco uses steel to define the art-works supports in a vehemently expressive way, evident in the unusual profiles and support plates of the stone works: metallic elements are designed with the awareness to draw expressive effect by combinations of contrasting shapes, rather than by an inert stylistic affinity [15].

The use of steel for change the content of the historic buildings allows to recognize its expressive potential as bearers of innovative instances without compromising the reading of the old values. From the contents to the container, the steel transfers its transformative potential directly on the architectural complex of the ancient building, taking on a distinct role according to the different levels of evidence with which the project proposes the inclusion of the new items.

Fig. 5: Museum of Palazzo Bianco, Genoa (Project: Franco Albini, 1949-1951) and Museum of Castello Sforzesco, Milan (Project: B.B.P.R., 1954)

3.1 Exposure through punctual elements

A full and punctual visibility characterizes the inclusion of vertical connections: the constructive element, since it's circumscribed in a defined spatial area, acquires in its space the maximum degree of expressive freedom, adopting linguistic codes skilled to affirm the identity of contemporary work. This design strategy, diffused in the Italian tradition, is used in the refurbishment project of the Museum of Palazzo Rosso in Genoa: the formal solution of the steel stair with an octagonal geometry, contained in a detached position respect to the crossed floor, coincides with the technological choice

to suspend it to metal rods positioned both inside and outside, next to the corners that define the octagon. The strategy of highlighting the added elements, with their formal and technological choices, is a way to leave the mark of contemporary interpretation of the ancient material: the perception of a vibrant and dynamic space, that lives in the Baroque palace, is reflected in the screwing movement of the stair, designed in order to recover the fluidity of space, inherent in the original architectural system [16].

Fig. 6: Museum of Palazzo Rosso, Genoa (Project: Franco Albini, 1952-1962)

3.2 Exposure through isolated elements

Otherwise, items proposed in an isolated position request a formal design which is more careful to the relations with the ancient walls, involving singular constructive components rather than whole elements: the metallic items probably have a less effective visibility than the last category, but definitely more widespread, quietly weaving a dense web of relations with the old building. The dialogue between past and present is established on isolated episodes that employ steel for structural components or not, quite diverse. In Castelveccchio Museum in Verona, in fact, steel is used for the long iron beam inserted with the intent to overcome the stiffness of the original spatial system and reconnect the rooms from the cubic volume in a single body; the metallic material becomes, along with original wooden beams, the protagonist of the construction of the roof, carved out according to orthogonal lines who follow an irregular profile; the steel finally participates in the configuration of the walkway below. The expressive power of the added elements is reduced to an handcrafted design, that pays attention not only to the relations between parts of the same nature, but especially those that have to be instituted with the old: in this context, the long iron beam rejects the use of standardized solutions preferring C-profiles with steel plates bolted to an angular profile, to the upper and lower ends; the detail of the intersection of the beam with the existing partition walls is resolved with the reduction of the resistant section of the beam and the subtraction of the material of the walls in the contact point. Similarly, a detailed design characterizes the complex system of coverage, in which the steel defines the support beams of the ridge, and the walkway below, in which metal double T profiles hold up the prefabricated concrete slabs [17].

Fig. 7: Castelveccchio Museum, Verona (Project: Carlo Scarpa, 1956-1964)

3.3 Exposure through diffused elements

The role of steel acquires other meanings if it's used for items of the same nature placed in the historical architecture with a fixed rhythm. From isolated to diffused elements, the metal components affirm unequivocally their identity establishing a double system of relations: the first is settled between items of the same nature, and the other with the existing elements. The continuous presence of metal allows to create a dialectical relationship with the old structure, characterized by balanced tones, using steel as a real means of contemporary historical layering.

In the coverage of the Manica Lunga of Castello di Rivoli in Turin, the steel takes on this meaning: in fact, it is employed to define the metal arches of the roof, arranged in spans of 2m to a total length of 140m. The shape of the metallic trusses is mixtilinear, as result of formal and technological requirements. The trusses are composed of a first straight portion near of the outer walls, and of a second curved portion on the centerline. The project defines an internal relationship in the beam through the design of L joints between the different sections and the strengthening shear consisting of a pair of metallic plates. The relationship with the existing masonry is instead established at the concrete curb, designed to a back position from the line of the internal perimeter; over the curb, the metal trusses rest through a sliding constraint. [18]

Fig. 8: Manica Lunga di Rivoli, Turin (Project: Andrea Bruno, 1974-1999)

3.4 Exposure through assembled elements

In conclusion, the steel exposure through elements assembled in a whole volume defines the last level of visibility. The transformation project acquires absolutely recognizable characters through a declared addition, setting up a complex system of relationships: these, in addition to set the connections between the new elements and the ancient material, are related with the urban context in which the volume is inserted. In contrast with the minimal intervention, the contemporary project is decidedly dominant, making steel the hierarchic element that governs the architectural addition. The building that emerges is at the same time old and new, because it respects the historical nature of the existing and also it doesn't reject the modern character of the restoration project.

The metal structure of the Museum in Convento di Sant'Agostino in Genoa proposes once again the volume destroyed by the war, with a figurative language that uses opaque elements for the outer casing, and transparent walls facing the internal court.

Fig. 9: Museum in Convento di Sant'Agostino, Genoa (Project: Franca Helg, Franco Albini, 1978-1985)

The attention to preserve the old sign is reflected on the reconstruction of the colonnade with the technique of anastilosi and in closing the porch by a vertical glazing set back from the edge of the columns. The steel also defines the external stair that connects the entrance floor to the upper, as well as the interior connective and the roof structure.

The steel disclosure, both in a general vision that in the detailed one, is suited to the need to recover the historical memory through contemporaries technological systems. "It's our opinion," write the designers, "that every time needs to express its language in the most characterized terms of expression and technology which best adapt themselves to the contemporary requirements, and, at the same time, are respectful and reinterpret, when and where they can, the meanings, the shapes, and proportions of pre-existing context." [19]

4. Conclusions

The role of steel in historical structure has gone through various design strategies, that are related to the size of visibility, understood as participation in the configuration and conformation of the old building. The interpretation of the rules and meta-rules, that substantiate the built, legitimizes the technical act, whether the project operates in the concealed sphere or in the exposed one: in the first field, however, the design choices are limited to the technical aspect, while in the second one, technological options are so closely related to the formal ones to entrust the solution of a lot of conservation features to this material, from the spatial and functional assets to the technical and constructive ones.

The constant research for a formal compatibility with the old, unusual for a material normally hidden, is the uniqueness of the Italian approach, that is balanced between the purpose of conservation, coming from the historical requests, and the aim of revitalization of the contemporary age: the renounce, for the project on the pre-existence, to industrial production techniques, in favor of an handcrafted design, aims to create a singular and unrepeatable building like the original historical one.

ALMOHAD STAMPED JARS OF SEVILLE

Daniela Lallone

Dipartimento di Architettura e Disegno Industriale; Seconda Università di Napoli, Italy
danielalallone@hotmail.it

Abstract

The study of the Almohad Stamped Jars (XII-XIII century), typical pottery production of Seville, aims to highlight the uniqueness of this peculiar class of pottery until today not much studied. The production is restricted chronologically at Almohad Empire (1147 - 1269) and its geographical distribution is attested mainly in the territory of al- Andalus with a clear predominance of material found in the Seville area, while poor or almost non-existent presence of it in the Maghreb. The research aims to give an historiographical interpretation of this ceramic class always associated at household context and possibly used for ablutions with a great sacred importance to the presence of Koranic inscriptions, and emphasize those characteristics so far not valorate, such as the strong decorative style, the big size and unusual morphology that make this production unique in the Islam world. The study of the Stamped Jars and their geographical distribution wants to identify the role played by Seville as the spiritual and political capital of Al Andalus, as emanating of cultural and artistic influences in the Maghreb and, finally, its commercial role in the Mediterranean world.

Keywords: Seville, archeology, Mediterranean heritage, islamic pottery

1. Introduction. The stamped jars, an atypical Almohad production

The research presented here is the result of several years of work focused on the study of stamped Jars from the city of Seville (Spain), a typical Andalusian Muslim medieval pottery production. The research was carried out by me under direction of Fernando Amores Carredano, Professor of Medieval Archaeology and Heritage of the University of Seville and professional archaeologist who was the director of the most important archaeological inquiries of the city of Seville.

Denominated as "Tinajas estampilladas" (Spanish for tinaja means a large container for the storage of water or foodstuffs with no artistic or artisanal value) - in which case we will call these jars (translation of the Spanish name Jarrón, in Castilian the distinction between Tinaja and Jarrón has a stronger value, the last one designates an object that has the function of interior decoration) - are the most striking features of the Almohad material culture throughout Al- Andalus. The Koranic austerity associated with manifestations of Almohads culture (Arabic: al- Muwahhidun which means the "Unitarians", attestators the oneness of God) agrees perfectly with the monotony and poverty decorative of the whole ceramic production of this period. The typical production is, in fact, made up of ceramic products for the transportation, refectory or kitchen, that are often presented, with simple and functional shapes, and above all without complex decorations, decoration more attested consists of three vertical lines on the body of the object and the covering of glaze is used only with functional purpose. In this situation of simplicity, the stamped jars call attention because of their monumental work. The extravagant and unique manufacturing of these jars is characterized by: big size, elegant and rare morphology with the presence of handles in the shape of wings, extreme complex decorativism (which could be defined as an almost feeling of horror vacui) based on horizontal bands of varied leaf designs, animal motifs, geometric, architectural, calligraphic and apotropaic (fig.1).

Fig.1 Almohad pottery and stamped jar (Photo by Daniela Lallone, Museo Arqueologico de Sevilla).

In addition to the physical characteristics of these objects, it is also very important to delineate the restricted geographical distribution and chronology of them. The presence of these jars is very rich in Almohad archaeological contexts with examples of discoveries over the area of Al-Andalus as Cadiz [1], Almeria[2], Algeciras [3], located with a time span between the second half of the twelfth century and the first half of the the thirteenth century.

Regarding the geographical distribution of the presence of jars is most significant in the field of Seville and its areas of influence in Western Andalusia and portuguese regions of Algarve and Alentejo (abundant findings have been done, for example, in the Almohad archaeological context of Mertola[4]). There are also findings in Eastern of Andalusia but are scarce and they have low production quality regarding both art and craft. Everything seems to set up a situation in which the city of Seville, the capital of the empire before the Almoravid and then the Almohad in Al- Andalus, played a decisive role in the creation, use, distribution and influence of these jars. After the conquest of Andalusia by the Western Christian troops, it seems that the production of the jars continued in the Muslim world , especially in the area of Merini influence (Algeciras, Cadiz) and in Nasrid Granada , where the evolution of them comes to the exceptional jars in blue and gold among the famous " jarron de las gazelas " , dated to the fourteenth or fifteenth century and preserved into the Alhambra Palace, Granada.

Done this brief presentation about morphological characters, chronology and geographical distribution of the material under study, it would be good to mention its functionality and be able to give an historiographic interpretation. The stamped jars appear increasingly associated with the domestic environment. In excavations of noble Almohads houses, and also in buildings such as the Reales Alcazares of Seville, were found small gaps, called "Tinajeros", made corresponding with what it was on the courtyard of the house, probably used to the placement of the jars . This is a very important information to consider since the courtyard, central space of the house adorned with vegetation, surrounded by beautiful architecture and typically had water fountains, is considered in Islamic culture as a representation of the antechamber of Paradise [5]. For this, it is reasonable to think that the jar

had relation with the water and that would serve to contain the water, that once purified, could be used for the ritual ablutions prior to prayers. To go into detail about this interpretation there is the presence of stamp in Kufic of Koranic verses, selected for their prophylactic with the purpose of protecting and purifying the liquid from any contamination.

2. The stamped jars and its historiographical question

Up to now, the studies carried out on this material, are focused on a mere presentation and description of it, as complete jars as simple fragments. There have been very poor explanations or interpretations offered about these productions so characteristic and exceptional Al-Andalus art. Analysing previous studies we realise that so many details that make this unique production have not been examined in depth or even have been almost ignored, leaving many unanswered questions and more important even today the stamped jars are still defined as simple containers for transport and storage. The first feature, not enough evaluated, is the morphological appearance of the jars: they are very big artifacts (an average of 80 cm in height and 60 cm in maximum width), of globular form, with narrow foot and large cone neck with shaped handles of wings (fig.2). Evidently this strange form made them impractical as transport containers, just think of the wing shaped handles that make it difficult or impossible for a good grip, especially when you consider that the jars once filled had to be really heavy.

Fig.2. Drawing of a stamped jar.

The second feature undervalued, but that it is also the one that stands out most to the eye, is the extreme decorativism of jars. All the jars are covered on the outside with a decorative pattern on uncooked clay with a mould as a stamp, made in Terracotta (fig.3).

Fig. 3. Example of a stamp preserved at Museo Arqueológico de Jerez de la Frontera (Cádiz, Spain).

Decorations can be present as all over the body, as only on the top to the belly (including neck), but never the opposite. The matrix stamp is repeatedly impressed on the clay, horizontal bands of well-ordered and never in a chaotic order and it seems to respond to a pattern: the top bands (fig.8) are narrower and inscriptions in Kufic are the most common decorative themes as al- mulk (power) , al- yumn (happiness) baraka (blessing), (fig.5), motifs of plants such as roses or flowers, animal motifs such as lions , geometric motifs such as the eight-pointed star (fig.4), and apotropaic motifs as the "hand of Fatima" (fig.6). Often these horizontal bands are interspersed with bead decorations. In the central part the motif recurring is architectural arches with poly-lobed arches and horseshoe arches (fig.9). Finally, in the lower part, the motif that is the more certificate is simple or double palm and the horizontal bands are higher than those of the upper part (fig.10).

Even the wing handles are often decorated and the motifs most commonly used are the roses, the architectural motifs and the "hand of Fatima"(fig.7).

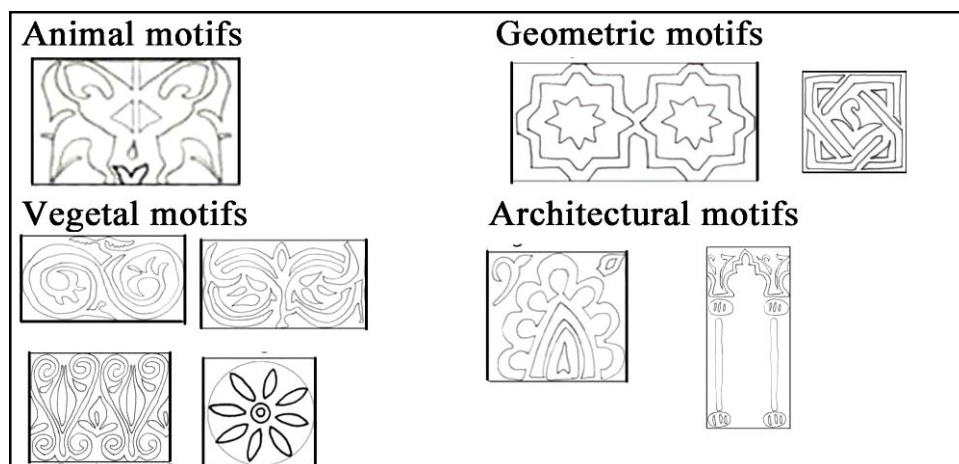

Fig. 4. Stamp motifs.

Al - tawfiq (Fortune)

Al - mulk (Power)

Al - yumn (Happiness)

Al - Salama (Safety)

Fig. 5. Koranic Inscription

Hand of Fatima

Fig. 6. Hand of Fatima

It seems clear that this complexity and careful workmanship of decoration, especially when you consider the time and cost that these artifacts assumed, is not compatible with the use in the pantry (an enclosed space in which the jars could not be seen), it is much more reasonable to think that they were objects considered precious and meant to be in a place visible to all or as ornate Andalusian patios .

Another physical characteristic not evaluated to date is represented by the covering used in the jars . It consists of , when it presents, a showcase of thick bright green color that covers the outer container or on the whole body or only on the top half up to the belly , and is always absent internally. Frequently glaze was passed above a layer of slip with the aim of making the green even more turned on. The functional technological explanation that has been given by scholars so far is that the external glaze had the task of maintaining fresh water inside the jar , logical and coherent explanation . The special feature to note is that , although in the Almohad ceramics were used in equal measure the glaze color of green and yellow honey (melado) in the covering of the jars the last one is never used .

If we focus on an analysis of the geographical distribution of the discovery of the jars stamped , the aspect undervalued is that this production is a unique expression that grows only in Al- Andalus and that is totally unknown in the medieval Arab world , except in the areas of influence in the Maghreb Moroccan and Andalusian . The city of Isbiliyya converted into capital of Al- Andalus at the time of the empires Almoravid Berbers (XI - XII century) and Almohad (XII-XIII century). His status as a port of the Guadalquivir River allowed her to connect with the Atlantic and the Maghreb which was crucial in order to achieve this new rank

and the role of Al-Andalus was instrumental in the development of Islamic art since the time of the Umayyad caliphate of Cordoba. All the experts agree on the fact that Al- Andalus was the point of creation of language and art and craft solutions that expand to the Maghreb and not the opposite , and Seville, the capital of the region, certainly is the central nerve and cultural spread. So it seems that Sevilla is precisely where the stamped jars production seems to have beginning. In fact, there is a greater shortage of this material as you move away from the capital and the shortage affects not only the quantity but also the quality of the production. Outside the Sevillian you notice a simplification of decorative patterns and impoverishment of decorative themes. The same stamps are less developed and in some cases take on a more naive .

Both productions from Cadiz and Portuguese have this formal simplification of which it is spoken.

Regarding the Maghreb area the presence of these jars is not attested but it must be said that, unfortunately, this may also be due to a lack of deep archaeological investigations on the area, the only area in which they were found at the is archaeological site Ksar Sghir (Tangier , Morocco) , positioned in correspondence to the Strait of Gibraltar, but turn out to be the import of Al-Andalus (Andalusia area and southern Portugal) .

After the overview on existing studies , the approach to research in the jars, we felt the need and opportunity to investigate the studies with the aim of abandoning the vision of these jars as simple artistic containers worthless and evaluate them as a manifestation of great craftsmanship , wealth and with aesthetic value and also symbolic.

3. Study Methodology and a symbolic interpretation

The research is founded with the goal of making careful and detailed analysis of the characteristics of the jars , exactly the type and location of stamps within the decorative scheme and use of the showcase green .

As mentioned above it seems that the decoration respond to a precise pattern , breaking away from the vision of the individual stamp in favor of a vision of the decorative as a whole , we note , first of all , like all the jars found to differ from each other . In all jars designed and cataloged so far did not find an equal to the other , this feature gives the jars a sense of exclusivity , the feeling is that every gentleman , every owner, wanted an exclusive and unique. But diversity is recognized in the language of execution, a repetition of patterns they have in common . As mentioned before you notice that the top is dedicated to accommodate those motifs with apotropaic and prophylactic significance as the "hand of Fatima" , the eight-pointed star and the inscriptions in Kufic , also motifs of plants the are different from those of the bottom half being mostly representations of flowers and fruit (typical is the representation of the pineapple) and treated in a more orderly manner . The central part is always intend for architectural motifs , that is, a serie of arches that can be poly-lobed or horseshoe shaped and be alone or supported by columns. The lower part, when decorated , is generally characterized by the presence of motif of plants and specifically simple or double palm trees . Even if , however, it always has an ordered execution , it seems that on the whole they wish to give a feeling of abundance .

The choice of this order does not seem random and does not even seem meaningless , already the very presence of apotropaic motifs and Koranic inscriptions in Kufic , means that behind these formal choices there are possible symbolic meanings .

Among the various lines of interpretation undertaken by Professor Fernando Amores and myself , which are still being analyzed , the most obvious is that they want to represent a kind of decorative garden , specifically the typical Islamic garden . Motifs such as roses, palm and fruit trees show, in fact, elements present in the typical Islamic garden and so the decoration in cord form that can be compared to water courses , a key element in this type of garden, and , no less important is the presence of architectural elements , arches and pavilions are always present in the gardens of Islamic architecture . In this perspective, also the green color in the covering of the jars relate to that interpretation . But going beyond the representation of the garden, the jar can be seen as a symbol of good luck, a gift that was made to the lord of the house to wish him wealth and abundance . The same Koranic inscriptions in Kufic significant blessing , happiness , power, luck (understood as divine assistance) , safety play a protective role and a wish for prosperity for the home that host the jar , even the "hand of Fatima" , present in many of the jars studied, has a meaning of protection of the dwelling. These elements, placed in relation to the representations of vegetation , a sign of a healthy and rich environment, and the color green has always been associated with abundance , had to become the object jar in a good omen symbol designed to accommodate the water , fundamental and indispensable element for life.

The jar is stamped accordingly with not a frivolous production in the context of austerity Almohad Empire , but a production full of sacredness and symbolism which agrees well with the morality promulgated by the Empire.

The need for this research thus becomes the study of the geographical distribution of this production in order to better understand the role of Seville as the political capital but also of spiritual influence in Al- Andalus and especially in Africa , where, apart from a few points of the Strait, little is the archaeological investigation .

The work done to date on these jars has been collecting and re-reading of the existing literature on this material in order to make a point of the situation and try to fill the gaps left by the old interpretive studies . It was thus decided that a comprehensive study aimed at understanding the jars in their entirety was essential to collect, categorize and draw those artifacts complete or almost complete , putting aside , for now, the multitude of fragments present in the warehouses of the various museums . This methodological choice is due to the fact that the individual fragments do not allow to identify the decorative scheme of the jar in its entirety and for a research that will lead to a correct interpretation of the material is essential to move away from a single stamp to focus the entire decorative plant . So far they have been designed , photographed and cataloged 28 jars preserved in the Archaeological Museum of Seville, Museo Casa de Lebrija (Seville), Reales Alcazares (Seville) and the Museum of Cadiz , creating , for each of them , a purely morphological design, a list of present decorations , the design of the decorative scheme and a design that comprehend all of them including covering (fig.11).

4. Conclusion and expectation

Taking this article as a first report on the stamped jars, it is hoped to continue the work and confirm or refute the hypothesis of interpretation set out above . Interesting and essential for the continuation of the research is to go on with the cataloging and the design of the jars found both in Seville and in the area which was Al- Andalus . The purpose is to ascertain the role played by Seville in the creation of

this production and see how far it pushed his influence both in art and in culture , not forgetting the political and commercial role that the city played also due to its position as a river port. About his commercial role is right to mention the discovery of a wreck on the northern coast of Sardinia . It is a relic of a commercial boat containing Islamic heterogeneous material from the Malgreb . The study of the material, made by the underwater archaeologist Domingo Dettori , presented at the XLV International Symposium of Ceramics in Albisola (SV) ,has identified in the load , the presence of about ten jars along with stamped amphoras for transporting oil from Seville. The origin was confirmed by chemical analysis of organic material that is kept inside the amphoras and esparto grass that enveloped them [6]. In addition, to confirm the commercial relation that Al- Andalus had with the Italian west coast is the presence of findings of stamped jars also in Pisa [7] and in Liguria [8], in the near future we hope to study this material in order to determine if it is Sevillian origin and understand better the influence and weight that this city had in the past on the Mediterranean World.

ART PRODUCTION AS SOCIAL, BUILT AND CULTURAL HERITAGE

Rita BREDÁ,¹

⁽¹⁾ Faculdade de Belas Artes, Universidade do Porto, Porto, Portugal (Masters student of curatorial studies)

ritabreda@gmail.com

Abstract

Art works and therefore art exhibitions can be promoters of debate, investigation and discussion on cultural and built heritage. Having a potential documental role, represent an investigation and assist on the development of awareness towards the construction of a collective memory. As they convoke the city, it's evolution in time, it's landscape from the 18th century's rural character, developing into an industrial society to today, mainly services, that forget its past and abandon its built environment, almost as if erasing it's hard-working and poor condition history, however, producing a disguised new low condition urbanity.

One single image has the power to take us on a journey through all the evolution stages, to introduce the past in today's present at the same time and moment, and to advert to a social reality that questions the political and urban decisions towards a specific environmental and cultural landscape, as well as its preservation. On the other hand, a sculpture that evokes an industrial past, a video of its voids and silences even when facing highways and train stations, are the starting point of a journey through, not just time but space, of tours and visits of an unknown territory though daily seen and crossed.

Photography and video are not merely technical representations of reality but explore and produce investigation today, on today's actions and reality; as to preserve and protect it is crucial to be aware of both the present and the past, in order to consciously act in the future.

Keywords: Artwork, Exhibition, memory, identity, preservation

1. Introduction

Campanhã is a neighborhood of the city of Porto, today the poorest, but in the past one of the most promising. Due to its morphology and connection to the river, it was always an agricultural area, providing for the city. Later, in the 18th century, came the farms and the *Solares* (summer palaces) of the rich bourgeois and noble families, and still today, their presence is evident on the landscape - having some been transformed into industrial places but today rehabilitated, for example *Palácio do Freixo*, with the City Hall's approval and assistance, into the biggest historic Hotel.

By the 19th century, after the destruction of a civil war and the Napoleonic invasions, the area went through a period of growth and prosperity, mainly due the expansion of the railway system with the introduction, in 1875, of the *Campanhã* train station - on the lands of the former *Quinta do Pinheiro* (Pine Tree Farm) - unquestionably one of the major factors of urban transformation in the city. It was the northern point of the train line connecting Porto (the second city in Portugal) to the rest of country, and to its capital, Lisbon. With the train station came a new phase of the industrialization of the region, new investments, and all over the region new factories and workshops appeared, dedicated to woodwork, lime production, wax matches, soap etc.

With the train station, the increase and ease of transportation, came a new phase of the industrialization representing a rapid increase of population, of jobs and therefore workers coming from the interior of the country in seek of a better life. They have settled largely in the vicinities of the train station but having such low income and economic capability, with the rapid need for housing,

have concentrated into a type of construction named *ilha* (island) - one single entrance from the street into a narrow and deep plot through a pathway and houses to one side, where several families would build small areas. The transformation of the territory imposed by the introduction of the train line represents a social transformation of the area but also, of its dynamic within the city.

Fig. 1: Campanhã area with a palace in the back and the railway tracks

“There’s a hidden city within the city of Porto. And a world to be revealed within that hidden city. To talk about *Campanhã* is invariably that: to understand what one sees – and what is shown – is always a small part of reality.” [1]

For an independent and new art gallery, dedicated to photography, born in the Campanhã area, on a rebuilt small warehouse that had been abandoned for several years, the artistic director (José Maia) and curatorial team (José Maia, Ana Carolina, Patrícia do Vale, myself and Suzana Correa) have prepared a program composed of a series of exhibitions, visits, conferences and cinema sessions. For the first exhibition, untitled *The vast space of reality (moving images and photography – Porto)* it was intended to initiate a discussion on the importance of photography as an artistic practice, its documental role, memory, relation with time, the city and different registries. Different works of different artists were presented however conscious of the site where is inscribed and the moment, the XXI century. The works presented a city and its changes over time, its new shapes, colors, sounds and from photography, expanding its boundaries, we’ve searched for new images, new narratives of the city.

1.2 *Isto Não é Manchester*, José Oliveira, 2013

When entering the exhibition space at the gallery *Espaço Mira*, one is immediately confronted with a construction remembering a brick chimney, which occupies almost the entire entrance space making the visitor aware of its physical relation with the real space. *This is not Manchester* is José Oliveira’s work, which title convokes another European industrial city, where the artist had studied. The brick round construction symbolizes the several factories and industrial past of the region, being incomplete, recalls it’s abandonment yet important and real existence with which every day, *Campanhã* inhabitants and passersby deal with. The curatorial team proposed the artist the construction of the tower right in front of the entrance door, as if strangulating the space, therefore making one aware of its existence and creating a filter that impairs the vision inside into the exhibition, despite the glass doors. Outside, on the street (in the city), the visitor is already convoked, begins the dialogue. The visitor becomes then aware of the tower and to enter, has to go around it, into the unknown, a new territory (both the exhibition and the warehouse, which had been abandoned for many years).

Fig. 2: The entrance of the gallery space (by Paulo Pimenta, www.publico.pt)

Campanhã is José Oliveira's theatre of operations, moving through space as his privileged action. With video and photography José captures the details turning reality visible, almost as mapping the territory; however a social map as the territory matters within a social context. More than a *flâneur*, he invites us on to his journeys. The route is important, thought, and translated into maps that are transformed into tours.

Fig. 3: Flyer, front and back, to be folded in three parts, of the first tour along the railway

Isto não é Manchester reminds us of the american artists Dan Graham's work *Homes for America* (1966-67) when his interest on the built environment, mainly the suburbanization occurred in the 60's, led him to document the mass production tract houses that gave rise to suburban developments, until then considered an unworthy artistic subject, and for that reason also, he presented it as documentation in a form of a magazine article (actually published), breaking with the notion of the artistic, museum type of object.

José Oliveira, a young artist living and working in Porto, presents us flyers and postcards in order to make the work/space real, convoking the visitor to take part, to handle the work, to take home, to read. All the elements are displayed next to the brick column on a low table, forcing the visitor to lean over in order to see, to handle; it requires the visitor's attention. Flyers but specially postcards are an entity that makes spaces real, even when we've never seen them or visited, we recognize them, we buy

them, we collect them, we send them, and those images stay in our memory as if they and reality are one and the same.

Fig. 4: Two of the postcards. An abandoned industrial building and the highway that also cuts the territory

Also on the table there is a projector showing a video on a small size picture (closer to a domestic size and not a cinema screen) that shows images of the *Campanhã* area, around the railway tracks. Though our mind would think of speed and loud sounds, connection with the outside and doorway in, it presents abandoned buildings, streets with no cars and silence, as if life had been sucked out and sent away on the first fast train. The pictures printed and displayed are of the same area, and the flyers are guided tours proposed by the artist and that will take place within the extensive program the curatorial team prepared.

Isto não é Manchester is a work in process that shows us the archeology of a site, diverse and multiple images of *Campanhã*, different yet physically so close to the city center. An important part of this work are the tours the artist planned and proposes in the form of flyers. Three tours: the first taken during the exhibition, on the 30th of November of 2013, along the railway tracks, where is possible to see how this urban transformation associated with connections has also separated areas and created barriers that change the space and social configuration. The second visit took place on the 22th of March 2014, it was also a walking visit through a social and political heritage in the form of graffiti, those that represent a form of popular political intervention very present in this territory and that gives us a different image and tell us a different, other story and part of the region. The third and last tour will happen in April of 2014 and is a longer tour, taken by bus, around the entire region including some of the most important factory buildings in the history of the region, the social housing blocks etc, as they are essential in order to understand the transformations taken place in this area so important for the city's history.

Preserving a city's history and its heritage is not only about preserving or conserving buildings of declared interest but to feed the signs of a social history, which defines its inhabitant's memory and identity.

"Artistic practices have frequently had representational functions of institutional realities, and sometimes present themselves with critical distance, rarely evoking what in fact is not there, offering alternative possibilities; not the ones of utopia, of the future, but examine the conflicts from the point of view of the everyday actions, in the simpler way they can be when they don't wish to renounce to the thickness of human complexity." [2]

Art work such as the latter are the result of an investigation and thoughts on a specific region and context, in this case *Campanhã*, that are capable of transforming themselves into entities that develop from their limited physical existence by allowing a group of minds to discover and discuss the space,

the territory, its changes, in different ways. Artworks have long escaped the atelier, but are also escaping the exhibition space, going outside and gaining a new life within each visitor.

1.2 CAPRI, Paulo Mendes, 2009

Paulo Mendes's work had a special dialogued with José's work, in fact, when entering the exhibition space, around José's brick column, one's eye would immediately be directed to the big image in front, that covered the entire wall. A familiar image, yet somewhat strange, it appeared to be a still image, a photography, but it was actually a video presented in loop, taken on a site right next to the train station, in *Campanhã* of an only image going from day to night, almost in real time.

In fact, *Campanhã* until the 50's and 60's hadn't changed much, when industry was no longer its main economic motor, having several factories closed down, others moved far from the city, to cheaper locations, leaving its infrastructures abandoned and either taking their workers with them, but mainly, leaving them jobless. In an attempt to repopulate and give life to the region, and also as a sanitary measure, the City Hall had been building several social housing blocks, taking people out of the *ilhas* – many with no running water or sewage system, where several family members lived and slept in one or two compartments. Slowly, we've seen the scenery change from an industrial region towards a housing block region with services, however, still connected to its landscape and rural past.

Paulo Mendes's work has the capability of summing up all of these changes, the transformation from a rural, then industrial with low quality workers houses, into a region of services, in an only image. This reality, from the agricultural past, the workers houses to the promises of a better future illustrated on the big new 20th century glass and metal façade construction, representing new jobs, that even when the city sleeps, and night falls as if disappearing, keeps on moving, is still visible, as if its engines never stop towards the future.

However, as the image returns to its beginning, and we again see that nothing has in fact changed and the land is there, the constructions are still poor, over and over again, we realize that in fact the dream and promises may not be real, and what once were the new jobs are in fact the new form of precariousness - low rights, benefits and income, workers without contracts and being easily and replaced. As we moved from having poor quality of life as farmers, to factory workers with low income and poor housing conditions, into a 21st century of fast connections, speed information but still, low quality jobs despite the new clothing of steel and light.

Paulo Mendes also convokes architecture and the territory, a registry of the dichotomy of what the region once was and what wants to be, placing the question of if in fact, there is such a big difference, socially.

Fig. 4 and 5: view of *CAPRI* from day to night

Today, all is intended to be quick and give fast results, it is important for a mayor and other political representatives for everything to happen within their mandates, which in itself is contradictory with a city's evolution. The hurry to build fast and see results or a finished image generates tension that prevents any intervention to complement the city's many scales and urban tissue. As both artworks illustrate, there are no finish and immediate readings or images of a city, it takes time to go through José's work and taking his tours in order to perceive the social reality of *Campanhã*, how the railway tracks have deeply transformed the region and therefore the city, as it takes time to go through the transformations presented on Paulo Mendes's video that looks like a still image but in fact captures different centuries in a single plan. In the same way as a quick look and approach won't give us all the information so it happens with the city where time thickens its existence. History gives us the reading and understanding of the past, while artworks paint us the picture today, and preservation is not just, or should not be, about looking back and trying to freeze an important action, condition or building, as

cities can't live without a future. José Oliveira presented us ruins, to be preserved and rebuilt, integrated in the city, built ruins but also social ruins. Paulo Mendes focused on an important building, because of its scale and presence in the territory and also for what it represents, but he showed us "its back side" (it is in fact filmed on the back part of the building), as the future won't erase the past and should contribute to solving the present. There cannot be "an important monument in a city without the existence of multiple anonymous constructions (...) in the evolution of a city, the loss of that sense of role of each construction is in front of everyone. The general ambition for protagonism makes it then impossible for any form of protagonism". [3] Hence, the awareness and knowledge of a cultural, social and built environment is crucial for the construction of memory and collective identity, which is essential in order to intervene in the city, either a square, a street, a building, an abandoned field etc, as we are always dealing with an organism in constant transformation where all factors intervene in order to produce a unity.

In this sense, artworks as well as exhibitions, or a curatorial project, can be perceived as tools and source of knowledge to communicate the city, architecture, material and immaterial elements important in order to preserve both cultural and built heritage.

Developmental dynamics of the Hypogea of *Piazza Duomo* in Syracuse

Abstract

The understanding of the urban fabric of Ortigia, peculiar example of stratified city, can not be considered exhaustive if not also concerns the epistemological study of the underground structure of the site of Syracuse, place of our unconscious, recognizing in it the same arcane and the same magic, as if to understand the nature of the mystery of the soul and of the psyche.

It is particularly challenging to get into these areas to trace the history of all or just one's own and, at the same time, to be able to rediscover and recover the tangible signs of an underground intricate fabric that over time has undergone transformations and reuses determined by the evolution of life of those times.

The story of the place, the documentary images, the memories, and the medium of memory that acts on man as a tool for identification of investigation are the summands of an intriguing scenario that, in an intention of noble aspirations, are able to define the thin lines of the reasons of the place and the algorithm of the systemic sets and of the textures underlying routes.

The reasoned knowledge, carried out through a thorough and detailed historical and representative exploration, wants to give order, direction and extent of the need, planned or spontaneous, that led to the evolution of the introspectively kept spaces.

The story unfolds through the eyes of the representation of the subject in the past and the redesign, arduous and complex, of the present, in order to give new life possibilities that are not only related to memory; specifically it aims to be the support to give a colour to the materiality of the cavities, with the aspiration of building a consistent interpretation of the voids, giving sap and vitality to underground spaces.

Keywords: Hypogeum, Memory, Knowledge, Protection, Recovery

1. The dynamic process of knowledge

1.1 The cognitive process for the conservation of cultural heritage (R. Valenti)

In a fluid society where everything is in a continuous transformation and contamination, thinking about a cognitive process aiming at conservation, protection and regeneration of well established historical sites involves the experimentation of a dynamic course directed to the development of epistemological strategies suitable for the needs of particular circumstances.

Generally, architecture deals with the material space meant as a superstructure of the natural landscape. The present study, on the contrary, points out at areas whose architectural quality comes from "removing matter", a creative approach typical of sculpture. In particular, if sculpture establishes a tactile and visual relation with matter and its formal continuity, the same thing cannot be said for the architecture this research is applied to.

This study is about “architectural works” where it is possible to appreciate perceptively the spatial emptiness and not the “envelope”; where it is possible to realize an explorative experience of all parts without visually overlooking them and where, though, it is not possible to have an immediate reading of the functions which, in the course of time, characterized their presence.

We are dealing with an emptiness meant not as a non-place but as an icon of the past, or even better, as a space narrating a complex story which has produced, with the changing of demands, a model of form which has evolved into the densely present structure.

These are the characteristics of the hypogea of Cathedral Square in Ortygia. Places which disclose themselves with a sequence of temporal and spatial events relating to the physical and historical journey of generative processes determining their final form. Those areas have a story guarded in a very introspective way and do not directly reveal the complexity of their own transforming themselves into a space.

There is no doubt that the epistemological processes, in the present study, are not limited only to what stands out but necessarily involve the implied areas as well. To state it differently, those areas which, though less clearly evident, determine a sense of completeness so to understand the combination of the surveyed “fabrica”.

As such, it is crucially important to arrive at the readability of the established interconnections between the hypogeum and its story as an essential preparatory action for the cognitive process of the complex structure. Only through the appreciation of the cultural and historical processes which hypogea originated from as an arrangement of space, it is possible to understand the meaning of the cultural messages which materially define those places.

Places attached to memories partly linked to the needs of life and partly to a past marked by the tragedy of war. In particular, the hypogeum in Cathedral Square appears as the final outcome of the anthropic stratification of the site. Therefore, it is necessary to gain a new understanding of the place as the result of all the occurred evolving processes.

The specific objective is to improve and sustain conservation raising the present quality standards, increasing accessibility not only from a physical and material point of view but, notably, from an epistemological one in the name of the so longed-for social inclusiveness. This can give a significant contribution to the maintenance of identity in order not to consider the cultural heritage as belonging to “others”, rather the deep expression of memory and of its conservation.

Since, as Heidegger states, human beings start pondering on the essence of things only when they miss them, the widespread awareness of the importance of historical heritage and its full knowledge starts its conservation process. In fact, “the appreciation of the cultural heritage is not limited to its material conservation rather it is fully realized only when the cultural heritage and its knowledge and the relations with the belonging context (both physical and not) can be enjoyed and used by the community.” [1]

Fig. 1: Hypogea of Cathedral Square in Ortygia. Praxeomorphic aspects: from the cistern to the air-raid shelter.

The aspect is particularly important when the nature of the common good is “praxeomorphic”, that is, connected to human activities in the course of time especially when they concern the needs of the community and its survival which are not acknowledged at present.

The oldest nucleus is represented in fact by the cistern of the Archbishop’s Palace realized in the early 1600s which was meant as a water supply system for the palace and which was, actually, used by all the people of the town as far as the XIX century. The digging out for the construction of the cistern was probably realized to find “in situ” the stones necessary for the extension of the old Archbishops’ Palace in Siracusa. The cistern was, at first, the quarry of the construction site. More recently, with the tragic events related to the Second World War, the cavity of the cistern was turned into an air-raid shelter whose works were organized by the UNPA Town Committee: the entries were reopened and the stairs under the Archbishop’s Garden, the gallery linking to the Marina and the gallery towards the north and south directions were also built.

A reasoned knowledge carried out through a deep and articulated historical and representative exploration, wants to give order, sense and measure to all the needs which determined the evolution of all these spaces introspectively guarded.

The research, as such, has the objective of developing and organizing complex information on the basis of a strategy which integrates 3D data acquisition with its analysis, cataloguing and project.

The reasoned survey is meant as a primary instrument of knowledge able to propel any revitalizing intervention. The contribution of the new technologies allows an overall reading, highly expressive and easily perceived even by the non specialists.

The formal characteristics of the hypogeum of Cathedral Square have suggested a tridimensional survey approach using laser scanning technology which granted a large quantity of metric data related to the time needed for the correlated relief operations, taking also into account the topology of the place.

Fig. 2: Three-dimensional views of the hypogea contextualized within the urban landscape.

The epistemological approach is configured in the monitoring of the area, differently arranged in the various periods of time, through the realization of models based on an updating multiscalar system able to contain a wide range of information regarding material physical and geometrical aspects.

The 3D graphic restitution of the hypogea contextualized within the urban landscape realizes the perception of the indissoluble bond between what comes to light and is immediately visible, and what is still underneath the soil.

Surely one of the problems connected with this research doesn't concern all the difficulties we came across during the planning of the survey campaigns. It rather concerns the method for the transmission of information both from the graphic and modelling point of view and from the data organization point of view. The followed methodology is based on image sequencing whose diagrammatic mosaic model allows the detection of articulated sequences of meaningful sections interpreted as information regarding the geometry and the external corrugation of the place.

The emotional, sensorial and tragic aspects connected with the use of these places during the war period illustrated through the large photo documentation available contribute to their complete understanding: geometry through the survey helps finding orientation in the dug out space; the photos transmit the pathos of the evoked past.

The past which leaves a permanent mark on anyone who goes down into the morphologically articulated cavity of the hypogea of Cathedral Square which constitutes an identity fragment of an unforgettable history chapter.

1.2. The geometry of Hypogea (M. Liuzzo)

The difficulties involved in the fixed procedure of survey of an important part of a land are generically tied with the need to achieve the knowledge - complete and also accurate and detailed - of its spatial, formal and materic components, without losing the essential tie with the *topos*, meant as a larger physic and relational unit, inside which the land itself exists and structure itself both geometrically and functionally.

This characteristic becomes particularly relevant when the inner and branched nature of the place to survey negates the possibility to perceive, in a unique way, the relations between parts and, moreover, the stronger relations with the surrounding structure. So the aim of the survey becomes to make mutually evident, virtually touchable and understandable stratified spaces, negated relation and invisible or hidden urban logics, which once were full of meaning.

To this end, the campaign of surveys of hypogea of *Piazza Duomo* in Ortigia was initiated, organized into the frame of a research about the complex places of the stratified urban fabric of the Arethusean island, under scientific responsibility of Giacinto Taibi and Rita Valenti. The activity, realized with a couple of 3d time-of-flight laser scanners, saw the synchronic cooperation of two teams of surveyors – afferent to the Crabnebula Laboratory of Representation of the University of Catania, in Syracuse, and to the Laboratory of Survey and Representation of the Territory and of the Environment of the University of Enna - composed by the architects Sebastiano Giuliano and Giusi Maniscalco, the

Fig. 3: The place as an expression of complexity: the planimetrical articulation of the hypogea.

engineer Salvatore Savarino and the learned architects Lucio Sirna e Roberto Cappuzzello, coordinated by Mariangela Liuzzo.

This combined activity made necessary to programme in a detailed way a precise operative protocol about methods, time, precision range and choice of points of control.

In particular, the union of the data collected by the two teams into an univocal reference system has been done with a procedure of scan and automatic identification of targets of high reflectivity, in the quality of point of passage, located among the tunnels and into the larger spaces from a minimum number of 3 for each linear section of about 15 meters, so they can be seen from at least 3 different scan points. Furthermore, the extreme targets were bounded to two couples of external control points, correspondent to the exits of *Piazza Duomo* and of the *Marina*. Thanks to these not only the correct integration in the survey of the interacting spaces – underground and open space – was guaranteed, but also the absolute reference to the geographical coordinates, with the use of a GPS. This anchoring to the geographical element, essential for the environmental surveys - but often neglected by the urban ones – assures the possibility of constant integration of other parts of the urban fabric of Ortigia, also in different time, basing on absolute coordinates, even if they are hard to be locally connected, thanks to a global model georeferenced.

This approach of study made also possible to define a series of analysis on the geometry of hypogea and on the relation with the topping structures, both private and public, especially by permitting to make hypothesis about the logics of the mutual relation between the previous urban structure and the geographic dimensions of places, nowadays so hard to read.

The achievement of a three-dimensional model, analyzed by a *frettage* of levels of sequential sections, highlighted a typological variety able to raise reasoning on the historical revisit and the morphologic genesis of the underground spaces.

Fig. 4: Spatial dynamics of underground places.

It was possible, in particular, to isolate sections correspondent to a typical geologic-operative classification, based on the definition of four categories of underground caves, in relation to a three-dimensional geometry referred to a Cartesian ternary system. This classification distinguishes the following classes: vertical developing caves (wells, skylights, aerators, etc.): their dimension on the z axis prevails on the horizontal dimensions, x and y; linear developing caves (tunnels, walkways, hallways, galleries, passages, etc.): their dimension on the x axis prevails on the dimensions of the other axes, y and z; planar developing caves (caves system of stratum, big archway canalizations, etc.): the horizontal dimensions, along x and y axes, prevail on the z axis; cubical or room – developing caves (crypts, catacombs, caves, funnel-shaped cave, cisterns, beehive tombs, rooms of the sirocco, undergrounds of reunion, reservoirs, room graves, troglodytic residences, hypogeum churches, caves store, etc.), where the x, y, and z dimensions are of the same order of magnitude. The dynamic analysis of the sequence of such sections applied to the hyopgea of *Piazza Duomo* of Ortigia contributes to the understanding of the stratifications of the hollow in the centuries, until we come to a distributive reading of the spaces and the functions during the most recent Second World War.

In this way, it is possible to walk through the hypogeum used as air-raid shelter, in accordance with the provisions of the U.N.P.A. (National Anti-aircraft Protection Union), along the winding of the long tunnels spaced out by larger gathering places - recognizable for the presence of several seats in cement or dug in the rock to welcome the crowd of the refugees -, by small vertical accesses to the outside, in correspondence of the public buildings, and by smaller spaces destined to welcome precious goods and functions or elite groups.

It deals with dynamic sections that, with the prevailing dimensions, recall the use of places now abandoned, but which were full of necessity, needs, pains and hopes up to not such a long time ago, using a specific study approach. This approach intends to achieve the cultural measure through the physical one and it considers possible to draw the lines of history and memory using the geometrical ones.

2. The design of sustainability

2.1. The strength of the colour as intrinsic sign of the place (T. Patanè)

The history linked to these underground places – lately interested by the dramatic episodes of the last wartime events - brings back the attention on this underground part of the city, where teams of rock workers called *pirriatori* enlarged the old quarry, digging new tunnels and opening another access to the galleries of the ancient wall of the Marina, in order to prepare an air-raid shelter. The following period has determined the abandonment of shelters and the consequently oblivion of this area; a great branched container has been hidden down there for a long time, characterized by unexpected volumes dug in the rock, long initiatory paths and zenith lights slicing through the dark.

It is almost a disruption of values and commonalities which were used to chain aims and aspiration over entire generations. A sort of liquefaction generated into the selfish and egocentric individual who act in a liquidness context. The human being, strongly disoriented in this flowing of modernity, has lost the benchmarks of the places of his past; places that have represented moments of high emotional intensity, hope and also angst and affliction.

The empty spaces of hypogea claim their own consistency and their meaning in this real dimension. The array of these empty spaces aspires to a renegotiation of their contemporary identity. The saving of hypogea settings represents a huge set of problems and interests particularly complex evolution systems.

Fig. 5: The fractal dimension of the 'words' of the underground places. (Photographs by L. Sirna)

The wish of making usable a good - which has represented the solution of many kind of needs through the time- becomes responsible for establishing congruity between the past role and the present reuse. Practically, we should activate a complex system of interrelationships between the interpretations of the place which has to be revitalized and the systemic whole of "*modus vivendi*".

In this case we can talk about the signs, both clear or hidden, of words and alphabet; in other words, we can talk about all those concept of identity and of right to the cultural heritage, which intentionally aim at the reconstruction of intrinsic character meaning underlying the aim of places. We should re-read those spaces using the words of a sentimental alphabet.

Simple words, as rocks, to which we have to give a specific "meaning". Free words, as the interconnections, that we can use to understand and discover. Words that help us in describing facts or feelings, in linking or in sharing, in communicating joy, pain, sadness and happiness. Words that can warm hearts, inflame aims, make us dream. Words that can hurt, reveal, move and denounce.

These places are characterized by a complex identity and they are founded on the irreducible contrast between nature and artificiality, primordial places relentlessly leading us back to the essence of our existence. They are strongly material places and with a strong emotive and sensorial impact; places where is hard to live due to the particular micro-environmental conditions, but for this reason they force us to invent a different relationship-wise system from the perceptual-sensory point of view.

We are facing an underground net crossed over by one of the oldest symbol of human race: the water. The water gives the sense of the flow of life, but in a context of strengths and values intimately related and herald of overflowing energies.

Although its direct transparency, the water has its intrinsic colour that gives colour to our values and to our past meaningful heritage.

The water is the unifying element of the millenary history of mankind and it goes beyond the difference of meaning of different cultures; in this specific place, the water is the protagonist of a physical and spiritual "reconciliation" and it succeeds in annulling the dualism Greek-philosophical and Jewish/Christian between body and soul and between life and death. A mysterious container able to synthesize Christianity and Judaism thanks to an ideal path between the Piazza Duomo and Jewish *mikvè* of Giudecca.

Nowadays this inhospitable place gives us the possibility of a walk in the bowels of the city; moreover, it gives us the chance to take its history back, physically and spatially restoring and "reconciling" these two parts of the city, in a definitive interactive dialogue.

Here the colours of main elements as Earth, Air, Water and Fire reunify themselves in an ostensible hostility. Underground places where the themes of colour, substance, light and shadow, sound and silence, acquire a deep meaning because they represent their own essence.

Precisely this "photomorphic" contribution of natural and artificial light, with its daily and seasonal changes, offers a plastic and chromatic dynamism to these places, characterized by an illusory petrified immobility.

The fractal dimension of the roughness of the rock allows us to read of the signs left by men and nature throughout the centuries. The existence of meaningful caves and parts added to the basic volume highlights the contrast of tonality, the plays of light and shadow, both in terms of chiaroscuro and chromatic effects and sensed and insinuated sounds.

These places impose themselves on the man because they force him to consider the different environmental and spatial qualities more ontologically. They are an unique and unrepeatable creative-planning chance, where the new architectural poetics is no more defined by the laws of science, but it depends exclusively on sensory entirety given by the interaction between colour, substance, light and shadow, sounds, feelings and images. The perceptive "coordinates" of the visitor are completely overturned in a different knowledge of the place using the five sense of the underground traveller; a new way in which the sense of sight loses its supremacy in favour of the senses of hearing, smell and touch.

Fig. 6: The tones and the glazes of hope.

2.2. A material and chromatic quality for place reuse. (G. Taibi)

Hypogaea are locations quite far from our memories and they are nowadays seen as dusty places and owners of a not-always-accessible knowledge. They suggest... by stimulating our soul and, during the time, they tend to change under the watchful eye of a public becoming more aware and participating.

In this systemic and cultural framework we are in the presence of a proliferation of museum-model structures, which become highlight moments for determination of new forms and new institutions.

The semiotic approach, above all the others, is - maybe for its own ontological nature - the one usable to catch all the multiple innovative variables inherent to the transformation of the hypogeum, building up sense paths connected to culture, memory and identity.

It may be interesting to structure an open dialogue that can turn that place into an essential attraction. We are talking about a complex and articulated dialogue which, in many cases, affects the social partners and which is not exactly solved. The importance of the contemporary viewer and of his relationship with the space is an innovative model of "concentration"; this can improve the place perception and make the aesthetic appreciation an essential point of the individual and social growth of the community.

The public has to be welcomed together with its own identity and it needs also to be positively influenced in order to manage independently the visitor route. The multi-sensory involvement is one of those innovative variables in which the semiotic look on a location of memory stratifications and intimate tensions becomes necessary to disambiguate sense and functions.

The place goes out of the traditional idea of a museum to enter in a new communication channel with the public and the city. A dialogic reconnaissance tracing innovative relations that can lead to new creations of meaning. Furthermore, if we leave the visitor totally free, it will be disoriented: the strategy of the new museums is a sum of different readings.

In this way, a museum is a stratification of meanings and part of a larger space, but it is also a container of dialogue elements. It has been enriched of new functions and it is now able to build up always new effects of meaning, which are the basis of the dialogic relationship between the material form and the whole scenery that has to catch the attention of the more and more participating visitor.

In order to set up a reasonable future, we need to think about realizing complex spaces conceived on a precise and specialized "ecology" that can describe the place as a net of structurally interconnected and interdependent phenomena.

In the current state, a great importance is given to the act of seeing. The sight is our most developed sense and it is the one used by community to create social conditioning.

All we can perceive is basically the results of a vision included into the three Cartesian dimensions that represent a very narrow viewpoint of reality.

Within a broader approach, we should give space to the other senses, factually under-employed in our interaction with the universe.

Our world experience should be based on a complex interaction of senses but, in general, the artistic shows – based on a superficial fruition - are generally invented and made for the sense of sight only; so they are pure images and they do not create a sensorial interesting setting.

Somehow we are facing a sort of visual art, that is a proposal-making form for the fruition of retinal images immediately comprehension.

However it would be better to refer to a morphologic reality considering an internal multisensory experience. An architecture that should be able to give emotions through the chromatic effects and to draw a space that can be measured with eyes, movements, touch, scent; in few words, it should put to use a contemporary presence of sensations useful to establish a strong perceiving relationship between our inner self and the setting.

The first step towards a sustainable spatial dimension which changes and harmonically models itself after our ways of feeling is to think, to conceive and to shape a new world using a global perception, going beyond the pure visual abstraction.

The visual input communicates complex data, inner elaboration and evocations, personally determined by important external incitements. The image stimulates and recalls in everyone personal reactions and memories; it can contain and recall symbols, it makes us relive emotions and produces suggestions. It is made of shapes, colours, light and darkness, immobility and mobility, chiaroscuro effects.

Our personal and peculiar ways of perceiving and usage of sensory channels gradually shape themselves. Our individual ways of mental reconstruction of a place – the object of our interest – come from them.

This mental image created by our brain is not the objective reality, as we believe, but it is our personal rework of sensory perceived elements.

Therefore, a negative feeling, coming from the fact that sometimes people are not able to feel that architectural product through all five senses, becomes representative of the unsuitability of the receiving person and it surely has to be investigated in the personal inability to perceive that specific message spread by the work.

Fig. 7: Hypogeum revitalized by zenithal light. (Virtual processing by R. Cappuzzello)

To this extent, the empty space has to be perceived as an icon of the past and as the effect of a cultural degradation which has deprived places of authenticity. They are empties originated by the history and they have a strong performative power that can generate categories for historical interpretation and, moreover, they can represent the basis of innovative proposal for these places, in order to re-negotiate their historical identity.

Proposals for the reuse of an hypogeum have to transmit this concept as Daniel Libeskind did in the Jewish Museum of Berlin, which perfectly represents the problems associated with the empties facing the complex relation with memory and history.

In a memorial architecture, a symbolic view of the empty space becomes expression of a tragic past we tend to remove because of problems of our subconscious. The bearing structure of revitalized hypogea has to rely on that empty spaces; with their symbolic energy, they are mediators and witnesses of the history.

The fruition of the space by a visitor needs to be solved in an evolving way: the entire path moves sinuously creating discontinuity between spaces.

The visitor passes through straight spaces broken by sudden bottleneck, segmentation, convoluted or hanging portions. In this way, the empties are bearing structures and point of equilibrium of the place, besides being clear traces of history.

The revisit of an hypogeum has to be identified in the intention of giving some mystery and dark appeal to those spaces using veils which represent the past.

We need to re-interpret the emptiness of the hypogeum -which is not a cultural one- through a system of veils unveiling the unseen. We have to cover the whole structure using nylon veils which can recall a sinister past thanks to the oscillation coming from air movements. From this sinister past, we can create a new and revitalized reality. To a certain extent it is a sort of emulation of the works of Christo and Jeanne Claude, who were able to raise new emotions.

In the meanwhile, an internal impetus, highly feisty, is born: the one of bursting into with dynamical lights that play their role with energetic slices and internal situations of duress inferred on the materic mass. The aim is to insert, during the evolution of hypogea, sources of extraordinary light, feisty and drawn as the frustum of glass cones. Thanks to their clearness, connecting hypogea with external parts, the cones radiate a mystic light into a definitely fractal place.

Fig. 8: Intersection between light and hope (Virtual processing by R. Cappuzzello)

Even the solution of a monumental glass pyramid celebrating the light, quite similar to the one invented by Leoh Ming Pei for the Museum of Louvre, can become an input for a revisit of a place that wants to raise again, despite its past as theatre of disasters. A new light through which we can raise big hope for the plan of a memorial museum.

The epistemological measure of the quality of the natural landscape

Abstract

All cultural agreements oriented towards environmental policies of our planet Earth establish signs of hope facing an inexorable decline in the natural habitat. The understanding of the man-made environment - having a different stimulating duality, of perceptual and sociological value, between insiders and outsiders - determines a deep psychological - emotional involvement and a particular way of perceiving that place, up to grasp its cultural roots, its soul, and even the smell emanating from *topos*.

The investigation on the formal perception of a geographical landscape relies on the relationship between communication tools and new possibilities for structuring visual form, related to the dynamics of temporal and visual development of that region. Moreover, understanding a place also means perceiving suggestions for its qualified modification.

Our disciplinary speeches, directed towards rigor and compliance with environmental quality, are intended to represent a moment of synthesis, framed in a synergistic relationship with the cultural content of the *European Charter of Landscape* in which it is crucial the issue of sustainable morphology, fixing a balance point between social needs, economic activity and environment.

Keywords: Sustainability, Landscape, Measure, Nature, Quality.

1. The measure of sustainability. (G. Taibi)

The cultural debate focused on protection and planning of the landscape tends, overtime, to assume an increasingly complex configuration and it cannot be seen as the historical moment of problem, whether it would be a conceptual, or a definitorial, or an idealistic one.

Actually, for most people, so busy with their daily happenings, the landscape is just what they can understand and perceive through senses by their own, and then explain with a plane language.

To this extend, the possibility of drawing a clear distinction between the insider – that is who intensely lives in that place, taking part to the political decisions about place modifications– and the outsider – that is who does not intensely live there but visit the place as tourist or visitor, enjoying the privilege of getting out of that scenery without responsibilities about it.

Precisely these responsibilities will lie on a painter, when he will be going to draw a landscape.

By painting, the artist has the duty to spread all the vocation owned by the place and that are not always evidently showed.

The landscape directly creates a tie, a commitment, an unconscious limitation, a psychological influence and logic of judgment.

Obviously, the subjectivity of the interpretation underlies all these processes.

The sets of signs and chromatic masses which have to recall a series of inner dynamics which are part of a systemic peculiar frame of the natural landscape.

Fig. 1: Physical depressions of the natural landscape.

The painter, strictly devoted to his role, has the task of drawing the character, the aim and the vocational peculiarities of the natural landscape.

In this sense, the artist has to know the place and his work should be addressed to the choice of subjects able to highlight the image of the natural landscape. This image is a sum of potential, quality and dynamic of the elements present in the landscape.

It is evident that the way we understand the natural environment surrounding us is essentially based on a complex process of interrelation of senses. It is also a great effort to activate a complex systemic set through which spread emotions using chromatic effects and draw natural environments measurable by eyes, movements, touch, smells; in other words, we should interrelate sensations usable for establishing an intense perceptive relation between our inner soul and the environment we are included in.

Fig. 2: The place between vegetation and massive systems.

The first step towards a sustainable spatial dimension which changes and harmonically models itself after our ways of feeling is to think, to conceive and to shape a new world using a global perception, going beyond the pure visual abstraction.

The specialists cannot escape from pondering and facing the three linked and consequent moment of representation; they also cannot escape from evaluations aimed to get the decisive moment of the intervention for the protection and the sustainable development.

Nowadays, when we talk about the sustainability of natural landscape, we feel the need to go far beyond that limit set as qualifying intervention on a field, because it is restricted to parts of intervention.

The reality calls a deep reflection, in order to canalize the systemic frame of the sustainability of landscape into the ecology of landscapes, that is a bigger local ecologic system. In this system, we cannot refer to a single units read as mosaic, but we should refer to a matrix whole that can be set up in a globally interacting frame. This is the key point of a specific goal, in which the strategic rehabilitation becomes the innovative concept setting the whole system in a global revival, with interventions focused on improving huge section in their entirety. It is the idea of an holistic system of a place where the whole does not coincide with the sum of the single units.

The professional thickness of who intervenes on the landscape has to protect these concepts - especially when the landscape cannot be reduced just to a geographic support or a visual perception – and to take in account the overflowing authority of the duplicity of the landscape, seen as a systemic and integrated set of vegetal, animal and human beings and their environment systems, spatially defined.

To understand a place means also to foresee how to modify it expertly.

We want to equilibrate social needs, economics and the synthesized environment, by those expert interventions, considering a synergic relation with the cultural contents of the European Landscape Convention. In this Convention, the theme of sustainable morphology is crucial. Therefore, our intervention on the field is basic and it has to tend to codify those cognitive processes which, when they will be codified in a set of shared rules, can be regulated by a new document recognized as a Quality Charter, in compliance with the European Landscape Convention mentioned above.

We aim to give a new life to an inexhaustible hermeneutic activity of those meaningful and productive logics we have to examine.

In this way, the natural landscape, filtered through this light of scientific accuracy, becomes an endless process of interpretation. There both objective and intrinsic characteristics of the place and the cultural quality of the operators, able to interpret it congruently, meet.

Thus the developmental progress of the computer system, set in a cultural sphere strictly connected to the theme of the phenomenal reality of the perception, is willing to take a leading role as main instrument for the planning and fruition of the *topos*.

Fig. 3: Natural trails.

Fig. 4: Styleme of the environmental system.

This happens into a context of reference where the integration between man and the environment underlies a sensory functionalism, which is determined by a strict interactive relation between artifice and nature.

It is the field of a specific ecology based on auto-generation, where the man will be perfectly aware of the evolutionary processes of the environment.

We should begin to think about our status and to rethink our genetic code, in order to awake our crucial multisensory sensibility to the environment we are going to bring out with plenty of contents.

As well as the traces and signs of the forces which have passed through a place are both a mental and material construction, the intervention of recovering the sense of a place should act both on the imaginary and on the physical experience.

It is a series of semantic emptiness that needs to give to who walks down the place possibility of a subjective and free interpretation.

We are referring to minimal interventions that found their effectiveness on the absence and on the subtraction of material from the place.

The work goes to slips of meaning; operations that are more semantic than structural and that are able to re-establish meaning and dimension of use of a place; moreover, they can clean the place from all the stuff left there because of human negligence and start an ecologic reconditioning and recovering.

The case studies give the chance to apply some ideas. They are general indication that are later apply on the specific case.

The basic idea for the layout inserted into the landscape is to privilege walkways in the midst of nature, full of naturalistic and environmental interests; it is also about moving to operations of cleaning and conservation, instead of embellishment.

Because of this, we need to understand the meaning of the landscape and privilege paths that moves in the midst of nature, where the naturalistic and environmental interests are considerable.

It is needed to leave the places into their original and natural condition. We just have to remove, by minimal interventions, what disfigure the place, that is the set of present stuff we consider incoherent in that place.

Case of study: Pantalica and the areas of the Anapo and the Ciane rivers. (S. Giuliano)

In the territory of Palazzolo Acreide, the Anapo river flows from the sources of the Guffari river on the mount Lauro, the highest peak of the Iblei mountains. The name “Anapo” has Greek origins and it etymologically recalls the immediate meaning of “invisible”. Its course is very articulated and, after about 40km, through the gorges of Pantalica and the charming valley named after it, the river flows down the irrigated plain of Syracuse through the Big Marshes – the old Syraka –, now drained, and it flows into the water of the Big Harbour, alongside of the Ciane river.

Fig. 5: Caves along the Anapo river.

The Anapo and Ciane rivers are two exquisite realities, which find their most inner peculiarity in being placed into a context that has to be safeguarded and protected in the respect of a wished Quality Charter and of the movements of the human soul.

They are part of a complex place which interpretation is a highly complex mental process. The Ciane river, in particular, that is a small and short river powered by the same source of the Anapo river, is world-wide famous due to the presence of the characteristic papyrus, which draws and colours an unique scenery, spontaneously growing alongside the Ciane banks.

Fig. 6: The slow flow of the Ciane river.

The natural landscape outlined by the presence of the rivers suggests, captivates and it has to be interpreted as a “sets of signs and chromatic masses which have to recall a series of inner dynamics which are part of a systemic peculiar frame of the natural landscape”.

In this case, the landscape should be interpreted as the sum of the signs of the topos, dynamically interacting between themselves and brought to life by the insider. The insider place himself as the main actor of the particularly delicate process of the naturalistic place. It is evident that the inhabitant of a place, especially for his innate characteristic of configuring himself as integral part of the natural landscape, needs to establish a dialectic relation between his inner self and the aim of the place where he lives, for the benefit of his own wellness.

To this extend, signs, chromatic masses, perfumes, sounds of the continuous flowing and the noise of the silence need to find a synchronic movement of harmonic correspondence, concatenating their function into the landscape. This landscape witnesses a glorious past which has left an unforgettable trace into the ancient times.

Many ancient poets and historians glorified the Anapo river, such asTucidide, Plutarco, Livio, Eliano, Silio and even Ovidio, who tells the myth of Anapo and Ciane, with a plot showing the love between natural elements as ultimate aim; the same myth has been told by Gabriele D'Annunzio into its Laudi. The Anapo river has been mentioned in the Sicilian Literature too. The writer Giuseppe Antonio Borghese wrote: “among the banks where the Primordial Arcadia appeared and found its expression, the tales comes down on the men and they go to meet them effortlessly, almost trembling”.

But the Anapo river, together with the Calcinara rivers, is framed in a larger environmental system, that is the one resulting from the necropolis of Pantalica, a naturalistic and archaeological place that lays on an upland surrounded by canyons formed during centuries: the Valley of Anapo. It is accessible from Sortino and Ferla and it is the representative upland of a place of high naturalistic and historical value.

We are in the prehistoric place of Pantalica, where the presence of the human being has been observed since the XII century B.C., as witnessed by the great necropolis of artificial caves and the majestic archaeological ruins still visible, which prove the existence of quite populated urban centres. It is a meaningful case of fractal nature equilibrium given by a spontaneous plan between the folds of the rocks of Pantalica and the irregularity of the plan of the natural landscape.

Into this real setting, the harmony making the insider an integral part of the landscape regards the total de-personalization of the man during the process of edification of the place. This process can be defined as “edification as subtraction” and so it allows the total “abandonment of nature” by man, both metaphorically and physically.

Fig. 7: Prehistoric place of Pantalica.

Fig. 8: The small urban center of Bucchieri.

So, the revival of this reality depends on the cleaning up of all those occasional decorations and on the recovering of the morphologic massive consistence and of the true values of the place.

The small urban centres of the mount Lauro cannot be neglected by our field of research. In those centres, the process of “edification as land folding” is set against the “edification as subtraction” one. It is here clear that the urban landscape perfectly matches the orthography of the land, where colours and materials harmonically accompanies the natural material of the place.

Also the built-up area of Bucchieri, on the slope of the mount Lauro, is a place where the main axis represents the cornerstone of vital and founding principles. This area, built on a land hollow, is full of archaeological records showing the presence of the human being since remote times.

According to a reading of harmonic integration with the natural landscape, the groups of houses, organically adapted to the winding curves of the mount Lauro, give the impression that the earth crust lifts up to form “natural steps” suitable for human life.

Moreover, the constituent materials of the anthropic landscape seem to be integral part of the natural one. The overview of roof and rock, which characterize the build area, answers to a natural mimetic dynamism, where the architectural emergences, identified in bell towers and in church facades, seem give equilibrium to the small hollow.

It is very important to be able to draw the character and distinctive sign of the places.

Fig. 9: Edification as subtraction. Edification as land folding.

In the end, the Anapo and the Ciane rivers must be protected, in full awareness of how much they have meant and spread during time, thanks to the incisive strength of their spontaneous values, able to arrange a place for the calm flowing of crystalline water and for the grace of the autochthon vegetation. So our minds has to be proactive and bounded not only in recovering paths of naturalistic route and minimal crossing, but mainly in recovering the values of the sounds of nature, silence and vegetation masses.

As well as the spontaneous growing of papyrus is the distinctive element of the Ciano river, the typical characteristic of the Anapo river is its holing underground in many point. In this way, it puts itself as an example of “natural mimesis” of eastern Sicily and, according to the principle of harmony, it becomes the basis of a strict and empowered dialectic relation between the “self” of the river and the aim of the place.

Abstract

Huge amounts of money amassed by organized crime groups through tax evasion, corruption, fraud to public institutions, are increasingly found to be laundered in art collections or high-value real estate.

Very often assets of this kind are not immediately subject to investigation or preventive measures, revealing their presence only at a later time usually during specific confiscation operations. This is the last step in a process that rarely takes into account the possible intrinsic cultural value of the confiscated goods which, in many cases, prove to be false or counterfeited.

This paper aims to focus on an urgent need to establish the best practices in the handling of assets that could be considered part of a country's cultural heritage. These have to be adopted from the early stages of the judicial work and must pursue a virtuous and proper management of "beni culturali" (according to *Codice dei Beni Culturali*) through the signing of memoranda of understanding between all public institutions involved, with the purpose of preserving the specificity of such goods.

Keywords: measure of prevention, seizure, confiscation, public institutions, cultural heritage

1. Seizure and Confiscation in the Italian legal system.

Aggression against property of illicit provenance is one of the main - if not the most effective - tool among the means of fighting organized crime and it takes the form of two specific regulatory instruments: seizure (or freezing) and confiscation, both applicable in proceedings of prevention or in criminal proceedings.

Italian regulations allow for various forms of penal seizure, but the essential characteristic that distinguishes institutions designated by the terms "seizure" is to temporarily prohibit the transfer, conversion, disposal or movement of property or to temporarily assume custody or control of property on the basis of an order issued by a competent authority.

In the present context, it is useful to focus on the assumption of the seizure under article 321 of Code of Criminal Procedure (permanent confiscation may follow under article 240 of the Criminal Code) which happens when there is foreseeable danger that, if a good connected to the crime remains available, it might aggravate or extend the consequences of the offence itself, or facilitate the commission of other crimes.

A seizure order is normally issued by a court (usually *Giudice per le indagini preliminari*, Judge for Preliminary Investigations), on the basis of a reasoned decree, but in particular cases of urgency, during preliminary investigations, the seizure can be issued by the *Pubblico Ministero* (Public Prosecutor) or by Judicial Police officers. The seizure is aimed at stopping the process of a criminal offense or at preventing new crimes, or at ensuring the confiscation of a good.

Prevention measures are involved *ante delictum*; they are intended to prevent a crime by a person considered socially dangerous and they are characterized by being applied regardless of the commission of an offense. In this context, the seizure is configured as a *sui generis* prevention measure, of provisional and precautionary kind, that can be applied when there is reason to believe that the property, directly or indirectly available to the subject of the proceedings, is part of the

proceeds of illegal activities or can constitute its reuse. Preventive measures on assets are applied, at the request of the Public Prosecutor, by a specialized court (*Tribunale – Sezione misure di prevenzione*, Court - Section prevention measures) that is established in every county, which, in addition to an order for the seizure, shall act on any request to revoke the seizure and decide whether to adopt the seizure (first instance). The seizure follows an investigation (direct or indirect) on the degree of danger posed by the individual, irrespective of criminal responsibility or even of a prior acquittal judgement.

With regards to the specific field of preventive measures on assets, over time, a long series of measures have been introduced, either aimed at the forfeiture of unlawfully acquired property or at preventing their subsequent reuse within the legal economy. These measures have given rise to a multi-layered legislation centered around two principles provisions: *Legge* n. 1423/56 [1] and *Legge* n. 575/65 [2]. Numerous special laws were grafted on them, generally as a result of emotional decisions taken at times of bitterness in the fight against crime, thus resulting in significant changes in the scope and method of application, management and allocation of assets, as well as in the powers conferred to the different authorities involved. The latest step in the regulatory framework is constituted by *Decreto Legislativo* n. 159/2011 [3], the so-called *Codice Antimafia* (Anti-mafia Code), designed and issued for the purpose of rationalizing and integrating the entire current legal framework of anti-mafia legislation, prevention and certifications anti-mafia. Title II of the new code regulates the delicate topic of preventive measures on assets, defining the following measures: seizure, confiscation, bail, confiscation of bail, judicial administration of personal property and judicial administration of assets related to economic activities. These are applicable to a wide audience of individuals - recognised as socially dangerous according to two categories. A "generic" type (i) i.e.: subjects habitually engaged in crime or who habitually live, at least in part, off the proceeds of criminal activities or are engaged in the perpetration of specific offenses, or a "qualified" type (ii): subjects suspected of belonging to criminal groups as defined by article 416 bis of the Criminal Code, including collusion or perpetration of crimes within the jurisdiction of the *Direzione Distrettuale Antimafia* – DDA (Anti-mafia District Authority) or crimes connected to terrorism or violence at sporting events.

The Italian Legislator has emphasized the autonomy of the prevention proceedings with respect to the criminal proceedings, opting for the choice of a "dual-track". In this context, the Anti-mafia Code (article 30) regulates the possibility of coexistence between penal seizure and preventative seizure which, in practice, has resulted in many application problems. While under penal seizure the law only provides for custody of the seized goods, in prevention seizure there are provisions for planned forms of management and administration of the goods themselves. Thus, in the case of coexistence of the two measures, prevention seizure should prevail, resulting in the involvement of a judicial administrator, in order to ensure, in the case of confiscation, the best destination of the assets [4].

2. The European legislation context.

On March 14, 2014 the European Union Council of Ministers has adopted the new directive on the freezing and confiscation of the proceeds of crime in the European Union. Only Poland voted against, while United Kingdom and Denmark did not take part in the vote. The text was agreed with the European Parliament which adopted its position on February 25 [5]. The directive, which is the result of the debate held in the European Council, Parliament and Commission, has already been informally agreed upon by national governments and has been welcomed by many. However, some like the European Criminal Bar Association – ECBA, for instance, have criticised it, suggesting that the new legislation could have an impact on the fundamental rights of the individual and could go against the proportionality principle.

The new directive establishes a clearer legal framework which can strengthen the judicial cooperation among the European Member States. The directive applies a new larger definition of crime proceeds (article 2: "any economic advantage derived directly or indirectly from a criminal offence; it may consist of any form of property and includes any subsequent reinvestment or transformation of direct proceeds and any valuable benefits") and property (article 3: "property" means property of any description, whether corporeal or incorporeal, movable or immovable, and legal documents or instruments evidencing title or interest in such property").

The new directive will apply extended confiscation to more crimes than before: active and passive corruption in the private and public sectors as well as active and passive corruption involving European Union and Member States' officials; participation in a criminal organization; child pornography, and cyber-crime. The list of offences enabling extended confiscation can be further widened by the European Commission to include other crimes.

Moreover, third party confiscation will be possible in the case of goods transferred for free or below the market price and when the third party knew or should have known that the purpose of the transfer or acquisition was to avoid confiscation. Confiscation measures are extended to cases of flight or illness of the suspected or accused person.

The directive also ensures the rights of victims of crime to seek compensation for their claims.

As for confiscation, the final text agreed by the European Parliament and Council does not endorse the initial proposal to establish a full regime for “non-conviction based confiscation”, (that is when, even in the absence of a criminal conviction, money or any assets could be confiscated where a court is satisfied or convinced that the money or assets derive from activities of a criminal nature) as it is the case in Italian law. As further action in the area of confiscation, a joint declaration by the Council and the European Parliament asked the European Commission to carry out a study on the benefits of confiscation in the absence of a criminal conviction, including cases of death and other situations not covered by the new Directive. Member States will have 30 months to transpose the Directive into their national laws.

3. Agenzia Nazionale per l'amministrazione e la destinazione dei beni sequestrati e confiscati alla criminalità organizzata - National Agency for administration and destination of assets seized and confiscated from organized crime.

As a result of a need to provide management, administration and destination of seized and confiscated properties in Italy, an *ad hoc* authority was established to guarantee a centralised and effective administration and allocation of assets seized and confiscated from organized crime, also through a stable relationship with the judicial and other authorities involved, in order to ensure a rapid deployment of these assets: *The Agenzia Nazionale per l'amministrazione e la destinazione dei beni sequestrati e confiscati alla criminalità organizzata* – ANBSC (National Agency for administration and the destination of assets seized and confiscated from organized crime) was established by decree *Decreto Legislativo* 4/2010, converted into *Legge* n. 50/2010 [6], now transposed in the Anti-mafia Code.

The principal scope of the ANBSC is to provide for the administration and destination of definitively confiscated properties, as well as to assist the judicial administrator under the direction of the Judicial Authority during the seizure phase until confiscation (Court of First Instance), after which the ANBSC assumes direct management of the properties.

Through close cooperation with the Judicial Authority, the ANBSC provides valuable support to the planning of assets allocation, even during the judicial phase, acquiring all necessary information and at the same time advising on how to overcome the issues that often hinder or slow down the reallocation of mafia assets to social purposes use by the community.

Of course, the activity of administration and allocation of goods carried out by the ANBSC, who are animated by the desire not to frustrate the efforts of law enforcement agencies and the judicial authorities, is accompanied by the constant monitoring as a guarantee of the actual social reuse of mafia assets, so that the institutional role played is not reduced to a mere statistic, but is translated into a real perception of the presence of the State on the territory.

The establishing law, in particular, has given the ANBSC important tasks related to the two phases in the management process, namely the judicial and the administrative phase.

In the judicial phase (i), ranging from seizure order until final confiscation, the Agency is required to perform the following functions:

- Assistance to the courts: since the beginning of the proceedings, the ANBSC is called upon to support the judicial authorities to resolve critical issues identified by the judge and the administrator. In carrying out this responsibility, the Agency has been assigned a role, "not as a mere executor of the provisions of the court, but as a forum for consultation and advice" [7];

- Administration of the assets during the judicial proceedings: after the conclusion of the preliminary hearing (in case of criminal proceedings) or the confiscation of First Instance (in case of a prevention process), the ANBSC is required to play the role of administrator of the assets, taking upon itself the duties which, in the initial phase of the proceedings, are the responsibility of the judicial administrator appointed by the court.

In the administrative phase (ii), which begins with the definitive confiscation, the ANBSC performs the important task of disposal of any confiscated property, even taking into account the programming done in the previous judicial phase. In this respect, the law requires the Agency to allocate the asset within ninety days of the final confiscation, extended term of ninety days in the case of more complex operations.

It should be noted that, in both phases described above, the Agency is also entrusted with the task to monitor and acquire data on seizures and confiscations, by programming the destination of the goods in view of the final confiscation and monitoring in order to the use of the assets after the allocation.

4. Destination of confiscated assets.

If a good has been seized in a normal criminal proceedings, once it is definitively confiscated, the Registry of the Court provides for its sale or destruction, except for some special kinds of goods for which a specific destination is required. Among them are works of art, rare objects, antiquities, or

object of scientific interest, all of which are redirected by the Ministry of Justice to the Criminal Museum in Rome or to other institutes [8].

If the confiscated goods are assigned to the ANBSC, they can proceed with the destination of the assets. Real estate (i) is managed by the directors of ANBSC and, only in rare cases it is alienated [9]. Any confiscated money (ii) which is not required to manage other confiscated goods or to be devolved to victims of mafia crime, must be transferred to *Fondo unico di Giustizia* (Justice Fund); other movable goods (iii) must be sold, and the income transferred to the Justice Fund, or re-used by the ANBSC for institutional activities or destined to other public administrations or regional authorities or volunteer associations for social purpose [10].

According to the Anti-mafia Code, the priority destination of confiscated assets must be its restitution to civil society through public destination or allocation for social purpose. The social and educational value of restitution of the proceeds of crime is amplified when such proceeds belong to the cultural heritage, which has social value in itself. Therefore, the allocation of movable cultural heritage must not follow the normal way and be sold and transferred as money would. It must be destined for a social purpose.

5. The work of art as a safe haven, source of investment and symbol of social ascent.

Seizures of works of art and antiques carried out by the *Direzione Investigativa Antimafia* - DIA (Anti-mafia Investigation Department) in the houses of the boss, show a lesser known face of organized crime, both in Italy and around the world. The purchase of works of art often conceals money laundering of the proceeds of drug trafficking, extortion and usury. Works of art therefore become a means of alternative investment but also a *status symbol*, a distinctive sign of power and wealth, but also of social redemption. It is not simply the ownership of an object: criminal organizations have learned how to manipulate the art market to create illegal opportunities to sell stolen art, stolen archaeological finds and fake or counterfeited objects. This particular form of organized crime is characterized by high specialization and figures with expertise in different fields, grave robbers or thieves, brokers, carriers and drivers, customs officials, art dealers, experts, restorers, employees of auction houses, etc. These people often work together, within an organization structured like a pyramid or cross-linked, often on a transnational level, and they perform the illegal purchase of cultural property and their illegal export from the country of origin, the production of expertise in order to raise its price, the laundering activities aimed at giving objects a false legal provenance. Such aggression against cultural heritage is waged by transnational criminal organizations that can count on a powerful commercial structure, important logistical means, and sometimes on the complicity and support of the political and administrative institutions of the State [11]. Cultural and environmental trafficking stands alongside trafficking in drugs, weapons or human beings. Criminal organizations have in fact developed the ability to quickly adapt their areas of intervention to fluctuations in demand and insidiously infiltrate legitimate businesses and financial circuits across national borders. They operate on a global scale amassing huge illegal profits to reinvest in several countries, including money laundering. Among numerous examples of these activities it is worth remembering the international operation that led to the return to Italy of important archaeological finds that were exhibited in major U.S. museums ([11] case ITA 1).

Alongside trafficking of cultural property another form of investment is counterfeiting and marketing of fake contemporary art. This is subject to fewer constraints and restrictions with respect to works protected by the *Decreto Legislativo* 42/2004 so-called *Codice dei Beni Culturali* (Code of Cultural Heritage) [12], such as the "Plotter case" ([11] case ITA 3), in which an organized criminal group, dedicated to counterfeiting and selling fake works of art from Italy and Spain to Germany and Brazil, was charged with trafficking in cultural goods, counterfeiting and money laundering.

A massive seizure of art by the DIA dates back to July 2008. During the operation "Metallica" coordinated by the DDA of Milan 21 works of art were seized. The same operation turned up 55 works of ancient and contemporary art, mostly paintings, including some exported illegally from Spain. The 24 people arrested for mafia association (article 416 bis of the Criminal Code) were affiliated to the 'Ndrangheta from Calabria and in particular to the clan headed by Giuseppe Onorato. Criminals reinvested in paintings and jewelry the proceeds of crime such as drug trafficking, usury and extortion. Onorato's clan made its money importing pure cocaine from South America, money which was then laundered by an associate, arrested with six other people, who would buy furniture, antiques, jewelry and works of art all over Europe. In particular, the purchase and resale of famous paintings in some well-known Italian auction houses allowed the clan to recover "clean" money to be invested back again in illegal activities of the Onorato group, for a turnover of several million Euros [13].

Trafficking in art and money laundering: art attracts organized crime because art means business. In this area, the interweaving between organized criminal groups, professional thieves, predatory adventurers, merchants, managers of galleries, auction houses and museums is becoming more frequent. Criminals place on the market art that might be stolen or illegally excavated and then

trafficked. When criminals do not carry out the theft themselves, they act as intermediary between private collectors and professional thieves. But art can also be used to turn money obtained via drug trafficking, into something of value that is easily portable and marketable.

According to experts, the control that drug traffickers have on the art world is so wide that, if they suddenly stopped buying paintings and sculptures for their money-laundering purposes, part of the art market would suffer a setback [14].

6. A case study: the Zappia seizure.

In November 2008 officers from the DIA raided a series of houses in Milan and Cattolica Eraclea (Agrigento, Sicily), belonging to Italian-American boss Beniamino Zappia.

The raid resulted from a seizure order by a Court in Rome and yielded 345 paintings including signed works by Guttuso, De Chirico, Dalí, Sironi, Morandi, Campigli, De Pisis, Boldini. In addition to the paintings, precious objects such as watches and jewelry (about 200), precious stones, vases, statues, bronzes and antiques were recovered. The Sicilian residence, in particular, had become a real "house museum".

Zappia had been in jail since October 2007, following his arrest during operation "Orso bruno". He was considered the Italian referent for North American Mafia families interested in winning lucrative contracts for the construction of the bridge over the Strait of Messina, linking Sicily to Italy's mainland: among them the Bonanno from New York, and the Cuntrera, Caruana and Triassi families from Toronto. The same Zappia was linked to two Rome based companies ("Made in Italy" and "Made in Italy Inc") used to launder proceeds of drug trafficking, and whose president Mariano Turrisi had been arrested in France in October 2007.

The 2008 seizure was the result of the application of preventive measures on assets, which had kicked in when Zappia declared to the Revenue Agency that he lived on a minimum pension of about €350 per month [15].

Despite the fact that Zappia was eventually fully acquitted in November 2012 by the the Court of Rome, the prevention measures proceedings ended with the final confiscation of his property.

Following confiscation, the judicial administrator appointed by the ANBSC to manage this huge fortune was then faced with the difficulty of dealing with goods of a special nature.

The movable assets confiscated, became State-owned, dating back over fifty years and which are the work of an author no longer living, are considered Cultural Heritage (as defined in Articles 10, paragraph 1 and Article 12 paragraph 1 of the Code of Cultural Heritage). As a result, they are subject to all the protection provision disposed by the law.

Despite the fact that, at the time of the seizure, the officers became aware of the presence of goods that could have some cultural and economic value, as in the case of high market value paintings signed by well-known artists, as well as other precious objects, they could not clearly identify the most important works of art. Thus they availed themselves of the support of an employee of a well-known Milanese warehouse and vault to separate artwork and jewelry from other goods and to then transport and store them in a suitable location. The goods were listed and photographed and then moved into the vault, where they are still stored for a fee. Looking at registration and photographs now, the limits of an operation conducted by non-experts is apparent. Photos are blurred and dark and the list too generic to be useful to identify single objects. Storage in a vault for over five years carries a significant cost to the State making it now necessary to assess the merits of the stored works, including whether they are authentic and to find a destination that allows adequate conservation, enhancement and public enjoyment of the goods.

7. Problems to be solved and proposals for best practice.

As seen in the above case-study, the richness gathered by organized crime groups, tax evasion, corruption, frauds to the public institutions, ends up increasingly as money-laundering in collections of artistic works of art or quality immovable properties.

Very often assets of this kind are not immediately subject to investigation or preventive measures, revealing their presence only at a later time, usually during specific confiscation operations. This is the last step in a process that rarely takes into account the possible intrinsic cultural value of the confiscated goods, which in many cases prove to be false or counterfeited.

The problem arises primarily from the fact that, except in cases of crimes against cultural heritage, (as in the emerging transnational crimes such as illicit trafficking in works of art), seizures of art mostly happens incidentally in the context of reinvestment of crime proceeds, as part of larger investigations of crimes of greater social impact.

It is worth considering that in cases such as Zappia's, for instance, where seized objects were not immediately recognized as potential carriers of cultural interest (after all, not all of them were) it often boils down to the individual initiative of police officers or the judicial administration the initiative to involve art experts in the early phases of the management of the goods. Not everything is cultural property yet art objects are not only paintings. There are a number of categories ranging from

archaeological items, to jewellery, to furniture to cars, making it difficult to differentiate management of the different objects.

According to current legislation, which transposes the wording proposed by Commission Franceschini in 1964 [16], cultural property is defined as a “material testimony of civilisation” (“testimonianza materiale avente valore di civiltà” – Code of Cultural Heritage, article 2), and as such it deserves to be recognized as belonging to the nation's Cultural Heritage. For its function, for that which it is able to represent more than what it is, it performs, through the public use, a cultural function of transmission of a memory of the past.

For this reason it is becoming increasingly clear that current legislation and its implementing regulations lack the foresight that seized objects could be potentially Cultural Heritage. For example, the Implementing Provisions of the Code of Criminal Procedure, at the moment of seizure distinguishes between the following: perishable goods, common objects and valuables (among which are numbered drugs and psychotropic substances in general, coins need to be maintained for procedural requirements, precious objects in general, and objects of scientific, artistic or archaeological value) with no regards to specific conservation measures. The ANBSC distinguishes the goods seized in four categories: corporate assets, real estate, registered movable property (i.e. cars, boats, planes etc.) and sums of money. In this perspective, we consider a missed opportunity the fact that the framers of the Anti-mafia Code did not take into account the possibility of equipping our normative system with *ad hoc* measures for identification and management of (presumed) cultural assets, with an aim to ensure various forms of judicial control in accordance to the different characteristics of the good.

The definition of good with potential cultural interest must be transposed by the criminal legislation in order to be able to intervene in the early stages of the seizure proceedings to provide specific procedures for goods that exhibit the characteristics of cultural heritage. A systematization of procedures is also necessary in the early stages: the *Ministero dei beni e delle attività culturali e del turismo* – MIBACT (Ministry of Cultural Heritage and Tourism) must be involved (through memoranda of understanding according to the article 113 of the Anti-mafia Code) from the very first step of the proceedings to make a first selection of what deserves attention (i.e. objects of potential cultural interest, on which to initiate studies and surveys about authenticity), and what can safely be discarded or treated as a normal object.

Another role that should be played by MIBACT is that of judicial custodian for those goods that are of potential interest by making available some of its storage vaults (one or two per region according to the needs, for example).

The involvement of MIBACT is also crucial because, if after seizure, the property is then confiscated by the State it will pass from a status of work of art to that of cultural property, subject to all the provisions for protection under of Code of Culture Heritage. Article 10, paragraph 1 and article 12, paragraph 1 determine that any public property made by an author no longer living dating back to more than fifty years, if mobile, or over seventy years if real estate (the case of listed buildings and real estate of potential historical and artistic value is interesting, but not addressed in this paper) are subject to law until the end of the verification proceedings required by the Code of Culture Heritage.

Another problem to solve is that of the destination. In the allocation of confiscated property should be a priority target the destination for purposes of public interest (i.e. maintenance to Tax Authority or transfer to local authorities) and their best end use in order to reintroduce them into virtuous circles involving the community: a property rendered to society weakens criminal organizations, states the rule of law and constitutes a resource for the territory. If, with regard to the process of administration, destination and re-use of the seized and confiscated assets (property and business), are not yet resolved, the operators of the sector will often encounter certain problems., At least in the field of cultural heritage we can adopt better practice because, for their intrinsic nature, cultural heritage fit perfectly in the social and public interest required to assign the confiscated property.

Cultural Heritage generates civilization, education, social cohesion. All concepts that are based on Article 9 of the Italian Constitution: “The Republic promotes the development of culture and scientific and technical research, The Republic Protects the landscape and the historical and artistic heritage of the Nation.” (“La Repubblica promuove lo sviluppo della cultura e la ricerca scientifica e tecnica. Tutela il paesaggio e il patrimonio storico e artistico della Nazione”). It emphasizes the primacy of the protection of the National Cultural Heritage even before other public interests and it is founding reason of policy of public protection and valorization. Cultural Heritage is related on one side to the essential identity, territorial and national value, and on the other side to the purpose of promoting the development of culture.

8. Conclusion.

In this paper we first analyze the current state of the Italian and European legal framework related to the institutions of seizure and confiscation in the Criminal Code, in the Anti-mafia Code and in the Directive of the EU Council on the freezing and confiscation of proceeds of crime, and we make an

overview on the tasks of ANBSC in the management of confiscated assets. Then we introduce a few cases of crimes directly or indirectly involving cultural heritage that ended up in confiscation of cultural property. In particular, we analyze a case in which a huge number of artworks were seized and then confiscated. This case shows the limits of the procedures currently followed in the seizure of cultural heritage and allows us to make proposals towards best practice in procedures of seizure and confiscation. In conclusion we propose:

- 1) Reform of the normative system regarding seizures and confiscation, including the addition of a new category of "object of potential cultural interest" to the list of categories of seized goods and a provision for the specific management of object or assets of potential cultural interest.
- 2) The signing of an agreement between ANBSC and MIBACT to establish all steps required for an adequate procedure.
- 3) Early intervention of MIBACT in the case of seizures related to cultural heritage.
- 4) Selection of warehouses or storage locations that can guarantee proper monitoring of storage condition of Cultural Heritage (i.e. temperature, lux, humidity) .
- 5) After permanent confiscation, ANBSC should submit a request of *verifica dell'interesse culturale* (Verification of cultural interest) according to Article 12 of the Code of Cultural Heritage. The verification distinguishes between Cultural Heritage and goods without cultural interest.
- 6) The final destination of confiscated cultural property must take into account its double value as proceeds of crime returned to community for social purpose and Cultural Heritage to be protected, enhanced, and destined to public fruition.

Abstract

Most probably due to its strategic location, Istanbul has served home to a number of glamorous civilizations whose traces are endlessly testified by the majestic architecture they left behind. Following its fall to the Ottoman Empire in 1453, the City has enlarged beyond its walls and spread over the two shores of Bosphorus, the elegant straits which bisect the settlement in two and mark the separation of Asia and Europe. In addition to impressive serails and palaces, beautiful wooden residences have been erected since then and after the proclamation of the Republic of Turkey in 1929 on the Anatolian and Thracian shores of Bosphorus. In the form of small agglomerations interrupted by the green, these beautiful Turkish- Ottoman dwellings, occasionally influenced by western styles, have exemplified a truly humane scale and a profound integration with nature. Economic conditions, cultural transitions and finally the appearance of new building materials and habits have gradually led to the extinction of the wooden building tradition in Istanbul to replace it with more profit- generating condominium- type concrete structures designed on imported models and permitted under local regulations on these high- value lots. It has only been few decades ago that authorities and academicians have realized the negative consequences of the concrete-plaster invasion and have initiated successive building restrictions to prohibit the destruction of the rare pieces of the architecture and the natural environment. Yet, the repeatedly revised and tightened legislation has not stopped the cultural massacre.

The present paper and the associated pictorial demonstration review and analyse the current state of the residential antiquities and the contemporary building trends in this unique context.

Keywords: Istanbul, The Bosphorus, Alp, Architectural Heritage, Conservation.

1. Istanbul’s History

Istanbul is reported to be founded on the peninsula at the mouth of Golden Horn by a group of Greeks originating from a place called Megara. Initially named Byzantium, the City’s strategic emplacement linking Asia and Europe and it’s natural harbor have fostered its development as a major center of trade and commerce. Following its inauguration as the capital of the Roman Emperor Constantine in 324 AD, its name was changed to Constantinople and it was largely remodeled with the Roman monumentalism in mind. In 395 AD, when the Roman Empire divided into two, it has continued to serve as the capital of the Eastern Roman Empire, and with its churches, monasteries and places it has become soon the focus of the Christian civilization.

In 1453, subsequent to a series of unsuccessful Muslim attacks, the Ottoman Emperor Fateh Sultan Mehmet conquered the city through a miraculous military maneuver and Istanbul commenced a new era as the capital of the majestic Ottoman Empire for 500 years. As the metropolis of the Islamic realm it was then called "Dersaadet" translated as "Threshold of Felicity." The City's population ascended to 400.000 during the climax of the Ottoman Empire in the 16th Century. The degradation of Ottomans, however, subjected Istanbul to once more experience the dominance of the West. In 1903, the cosmopolitan population reached 1.200.000 (see table). Following the World Wars Istanbul became the major center of the Republic of Turkey. Today about 15.000.000 people live amongst the Great Ottoman master Sinan's mosques of unsurpassed grandeur and elegance crowning the City's seven hills with their gigantic domes and slender minarets.

2. The Bosphorus, its Architecture

The shores of Asia and Europe intertwine and come to meet at the Bosphorus which divides today's Istanbul into two major parts. Spanned by two elegant suspension bridges the Bosphorus joins the waters of Marmara Sea at the South and Black Sea at the North in a legendarily beautiful setting. Gentle or abrupt slopes crowned by colorful woods attribute the Bosphorus an unique character further jollified by its delicate architecture. In addition to splendid palaces, fortifications, mosques and pavillions sited on both sides by the earlier occupants, the wooden houses describe picturesque villages. Those initially confined to valley-heads, today expand continuously along both shores. Now integral parts of the city, the Bosphorus' settlements were mostly suburban resorts hosting the local population of fisherman and garden-keepers, elite families and foreign missions' residences. The Bosphorus where natural and built environments are delicately interwoven to each other has always meant pleasure and repose, luxury and elegance, distinction and prestige. The wooden houses on the shore-front, or "Yalis" stretch out in rows and project onto the waters while on the banks perched among trees, they blend with the woods enchanted with multicolor flowers. The Bosphorus' timber houses, mostly of two-to-three storeys, exhibit cantilevered loggias or "cumbas", deep-projecting roof-eaves, 1/2 ratio windows screened by delicate lattice-work and ironwork, splendid arcades and rich balustrades. Covered by red roof tiles or "ardoise" sheets, they either refer to dynamic balance or symmetrical formality in their plan and elevations.

Fig. 1: Vertically elongated windows and red brick roof projecting on the water are typical characteristics of the Bosphorus' sea-front residences or 'Yalis'.

Occasionally influenced by Western styles, Bosphorus' houses exemplify excellence in timber structure and craftsmanship.

2.1 Threats to the Architectural Integrity

Not only because craftsmanship has not been transferred to younger generations, but economic conditions, cultural transitions and dominance of new construction technologies and materials have brought the end of timber architecture in Istanbul. The construction industry and its speculators as well as insensitive individuals have sadly initiated a gradual architectural degeneration process on both shores of Bosphorus.

Even before the fashion for concrete apartment structures started, Bosphorus had its own problems. There have been state-owned factories positioned here and there, tobacco warehouses and others, giant fuel storage tanks, coal distribution posts right on the shorelines; there have even been a shipyard, many private sand / gravel dealers with their frighthening machinery along the costs. However, those were still acceptable since they have been few in quantity and had become landmarks to the habituated eye in sharp contrast with their surroundings.

Fig. 2: Measured drawings of "Rasim Pasha Yali".

Dangers of more serious nature have appeared later. Economic conditions and cultural transitions, over-population and concentration in big cities, ineffectiveness of the authorities, passive attitude of the community and academicians and many other contributory factors opened the gates to developers to erect profit generating condominium-type concrete structures insensitively designed on imported models and permitted under local regulations. The situation has worsened when illegal building activity either in the form rural population on the other hand invaded the banks of Bosphorus. Finally, large scale cooperative-housing schemes climaxed the threat to the integrity of the Bosphorus natural and built heritage. The tasteless apartment blocks and the slum housing or 'gecekondus' built overnight by the immigrated poor did not leave the picturesque wooden houses untouched. Not only that they lost their inspiring environment, but a quite large number of them were sacrificed in the search of financial profit and "modernization" as a side benefit.

2.2 Remedies

Since some decades, a certain awareness of the disastrous stream of events have forced the concerned bodies to try to slow down, if not stop, the architectural and environmental massacre. However, almost all of the plans, legislation and restrictions have been of short-lasting effects. A strategy that proved itself relatively successful was to control building activity involving historic structures. Accordingly, architecturally significant residences were divided into three groups of respectively high, moderate, and low aesthetic and historical merit. Approved repairs only were permitted for the first category. The houses in the second category could be demolished with the condition that an externally replica will be rebuilt allowing internal changes only. And the last category was set free for new, yet size-wise controlled construction provided that an approved set of measured drawings of the original house is filed with the authorities. That was followed by a specific decree intended specifically for the Bosphorus site banning all sort of new building activity. All such attempts have naturally initiated reactions and legal problems intricate to solve.

3. Conclusion

Its skyscape of thrilling beauty, its landscape of enveloping charm and its picturesque architecture still classify the Bosphorus as one of the most appealing, characteristic and mystical spots of the World. Isolated efforts, enforced rules, and cries of some faithful intellectuals have appeared to be not sufficiently effective and long-lived to save its heritage. The experience from the past indicates that a much more encompassing strategy dealing with issues of zoning, building limitation and restriction, land subdivision control, restoration and adaptive-reuse, landscaping and tree replantation, aesthetic controls for new dwellings, valuation of open lands, prevention of loss due to fire and aging, maintenance, land tax regulation and educational programs may possibly contribute to establish a stable balance of the economic, political, cultural forces that have always been battling over the Bosphorus.

Mosques of Madinah: Designing towards Authenticity

MANNING Mahmud¹, ABU AL HAIJA Ahmed²

¹ Urban Design Consultant MA Urban Design, Birmingham City University

² Faculty of Engineering – Executive Director, Centre for Islamic Urban Heritage, Taibah University

E-mail: zvsvol@gmail.com - alhaija2@gmail.com

Abstract: The architecture of mosque design since the establishment of Islam in Madinah has witnessed various forms of development and political precedent. Form and function, construction methods, material use and decoration have led and sometimes followed technological innovation. The majority of mosques built in Madinah in the 20th century have a single communal character; a copy of historic architectural forms without a connection to that historical culture or politic.

Various contemporary positions within the nature of these changes are held; some consider that contemporary design does not need to have historical references to buildings which are not part of that political or geographical arena, while other thought recognises historic layers even if out of context with building methods, materials or social norms.

This paper discusses in brief the principles of historic mosque architecture within the first city of Islam in terms of architectural and artistic expression which illustrates the intellectual and physical factors contributing to this architectural heritage. A philosophical criticism is helpful in order to establish some reflections concerning the relationship between authenticity and concept of design in the 21st century.

Key words: Principles, Imitation, Tradition, Innovation, Authenticity.

1. Introduction

From a Muslim perspective, Madinah represents an eternal archetypal city and place of wisdom received through revelation by the Prophet Muhammed 1435 years ago. Governed according to the innovative treaty of the 'Sahifat al Madinah' (Amatulla) the city became a declaration of social justice and reflected the new society's purpose and the establishment of Madinah's first Mosques within Islam.

Madinah was a fertile crossing point within a harsh desert climate; a geographic bowl, where rain-water drains into from the surrounding mountains. It became a centre for trade caravans. Watch-towers were built as protected look-out posts against marauders and bandits. Madinah was not a walled city; its defense was in part due to the difficulty of its approach and harsh climate.

The initial buildings of note were built using local materials of Basalt and lava stone with red earthenware clay. The lava stone spread throughout the region from volcanic eruptions and lava flows. The stone is strong and yet friable and was used for foundations and walls which rose above grade. Clay walls would continue in the French Pise tradition of building, as well as the production and use of unfired clay brick. Roofs were flat with palm trunk spas and joists. Domes and vaults were not known or used until the Mamluke and Ottoman eras.

Fig. 1 Simulation of the Mesjid Nebawi; the early mosque built during the establishment of Islam

The main element of a mesjid is primarily a clean open space to pray together. A further element is the direction to pray, incumbent to face Mecca and its centre, the Kaaba, an open house with a celestial stone embedded within one corner. A raised platform or tower enables a person to call people to the daily prayers but is not mandatory. Lastly there must be a facility for washing, enabling cleanliness for the prayer to be performed in an accurate manner.

From these elements of purpose sprang an architecture which contained these criteria, using the modest and available local materials. This early architecture in its simplicity was a collective response to need and identity; not just a spiritual identity but one informed through governance and directive.

The various Muslim governments and their societies brought layers of expansion to each mesjid. These were sometimes due to fire or lightning, which required repair or the need for an expanded space as the Muslim population grew. Mesjid al Nebawi grew from simple clay walls and palm

trunks to stone pillars during the authority of the Caliph Umar. Rock wall foundations and further stone pillars under the Umayyad Dynasty were added; each dynasty and epoch adding and imprinting their own skills and architectural elements.

These expansions and developments reflected the governance and societal aspirations as well as skills and developments in building; new techniques and materials were incorporated within each new build. These reflect each epoch and therefore become a true critique and reflection of that society. Each governing epoch portrayed its own outlook, expressed through the skills and knowledge of its artisans. The simplicity of clay and its direct community involvement led to the use of stone and a specialized workforce.

Contemporary mosque architecture also becomes an accurate reflection of society and is worthy of investigation and comprehension. Our aim here is not to show the historical step by step development of the main mesjids of Madinah, but nevertheless to show and reflect the society as portrayed within the architectural models.

We conclude with a deeper appreciation of tradition, while acknowledging that pastiche and imitation is not enough to accept a 'historic' architecture. Respecting an environmental context, a memory of place and the cultures of local people are important but allied to authentic use of space and physicality with appropriate functionality.

This linear outward enquiry has three streams;

1. An historical reference and displacement using pastiche motifs and modern materials.
2. A post modern sensibility which recognises a cultural/historic legacy and its connection to place while bringing a layer of empathetic personal identity.
3. A contemporary approach without location or historic reference.

2. Tradition and its meaning

A point to be clarified helping us understand the world of people living before our 'modern' age is to understand the meaning of tradition which concerns aspects of material culture, local techniques of building and principles of common life, including faith and intangible heritage. Therefore, the process of industrialization and its effect of globalization have widely marginalized the spirit of creativity and authentic expression of specific cultural groups, affecting social and individual behavior, transforming a local identity into a globalised identity. (Abu Al Haija, 2014)

Tradition should be understood from a tangible and intangible realm embracing culture. Each age and people still held to innovative techniques bringing out a particular genius established through their geographical location and identity. A tradition is tempered by hand skills and a passing on of knowledge without the use of heavy machinery or an industrialised process. (Foster, 1973) It is not the buildings per se which are traditional but the society which produced them.

3. Three streams of Identity

We have within contemporary architecture three streams of identity which we hope to elucidate here and which in fact reflects the social condition of our age. Madinah is not separate from this and can be used as an example of inquiry which helps elucidate our modern condition and situation. We have a dichotomy between Traditional society and Modern/Contemporary society which still needs to be examined deeper in order for us to arrive at an appreciation of what is in front of us.

These streams must be recognised as the inheritors of a lost or at least a broken 'traditional' architectural identity which reflected a 'traditional' Islamic society. Traditional Islamic societies have become technological. Echoes are in place; both in terms of building footplate and cultural heritage, although society itself moves away from that echo within each passing decade. Mythos is discarded, only logos remain. (Armstrong, 2004) This linear post traditional enquiry has three streams;

2.1 Stream one: Imitation

The first stream emerging from this loss of tradition acknowledges historical style within a design process. This style in fact becomes an icing on a concrete cake. It usually does not use the materials of the past, (whether stone, wood, clay or fired brick) but the convenient materials such as steel and concrete with various hollow brick infill. This style may also be adoptive and eclectic, traditionally never simply surface decoration but something deeper, connected to use, function, geometry and meaning. The 'Muqarnas' within the 'Mihrab' (or prayer niche) is a good example, this stalactite form was not simply a decorative transition of square to circle, but an amplification of sound, allowing the voice to be projected back to the far wall allowing all to hear and therefore participate.

This historical necessity becomes a pastiche from its original source, an outward recognition but hollow in its authenticity. Geometry (as visual number) is not considered in the buildings conception and an identity to local people or their governance is not expressed. The mosques of Qiblatain and Miqat, in their new emergence and enlargement receive a 'Mamluke' style, with interiors of Moroccan and Ottoman decoration. Mesjid Al Nebawi has an Andalusian 'Umayyad' style reminiscent of Seville and Damascus (Fig 2). When the decorative elements of yesterday are copied and re-elaborated using modern technology.

Fig. 3 Shade umbrellas are in place within the pavilions of Mesjid Nebawi. This innovative design allows for a flexibility of space during different types of weather, they are not overbearing in scale or foot-plate and are folded when not needed allowing a clear view-site.

2.1.1 Mesjid Qiblatain (Mosque of the two Qibla's) and Mesjid Miqat

Within the Qiblatain mesjid, the previous direction of prayer (to Jerusalem) has been removed, excepting a small marker as reference. The scale and footplate is enlarged with external Mamluke style decoration yet without the wonder of the carved sandstone dome present at the Muayyad mosque or the simplicity of the Ibn Tulun Mosque at Cairo. So we start to see a difference between past 'Traditional' society and its build criteria and today's 'contemporary' pragmatic use of diverse internal decoration, applied as a surface aesthetic without connection to the meaning of the whole architectural expression.

The Miqat and Qiblatain mesjids are mainly built of an extruded and fired 'light' clay brick. The arches contain a hidden reinforced concrete load bearing structure, although the Pendentives and Domes are built in a manner reminiscent of the Nubian constructions of Upper Egypt. It is a necessary compromise considering load and compressive strengths of the red brick when dealing with this scale and the increase in load-bearing weights, time constraints and monetary budgets.

These monumental buildings are outwardly impressive and have been achieved with difficulty and compromise. It still raises questions of accuracy in terms to our reference of history and governance. What is the connection in design terms to the Mamluke period and the established Saudi Kingdom?

However beautiful they may appear, scratching the surface of decoration produces an eclectic mix divorced from local skills, governing directive or integrated build structure. Instead it relies on an imported historic style devoid of governing directive.

2.1.2 Ibn Tulun Mesjid, Cairo 9th Century Egypt and Mesjid Miqat, Madinah 20th Century

The contemporary mesjid of Miqat shows how materials and technology have driven the final design. The mesjid of Miqat takes as a reference the Cairene mosque of Ibn Tulun. The mesjid of Ibn Tulun's unique design, with its minaret staircase is also an echo of the mosque of Samarra, Iraq (Fig. 6). It uses sandstone as its main material, while its scale still evokes a human measure. A modesty of scale becomes intimate and inviting, not intimidating. The build materials are transparent and have a quality of directness and honesty.

Fig. 6

Fig. 7

Cast concrete blocks (Fig. 8) are made for the Miqat capitols while a heavier scale and design sensibility is introduced. The design above the doorways become heavy and arbitrary with loop-holes as décor (Fig. 9) while the Minara becomes a totem; a symbolic place for calling the prayer. The brick remains visible, with a weather-proof paint coating and double pillars give an impression of strength and scale, although are hidden reinforced and cast-concrete pours.

Fig. 8

Fig. 9

3.2 Stream two: Revised Modernism

The second stream is post-modern; one of re-connection to a historical/cultural past as well as a consideration to location and specific use. It may embrace technological innovation and current materials. It does bring innovation and is usually creative.

3.2.1 The Grand Mosque of Rome

A strong example outside of Madinah would be the Mosque built in Rome and completed in 1995 by the architect Paolo Portoghesi. His architectural design is based upon hands raised in supplication and prayer, while structurally it serves a purpose by holding a large covered prayer area without heavy intervening pillars which can interrupt prayer lines (Fig. 9). It fulfills a similar concern as the Ottoman mosques of Sinan. Scale and space is achieved yet with an integral structure and design/concept sensibility. It uses modern techniques and materials imaginatively which complement and illustrate the concept of prayer and supplication (Fig. 10 and 11).

Modern technological systems are used to enlarge the open space of prayer. The structural elements have also an expressive message in terms of forms and natural lighting. This example may however become overly complicated, even a distraction to the main purpose of collective worship. A design criteria concerned with its patronage may also have created a flamboyance or overly complicated structural solution.

It does not reflect a specific Muslim community or governance; indeed it represents a community mix with various outside patrons within a host Christian country and represents integration to a city fabric. It aims to reflect a social integration of Muslim immigrant populations into a wider host community. The interpretation of some religious actions into the use of forms abandons a traditional expression in favour of shapes reflecting a concept of design. (Hands raised in prayer.).

3.3 Stream three: Innovation

The third stream is of a contemporary style and divorced from place or cultural identity. It is its own statement and a landmark building of notice and attraction. It may contain various materials, though usually of reinforced concrete, glass-plate and clad materials. This character may carry its own concept usually independent or personal to the architect.

Jamia Mesjid in Prishtina, Kosovo

A design proposal for a Jamia Mesjid in Prishtina, Kosovo, showcases an individual approach which is truly a 'Tabula Rasa' after the social and political traumas of its recent past. It does however have its own honesty of approach, imposing its own awe over the congregation, spiritual or otherwise, despite an absence of historical reference (Fig. 12 & 13).

This example does bring simplicity to the internal space; an opening within the roof considers natural light as well as the movement of the sun, while also promoting a cosmological awareness and sense of spirit. It is calling for a shift in paradigm which is of worth and may indeed become a model of aspiration for a return to first principles.

This model is not integrated within an urban context. According to the historic function of a mosque it related directly with society and the urban fabric rather than a monumentality of building. It continues to be technological and outside the skills implementation of the local people it serves.

4. Conclusion

The historical element proclaimed a societal identity intrinsic to its structure, (through geometry) as well as its decorative form as an outer expression of its political identity, whether Umayyad, Mamluke or Ottoman. Contemporary architecture is essentially defined by technological terms with a style identity added on; buildings reject a distinctiveness reflected in people as a governing identity.

We can see that respecting tradition superficially may not be the same as standing within a Tradition; a point perspective looking out from a confirmed source. We also recognise that traditional Muslim societies are not in place and therefore allow an architectural confusion to occur. Respecting an environmental context, a history and memory of place and the culture of local people is important but also needs to be deeper. Is it an inside-out or an outside-in sensibility?

Architectural elements should reflect not just an honesty of materials and technology integrated to form and function, but should still be wary of imitating historical and previous political tradition, especially if it is out context to the people the building serves. Imitation of traditional forms doesn't mean a respect of tradition, but a shortage of creativity and correct architectural vocabulary. This lies with the governing polity as much as the architect.

Importantly for an architectural expression to occur which is true to source, a re-appraisal, even a new Nomos (C. Schmitt) is needed within architecture and Muslim society. It can be suggested that this is achieved architecturally by a return to first principles including the important integration of social inter-action and urban texture around mosques. Simplicity of space and importantly a sense of spirit, as well as an inspiration for local governance within the collective must be addressed. This may mean that the Dome or Minaret are seen as secondary elements, historically important but not conditional.

A re-evaluation of human scale and compatibility as well as the essential elements of a clear or flexible open space, without visible intimidations of worldly power would be a welcome return to first principles.

The architecture of mosques and cities ultimately reflect the society they contain, not just a philosophical position but its governing polity. This position is all encompassing including its wealth and trade transactions. From this primary position the secondary important considerations of durability, context within environment, human scale and cultural identity can then be formed.

The accessibility of archaeological area of Pompeii. Knowledge methodology and sustainable proposals

Renate PICONE

Department of Architecture, University Federico II, Naples, Italy
repicone@unina.it

Abstract

The paper will explore experimentally the improving accessibility of archaeological site of Pompeii, in the broader sense of adaptation, not only to the instance of the removal of architectural and perceptual barriers, but also to the more general enhancement of the site. This latter must be interpreted as the improvement of services for safety and comfort, and as a knowledgeable and informed perception of the archaeological area of Pompeii, one of the most visited in the world.

The contribution will deal with a research methodology that started from a survey on the “state of the art” about the subject, a careful analysis of the present state of some selected areas, chosen as study-cases, arriving to identify the main morphological and material matters for broader use of the site of Pompeii, and the strategic nodes to implement to support the fruition and development.

The research has dealt with users with greater difficulty, made up of people with disabilities, intended not as a separate category, but as part of a whole. In this context, the aim was to propose experimental solutions, careful to the issues of reversibility and material compatibility.

Thus, the research started from the field analysis of some case studies and from the ‘hermeneutic’ exercise of conceiving some possible solutions in line with the most updated and shared criteria of restoration, such as the principle of minimum intervention, reversibility, material compatibility with the ‘fragile’ ancient materials of Pompeii, as well as the *figurative contemporaneity* of modern elements added to increase accessibility.

Keywords: Accessibility, Pompeii, archaeological heritage, conservation, enhancement.

1. Heritage preservation and improvement of accessibility

This topic is based on the outcomes of the research project “Accessible Pompeii. Guidelines for a broader use of the archaeological site” funded by the University of Naples “Federico II” that I have coordinated between July 2011 and January 2013 [1].

At the dawn of the third millennium, the strategies for the future of the archaeological site of Pompeii must take into account aspects related to the site protection and development, raising the quality of its use and preventing the adverse effects on its preservation. This is also in line with the most recent legislative framework, which – following the amendments brought to the *Codice dei Beni culturali e del Paesaggio* in 2008 – lists among the enhancement measures those actions aimed to “ensure the best conditions for the use and enjoyment of public heritage, even by person with disabilities”.

With a well-established literature on the subject, resulting from over twenty years of academic debates, the work draws upon the Guidelines to overcome architectural barriers in cultural heritage, issued by Ministry of Culture in March 2008 [2], which was drafted by some of the members belonging to the research team.

The aim of the research was to take on an experimental stance in investigating new ways to improve accessibility in Pompeii in its broadest sense, not only in terms of removing architectural and perceptual barriers in some areas, but also in relation to a more general enhancement of the site. The

latter includes guaranteeing higher safety and comfort in order to allow for a conscious perception of Pompeii, which is one of the most visited archaeological sites in the world.

Fig. 1: Pompeii. Archeological area. View of the Honorary Arch with the Vesuvius on the background. Photo Serena Borea 2012

The research methodology started from a thorough examination of the state of the art on the topic of accessibility, both in terms of debate and critical literature, and of Italian and international legislation regulating this issue. The research has also discussed the main projects on accessibility in archaeological sites abroad and in Italy.

The historians of the research team have also carried out a critical study on the use of the Pompeian site across history through the descriptions of travellers, artists, and architects from the *Grand Tour* to date.

These surveys based on 'indirect sources' have been integrated by a thorough field survey, which has described the status quo of some sample areas selected as case studies, with the detection of differences in height and in physical and perceptual barriers. These data have been obtained through the material survey on the pavings and elements up to 90 cm of height in detailed scale and in some cases with complete surveys using 3D laser scanners.

In sample areas, the researchers have identified not only the physical and perceptual barriers, but also the main morphological and material criticalities that prevent a broader use of the Pompeian site. The research has also identified the strategic nodes to be implemented in the system to support the use and enhancement of the site, also by experimentally outlining some guidelines and shared solutions in response to specific or frequent criticalities.

Thus, the research started from the field analysis of some case studies and from the 'hermeneutic' exercise of conceiving some possible solutions in line with the most updated and shared criteria of restoration, respecting the parameters of restoration, such as the principle of minimum intervention, reversibility, material compatibility with the 'fragile' ancient materials of Pompeii, as well as the *figurative contemporaneity* of modern elements added to increase accessibility [3].

Then it merged into a project of preservation and adaptation that, without claiming to achieve full accessibility of the archaeological site, has tended to increase as much as possible the number of people who can access and enjoy the archaeological city, while improving the quality of the overall cultural experience.

Fig. 2: Pompeii. Archeological area. General view of the Basilica. Photo Renata Picone 2008

2. A multidisciplinary approach. Aims and methodology of the research

From this perspective, the research focused on physically challenged users, that is to say people with disabilities, not considering them as a separate category, but as part of a whole.

The research took on a strong interdisciplinary slant, involving experts in the field of restoration, history of architecture, urban planning, design, and structural and materials engineering. The issue of accessibility and enhancement of historical heritage is part and parcel with the restoration project, which, interdisciplinary by its very nature, needs a complex approach that requires awareness of the issues involved, ability to listen and dialogue with specialists, but also conciseness, which cannot be overlooked when it comes to designing solutions. The restoration works done in Pompeii over the last century proves that the combination of incompatible materials or the use of materials that do not stand the 'test of time' can lead to the degradation of archaeological ruins, or even to the collapse of entire parts of the ancient *domus*, as recent events have shown [4].

Collaboration with the institutions for the preservation of archaeological sites (Ministry of Heritage and Culture, Directorate General and Regional Archaeological Superintendence of Pompeii, etc.) has been crucial for the development of our research as their officials were involved as external experts on the site. The collaboration between scholars and officials also meant the possibility to have access to: an updated knowledge of the programs already implemented by the Ministry of Heritage and Culture and by the Superintendence to improve accessibility and remove architectural barriers in the archaeological site ("Friendly Pompeii" and the "Empler" project, etc.).

The ancient city of Pompeii has an urban dimension, is first and foremost a cultural experience, and this cannot be separated from its enjoyment, which involves walking through its paths, intersections, living within the antique city in complete safety and comfort. On the other hand, culture presupposes some sort of exchange, open communication with mankind in the broadest sense, without distinctions of any kind, disabilities included. Heritage conservation has the purpose to educate and keep the historical memory alive for future generations, it concerns every citizen's education and quality of life, in the broadest spiritual and material sense [5].

The design solutions proposed to upgrade the Pompeian site therefore arise from a thorough knowledge of the current state of the individual areas under examination and of their accessibility-

related problems, identified by means of an urban scale approach to the site, which is considered as a city and a urban system rather than a collection of *insulae* and public and private spaces.

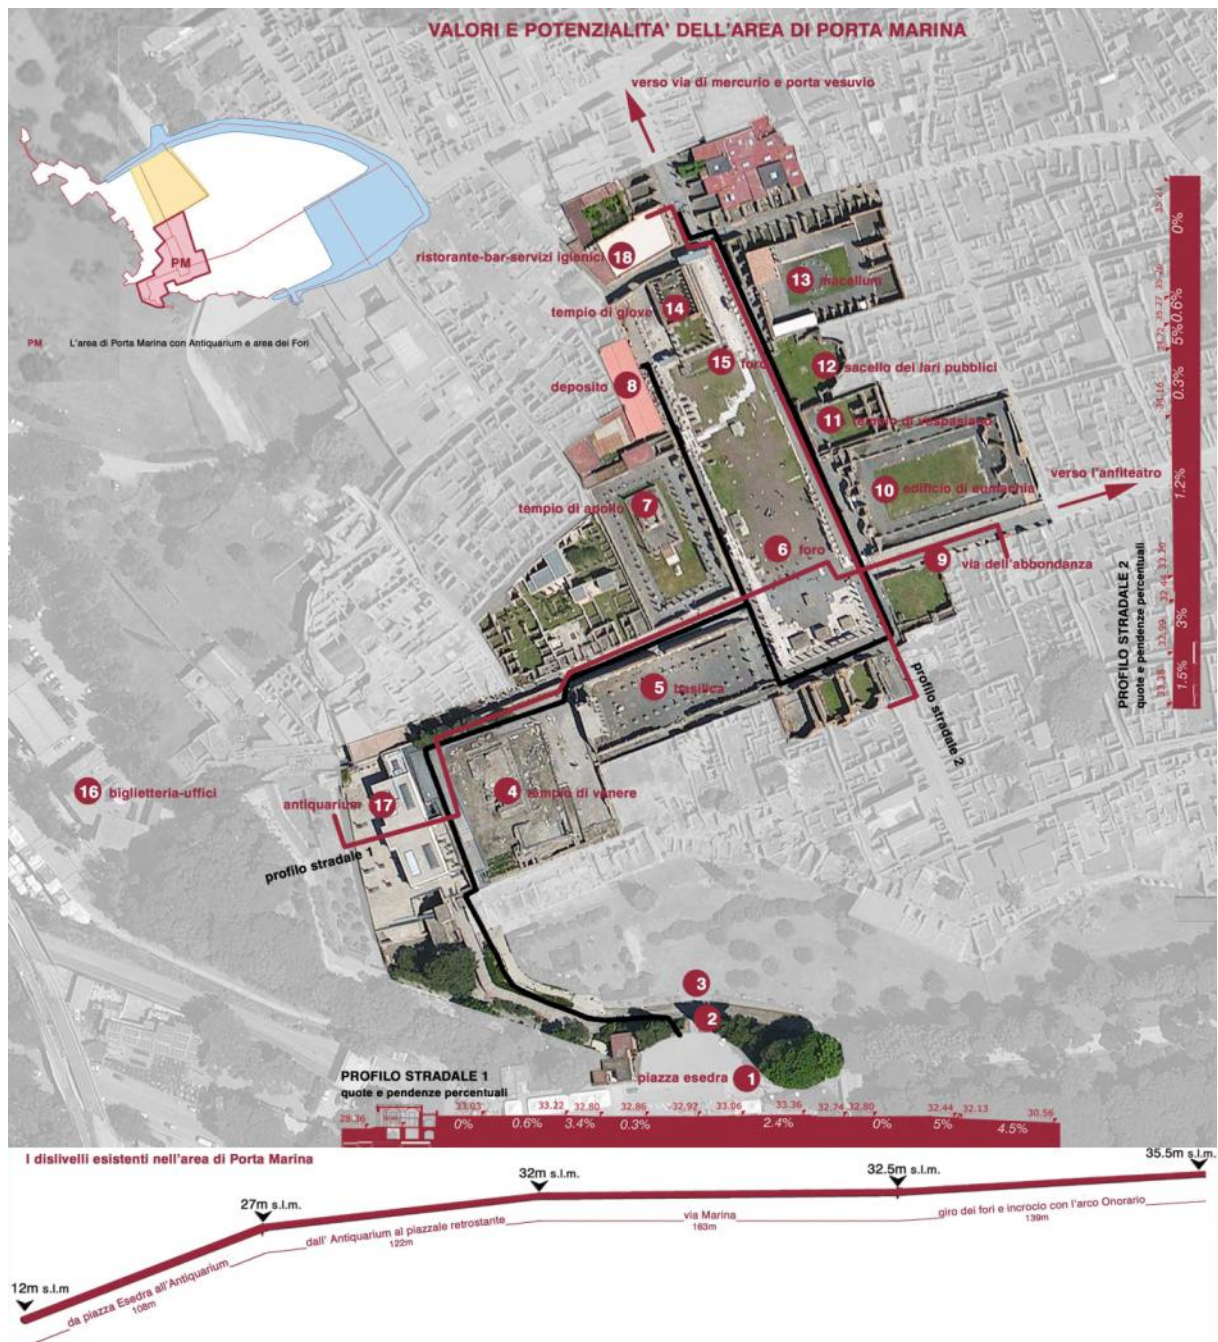

Fig. 3: “Accessible Pompeii. Guidelines for a broader use of the archeological site”. (2011-2013). Table with the recognition of the hubs and paths of the Porta Marina area. Renata Picone, Andrea Pane, Paolo Giardiello, Arianna Spinosa, Luigi Veronese, Maria Falcone, Viviana Saitto.

It was also necessary to analyse the archaeological site as part of the entire city of Pompeii, paying attention to its interaction with other urban structures and flows of religious tourism, which also characterise the city.

Within the archaeological site, the solutions that our research has identified are intended not only to facilitate accessibility to the various parts of the ancient city by a broader number of people, but also to give visitors the possibility of 'living' the site in a conscious way and continue to perceive the message of the time they recall. This is the reason why, for example, in the House of Meleagro in Via di Mercurio visitors can experience what living in a Pompeian house was like, moving safely inside it and respecting its values.

The conservation of the archaeological heritage remains the primary objective: Pompeii is a world heritage site and the project of improving its accessibility and use should be respectful of the pre-existing structures, keeping high standards of design quality for any type of intervention. The relationship between archaeological heritage and accessibility has been brought to the attention of experts in restoration about fifteen years ago, in the wider framework of the connection between preservation and accessibility, to the extent that accessibility is now widely recognised as part of the project of conservation and restoration [6].

3. The four study areas

Once having surveyed the conditions of the areas on a urban and architectonic scale, indicating all the parts of the site that could be visited, the research work shifted to the drafting of some thematic maps, which would highlight the various forms of architectural barriers found in the historical site, starting from physical obstacles - such as stairs, ramps, paths with slopes, elements creating discomfort, danger, and obstacle for people with reduced mobility, as well as 'perceptual barriers', relating to people with sensorial disabilities

The study then focused on four pilot areas, showing different characteristics:

1-The area of Porta Marina with its access to the Forum and the Basilica and the node with Via dell' Abbondanza;

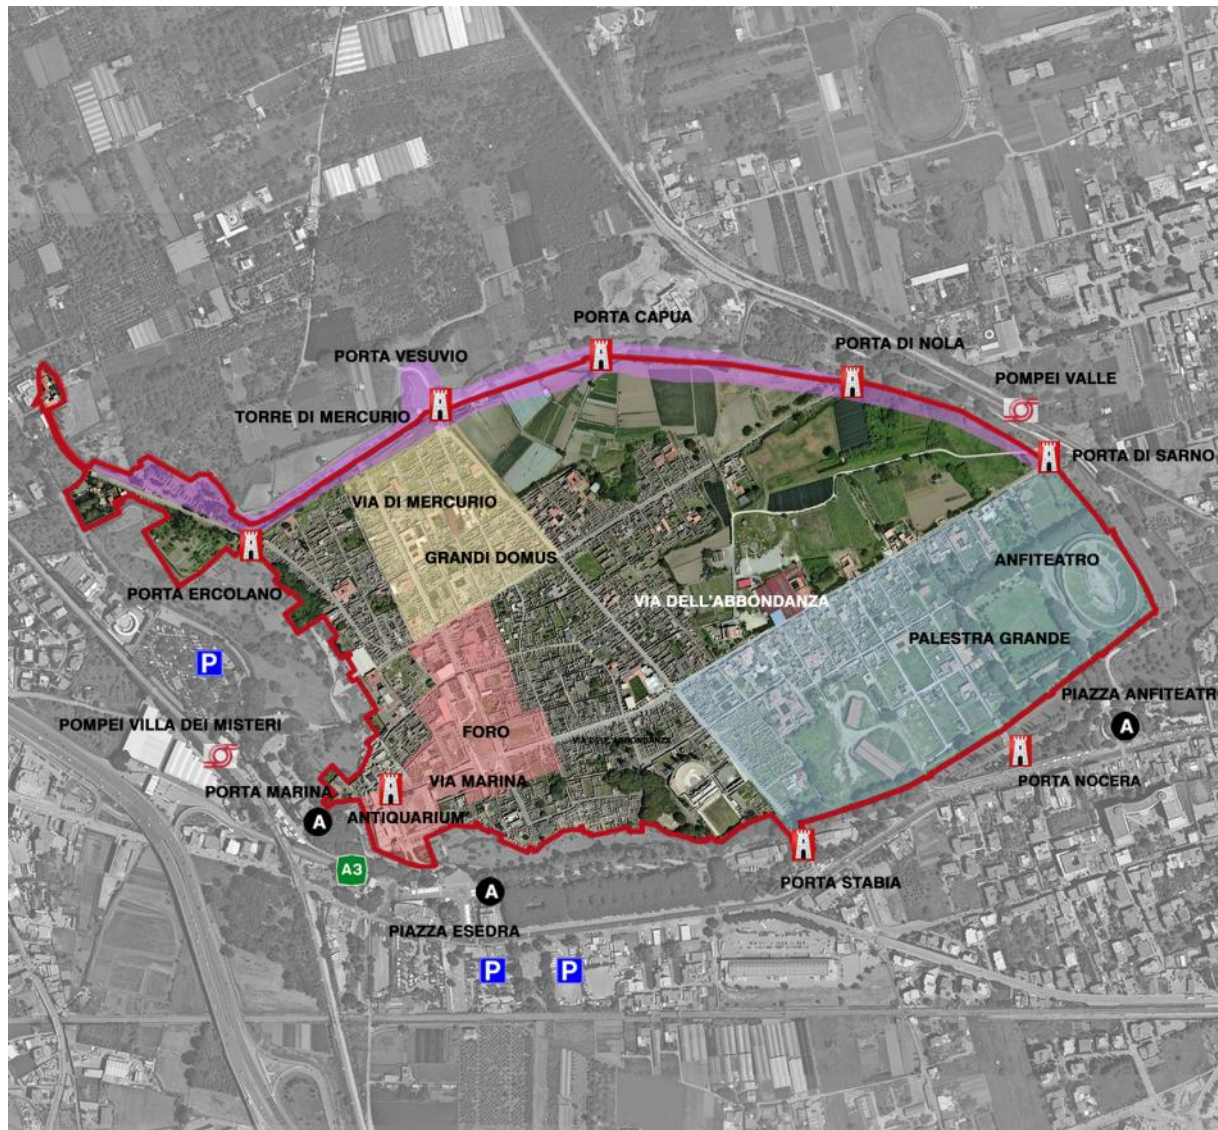

2 - The area of Porta Vesuvio and its system of ancient walls;

3 – Via di Mercurio with the House of Meleagro;

4 - The area of Porta Nocera and the Eastern walls.

In this way, we have identified three routes within the ancient city, with accesses respectively from Porta Marina, Porta Anfiteatro (Porta Nocera), and Porta Vesuvio to the north, and a 'path' through along the walls and the towers - already indicated by Amedeo Maiuri [7] in the forties of the twentieth century as a way to visit the city – which should be made accessible.

The four study areas are all linked together, so that they can be viewed comfortably in their entirety, going through the excavations from Porta Marina to Porta Vesuvio, or can visited separately, also at different intervals.

L'Area di Porta Vesuvio

Fig. 7: “Accessible Pompeii. Guidelines for a broader use of the archeological site”. (2011-2013). The recognition of the four study areas.

To avoid the presence of unsuitable materials being used in the archaeological site, these were selected on the basis of:

- physical, chemical and mechanical compatibility with ancient materials;
- durability, given the continuous exposure to atmospheric agents; laboratory tests were conducted at the former Department of Materials Engineering, University of Naples 'Federico II'. Given the specificity of the site under examination and a limited literature in the field of physical and chemical compatibility of innovative materials with materials of archaeological interest, some of the expected results had special scientific relevance.

- easy maintenance, also by unskilled labour;
- reversibility;
- recognisable devices for people with sensorial disabilities, also for innovative materials, such as structural glass.

For the four study areas identified, the main outcome are the guidelines for a broader use of the site and specific design solutions.

This has enabled to focus on a methodology which can be later on extended to other areas of Pompeii and, above all, used in other archaeological contexts.

This latter aspect has high scientific relevance: the product of this research will constitute an essential reference for other studies in the same field, and will also be used to define a 'pilot project' in the context of the current guidelines of the Directorate General for the Promotion of Cultural Heritage.

ORNAMENTS AND VIBRATIONS IN THE GEOMETRY OF THE SOUND

Rosario Giovanni Brandolino, Domenico Mediati

Department of Architecture and Territory (dArTe), Reggio Calabria, Italy

gianni.brandolino@unirc.it, domenico.mediati@unirc.it

Abstract

The musical instruments are not simple mechanical objects. They express specific formal qualities and evocative that go far beyond their function vibrating. They are sometimes complex objects that are derived from empirical cultures, craft skills handed down from ancient folk traditions, spontaneous demonstrations of artistic vocations, ethnic and tribal residue, reminiscences to ancient myths and symbolic universes, spontaneous studies of geometric harmonies and "topological" shapes. Are obvious references to the forms of nature, from which they draw a vocation to production and transmission of sound.

To analyze shapes, patterns, decorations, materials and the mechanical of sound instruments, means tracing a path through history, mythology, material, empirical and figurative culture of peoples. They reveal themselves as inclusive material entity, where multiple expressions of arts and crafts converge. The sound instruments manifest themselves as an expression of an ethnic design that does not derive from an aulic and cultured language. It stems from the layering of popular traditions, the most genuine and far from dominant cultures, but capable of expressing the deepest essence of a people.

The research collects and elaborates some thoughts about music, art, myth, geometry, architecture, resulting from the didactic and research practices carried out by the University "Mediterranea" of Reggio Calabria. The instruments, surveyed and drawn by the students, belong to the collection of the *Museum of Musical Instruments* of Reggio Calabria.

Keywords: drawing, relief, musical instruments, organology, music.

1. Introduction to Research

In the definition of sound experience, involved multiple factors that contribute to define an perceptual universe broad and inclusive. Arithmetic, geometry, shape, proportion, harmony, rhythm, vibration, are all determining factors. It is from them that comes a common territory where art, architecture, poetry, literature and music enter into a virtuous dialogue, expanding their potential evocative and emotional.

The music expresses itself in an intangible, like the emotional feelings that arise from the use of the visual arts. Every visual or sound emotion comes from an objective referent that produces it. The painted canvas suggests a symbolic path to the soul; both rational and emotional. The material space of architecture evokes impressions and sensations that go far beyond the function of the space built. Similarly instruments produce incorporeal sound vibrations that stress passionate emotions perceptual. All this comes from material!

The shape, the material, the geometry and size determine the type of vibrations that generates sound. They affect the sound characteristics to the instruments, revealing a close connection between geometry, material, vibration and tone.

The shape, the material, the geometry and size, determine the type of vibrations that generates sound. They affect the sound characteristics of the instruments, revealing a close connection between geometry, material, vibration and tone.

Musical instruments are not simple "vibratory mechanisms", they have hidden formal qualities and evocative inside, that go far beyond their sound function. They are mechanical objects which are

Fig 1: *Septem Artes Liberales* (The Seven Liberal Arts), 1590-1658. London, The British Museum.

sometimes complex; empirical expressions of cultures; manifestations of craft skills; instinctive revelations of artistic vocations; spontaneous narratives of ethnic and tribal cultures; references to mythological and symbolic universes; unaware studies of “topological” forms that, in an obvious derivation of the forms of nature, replicate the spontaneous vocation for the production or transmission of sound.

It is in this unusual area, analysing geometry, patterns, materials and mechanical musical instruments, a path that runs along the history, mythology, empirical and figurative culture of peoples.

2. The arts, harmony and multisensory trials

The sensations produced by sound, as well as the effects that result from the use of a work of visual art, can't be reduced to trivial acts of perception. Hearing and vision take on meanings that go far beyond their intrinsic functional vocation. Through them we express spiritual implications that lead inevitably to deep contamination. It is a progressive path that leads to virtuous and profitable relationships between disciplines and art forms, arising from distinct bodily sensations. Gradual integration that leads to the most recent multi-sensory experiences.

Martianus Capella, in his academic treatise *De Nuptiis Mercurii et Philologiae* – the first quarter of the fifth century – provides a description of the ascent to heaven of Philology to marry Mercury; the Eloquence. The seven *artes liberales* [1] take part in the wedding, as guests. The allegorical narrative proposes, de facto, an encyclopaedia of classical learning which will then become widespread in the culture of the Christian Middle Ages. Inside a canonical classification is found which will be crucial for the medieval encyclopaedic education that will continue, thanks to the commentaries and scholastic traditions, until the Renaissance and beyond.

In most of his manuscripts Martianus Capella attributes the term “Harmony” to the music, assigning a synonym that will prove decisive for the understanding of the essence of music. It is not just a play of sounds but superior cosmic principles aimed, in fact, towards the harmony of celestial space.

Among the seven *artes liberales* there are no traces of the figurative arts, which have been relegated to simple *artes mechanicae*. Music, by contrast, occupies the absolute role of respect. The organization of medieval studies and the resulting prestige accorded to the disciplines that were deemed necessary to the formation of *free men*, leaves no room for doubt. If arithmetic, within the *quadrivium*, is the foundation of scientific knowledge, then music determines its completion. In it lie the science of numbers, the science of the motion of celestial bodies, verbal metrics rules derived from rhetoric. The art of music offers itself as knowledge to the understanding of reality, but at the same time recognized as an applied science. It is capable of revealing the order present in relationships between numbers, transferring them to the soul. «Without music – says Isidore of Seville – no discipline can be considered perfect, nor is there anything that is without it» [2].

It will be a long and arduous path, however, that will lead to the recognition of the status of a discipline, such as figurative art, which will begin to feel more and more the need to relate to teachings which are already included among the *artes reales* (the arts of the *quadrivium*). The discovery of perspective and the study of its geometric laws approach the pictorial forms to the geometry; while the arithmetic and the consequential analogy with musical relations.

The relation between music and painting is a constant in the world of figurative arts. Pictorial forms are not simply myths and instruments relating to the musical tradition, but a strong tightening relationship between arithmetic, geometry and music. They express, in such a ‘visible’ manner, the harmony of human elements with mathematical, harmonic and rhythmic rules, in a word the *concinntas*.

Fig. 2: Georges Seurat, *The chahut*, 1889-1890. Otterlo, Rijksmuseum Kröller-Müller.

Fig. 3: Jean Dubuffet, *Jazz orchestra*, 1944. Paris, Centre George Pompidou, Musée National d'Art Moderne.

Fig. 4-5: Anish Kapoor, *Marsyas*, installation, 2002. London, Tate Modern Gallery.

All of this, together with the theoretical studies about perspective of Leon Battista Alberti, Piero Della Francesca and other Renaissance treatises, contribute to the elevation of the figurative arts and their final acquisition among the *liberal arts*.

The upheavals in the visual arts in the late nineteenth century, which continued with the historical avant-gardes of the early twentieth century, will have an influence not only on the techniques of expression, but even on the themes and content of pictorial representations. Paintings with mythological or contemplative characters, with some rare exceptions, will be eliminated from much of the scene. The focus shifts from the programmatic intentions of mystical and religious to the scenes that recall the pleasures of bourgeois life. Music and musical instruments become significant in this thematic program.

The conceptual and operative mutations introduced in art in the twentieth century, however, do not only produce effects on the subjects and themes of the representations, but introduce new techniques of artistic expression which were not necessarily limited to painting. The use of musical instruments – elaborated, transfigured or merely ‘alluded’ – is of considerable interest in the realization of non-conventional works, performances and installations of modern and contemporary art.

The multisensory integration that over the centuries aspires to greater intimacy between music and visual arts, hearing and visual perception, is enriched with more complex relationships which are able to express, but also to solicit, the motions of the spirit. It is a music that, in the expansion of perception and of expression, seems to realize the prophetic definition that Thomas Mann writes in *Doktor Faust*:

Fig. 6: *Gamelan Garasi Seni Benawa*, Indonesia. Festival of the imagination, House of World Cultures. Entertainment at the Opéra Bastille, Paris. Photo by Jean-Pierre Dalbera.

Fig. 7: *Kora* player.

«[...] perhaps the most intimate desires of music is not being heard nor seen nor sensed, but, if possible, understood and contemplated in a manner beyond the senses, and even the soul, a spiritual purity» [3].

The cosmic order, the harmonic relationships, the numerical proportions, ethical and mythological references, rhythmic and formal balance, variations in tone and colour are readable translations of an incorporeal experience: legitimate aspirations for a song that refuses to be only “seen or heard” but that aspires towards an intimate dimension, intently spiritual and contemplative.

3. Places of sound and ethnic affiliation

The proposed study underlines two essential elements of the sound linked to the anthropological and ethno-musicological aspect. The historical-cognitive survey focuses on the factors of origin and on the practical use of the instruments [4]. This involves the study related to traditional motives, technical skills, languages and constructive operations. It is a route that highlights the anthropology of musical instruments and the traditions connected to them, including sound function and ritual practices, together with concepts related to sound and the musical taxonomies [5] of different cultures.

Drawing means knowing how to observe and document the tradition of various peoples, by completing and formulating a species of mini atlas of the different cultures of the sound. It results as a flow of information and observations on forms, instruments, changes, repertoire and modality of the musical use.

Changes or cultural influences are an area of interest through which it is possible to undertake a study of traditional music involving multiple geographic areas, with many musical cultures which belong to the whole world. Musical practices are continually changing and generate new experiences and musical traditions. Technical and formal innovations are accompanied by structured processes that affect the conceptual and symbolic universe of sound expressions.

Ethnic instruments, made with “rudimentary” techniques, which express a virtuous relationship between sound, art, technique and instrument, which transmit the ethnic identity of *genius loci*. Constructing, albeit in miniature, means dealing with the technical and aesthetic problems of detail. There are complex constructions that result from a spontaneous culture, made up of materials and shapes, curves and strings, casings and joints. Musical instruments are stories and histories that mark a post production on the anonymous space of tribal art. Mechanisms and tasks where physical contact enters into the production of sound objects.

Territories are often a testimony to the peoples who settled them where sediment traditions remain according to a cultural identity. In the same places at the same time the migratory flows transfer cultures and traditions in a virtuous cycle of contamination. The cultural wealth of a people and the processes of development are based on their ability to understand and accommodate multiple identities.

Fig. 8: *Bandoneón* player.

“Sedentary” peoples and “transplanted” peoples are vehicles of identity and contamination: two major pillars of history and culture of the territories.

The Mediterranean basin is an exemplary place of cultural syncretism. Trade flows and alternating dominations have allowed widespread contamination that has affected the peoples of southern Europe, North Africa and the near Middle East. Europe welcomes musical instruments from Asia – mainly chordophones and aerophones – while the lyre is the only instrument that can categorically be considered of European origin.

There is an equally strong influence from Asia and the Middle East on the Mediterranean coast of Africa, which is relevant, as well as the Arab influence in southern Italy. In sub-Saharan Africa, less affected by migration flows, there is a larger consolidation of features more native, linked to indigenous tribal rhythms. Musical instruments with a strong identity are the drum, a means of communicating rhythm, and the kora, a symbol of oral communication entrusted to the *Griot* or *Jali* that narrates ancient tribal legends. Another peculiarity related to African musical culture is the strong relationship between music and dance, a strict association of the arts, an alternative to the European idea of separation. Rhythm, on the other hand, is a distinguishing feature both for music and for tribal dances. Rhythm and Polyrythm, vocal and instrumental, are also found in some Latin American countries.

African and European influences are particularly present in the tradition of Brazilian music. The typical instruments of percussion such as the *Chocalho* and certain dances such as the *Fandango* and *Catimbó* are typical of an autochthonous culture. Later these traditions blend with the syncopated rhythms from Africa, enriching the instrumental tradition of the Indians with drums (*atabaques*) and the metal bell (*agogo*). Towards the sixteenth century popular Brazilian music is enriched by the influence of European music, but we will have to wait for the early nineteenth century to witness a process of integration between indigenous musical culture and tradition from the Old World, the result of the processes of colonization.

There will also be strong African influences on North American music. Both blues and jazz are direct expressions of an evolutionary contamination that combines African rhythms of colonial origin with the traditions of European and American music, creating highly expressive new musical forms.

The musical intertwining express a cultural commingling in which identity and evolution coexist. The sound instruments often become concrete evidence of this hybridization. The production techniques, the decorative traditions, are signs of identity of places, but at the same time receive and manifest virtuous contamination among sedentary populations and civilizations migrants. There are flows of people who, in their voluntary or induced search for new lands, do not relinquish to the confirmation of identity. They receive, along with earth’s substance, also its spirit, culture and tradition, which transforms sound waves into the harmonic fruits of the “territories of sound”.

4. The organology, measurements and analyzes

There are several criteria for the classification of musical instruments: from the more empirical methods to those related to more technical or functional aspects, depending to how sound is produced. The main distinction, which is especially widespread in Central Asia, is based on the material used: metal, wood or other.

Figg. 9, 10: *Ciaramedda "key"*, Bagpipe, Aerophone, Samo, Italy. Survey and drawings by Federica Angelelli and Milly Basile Rognetta.

This classification was spontaneously adopted in most ancient cultures; it has actually been partially used in the Western classical orchestra for the distinction between *woodwind* and *brass*. A taxonomic methodology that reveals an obvious incoherence, denounced by the fact that between the wood include tools - such as the flute - originally made of wood material but which today are constructed in metal alloy.

Other types of classification, however, assume empirical and functional parameters which are tightly connected with the use of the instrument. The destination for religious or devotional purposes, rather than for domestic use or military use, determine distinctions of class purely based on functional criteria. More relevant to the sonic characteristics of the instrument is the classification that takes into account the non-use function, but the musical function that the instrument uses during execution: rhythmic, melodic or harmonic.

A decisive contribution towards a widening of the horizons of organology study is provided by Erich Moritz von Hornbostel and Curt Sachs in 1914 in the book *Zeitschrift für Ethnology*, in an article entitled *Systematik der Musikinstrumente. Ein Versuch*. They publish a cataloguing system, which takes the names of its authors [6]. This system is still widely in use for the classification of musical instruments today. Compared to developed a few years earlier by Victor-Charles Mahillon, the new method offers the advantage of greater flexibility, allowing the insertion of any instrument without geographical or cultural barriers. It is based on the physical modalities with which one determines the vibration that generates the sound. The four top level categories – *aerophones*, *chordophones*, *idiophones*, *membranophones* – branch out into additional groups and subgroups, allowing a subsequent option of upgrading and the inclusion of additional classes and subcategories [7]. A few years after the initial formulation of the system, in fact, an additional class of *electronic* is added to the original four, and

Figg. 11,12: *African violin*, Popular fiddle, Chordophone, North Africa. Survey and drawings by Caterina Candido.

includes modern instruments in which the sound is no longer generated by mechanical vibrations but by electrical circuits.

A turning point about musical studies is imprinted in the late nineteenth century after the birth of a branch of musicology which took its name, too generic of *comparative musicology*. This discipline, which moves in close relationship with the contemporary ethnographic studies, deals with the oral musical traditions of all peoples, with particular attention to those outside Europe. The term "comparative" is derived from a systematic comparison between different types of music outside Europe and between them and those of the European peoples.

Studies on comparative musicology, after 1950, will take the name of *ethnomusicology*. This renaming coincides, among other things, with a redefinition of the research methods and the role of the scholar. If before there was a clear distinction between those who collected the documents in the field and these who would have done, subsequently, the operations of cataloging and analysis. By this time the two roles merge into a single figure of a scholar. This leads to a greater awareness of the importance of all aspects, hitherto neglected, which are closely related to the musical episode studied. Contemporary scholars of ethnomusicology can't ignore the contextual study of popular culture and the traditions that concern the event itself.

The studies proposed here, result from the didactic and research experience carried out at the *Mediterranean University of Reggio Calabria*, during 2004-05, as part of the *Laboratory of Basic Drawing*, conducted by Rosario Giovanni Brandolino e Domenico Mediati.

The drawings, made by the students, adopt and specify further classification by Erich Moritz von Hornbostel and Curt Sachs, focusing in particular on the four original categories of this classification

Figg. 13,14: *Angklung*, Idiophone percussion – Xylophone, Island of Java, Thailand. Survey and drawings by Angela Fazzari.

system, which are more closely anchored to a craft technique that allows us to express hidden or explicit artistic qualities: *aerophones*, *chordophones*, *idiophones* and *membranophones*. The subcategories further adopted, resulting from trends that science of organology has produced in recent times.

These instruments belong to the private collection of the *Museum of Musical Instruments* of Reggio Calabria founded by Demetrio Spagna. It represents a rare documentation of artistic and techniques cultures, going back to multiple times and locations. A sort of historical and ethnic sample collection of arts considered "minor" but, on the contrary, it reveals an extraordinary ability to combine utility and aesthetics, form and geometry, art and technology, innovation and tradition, vision and hearing. They present themselves as objects of an ethnic design in which the sound function does not renounce to attention to the decorum. The same form of manufactured goods, with the geometric complexity that characterizes them, respond to functional needs and requirements harmonics, but at the same time adds to the objects formal quality. The profile of the resonance chambers allows a correct amplification of the sound, but it is also the identifying characteristic of many tools. They are often the result of an unconscious and "uncultivated" search of topological geometries, similar to the forms of nature. It is no coincidence that many of the sounding instruments - mostly ancient but still present today in the musical traditions of primitive peoples - were built with remnants of natural elements: shells, animal armors, peel of coconuts, hollowed and dried gourds, etc.

The shapes of the instruments replicate the soft geometry of nature. They respond to the demands of function and give emphasis to the objects: a kind of prelude to the sound harmony that they are able to release. It's the same harmony that pervades the geometric laws of nature products. They have no rigid rational mesh but are dense of a spontaneous logic. They represent an intrinsic process of evolution

Figg. 15,16: *Darbuka*, Calyx tubular drum, Membranophone, Iran. Survey and drawings by Angela Campi and Maria De Sensi.

and growth that translates the function in geometry "flexible". The polycentric curve dominates the profiles marking a formal continuity necessary for a correct reproduction of the visual and sound harmony.

The instruments surveyed were analyzed with a view to reinterpreting the hidden geometries. A volumetric analysis, recurring matrices, mechanical reproduction, a reinterpretation of the decorations, three-dimensional modelling, help to illustrate a technical, formal and artistic image of the instruments. They are broken down into their constituent elements, analyzed in detail, the underlying geometric matrixes are identified, the chromatic character is reproduced, and the decorations are redesigned and enhanced to explain their explicit ethnic identity. They are not just technical reproductions of artefacts but aspire to be a narrative that brings together mechanics, geometry, ornament, tradition and harmonic emphasis. The detail drawing and the geometric and formal analysis intertwine with the study of the decorative qualities of the objects. They sometimes manifest themselves through ethnic drawings; other times are determined by the skilful use of the interlacement for the tuning of the membranes, or by reuse of elements derived from natural or artificial scraps.

It is an unusual and complex analysis that led to grips with survey, representation, geometry, design, lute art, decorative analysis and ethnic traditions. It's an attempt at cataloguing – non-exhaustive – that makes use of innovative techniques and methods, three-dimensional modelling and geometric analysis, to give shape and concept to the sound of tradition.

5. Conclusions

The experience of relief has proposed an in-depth analysis: functional, metrics, geometric and decorative. A progressive path: from the relief of shape, size, underlying geometry, to the analysis of

decorations that characterize the geographical and cultural affiliation. A theme of "small scale", little explored: between functional detail, popular tradition and ethnic design. An unusual experience that – away from "large-scale" themes like urban planning and architecture – gives weight to the most spontaneous expressions of popular cultures, from various geographic areas.

These are the areas in which it is expressed the persistence of traditions and cultures, sometimes now lost. This is where we highlight the fruits of cultural influences between different peoples. The "sound objects", for their "vocation" of the border between music, art and crafts, show a contact between multiple experiences and multisensory expressions. They are objects of daily use but at the same time instruments of socialization and public images to display in the popular festivals. The sound instruments manifest themselves as an expression of an ethnic design that does not derive from an aulic and cultured language. It stems from the layering of popular traditions, the most genuine and far from dominant cultures, but capable of expressing the deepest essence of a people.

Paragraphs 2 and 4 of this essay has been edited by Domenico Mediatì. Paragraph 3 has been edited by Rosario Giovanni Brandolino. Paragraphs 1 and 5 by both authors.

Architectural conservation in China. The master plan of *Nanjing heritage park*

Alessandro PERGOLI CAMPANELLI

DiSBEF, *Scuola di Conservazione e Restauro dei Beni Culturali*,
University of Urbino Carlo Bo, Urbino, Italy
alessandro.pergolicampanelli@uniurb.it

Abstract

Architectural conservation in China is analyzed by an important international conservation project: the master plan of *Nanjing Heritage Park*. The topic is the accommodation of a large urban area extensively damaged by modern interventions, where the ancient monument is now deprived of its dignity, identity and symbolic value, that should be at least partially evoked. The project covers three different aspects: urban and landscape restoration, museum design (with reconstruction of the lost volumes) and conservation of the ancient pre-existences. A theoretical coherence join the restoration project on the ancient parts (conservation and re-integrations of lacunae) and at the landscape level (re-integrations of volumes), proposed with two different technologies: one for protective structures of ancient parts (in glass) and other for volumes reconstructions (traditional, in accordance with the ancient phase). The choice of a transparent material, as well as to qualify unequivocally as a modern intervention is motivated by the desire to render to the visitors the charm of the open excavation. The size and the profiles of these structures allow easy understanding the unearthed relics through their inclusion within a space which is evocative of the original. The most significant element is the great pagoda, the visual centre of the complex with its 100 m. high, where exhibit Sakyamuni's relics, highly sacred for Buddhists, which symbolically represents the sign of the new foundation of the site.

Keywords: Heritage Conservation, Nanjing Bao'en Temple, Critic conservation, Heritage resources and local development, archaeological heritage park.

1. Architectural conservation in China

The protection of historical and cultural heritage in China is a very complex problem. In this respect Heritage conservation it has not yet been considered an independent discipline (I say this even though I myself have taught in 2011 Architectural Conservation at the *School of Urban Design* of the Whuan University in China).

In Beijing, for example, not until people have demolished the ancient Walls a few decades earlier, they were conscious of the value, as noted by an eminent historian: «When they were lost or damaged, we begin to pay much attention to them»[1].

Moreover the same idea of architectural conservation is not of univocal translation. With two ideograms (pinyin: *xiū*) 修 and (*fù*) 复, you approach a conservation idea next to restoration: the first ideogram indicates the action of "repair" while the second stands for "turn back to a previous state". Understood in this way conservation coincides with the operation of restore something that has been damaged (a physical degradation), interrupted (a figurative lacunae or a lack of parts) or entirely lost. Two other logos, however, could make better sense of works on the cultural and historical heritage: those of 保护 (*bao hu*), where (*bao*) 保 is for "protect" while (*hu*) 护 means "keep to defend".

Their union expresses an idea similar to our "preserve", something better suited to operations aimed at conservation and perpetuation. The difference between these two logos is great. We need to understand it while working in one direction and in another, or rather, to possess a shared method.

The aim is the conservation and re-evaluation of the authentic object, preserving its historic stratification and original material, and avoiding falsification.

The Nara Document [2], however, could become a dangerous alibi in front of a development which is too fast and attentive only to economic values[3][4]. Harmonizing the European authenticity concept with the Chinese culture is possible to reach at a harmonious development of ancient and new, as in the thought of a great Chinese historian of architecture as Liáng Sichéng [5][6][7].

The focus reaching a new definition of conservation is the expression of contemporary Chinese culture and not only an imported aesthetic expression without roots. The theme will be developed with a recent example: the master plan of Nanjing *Da Bao En Temple Heritage Park*.

2. The master plan of Nanjing heritage park

2.1 Introduction

The project explained is the same 2nd prize winner in 2012 international design competition for Nanjing Jinling Giant Bao'en Temple Heritage Park on Chinese city of Nanjing.

The project team presents a mixture of Italian expertise (ranging from archaeologists, restorers, experts of Chinese art and culture, museum designers, exhibition designers, museography experts, lighting designers, economists for cultural heritage and structural engineers) to obtain an organic whole project of new architecture and conservation of ancient monuments.

The aim of the team was solve the problem of studying the place with his historical architectures in order to arrive, with perfect consciousness, to the project of restoration.

Project team members are: *n!studio*, Mu Xingyn e Li Jinwen (Chinese consultants), Marcello Minuti - Struttura Consulting, Alessandro Leon - CLES srl (economists), Maria Luisa Giorgi (Chinese art consultant), Alessandro Pergoli Campanelli (conservation consultant), Engram – FAENZA (pictures). International design competition was published on September 2011 from Nanjing Municipal Culture and Broadcasting Administration, Nanjing Municipal Cultural Investment Holding Group, Nanjing Daming Cultural Industry Co. Ltd. The master plan of Nanjing heritage park covers three different aspects: urban and landscape restoration, museum design and reconstruction of the lost volumes, conservation of the ancient pre-existences.

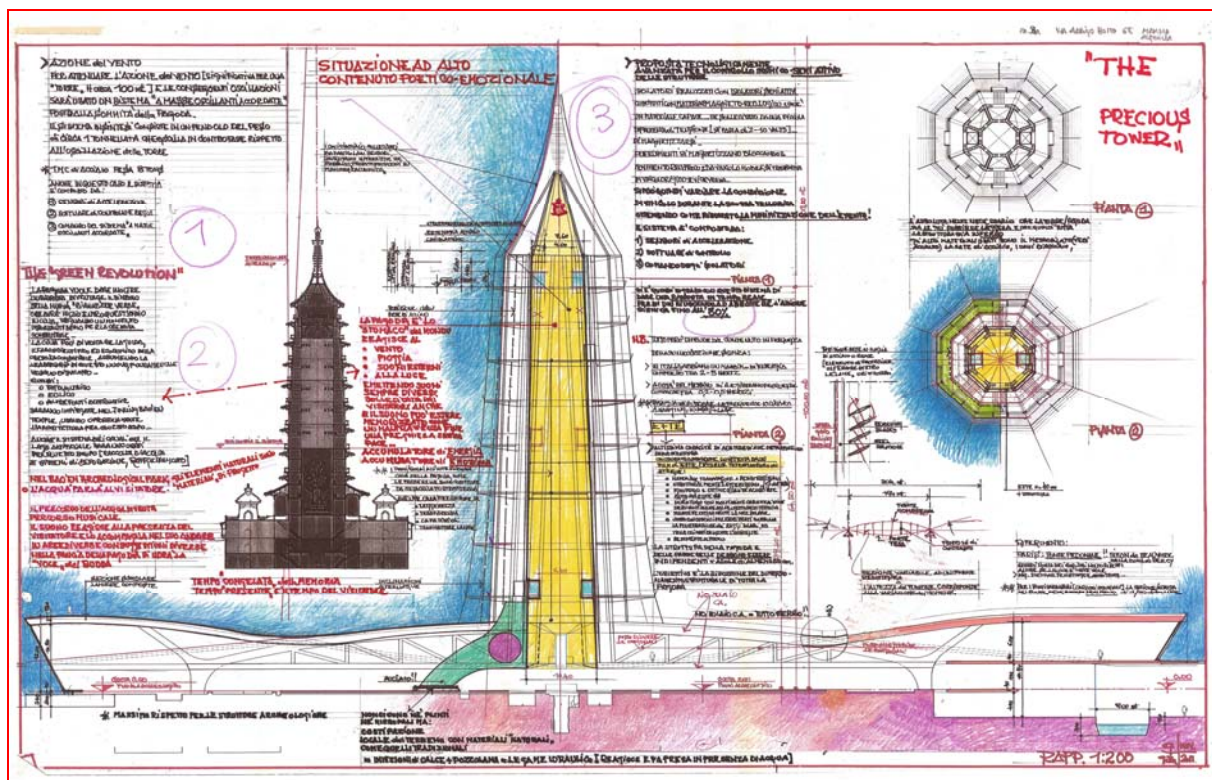

Fig. 1: Preliminary sketch of the new tower.

2.2 The methodical approach to conservation and restoration

The approach to historical and cultural heritage and the enhancement of historical centres, has been increasingly consolidating in Europe since 1964 when the *Venice Charter* was approved. It was to conclude a long and winding process that lasted a century and a half, which had finally asserted a more culturally advanced and functional attitude based on a 'critical' rather than dogmatic and

ideological approach. In this process a key position had been taken since the late nineteenth century by the Italian culture of restoration, which had found its highest expression and coherent development in the "theory of the restoration" set up by Cesare Brandi in the 50's and the consequent activity he performed at the direction of Central Institute of Restoration (ICR).

The *International Charter for the Conservation and Restoration of Monuments and Sites* [8] was introduced in 1964 in Venice (and so called the *Venice Charter*) with the following words: «Imbued with a message from the past, the historic monuments of generations of people remain to the present day as living witnesses of their age-old traditions. People ... regard ancient monuments as a common heritage. ... It is our duty to hand them on in the full richness of their authenticity. ... The concept of a historic monument embraces not only the single architectural work but also the urban or rural setting in which is found the evidence of a particular civilization, a significant development or a historic event».

It is the application of Italian consolidated methodology to the analysis and conservation of historical heritage. Cesare Brandi wrote that «restoration constitutes the methodological moment of the recognition of the work of art in its physical consistency and in the two-fold aesthetic-historical polarity, in view of its transmission to the future»[9]. Restoration works are not fully reversible, so every mistakes made during interventions may cause further damage, consequently putting at risk the entire project. It is necessary, therefore, to carry out conservation work step-by-step, according to an established process where each criteria is a step that, if correctly implemented, becomes the starting point for the next one.

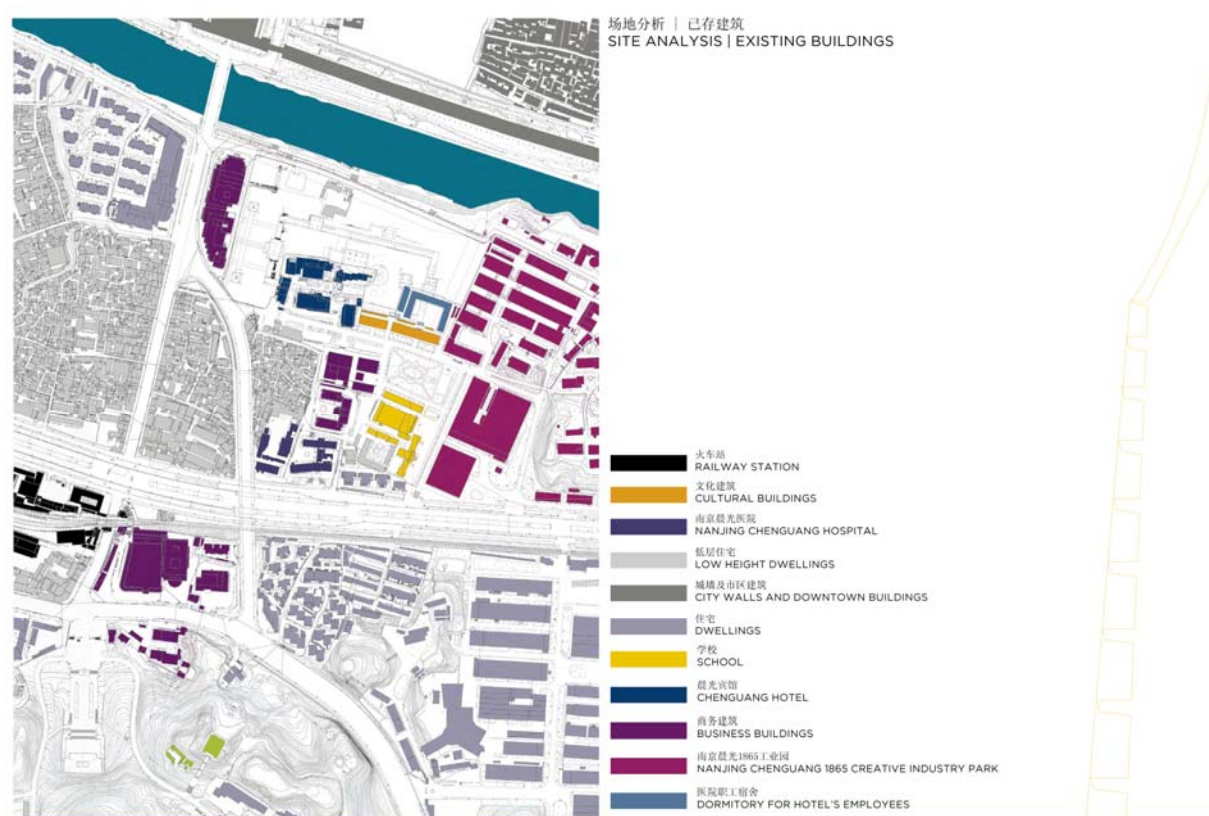

Fig. 2: Site analysis.

2.3 The principle criteria

According to Italian methodical approach were specified the most important theoretical precepts useful for correct design aimed at conservation and usage renewal. It is worth recalling the following points of the fundamental criteria of methodology in the field of protection and restoration of cultural heritage:

1) Conservation. First aim is the best possible transmission to the future of a historical-artistic heritage that is by definition unique and unrepeatable (the functional issues and other practical problems are the means and not the end of the intervention); everything should be based first of all on justifications of a cultural and conservational character, with all other considerations remaining secondary.

2) Minimum intervention. From this criterion follows a design work that maximize the efficacy and minimize the weight of each intervention. 3) Authenticity. The universal value of historical heritage depends on its authenticity. The restoration, as it regards authentic historical heritage, must be connected to the philology and critical analysis of the textual evidence; therefore any temptation of falsification involving imitation of styles must be avoided, in the awareness that we are not operating

with historical certainties, but at best on the basis of valid critical hypotheses. 4) Distinguishability: any additions should clearly demonstrate their modern character, with their own contemporary expressive efficacy, so that the new and the old will remain such, without any risk of introduction of counterfeit parts. The reconstruction of original parts or reinsertion of architectural and decorative elements should be visibly distinguished from the original parts. A reintegration is allowed under specific conditions, if it can be achieved without committing an artistic or historic fake. 5) Reversibility of any new intervention. 6) Compatibility (physical, chemical and aesthetic) of the restoration. 7) Adaptability of the new buildings to the progress of archaeological excavations. 8) Maintenance program.

The aim was to restore the monument to its history and to the city, making it comprehensible and usable, increasing knowledge of the place and intervening in its internal and external conformation and presentation. This is to be accomplished through careful restoration and also a rethinking of the spaces, the levels and the accesses. Particular care should go into questions of the overarching plan for development of the site, (i. e. avoiding architectural barriers) to permit a full and safe utilization of the monument, and also a plan of relations and modes of connection of the monument with the surrounding edification, and with the urban and archaeological context. In conclusion, the definition of a project of restoration of the monument that reflect its different functions today (as an archaeological site, a place of worship, a museum and an urban centre) that bring out the historical-artistic and landscape setting in which it is inserted and that identify paths of access and visiting that are consistent with the historical values of the site.

2.4 The restoration project

The project concerns a wide area of the city devastated in modern times (Fig. 2). The large archaeology parterre is planned in a context that proposes volumes alike with those monumental buildings whose the remains were part of. In November 2008, archaeologists unearthed a little pagoda in the site of Dabaoen Temple; a stupa-shaped casket, which is believed to be one of the 84-thousand stupas of King Asoka that contain relics of Sakyamuni (according to legend, it is a pearl-like Shells from the cremated ashes founded when Supreme Buddha Sakyamuni died two and a half thousand years ago). That's why the most significant element of the project is a modern pagoda, (Fig. 1, about 100 mt. high, it's the visual centre of the complex) where exhibit the relics, which symbolically represents the new foundation of the site.

Fig. 3: Aerial view of the project from north.

There is also a theoretical coherence between the restoration project on the ancient parts (conservation and re-integrations of lacunae) and at the landscape level (re-integrations of volumes), proposed with two different technologies: one for protective structures of ancient parts (in glass) and other volumes reconstructions (traditional, in accordance with more ancient phase, philological known and documented).

The archaeological area (Fig. 4) includes remains of buildings of different materials, from stone to clay. The first step of the project was to characterize the ancient materials employed, adding all the necessary analysis to help understand their current performances. The results of this analysis will allow to draw a detailed plan with no harm to the ancient remains, the methods of their use and functions within the planned archaeological park. It is expected that the stone structures can still bear a controlled walking, while the clay must be protected against atmospheric agents and can withstand only carefully calculated loads. Stone structures need a continuous maintenance, also in order to avoid the roots of vegetation between the joints. Temperature may cause cracks, which can be compensated and stabilized with appropriate consolidation works. Greater attention should be paid to the stone used in ancient structures for water supply: as a matter of fact, the effect of consumption of water and the growth of mosses and similar is well known. Clay structures in general must be protected against atmospheric agents through a comprehensive and careful study aimed at improving the flow of rainwater and avoiding the stagnation of ground water.

A methodological approach to the restoration is primarily concerned with three aspects: the so-called "urban landscape" restoration, the true restoration of the ancient pre-existing and, finally, the - the reconstruction and musealization of ancient destroyed assets. This is only a preparatory division to a better description of the project, since each different theme is closely dependent on the others and never entirely separable; during the development of the project, in fact, thanks to the interdisciplinary composition of the team, all the different aspects are been evaluated and resolved at the same time always in search of a full harmony between the various requirements (composition, exhibits, plant, structural, etc..) keeping clear the primary purpose of conservation.

Fig. 4: Archaeological site analysis.

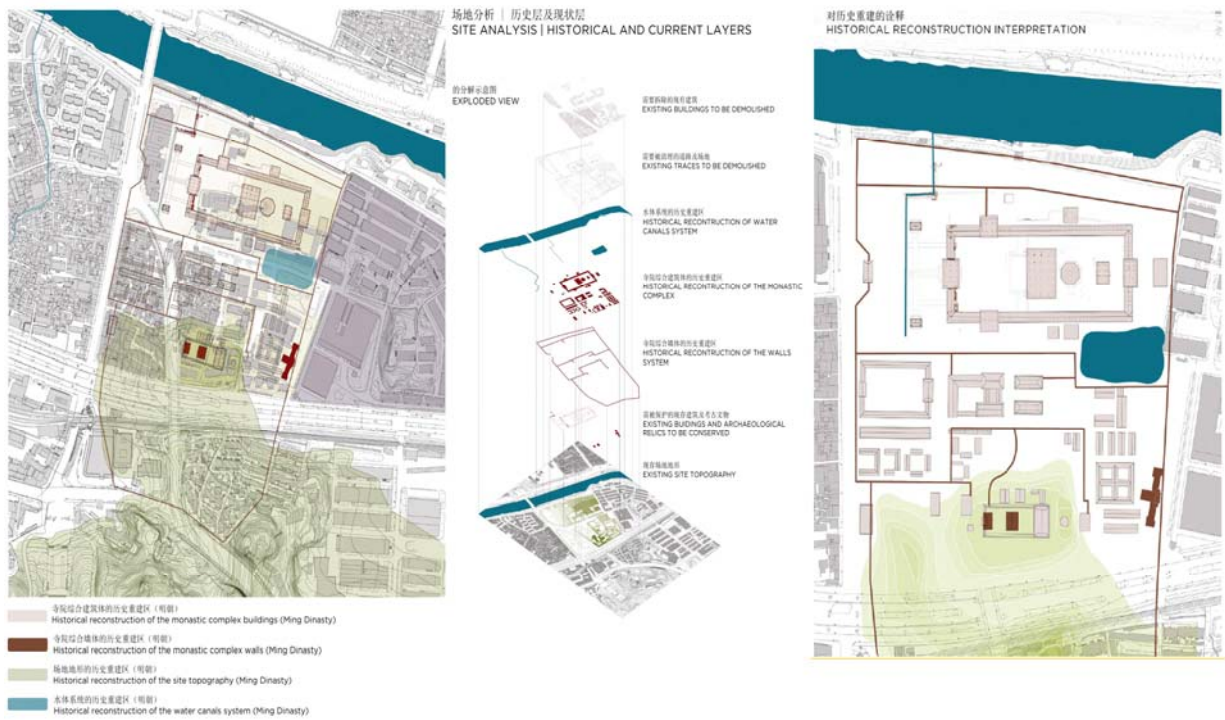

Fig. 5: Site historical analysis and interpretation.

The final result (Fig. 3) is, therefore, a whole organic and not a simple summation of several project parts that, only for greater synthesis and clarity, are hereby described separately. As for the urban and landscape aspects of the restoration, the overall theme requires the accommodation of a large urban area, with particular attention to the adjacent pre-existing historical context. The project aims to redevelop the historical context of the site, extensively damaged by modern interventions. The ancient monument, in fact, is now deprived of its dignity, identity and symbolic value that should be at least partially evoked. The most relevant aspect of the project is the rediscovery of the archaeological site unearthed after those modern buildings have been demolished (Fig. 6).

Fig. 6: Archaeological site master plan.

This set of archaeological remains, in order to be fully understood, needs to be included in a spatial context, which redefines new buildings consistent with those same monumental buildings that were part of these remains (Fig. 5). From this the choice to redefine the urban landscape of the site, recreating the lost axial system along with the progression of green spaces that comes from the hill up to the system of waterways (canals). The main sacred area, in fact, was located into a structure included between the protection of the mountain and the flowing water of the canals. The hill system - now illegible - is then repeated in the buildings of the south area, with their green roof echoing its memory. Moreover the project aims at restoring the original continuity of the hill interrupted by the great road structure and restoring the pedestrian link with the summit. The most significant element of the complex is spatially represented by the reconstruction of the great pagoda, with its height of 100 meters recalls the old image of spatiality, restoring the visual centre of the complex. Its structural characteristics, and spatial composition are the result of complex design choices guided by precise restoration. First of all the attention to the sense of the place. A careful study aimed to recognize the historical and cultural characteristics that distinguish the site in a symbolic, typological, morphological, construction, environmental and urban sense has led to the choice to reproduce the shape and the size of the best known phase of the pagoda among the various one historically documented. In doing so two instances, apparently conflicting with each other, the more strictly archaeological on one hand, (related to scientific investigation and restoration of existing buildings) and architectural on the other (the identification and qualification of the modern urban space) are solved together in a single gesture that is modern and, at the same time, evocative of ancient spaces. Throughout the site a modern element of connection and continuity typical of these places (water) has been designed with the double purpose of keeping the memory in its path of the lost lines of ancient boundary walls and at the same time, re-inserting into the landscape the water element that was originally present close to the monumental complex. The rationalization of the access system will also allow the connection to the rest of the city and, in particular, with the close system of industrial archaeology, thus recreating a layered fabric of the city placed inside a large, modern complex of museums. With particular regard, however, to the aspects of the restoration of the existing buildings, the guidelines suggest, first, to act in full respect of the preserved assets operating minimal actions that are aesthetically, physically and chemically compatible with the ancient materials. Each new addition has also been designed to be reversible, so as to ensure the least possible invasiveness and the possibility of future changes or corrections without damaging the old parts. The structures for the protection of archaeological remains present themselves as modern and 'smart' glass volumes that ensure optimal environmental parameters. The choice of a transparent material, as well as to qualify unequivocally as a modern intervention is motivated by the desire to render to the visitors the charm of the open excavation.

Fig. 7: The new pagoda and the exhibition area with the ancient pagoda of King Asoka (273 BC - 236 BC) that It is believed to contain Sakyamuni's sarira relics, highly sacred for Buddhists.

The size and the profiles of these structures, however, reproduce those of historic architecture to allow easy understanding of the old functions of the unearthed relics through their inclusion within a space which is evocative of the original. To facilitate this understanding in the new structures there is a wide exposition of the results of the studies on the monument and an equally copious documentation of the stages of restoration. It is important to recall, however, the principle of distinctiveness of the new integrations, that is present in both large and small scale: one of the strengths of the project is, in fact, the theoretical consistency between the detail on the intervention on old parts (reinstatement of gaps) and volumetric one at the urban scale (re-integration of the image). The principles adopted refer to the substantial unity of method and, therefore, there is a similar distinguishability of the modern restoration, whether it is directed to individual stones of the monument or to the revival of the lost volumes. Two different reconstructive procedures have been adopted, one for those structures that cover the remaining parts (glass) and one for those structures that have nothing to hide beneath them. In the latter case, these new museum buildings (for educational purposes only) are not meant for the protection of relics, and the design choices deliberately preferred to reconstruct the lost volumes in the traditional manner, in accordance with more ancient, better known and philologically documented phase of the complex. This restoration has purely didactic and educational scientific purposed, through careful research of materials similar to the original ones. There will be two clearly distinguishable parts of the same building, though spatially identical: one made according to traditional materials and methods and another one made with contemporary materials and forms that covers the ancient relics. The continuity between the two parts is guaranteed by the glass closure of the 'traditional' building that recreate, seen from afar, a single continuous surface with the 'modern' part (the one that protects of the archaeological excavation); moreover, the use of glass ensures a comfortable interior space management for museum exhibition even for those parts made according to traditional techniques.

Fig. 8: Night view of the exhibition area.

The distribution of interior space aims to ensure the best visibility and accessibility of archaeological excavation, even during the excavation and restoration phase, and to host a large restoration workshop (maintenance, testing new materials, teaching, etc..). The care of the places will be ensured by the choice of locating appropriate functions inside the museum buildings out of the archaeological area: as a matter of fact a wide range of exhibition space will be located south of the site for any new acquisitions, exhibitions, libraries, media etc. The core of the complex is represented now, as it was in ancient times, by the reconstruction of the main vertical element, the pagoda, reinterpreted in the new project starting from the historical record of previous phases of the monument. The principle of restoration of the new intervention is resolved with clear contemporary aesthetic choices, as evidenced by the use of materials in some cases even futuristic. Modern tools and technologies are always used with the ultimate goal of protecting and preserving the ancient site.

Fig. 9: View of the project with the great pagoda on the right.

The use of highly advanced technologies, in fact, allows the pagoda (Fig. 9), despite its height, to have its structural supports outside the ancient perimeter, without foundations that may damage the archaeological relics.

Particular attention is posed in the recall, through contemporary choices (with a resonant steel cable system) the sounds that were originally produced by the vibration of the wind around the pagoda bells. Likewise, the possibility to illuminate the pagoda at night will recall the main role of the ancient tower as urban element of recognition.

The most important treasure of the site will be located, once again, in the hollow space of the new pagoda, suspended above the pit of the foundation (Fig. 7-8) from which it has been recently extracted. Besides being fully visible and accessible the relics will symbolically represent the sign of the new foundation of the site.

Abstract:

Tourists are now seeking alternative forms of experiencing cultural authenticity by redirecting the “tourist experience” at a slower pace in rural communities. Slow food tourism provides an opportunity for tourists to gain knowledge of the local culture from a “bottoms up” mind frame of experiencing food of a community. However, slow food tourism is a significant strategy for community empowerment to preserve regional cultural identity and local products that would otherwise not be experienced by tourists. This inquiry examines Ciociarian cuisine as practiced by the peoples of Sant’Elia, Fiumerapido, in the province of Frosinone, Italy. Ciociaria is derived from the Italian word *ciocie* meaning “primitive lace up boot” that local shepherders once wore indicating this cuisine is framed in humbleness and simplicity by honoring the products of the region. This paper addresses how Sant’Elia’s are empowered by communicating their regional identity while preserving Ciociarian cuisine through slow food tourism objectives: (1) Economic sustainability and collective empowerment through tourist entrepreneurship, creation of employment, and establish business networks to draw in tourists to Sant’Elia and other Ciociarian cuisine regions; (2) Distinction of local commodities, revive community pride as Sant’Elia’s; and (3) Inscribe as well as safeguard the preservation of Sant’Elia Ciociarian cuisine as an intangible and tangible cultural heritage.

Keywords: slow food tourism, identity, cultural heritage, empowerment, entrepreneurship

1. Communicating Identity, Authenticity and Preserving Cultural Heritage Through Slow Food Tourism:

According to the website, *Create the Good Life*,

“The ‘Slow Food Movement’ is a term describing a wide range of efforts taking place around the world that seek to connect us more meaningfully with others, with place, and with ourselves. It emerged as an effort to counteract the fast-paced, commodity-focused unbalanced, and impersonal nature of much of modern human culture. The main tenet of the Slow Food Movement is that by taking the appropriate amount of time to experience the various activities of our lives, we are able to get in touch with what is deeply satisfying and fulfilling.”

The “Slow Food” movement was born in 1986 when Carlo Petrini protested against “fast food” in Italy when McDonalds’ opened its first store at the Spanish Steps (Square). Petrini established the “Slow Food” movement to promote the use of fresh local foods, grown with sustainable farming methods, prepared love, and consumed in a leisurely manner in the company (conviviality) of good friends and family. For Petrini and others, food was just one more aspect of life that benefitted from this type of “slow cultivation.” The Slow Food movement is also a philosophy and way of life that can be applied to daily activities and all aspects of life to travel on a road less traveled or what is also known as “Slow living” (Petrini, 1986). The Slow Movement is not about moving slowly but a practice to focus on quality, long term benefits and well being in our daily lives and how we connect more thoughtfully with nature and human kind. The Slow Food movement has a social conscience, a love of delicious food through political activism by protesting against globalization and the spread of Genetically Modified Organisms or GMO’s. Petrini and Slow Food efforts are also opposed to the homogenization of food around the world and are determined to assist the small producers from becoming extinct and to stimulate, revive and celebrate flavors and localism via national associations, charters and conviviums. Slow Food movement is comprised of a network of collaborators to promote and preserve traditional sustainable local food and regional cuisine, and encourage the farming of plants, seeds, and livestock characteristic of the local market.

In response to tourist marketing, economy and society in the Mediterranean area, tourism can no longer be viewed as a leisure activity of only promoting and experiencing popular urban cities. Tourists are now seeking alternative forms of experiencing cultural authenticity by forgoing urban settings and redirecting the tourist experience at a slower pace especially in rural communities. Slow food tourism aims at the “unhurried experience” by providing an opportunity for tourists to gain knowledge and experience the local culture at a slower pace from a “bottoms up” mind frame of experiencing food of a community. However, slow food tourism is a significant strategy and serves in other capacities especially for local empowerment to encourage, reify and preserve regional cultural identity. In addition, slow food tourism supports the commodification of local products and service that would otherwise not be brought to the global forefront for tourists to experience and serve as markers of cultural heritage. According to Timothy and Ron (2013), the end result is the production of culinary food service and food products that is a mixture of tangible (local products) and intangible (eating traditions, smells, recipes, etc...) assets that frame a regional cuisine and is preserved as a cultural heritage as well as celebrated as a heritage food. Van Esterik (2006) adds, “Heritage foods become the commodities through which national and regional traditions are identified and preserved.”

The cuisine of a region also communicates, authenticates and preserves cultural identity. Food is a temporal tangible and intangible product that links the past (what is preserved), present (what is currently celebrated) and to some degree the future (what may be perpetuated) and like cultural narratives or stories, recipes are passed on from generation to generation. Ethnic foods establish or reinforce, (temporal, physical and mental) by sight and smell from direct experience with regional gastronomy to further support and preserve indigenous identity (Timothy & Ron,

2013; p. 101). Even immigrants who have been displaced or moved from their homelands are temporally linked back to memories of home at the trigger of sight and smell of their native foods (Bhaba, 1994; Alonson & Krasjic, 2013); thus, authenticating their cultural identities wherever they are. Cuisine authenticity can be a contentious space of power of who gets to claim “authenticity” of regional foods and what is considered as legitimate cultural cuisine continues to be debated. However, Presenza and Del Chiappa (2013) in their studies of Italian cuisine in Sardinia and Molise do provide insight that local foods mean more than “authenticating” the regional gastronomy but is also a strategy to create community cohesiveness and can revive cultural pride of the local peoples to be active in preserving their cultural heritage (Timothy & Ron, 2013).

2. Ciociarian Cuisine:

Ciociaria is a culinary region in central Italy, south of Rome, north of Naples, between the Tyrrhenian coast and the mountain of Abruzzo. The cuisine of Ciociaria is grounded in the rural, slow, bucolic life of the shepherd and praised for its simplicity and authenticity as well as for the importance it attaches to friendship, conviviality, and to the family. Ciociaria has a long culinary history, as the area was once the breadbasket of the Roman Republic and Roman Empire until the 4th Century. The name Ciociaria was imposed on this area much later, and is derived from the Italian word *ciocie* meaning “primitive lace up boot” that the local shepherders once wore. It indicates that this cuisine is framed in humbleness and simplicity. Ciociarian cuisine honors the products of the earth and local vegetable specialties such as sweet red peppers known as the Sant’Elia beefsteak because they are so meaty and *broccoletti* a type of broccoli particular to Sant’Elia and cannellini beans from nearby Atina as according to *Food and Travel* (2013), “that in the final state of culinary presentation are rarely mixed with one another and are devoid of being smothered by fancy sauces.” The article also adds there is an explanation that continuity and tradition are all-important in this Ciociarian region, which may be why the food, while simple, tastes so delicious because there are no fanciful sauces but the mixture of pure ingredients such olive oil, spices, local cheeses, vegetables, fruit, and meat. ‘It’s all about the earth’ says Salvatore Tassa, chef of Michelin starred *Le Colline Ciociare* (2013) as he adds, “This is such a poor region that we make the most of all the ingredients we have. Everything tastes so good because of the soil in which our produce grows and because of what we feed our animals”.

The Ciociaria culinary region encompasses not only Sant’Elia Fiurmerapido but other towns such as, Cassino, Aquino, Alvito, Frosinone, and other more touristic sophisticated towns like Atina and Picinisco in the Val di Comino who have a large population of returning immigrants that bring with them business ideas that they learned abroad (pp.1-2). One example is entrepreneur Cesidio de Ciacca who had great success in Scotland and has now returned to his home town of Picinisco to invest by buying up separate but adjoining structures in the historical center of Picinisco. He has transformed these luxurious 5-star town homes into a hotel under the name *Sotto le Stelle* meaning “under the stars.” To lure and attract guests to the region, Di Ciacca created an effective network of Slow Food--Slow Travel businesses that include the nearby winery *Cominium* that adheres to the Slow Wine philosophy. The network includes hotel arranging Spa services, tours to nearby points of interest, cooking classes with master chefs and local cooks of the region. In addition, *Sotto le Stelle* can arrange wine and marzolino cheese tasting at Casa di D.H. Lawrence, a restored farmhouse that belongs to the Sora Slow Food Presidia convivio chapter. As a result, Di Ciacca has benefitted from Slow Food tourism support and collaboration from like-minded businesses by creating a gastronomy cluster for easier branding and marketing of the Ciociarian region.

2.1 Sant'Elia, Ciociarian Cuisine and Slow Food Movement Tourism:

Sant'Elia Fiurmerapido is part of the Ciociarian region and has a long history of food production as it was once part of the breadbasket of the Roman Republic and Roman Empire that produced wine, olive oil, wheat, and a variety of fruits and vegetables. Even the Sant'Elia *Rapido* river was once named *Vinius* during the early Roman times because of the abundance of wine that was produced from the vineyards in this fertile area of the Roman countryside. In the early 1800's Sant'Elia's river produced electricity (the first Italian town to have it) which gave rise to flour mills, olive mills, a Merino wool factory, and a paper mill which supplied the scriptorium to the Abbey of Montecassino. During the Unification of Italy in 1870, Sant'Elia's industries were transferred to the North and the town suffered a major economic set back. However, increased economic devastation continued with World War II as Sant'Elia was 93% destroyed during the bombing of the Abbey of Montecassino. This economic devastation created an outmigration since there was minimal source of employment after the war. Sant'Elia is continuing to experience massive outmigration due to the more than 40% unemployment in the town, especially among young Sant'Elians. The result of high unemployment in Sant'Elia has had a systemic effect of deflated pride and lack of communal involvement by the town locals. The *mordi e fuggi* or "eat and run" tourists that visit nearby Montecassino is only a few kilometers from Sant'Elia but unfortunately, Sant'Elia has been not provided tourist benefits. However, Slow Food Tourism offers a glimmer of hope to arrest the outmigration, preserve the local culinary and cultural traditions, and save the surrounding mountains that are covered with olive trees from being destroyed by sand excavators.

In the footsteps of Picinisco's Slow Tourism entrepreneur, Cesidio de Ciacca, Sant'Elia born Liza Salvatore, has created her California based *TerraBella Travel Services* primarily to help her revitalize Sant'Elia. She has been operating her Slow Food style of tourism in Sant'Elia for five years by bringing groups of people for week-long cultural programs that include cooking classes with chefs from the nearby culinary institute as well as lessons from local cooks. In addition, her cultural programs include a half-day of olive harvesting, then a visit to an olive mill to see how Sant'Elia's prized extra virgin olive oil is made. The olive harvest and olive mill visit is followed by olive oil tastings and a cooking class. Dinner is always served with local wines such as *Cominium* winery's special white wine or Atina's award-winning Cabernet Sauvignon as well as *Tullio* Winery's rose which is currently having a resurgence in the area. *TerraBella* tours also includes guided visits to the historically important Abbey of Montecassino where the Gregorian Chant and the Italian language began, manuscript illumination and Benedictine art was created, as well as a train ride to Rome for an all-day historical tour. More importantly, participants in *TerraBella's* week-long programs immerse themselves into the local culture by cooking and dining with the locals who proudly share their tradition and history, in a convivial setting around the table, as the program participants contribute much needed tourist dollars to local cafe's, trattorias, pizzerias, country Relais, and local transportation providers. Liza Salvatore's program provides an authentic and unique mutually beneficial cultural exchange to the visitor who works side by side with Sant'Ellian locals who proudly transmit their history, cuisine, and culture to the visitors, thus preserving it and disseminating Sant'Elia Ciociarian cuisine for future generations.

2.2 The Politics of Sant'Elia Ciociarian Cuisine Slow Food Tourism:

Sant'Elia Slow Food tourism operator Liza Salvatore of *TerraBella Travel Services* sees Slow Food travel as a way to save Sant'Elia's culture by creating jobs and provide entrepreneurial opportunities for Sant'Elia. Salvatore believes Slow Food Tourism is one way to stop the decline of Sant'Elia but there needs to be local administrative support as she had to start from

scratch to create *TerraBella Travel Services* without the assistance of those in charge of tourism on the local, provincial, and regional level. In her five year involvement, she has had to establish a business network by initiating several alliances such as creating a Sister City agreement between Sant'Elia, Italy and Santa Monica, California. In order to reignite and revive the pride of local Sant'Elians, Salvatore has donated prize money for local flower competitions for beautification as she has also donated a monumental welcome panel at the entrance to the town to spark tourist interest. These initiatives have endeared her to the townspeople, but she has received very little support from the regional, provincial, and communal tourism "ministers", who have not in any way assisted her in finding service providers for her programs, such as cooks, wineries, farmhouse and Relais hotels, and local transportation. Salvatore has also encountered a little enthusiasm from a few locals, but a lot of skepticism from most of the 6,400 Sant'Elia inhabitants. At the moment, Sant'Elians are very cynical that the local administration will change its policy toward allowing sand extractors to continue mining for sand in their mountains and excavating historic olive trees, since the mayor has a personal interest in continuing that activity rather than supporting tourism. For example, in Sant'Elia, the minister of tourism, Gian Carlo Vacca was also in charge of small businesses and was asked by Liza Salvatore of *TerraBella Travel* to collaborate in developing and promoting Slow Food Tourism in Sant'Elia. This type of collaboration would bring small tourist groups to Sant'Elia to engage in week long tourism programs and support the local economy by staying in local hotels, eat in the local restaurants, as well as use local transportation businesses. However, Vacca's reply to Salvatore (2013) was that he would rather collaborate on initiatives that help other small businesses as he did not consider Slow Food Tourism as a reputable type of business that could encourage local; especially, young entrepreneurs to enter the tourism niche in Sant'Elia. For Salvatore, this was an opportunity to lower high unemployment, while preserving Sant'Elia Ciociarian cuisine, cultural traditions, and save the local mountains from the uprooting of hundred year old standing olive trees in lieu of sand excavation. Sant'Elia residents are now at the crossroads and must now act if they want to vote out the leaders who have ruled for decades in order to preserve their culture, their mountains, and their culinary-cultural traditions, or allow sand extractors to turn Sant'Elia into a quarry. For many Sant'Elians; especially, for Salvatore, the two activities cannot co-exist without severe impact on the peoples and environment of Sant'Elia Fiurmerapido.

Additional politics of the Ciociarian Slow Food Tourism in Sant'Elia include "institutional traps" (Rizza, 2013) which are powerful obstacles created by specific groups of people belonging to socio-cultural institutions within society preventing further economic development. Often local officials (LO's) establish perverse intersections that result in unequal transactional exchanges occurring among local politicians, central governments, state enterprises and elite townspeople. For these specific groups, there is no compulsion or feelings for any incentive to change the *status quo* because of supporting their own agendas that are only beneficial to exclusive individuals. Bargains are implemented between and among elite groups to support the *status quo* even if this would mean additional jobs would be created for economic growth in Sant'Elia. Over time, such bargains are molded and establish an underground scheme that reinforces the distribution of resources and local elite power to continue to stay at the top in support of the *status quo* and not embrace any change. This could be exemplified in the case of exchange through "voting blocks" during general elections that create "Double-Binds" for many Sant'Elia who wish to establish any tourism business in Sant'Elia. In order for local townspeople or local businesses to conduct *any* type of business or business survival, Sant'Elians are often forced into compliance to support inequitable bargains. Regardless, *all* participants either local politicians, government officials, state enterprises and elite and local townspeople "fall into these institutional traps" resulting in a vicious circle of severe underdevelopment that will have a socio-economic impact on Sant'Elia.

3. Future of Sant'Elia Ciociarian Cuisine Slow Food Tourism:

The future of Sant'Elia Ciociarian cuisine through Slow Food tourism is promising but there is much need for infrastructural support and organizing. Currently, there are not many slow food networks, national associations, charters and conviviums in the Ciociarian region. There are some emerging "slow" tourism areas such as Atina and the Val di Comino but they are not using the "Slow Food" name; although, they practice a similar philosophy, which raises the question is it an advantage to use the Slow Food name and logo to attract Slow food travelers to Sant'Elia and the Ciociarian region or is it enough to simply adhere to the slow philosophy and forego the rest? It appears that the vast network of Slow Food tourism with convivio chapters could be very helpful to Sant'Elia and the Ciociarian region in creating gastronomic clusters and branding which could aid in developing a more thriving Slow Food and Slow Travel industry. Thus, ensure success to Slow Food entrepreneurs such as Sant'Elia Liza Salvatore and Piconisco's Cesidio de Ciacca. Interested upcoming Sant'Elia Ciociarian Slow Food Tourism entrepreneurs and practicing operators need to create an association of joining the European Slow Food Tourism network that already has over 100,000 members worldwide and who are all part of local chapters or conviviums that organize events and activities in practicing the Slow Food philosophy in their respected communities. Slow Food Tourism networks would be an active strategy for the promotion of Sant'Elia Ciociarian cuisine through the communal organization of wine and olive oil tastings or convivial activities such as group meals, beginner wine courses, and educational lectures. However, no convivium exist in Sant'Elia Fiumerapido nor are there any food fairs or collaborations between local restaurant chefs and food growers. Entrepreneurial marketing has to be done individually and without any governmental support. Perhaps the greatest challenge and obstacle to Slow Food Tourism in Sant'Elia Fiumerapido and for most of the Ciociarian region is the absence of vertical and horizontal integration from local, provincial, and regional tourism boards indicating the lack of ground support to "would-be" Slow Food entrepreneurs. Liza Salvatore of *TerraBella Travel* has experienced the lack of support as she reached out to the Lazio Region assessore (minister) of tourism for assistance in promoting Slow Tourism in Sant'Elia Fiumerapido but was confronted with the reply "...but why do you need to reinvent the wheel? Why go to Sant'Elia and have to create interest in something new when Rome has so much history, and great restaurants to offer tourists. My home town of Arezzo has beautiful mosaic art. I can be a great help there [Arezzo]" meaning that Sant'Elia had nothing to offer to tourists in the realm of experiencing Italian culture.

Due to the lack of local and regional governmental assistance, Sant'Elia Ciociarian cuisine Slow Food tourism would benefit greatly from joining Slow Food Tourism networks or establishing a convivio in Sant'Elia Fiumerapido. For example, the Bra Gourmet Association in Italy is also part of the Barolo & Friends network that aims at exploiting wine culture and specific territorial wines through special events. In just three years, membership grew from 3,000 members to 8,000 as their mission was to promote tourism and to distribute wines and other products. As a result, a local restaurant in Bra, *Osteria del Boccondivino* was opened and with *Slow Food's* publication of *Osterie D'Italia: A Guide to Traditional Places to Eat and Stay in Italy* (2007) has helped revolutionize restaurants by introducing concepts like "regional food, tradition, simplicity, hospitality, and reasonable prices." According to Van Der Meulen (2008), such actions resulted in the survival of hundreds of small, traditional restaurants and their suppliers. Founder of Slow Food Tourism Carlo Petrini states, "We want to defend the richness in agricultural food products against the deterioration of the environment, protect consumers, and high-quality products, stimulate research and promote gastronomic pleasure of eating together" (Petrini, 2001; Van Der Meulen, 2008). Therefore, it is imperative for Sant'Elia to reach out and make these connections by joining various networks in order for Ciociarian Slow Food Tourism to work.

Although, Slow Food Tourism could offer an opportunity to arrest Sant'Elia's decline and even offer a rebirth of its traditions and culture but Slow Food convivia are too few in the area. In addition, the Sant'Elia mentality is skeptical from that of adherents of the Slow Food philosophy which many accuse as being too elitist (Van Der Meulen, 2008). Critics say the Slow Food movement demonstrates its elitism by stating that it wants to protect itself by being available to only a select group of tourists rather than the masses (pp. 234-235). Whereas, many local Sant'Elia may claim that "Slow Food" will add to the burden of the average Sant'Elia because unlike Slow Food tourists who are more affluent and have the time and money for developing 'taste', 'knowledge' and 'discernment', the average Sant'Elia is just struggling to survive in order fulfill basic daily needs. Therefore, Sant'Elia Ciociarian cuisine Slow Food tourism maybe viewed as a pipe dream rather than a tangible asset to support entrepreneurship and as a significant strategy for community empowerment to alleviate economic poverty, preserve regional Sant'Elia Ciociarian cultural heritage and promote the local products of Sant'Elia.

4. Conclusion:

Tourists are now seeking alternative forms of experiencing cultural authenticity by forgoing urban settings and redirecting the tourist experience at a slower pace especially in rural communities. Slow food tourism aims at the "unhurried experience" by providing an opportunity for tourists to gain knowledge and experience the local culture at a slower pace from a "bottoms up" mind frame of experiencing food of a community. However, slow food tourism is a significant strategy and serves in other capacities especially for local empowerment to encourage, reify and preserve regional cultural identity. In addition, slow food tourism supports the commodification of local products that would otherwise not be brought to the global forefront for tourists to experience and enjoy. This inquiry examines Ciociarian cuisine as practiced by the peoples of Sant'Elia, Fiumerapido, in the province of Frosinone, Italy. Ciociaria is derived from the Italian word *ciocie* meaning "primitive lace up boot" that the local sheepherders once wore indicate this cuisine is framed in humbleness and simplicity by honoring the products of the region through simple preparation and presentation. This paper addressed how Sant'Elia's have an empowering incentive to communicate regional identity while preserving Ciociarian cuisine through slow food tourism objectives of economic sustainability and collective empowerment through tourist entrepreneurship, creation of employment, and establish business networks to draw in tourists to Sant'Elia and other Ciociarian cuisine regions. In addition, Sant'Elia Ciociarian Slow Food Tourism can also showcase and distinguish local commodities, revive community pride as Sant'Elia; and inscribe as well as safeguard the preservation of Sant'Elia Ciociarian cuisine as an both a tangible and intangible cultural heritage.

Abstract:

The attribution of cultural heritage is one thing, but the management of it is quite another. Governments around the world are attempting either surreptitiously or in broad daylight to extricate themselves from the burden of heritage management. Cultural built heritage management is regarded as costly involving too much red and green tape. Private owners, politicians and developers take a dim view of the heritage profession and have come to regard it as both arcane and unpredictable. There is very little consistency in management style. Some local municipalities do it one way but the neighbouring municipality will do it completely differently. Managing cultural built heritage is expensive because it is highly detailed and draws upon professional skills to do it right. Against this backdrop, the paper that I will present will show how heritage management can become self-funding and beneficial to both owners and municipalities. Its attention is focused upon incentivising and reward mechanisms and greater participation and profitability for private owners.

Keywords: heritage incentives; tax credits; urban regeneration; conservation; preservation.

1. Introduction

This paper addresses the complexity of relationships that exist in heritage management today. Various actors and agencies at various levels of government, community and private enterprise come together to effect urban regeneration projects all over the world today. Successful urban regeneration projects are premised on a healthy mix of projects, professionals, bureaucrats, businesses, owners, developers and incentives. It is the last of these – ‘incentives’ that constitutes the focus of this paper. Against a backdrop of urban regeneration, three incentive schemes are discussed. These are the ‘Belvedere Memorandum’ in the Netherlands; the English Heritage Lottery Fund and; rehabilitation tax credit scheme in the USA. Each scheme is analysed in terms of mandate, operation and effect and then in the conclusion of the paper, a brief comparison follows.

2. The nature of urban regeneration projects

Common to most urban regeneration projects is the perception that the historic environment is one way of regaining a concentration of people and activity back in the city centre. Local authority expenditure imposed from central government promotes the conservation of the historic environment to boost locally generated income and thus taxes (Madgin, 2010). Different types of funding to lever private investment are used in combination with fast track planning. Single purpose agencies with a financial and administrative mandate are specifically formed to accelerate the pace of regeneration. Governments rely upon market forces by courting private sector investment. Public funding is used to invest in infrastructure and reduce the risk to the private developers. Hence partnerships, often called PPPs, are utilised as a project delivery vehicle.

However, the sensitive treatment of urban regeneration projects is crucial to the urban regeneration project because of the pressures it faces. Such projects contain a unique and irreplaceable heritage of physical fabric and evidence of earlier cultural histories. As the centres of sometimes substantial urban complexes, they are expected to continue to provide for the social, cultural and commercial requirements of present populations, which in turn places a tremendous strain on a fragile environmental structure (Mageean, 1999). The unique quality of their environments makes them attractive to tourists and other visitors. The combination of these roles has to be recognised and addressed in any effective conservation strategy.

The need to achieve continuity between the past and present is still a generally accepted starting point for such projects, but concepts of how this might be achieved on the ground are weak. The problem of defining a clear philosophical framework hinges on the fact that different things and places may be differently valued by different people. Within the context of managing the built heritage in urban regeneration projects, there must be adaptability to change. It remains a problem of balancing interests: social, political, commercial and environmental (Mageean, 1995).

The economic and social composition of cities in the developed world has been profoundly transformed in the past six decades by the processes of globalisation, deindustrialisation and tertiarisation. A key contemporary challenge for city governments and their partners arising from this transition, is balancing an aspiration for economic competitiveness, i.e. promoting a better mix of attributes for business and business success with an imperative to promote social inclusion (Barber & Hall, 2008).

Barber and Hall (2008) explain that a distinctive 'entrepreneurial' model of urban economic development has evolved in urban regeneration projects. They involve investment in service-sector physical infrastructure, promotion of 'creative' industries, 'boosterist' city marketing campaigns, development of up-market housing in the central business district (CBD), hosting internationally-important sporting and leisure-related events and 'themed' neighbourhood regeneration (Smyth 1994, Hall & Hubbard 1998). These interventions are designed to reinvigorate economically urban areas and, thus, contribute to economic competitiveness. They are commonly branded as examples of 'urban renaissance'. Such entrepreneurial strategies are typically conceived, funded and implemented by coalitions of local government and business stakeholders and are characterised by exclusive, corporatist forms of political process (Davies 2001).

Contemporary relationships have developed between the policy spheres of conservation-planning, regeneration and economic development. In so doing, it is argued that conservation has largely repositioned itself successfully from being regarded as a barrier to development to being regarded as an active agent of change. In the process conservation-planning, whilst sharing ancestry and values with other spheres of conservation activity, has become something distinct and different (Pendlebury, 2013).

Pendlebury (2013) explains that today, conservation is seen as a force for continuity balanced against forces for change. It has been presented as an active agent of change in itself. The concept of change has been decoupled from physical change. It no longer tends to be associated with the erasure of existing physical environments and their replacement with new. Increasingly, the discourse embodies necessary change that can be achieved and enhanced by conserving and recycling historic buildings in ways compatible with conservation objectives.

Conservation-planning is considered to be an assemblage that helps us conceptualise the complexity of the social relationships in the sphere of heritage management. It helps draw out the horizontal and shifting power relationships that exist in contestations over the management of places, alongside the hegemonic vertical power relations that also exist (Pendlebury, 2013).

Fig. 1 - Decision Factors by Agent Type—Similarities and Differences in Rhodes, M & Murray J (2007) Collaborative Decision Making in Urban Regeneration: A Complex Adaptive Systems Perspective, *International Public Management Journal*, 10:1, 79-101

Høkerberg (2013) explains that the concept of heritage can be perceived as a process rather than a static phenomenon; it is constantly redefined in the predominant social and cultural context. It signifies an interpretation or a reconstruction of the past to fulfil the needs of the contemporary society and the institutionalisation of a collective memory. It is a practise that 'clarifies pasts so as to infuse them with present purposes. The social and cultural consequences of such a definition of heritage has democratic implications. It needs to respond to certain standards of legitimacy and representation. Heritage is a frequent issue on the political agenda. More people are becoming involved and aware in a much broader and a deeper array of heritage phenomena than ever before (Harvey 2001, p. 336).

Urban heritage is now recognised as an important contribution to the historical continuity and complexity of our cities. Today, there is a methodological urge to develop new parameters for the assessment of heritage including not only aesthetic and historical qualities but also social values and other aspects that contribute to the complexity of the concept of heritage (Høkerberg, 2013). The focus of heritage discourse has been gradually shifting from the extraordinary and unique to the typical, inspired by the reorientation in landscape heritage discourse where the ordinary landscape is subject to conservation interest. The everyday landscape is acknowledged as an important part of the quality of life as well as areas of 'outstanding beauty. It contributes to the formation of local cultures and it is considered an essential component of an area's natural and cultural heritage (European Landscape Convention, 2000).

Rautenber (2012) posits that the extended application of the category of heritage to new objects such as industrial vestiges or expressions of collective memory, has been among the most important cultural phenomenon of the last three decades of the twentieth century. It can be seen as one expression of the rise of a 'contemporary regime of historicity' (Koselleck, 1990) that has emerged. According to Koselleck, today there is a tension between our collective experience and expectations. Faith in progress is fading and the past takes a weaker place in our collective representation of time. Consequently, as Hartog (2005, p. 15) states, we would be entirely engaged in the present, an omnipresent that has no horizon other than itself. Heritage has become one way of experiencing ruptures with the past and reducing them for our own purposes. Heritage is called upon to preserve the diversity of culture, to promote local empowerment and sustainable development (Hartog, 2005).

Morisset (2009) defends the notion that 'the idea and object of patrimony are specific to the time and place to which they belong (Morisset 2010, p. 55). She argues that, unlike history, heritage or patrimony links our present not only to time but also to our material environment which objectifies our identification of feelings by putting them in physical places and in other people or social groups that form our territory. Heritage is supposed to tell us something about ourselves: who are we; where we come from. Each period of the past has built its own interpretation of authenticity and patrimonial objects which, like fossils, accumulate meanings that emerge from collective memories as archives of the past. Such aspects of authenticity originate in seeing the patrimonial object as a container or vehicle of patrimonial investiture according to a process of accumulation and fossilisation (Morisset

2010, p. 56). We must consider the patrimonial object as the expression of a balance between relationships with Time, Space and the Others (Morisset 2010, p. 56).

This paradigm of urban policy is linked to a more general evolution of a governance that embodies all the rules, networks, public institutions and collective practices, which facilitate the management of the cultural built environment. The framework of relationships between cities and states has changed. It no longer follows the top down approach whereby the centre dictates to the peripheries. The state is no longer the central entity because of the multiplicity of new social, economic and institutional actors. With free choice, contemporary society has adopted concomitant forms of individualism. With an increase in mobility, we are more autonomous than ever before and we appear to have fewer functional links to the territory in which we live. But, because we choose where we live, we are more interested in such places. The territory becomes a central element of our individual experience (Rautenberg, 2012).

3. The Belvedere Memorandum

The Belvedere Memorandum and its incentive programme (1999–2009) initiated by the the Dutch government actively encouraged the integration of heritage conservation with spatial planning. During its operation, the Belvedere Memorandum contributed to a reorientation of heritage conservation practises. After its closure, Dutch heritage conservation faces new challenges as a result of reduced involvement in conservation and spatial planning. It faces a socio-economic change in demographic and development (from growth to shrinkage) as a result of the post GFC European property market crisis.

In the 1990s, many European countries recognised that heritage planning had to move from control and command type approaches to those based on dynamic management of change (Fairclough & Rippon, 2002). Several governments developed public policies and national strategies for a renewed direction in the heritage conservation of the historic environment. In order to use heritage more proactively as a resource for urban development, it was generally recognised that there would need to be an integration of conservation policies within the planning framework (Janssen et al, 2014). Shifts in state-led heritage policies were initiated, connecting heritage more closely to tourism policy and regional development (Poirrier, 2003). In Germany, the so-called Denkmalpflegediskussion focused on the question of how state-led heritage policy could become more dynamic and decentralised, thus clearing the way for local actors, the public and private stakeholders to work together (Holtorf 2007). Essentially, denkmalpflegediskussion asks whether in a democratic society heritage management should be liberalised to the extent that it becomes the responsibility of local communities and individual citizens rather than the state. The discussion raised criticisms concerning existing practices of heritage management, some of which were said to alienate and patronise people despite the best intentions. In the course of the public exchange, it was suggested that more influence should be given to owners. The overriding criterion for listing should be a site's ability to move people, in other words its 'beauty' rather than some complex academic reasoning about historical significance. The Denkmalpflegediskussion had wide influence in the UK, The Netherlands (Belvedere) and Sweden (Agenda Kulturarv project – Putting People First, 2004). The polemic resonates with the work of Laurajane Smith on Authorised Heritage Discourse (Uses of Heritage, 2006).

A call for a more integrated and inclusive heritage planning began to influence the debate on heritage conservation and spatial planning in the Netherlands. In the Dutch heritage sector, the 'culture of loss' that had traditionally dominated heritage management turned into a 'culture of profit', entailing an approach to spatial, economic and ecological issues that had a broader social base and was more inclusive (Kolen, 2007). This shift was accompanied by revival and revaluation of historical interest in Dutch society together with a growing interest in heritage. The paradigm shift was accelerated and intensified by the 'Belvedere Memorandum' (1999).

Janssen et al (2014) explain that Belvedere was a programme in which the national government defined the outline for a reform of the relationship between heritage and spatial planning. It was a response to the prevailing fragmented and defensive heritage management practice in the Netherlands at the time.

Page 7 of the Memorandum (1999) sets out the philosophical parameters of the scheme;

In a dynamic and vital society such as ours, the loss of historic features is sometimes inevitable. After all, we cannot live in the past. We must build and design to meet and reflect the culture of our own age. Planning, designing and building result in a new cultural quality, but paradoxically that is the greatest threat of all to the past qualities. The tempo and scale at which our environment is being adapted to meet the demands of today have become so great that the effect can be destructive. If no deliberate policy aimed at preserving the cultural-historic heritage is adopted, the unique quality of our country which took so many centuries to develop will be obscured entirely by the new design. The result will be that areas in all parts of the Netherlands will start to look very much like each other. This blurring and erosion of the diversity in our surroundings should be a concern to everyone. We must seek strategies and solutions whereby development and conservation can go hand in hand wherever possible, whereby the links between past, present and future will be strengthened.

The Memorandum set out to include professionals within the scope of its purview. It introduced the idea that the future of heritage management lay in its relationship with spatial planning. The heritage sector would have to become future-oriented and more pragmatic in order to lock step with developments in society.

The Belvedere Memorandum was conceived to be a broad based national heritage incentive program. Over the course of 10 years, more than 400 projects of both national and local scale were initiated and developed. A project office was set up to put the Belvedere approach into practice with the help of grants for eligible projects. Meetings between heritage specialists, planners and designers and design workshops were held. The approach was focused on those areas in the Netherlands which were seen as most valuable in terms of heritage, the so-called Belvedere areas, but later, the focus widened to the Netherlands as a whole (Jannsen et al, 2014). The intention of the programme was to provide incentives, policy guidance, seed funding and expertise in support of local projects devised and executed by local public and non-statutory agencies and private firms. The scheme united the heritage sector and found new, more productive links between heritage, management, property development and leisure. Monuments, historic buildings and historic landscapes that were seen as symbolic to the identity of the country were given new leases of life and designers, users, investors and administrators were actively encouraged into the program. The scheme had the effect of fostering stronger collaboration between the hitherto fragmented and siloed cluster of heritage disciplines, each with their own knowledge bases, rules, values and languages. The Belvedere innovation program produced a wide range of results. Four are listed below.

1. Broadening of the concept of heritage to encompass archaeological, built heritage (including urban planning), historic landscape heritage, physical objects and the non-material (intangible) dimension of heritage.
2. Rejuvenation of the concept of heritage especially among professionals
3. Public participation especially from non-experts and local communities
4. Greater interest in and input from designers to find better and more appropriate development. Solutions involving fragile and rare heritage fabric

The Belvedere programme ceased in 2009. However, it constituted a programme that called into question the closed system of professional assessment and material fixation. It provided a new strategy for the preservation of historic buildings and sites. It was a strategy designed not to turn built heritage into museum pieces but to keep them in social, functional and economic circulation (Jannsen et al, 2014). The traditional heritage management system involving experts was challenged and the public was allowed more input and participation.

4. The Heritage Lottery Fund (HLF), UK

HLF was established in the UK as a result of the National Lottery Act, 1993, which identified National Heritage Memorial Fund (NHMF) as the body to distribute funds raised by the National Lottery to the heritage sector throughout the UK. NHMF was itself established as a funding body for the heritage by the National Heritage Act, 1980. At that stage, the operational definition of heritage was essentially a culturally conservative approach focussed on material evidence of past hegemonies, such as great houses and works of art. Since the advent of HLF, the heritage approach constitutes a broadened definition involving more socially inclusive practices that, in addition to material objects, involve less tangible matters such as language and customs. This broadening has become a guiding principle

during the HLF's tenure and has led to a significant redefinition of the concept of heritage (Demos, 2004).

Clark and Maeer (2008) explain that from its inception in 1994 to the end of 2006/07, the Heritage Lottery Fund had awarded £3.97billion to 26,000 heritage projects of all shapes and sizes - from tiny community events to multi-million pound capital projects. Over the years HLF refined its procedures and its approach, partly in response to greater public and government scrutiny, but also due to an internal management desire to understand how well the Fund was working. As the number of applications for grants increased across larger geographical areas but under fixed budgets, data collection became an essential tool for cost efficiencies in order to deal with the full range of heritage, social, economic, environmental and organisational challenges. In response to this, the Fund worked with think-tank Demos in 2004 to develop an evaluation framework to help articulate those challenges. The framework was based around the idea of public or cultural value and set out to identify the different kinds of value that the organisation might generate for the public (Hewison & Holden, 2006, 2006; Clark, 2006).

At the time of reporting (Demos, 2004), the Fund was operating its second strategic plan (2002–08), which had three aims:

- to encourage more people to be involved in and make decisions about their heritage;
- to conserve and enhance the UK's diverse heritage; and
- to ensure that everyone can learn about, have access to, and enjoy their heritage. (Heritage Lottery Fund, 2002, p. 5)

Clark and Maeer (2008) explain that the Heritage Lottery Fund distributes funding from the National Lottery to heritage projects across the whole of the UK. Over 200 staff is located in central, regional and country offices. Government-set policy and financial directions provide HLF with the operational guidelines for funding and how they are to be allocated. There is a board of Trustees (appointed by government) and committees in each region/country of the UK. Funding decisions are made by Trustees, committees or staff (depending upon the amount) using criteria based on the organisation's aims and policy directions. HLF views heritage as anything that has been inherited; is of value and needs to be passed on to the future. This includes cultural heritage such as museums, historic buildings and archaeological sites, natural heritage such as landscapes and biodiversity and intangible heritage; language, fashion, custom etc.

The types of projects that the Fund awards vary from large capital projects that help to conserve or restore historic buildings, landscapes or museum collections to activity projects based around heritage, such as surveying wildlife, learning about a building or recording oral histories. The Fund's 2002 operational guidelines emphasise;

- the needs of the national heritage;
 - the need to ensure that all parts of the UK have access to funding;
 - the scope for reducing economic and social deprivation but creating heritage benefits;
 - the need to promote access to heritage, for people from all sections of society;
 - the need to promote knowledge of and interest in the heritage by children and young people;
 - the need to further the objectives of sustainable development.
- (Heritage Lottery Fund, 2002, pp. 43–44)

According to its website, the Fund maintains that over the past 17 years, it has given over £1.5 billion to projects that have conserved more than 14,000 historic buildings and other structures including 2,750 listed at Grade I/A and Grade II/B. The funding is used to repair and transform a wide variety of buildings that people want to keep and hand on to future generations. The website asserts that the transformation of prominent historic buildings can be a catalyst for urban regeneration, the promotion of heritage and the creation of jobs. The Fund's 2002 and 2005 income and operational costs are reported in the table below

Table 1 – Heritage Lottery Fund Income and Operations Costs for 2002 and 2005

	2005/06	2002/03
Income from Lottery proceeds	£230.4 m	£296.2 m
Value of commitments made during the year	£322.8 m	£356.3 m
Operational costs	£23.0 m	£21.5 m
Operational costs as % of income	10.0%	7.3%
Operational costs as % of commitments	7.1%	6.0%

As the millennium approached, the UK Government conducted a major review of policies covering one part of HLF's remit; the historic environment. The first stage of this was the publication of the seminal report 'Power of Place' in December 2000 by English Heritage, which had been identified as a major policy document in England for the sector. This was followed in December 2001 with the publication by the DCMS (Dept. For Culture, Media & Sport – UK Government) of 'The Historic Environment: A Force For Our Future'. This second report presented the Government's vision for the historic environment as;

- **Providing Leadership:** to respond to public interest in the historic environment with firm leadership, effective partnerships and a sound knowledge base from which to develop policies.
- **Realising Educational Potential:** to realise the full potential of the historic environment as a learning resource.
- **Including and Involving People:** to make the historic environment accessible to everyone and ensure that it is seen as something with which the whole of society can identify and engage.
- **Protecting and Sustaining:** to protect and sustain the historic environment for the benefit of our own and future generations.
- **Optimising Economic Potential:** to ensure that the historic environment's importance as an economic asset is skilfully harnessed.

The above five areas appear to underpin the Government's policy objectives for the historic environment, although a further policy document; 'People and Places: Social Inclusion Policy for the Built and Historic Environment' was published by DCMS in June 2002. This document reinforced the Government's commitment to social inclusion, warning that "engaging with a social inclusion agenda may require substantial cultural change from heritage organisations" (Demos, 2008:18)

5. The Federal Tax Reform Act of 1976, USA

Up to the enactment of the Great Society legislation that created a host of social and cultural programs, support for historic preservation as with other social and cultural activities in the United States, had been largely episodic and undertaken through private initiative (Swaim, 2003). Today, a shared cultural heritage is considered to be a public good commensurate with public subsidy. The growth of legislation and federal cultural agencies in all the US states has engaged the interest of various publics. In conservation (preservation), these publics comprise real estate developers, bankers, preservationists, legislators, and bureaucrats. Their interest in preservation results in government policies, programs and support that leverage private efforts (Swaim, 2003).

Until the 1970s, the federal tax code made it more financially beneficial to demolish and build new. Congress ameliorated this situation in 1976 with the adoption of federal tax incentives for historic preservation. Two years later, Congress established an investment tax credit for rehabilitation and by 1986 the current structure of the historic tax credit had been established: a 20 percent credit for qualified rehabilitation expenditures on historic structures and a 10 percent credit for non-historic buildings built before 1936. Rehabilitation tax credits (RTCs) have now contributed to the preservation of more than 38,000 historic buildings—many of which exist in urban neighbourhoods and downtowns throughout the nation (Ryberg-Webster & Kinahan, 2013). By the reckoning of Rutgers University Centre for Urban Policy Research, federal tax incentives for historic rehabilitation since their inception have generated 2.2 million jobs and leveraged nearly \$100 billion in private investment to rehabilitate 38,000 historic properties. The program has paid for itself, generating \$24.4 billion in federal taxes to

more than offset the \$19.5 billion credits allocated by the National Park Service (Preservation Leadership Forum, 2012).

To further incentivise preservation, thirty-one states now offer a state-level tax credit, which can typically be partnered with the federal credit (Schwartz, 2013). Developers can pair the rehabilitation credit with other federal programs including Low-Income Housing Tax Credits, New Markets Tax Credits and Community Development Block Grants (Listokin, Lahr, and Heydt 2012) and many cities and/or states offer property tax relief and low-interest loan programs for historic preservation projects.

Federal RTCs catapulted preservation and the adaptive reuse of industrial and commercial buildings to the forefront of urban revitalisation. Some of the most recognized historic preservation projects which have made use of the tax credit are former industrial districts or buildings that have undergone wholesale transformation such as New York City's SoHo, Richmond's Tobacco Row and Shockoe Bottom, Cleveland's Warehouse District, St. Louis' former garment district, and Seattle's Pioneer Square (Ford 1974; Zukin 1982; Birch and Roby 1984; Silver 1984; Wonjo 1991; Listokin, Listokin, and Lahr 1998; Stanziola 1998).

Private-sector developers had begun to envision the possibilities (and profits) of adaptively reusing vacant and outmoded urban buildings as early as the 1960s. The 1964 conversion of San Francisco's Ghirardelli Square to a retail and entertainment destination is generally considered the first major adaptive reuse project (Wonjo, 1991). Also indicative of early adaptive reuse was James Rouse's 1976 transformation of Boston's Quincy Market and Faneuil Hall into a "festival marketplace" (Sagalyn, 1989).

The primary economic incentive offered by federal policy is the historic preservation tax credit which allows a credit of up to 20 percent of the cost of renovating a property of historical significance. According to the National Park Service (NPS), the tax incentive program is one of the most successful revitalisation programs ever created (Swaim, 2003). The National Park Service administers the program with the Internal Revenue Service in partnership with State Historic Preservation Offices. The tax incentives promote the rehabilitation of historic structures of every period, size, style and type. They are instrumental in preserving the historic places that give cities, towns and rural areas their special character. The tax incentives for preservation attract private investment to the historic cores of cities and towns. They also generate jobs, enhance property values and augment revenues for State and local governments through increased property, business and income taxes. The Preservation Tax Incentives also help create moderate and low-income housing in historic buildings. Through this program, abandoned or underused schools, warehouses, factories, churches, retail stores, apartments, hotels, houses, and offices throughout the country have been restored to life in a manner that maintains their historic character (NPS, 2012).

However, current proposals to overhaul the federal tax code pose a direct threat to the credit, spurring the National Trust to issue a policy alert stating that "deficit reduction measures are currently being debated on Capitol Hill, and the federal historic tax credit program is at risk" (NTHP, 2013). The recent *Commissioner of the Internal Revenue v. Historic Boardwalk Hall* decision has caused widespread panic, calling into question the typical investment structure for historic tax credit projects. It has generated uncertainty about how to structure tax credit deals in the future (Preservation Leadership Forum, 2012).

Those critical of historic preservation emphasise equity issues and draw on long-standing perceptions of the field as an expensive, elitist practice. They argue that preservation standards require large expenditures that the poor cannot bear and that, property value increases will drive out low-income homeowners and renters (Listokin, Listokin & Lahr, 1998). The legacy of the perception is a burden on the profession, particularly when working in low-income communities (Listokin, Listokin, and Lahr 1998, 465). Some studies that empirically question the relationship between preservation and gentrification reveal that the connection is tenuous causing minimal neighbourhood change and/or a more complex relationship (Ryberg-Webster & Kinahan, 2013).

Inequitable outcomes from federal tax scheme raise questions about who benefits from preservation and how resources for preservation are distributed. Domer (2009, 97) argues that preservationists do not know how to "balance the integrity of the past with the utilitarian and aesthetic needs of the present and future" and that preservation standards result in the construction of a "preferred past"

that “fits the values, aspirations, and desired associations of white upper- and middle-class men and women who own and invest in those projects and who are strongly motivated by capitalistic goals” (Domer 2009, 99). Swaim (2003) analyses distributive issues related to the federal rehabilitation tax credits concluding that they are a powerful, but understudied subsidy that confers benefits to wealthy investors and developers who possess the necessary financial and political savvy to undertake often complex, risky, and expensive projects. In other words, he finds that the credits are “a classic example of good politics but bad policy: easily enacted, largely hidden from view, seldom cut back, transferring billions of dollars to powerful but undeserving constituencies” (Swaim 2003, 38).

6. Conclusion

The three heritage incentive schemes discussed above include a fund (Heritage Lottery Fund) a Memorandum (Belvedere Memorandum) and a rehabilitation tax credit scheme (RTC). Although each is conceived differently, all three constitute national schemes that disseminate their largesse to the states and municipalities without apparent boundaries or geographic preference. The Dutch and the UK schemes comprise not only grant money dispensed to applicants but active heritage promotion as a public good in society. They seek to proselytise, socialise and edify the nations’ business, development, professional and bureaucratic communities along with the citizenry about the good causes of cultural built heritage. While the USA scheme is merely a tax credit arrangement, it can be argued that it has had a similar effect i.e. the rehabilitated buildings speak for themselves. They constitute the promotional aspects of heritage through the encouragement of ordinary tax payers to make use of the system possibly with less pre-qualification and eligibility than the other two schemes. Further, it may be argued that even in the absence of a manifesto for cultural built heritage, the US tax credit scheme for heritage is larger, bolder, longer-lasting and further reaching than either the Dutch or the UK schemes.

In comparing the three schemes, the question is whether the goals of revitalisation (regeneration) and preservation (conservation) are best achieved through tax incentives, unassisted market mechanisms or direct government spending. There are questions of fairness and equity. First, should the tax system allow a relatively small sector of society to reap gains from rehabilitation projects? Second, is there a better way to ensure that important cultural resources like historic buildings are preserved? If the fundamental goal is to maximise the number of rehabilitation projects, then the credit is probably the most feasible way of accomplishing that goal (Law & Contemporary Problems, 1985: 258). The tax credit will maximise the number of projects because the credit is limited only by the supply of properties available and not by factors such as grant budgets.

Arguments in favour of investment tax incentives include; tax incentives clearly enhance returns on investment; they may be justified by positive externalities stemming from investments; they are relatively easy to target and fine tune; they signal openness to private investment; they are useful in a world of capital mobility; they are necessary for responding to tax competition from other jurisdictions; they compensate for other deficiencies in the investment climate; they enhance revenue by stimulating investments that generate other taxable income via employment and linkage effects and; they offer political advantages over direct expenditure programs to stimulate investment (Bolnick, 2004).

In terms of heritage conservation, tax incentives generally have one of three objectives: (a) to reduce the cost of maintenance or restoration; (b) to reduce the ‘opportunity cost’ of retaining a building rather than demolishing and rebuilding; or (c) promoting the flow of resources to non-profit bodies in cash or property (Making it Happen, 2004). Granting a tax incentive implies that the listed heritage stock is considered too vulnerable to market failure and that either the tax system is the obstacle or other obstacles exist that can be compensated by the tax system (Klemm, 2009).

As long as there are investors and properties, the process can continue. However, if the concern for the greater good also factors in social spillover effects from rehabilitation, a direct spending program, or even refundable tax credits, might allow more investors access to this program. By giving grants for rehabilitation work, the government would remove a bias against those who possess rehabilitation expertise but lack experience in tax matters. Refundability would allow investment by those for whom the non-refundable tax credit does not add enough of an incentive (i.e., those whose tax burden is not reduced significantly). In addition, a direct spending program could be regulated much more closely before projects begin, whereas a tax credit is approved only after the money has been spent and the

project completed (Law & Contemporary Problems, 1985: 258). Choosing between rehabilitation projects before they begin would allow other factors, such as location, type of building, and benefit to the community, to be considered.

This would probably minimise concentration of rehabilitation resources in expensive warehouse conversions or similar projects and may lead to the selection of a more beneficial mixture of projects. Although the cost and the size of the program budget can be limited prospectively in contrast to a tax expenditure which is only limited retrospectively, a labour-intensive grant approval process such as the HLF and the Belevvedere Memorandum, has the tendency to delay projects and cause money otherwise spent on rehabilitation to be spent on administrative costs. Direct spending programs are also susceptible to politicisation, resulting in projects chosen not on merit, but on the basis of legislative compromises (Law & Contemporary Problems, 1985: 259).

Abstract

France has classically been tied to the idea of protection of cultural heritage, so much so that the birth of the concept of European cultural heritage can be traced back to its 19th-century vision of *patrimoine*. In addition, it has developed, over time, a regulatory apparatus of the most complete, especially in relation to protected areas. From the law of 1913 on historic monuments to that on natural sites of 1930, from the extension of protection to the surroundings of monuments introduced in 1943 to the creation in 1962 of *secteurs sauvegardés* and then of the *zones de protection du patrimoine architectural urbain et paysager* (today AVAP), France has been able to organize a legal system of proven effectiveness. In a spirit of a necessary conceptual and operational maturation, with the new *Loi Patrimoine*, France intends today to reorganize the field, according to a comprehensive and integrated approach, founded on the knowledge, communication and shared decision making, really aimed at the transmission of heritage to future generations. The primary objective is to meet the new demands posed by a sustainable development of the territory while responding to essential questions: why do we need to safeguard? How to reconcile conservation and innovation? Which are the economic, social and cultural benefits that may result from a conscious and conscientious exploitation of cultural heritage?

Keywords: historic monuments, cultural heritage safeguarding, conservation areas, France

1. From the advent of the heritage's concept to the first laws

The current concept of heritage is certainly to be considered as the outcome of numerous factors. It results both from the "physical reality" of the elements composing it, and from the aesthetic, documentary, descriptive and even sentimental values that the common knowledge gives them, as well as from the legislative apparatus that has been produced over time in order to know, study, protect and make it accessible to as many people as possible.

Its origins can be traced - according to an "*étrange paradoxe*" [1] - in the French Revolution: the period in which this notion mostly evolves, changing from "sacred well" to "collective public good" [2, 3, 4]. As the bearer of a tremendous memory's value, heritage is considered as an element that can substantially contribute to the formation of national identity that is reflected in it.

During the revolutionary period, in response to the many acts of devastation that accompanied the popular uprisings, France developed legal and administrative instruments devoted to the understanding and protection of its historic and aesthetic heritage. The safeguarding of monuments, of these "*pierres durables*" that far from being just ornamental elements were, however, one of the key element of the Nation was, beyond the important destruction made in the early years, an explicit goal of the revolutionaries. "*The transmission to posterity will be henceforth the result of reasoned actions, specifically oriented in this direction*" [5]: in this context, cultural goods would be considered as a resource to reorganize, not more to the benefit of the elites but of the entire national community.

A season marked by a genuine patrimonial vocation will be, therefore, that of the July Monarchy. A time during when - through the creation of specific figures/bodies (the *Inspector général des monuments historiques* in 1830 and the *Commission des Monuments historiques* in 1837 endowed with a specific budget for the restoration and conservation), a census on historical monuments in need of safeguard (1840) and the establishment of specific protection modalities (the law of 3 May 1841 on expropriation for public utility) - the public engagement in the field of cultural heritage developed.

In 1887, after the excitement caused by the destruction of the monuments that took place between the summer of 1870 and the spring of 1871 (the war against Prussia and then the Commune), the first organic law on historical monuments will be approved (*loi du 30 mars sur la conservation des monuments et objets d'art ayant un intérêt historique et artistique*). This tool clarified in a systematic way the modalities of protection and the role of the State in the processus: the criterion of so-called "national interest" will be taken as the legal basis of the French politics of memory. In addition, the law will introduce, the legal concept of "*classification*" for the monuments of public property and the exclusivity of the intervention on national protected assets, laying the foundations for the national heritage politics.

In the next years, the French heritage consciousness will reach a big leap ahead. The popular feeling against the *patrimoine* will become more extensive and directed even to goods, which, while not having an exceptional character, would be considered worthy of protection. The administration in charge of historic buildings safeguarding will continue to evolve around three axes: development, professionalization and nationalization [6]. This will inevitably be accompanied by a regulatory fervour. The approval of the 1905 French law on the Separation of the Churches and State (*loi du 9 décembre 1905 concernant la séparation des Églises et de l'État*) will play a significant role in the debate about heritage. Religious buildings will become public; in particular, churches will be placed in the ownership of local administrations (communes) while cathedrals and other religious buildings will be taken over by the Central government. This led to the need of redefining what should or could be protected since "religious" was not necessarily the same that "national", as well as to the necessity of rethinking the 1887 law that will result in the organization of a new protection system [7]. On 21 April 1906, the law on the protection of natural sites and monuments of artistic character will be voted; the law of 18 July 1909 will introduce the classification of objects of private property and the law of 20 April 1910 will prevent the billposting on the historic monuments.

Despite this, the legislative body still seemed insufficient. Various proposals were developed for the purpose of re-formation of the 1887 Act. From their synthesis finally born the law of 31 December 1913 that will complement and enhance the provisions taken in the previous tool (fig. 1). The law will introduce a dual organization of protection based on the one hand, on the *classement* and on the other on the inscription on the supplementary list (*inventaire supplémentaire des monuments historiques*). The first will be by now applied to any type of good - movable and immovable - including those of private property, without necessarily obtaining the consent of the owner. The second will provide for the possibility of entry of the goods worthy of protection: a sort of waiting list for the classification in order to make up for the slowness of the procedure. This instrument for inventory will be later transformed by the Act of 23 July 1927 in a real protection tool: less complex than *classement* and thus easier to implement.

The 1913 Act marked the end of the 19th century evolution of the concept of heritage and its preservation. It subordinated the right of ownership to the imperatives of heritage protection. This right, a consequence of the Revolution, now also assumed a "social function": that of preserving - not only for themselves but also for the community - the monumental assets, so reflecting the 1832's vision of Victor Hugo: "*There are two aspects to a monument: usage and beauty. Its usage belongs to the owner; its beauty belongs to the world, to you, to me, to all of us. So destroy it is beyond our right. (...) we must account of the past to the future*" [8].

From then on, with the acceptance of wider definitions, more subjective criteria for listing would be applied, so allowing, in spite of the continuing centralism of the system, the increasing preservation of buildings of "local" rather than "national" interest. In addition, this would gradually reduce the apparent conflict between categories of heritage: "*the one national and 'major', the other local and 'minor'*" [9].

2. The extension of the concept of heritage to sites and protected areas

In parallel with the elaboration of the first instruments of urban planning, but independently, specific provisions were then issued and directed to "territories" recognized as exceptional and/or significant from the cultural and aesthetic point of views. With this in mind, the law of 2 May 1930 related to the protection of natural monuments and sites of artistic, historic, scientific, legendary or picturesque interest was enacted. Its title III defined a new category of "protected zones" guaranteeing the safeguarding for natural sites as well as for the areas around the monuments, such as, for example, the cathedral of Rouen (1938), the neighbourhoods of the cathedral and of the town hall of Aix-en-Provence (1942), or even Carcassonne, Villeneuve-Les -Avignon, Concarneau, Provins, etc.

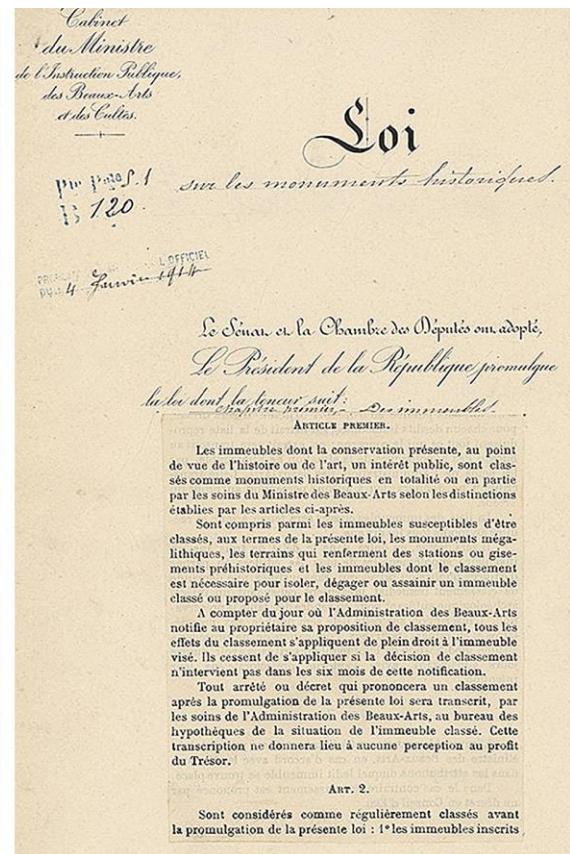

Fig. 1: One of the first monuments *classes*, the Saint-Pierre Church in Aulnay (left) and the 1913 Act (right)

This legislation marked the beginning of the extension of the concept of heritage. However, based on a very complex procedure and largely focused on the "buildings' exterior", it proved unsuitable for larger urban sites [10]. Unfortunately, the idea that the monument could find the ideal setting for its development only through an appropriate "isolation" was still too rooted in the mentality of that time to promote a broader vision of protection at the urban scale.

The years immediately after, however, will be full of reflections on the subject, conducted by technicians and intellectuals who will compete on the controversial issue of the safeguard of the *quartiers historiques*. Between the two World Wars, a kind of real militancy towards the protection of architectural heritage developed and took force. This, especially thanks to the work of the many organizations that flourished in France at the time, such as the *Ligue urbaine et rurale pour l'aménagement du cadre de la vie française* re-founded in May 1943 by Jean Giraudoux in order to fight "all attacks on beauty, health and dignity of the country" [11].

From the beginning, the L.U.R. focused its activity on two separate but complementary objectives: the defense of French natural and monumental heritage and the promotion in the field of urban planning and reconstruction, of the advent of a new French humanism.

In the spirit of Jean Giraudoux and his friends, "some modern architecture" had given too much importance - although legitimate - to biological needs (air, sunshine, greenery, space), without taking sufficient into consideration the "psychological and moral reactions" of people. Actually, they intended to highlight how the attachment to the past did not preclude in any way seeking bold solutions. In a period in which both parties fiercely opposed - the "defenders of traditional architecture" and the "champions of utilitarian architecture", the L.U.R. proposed a compromise solution rich in realism and tradition. Reconstructions should play, in fact, the role of weld between old elements to achieve wealthy and rationally designed cities but as far as possible, respectful of the past. It was, indeed, a very modern thinking, which sought to reconcile protection and development purposes.

In August 1941, a report prepared by the Secretariat of State for Education and Youth highlighted numerous threats made to some of the most beautiful sites in France. In Marseille, Avignon, Valence, massive constructions were undertaken or planned, that may destroy or seriously impair, unique landscapes. The administration of *Beaux Arts* would be able to oppose the continuation and achievement of these constructions only by allocating higher compensation to owners and builders: *ad hoc* legislative measures were therefore necessary with greatest urgency.

The real turning point will be the promulgation of the Law of 25 February 1943. In addition to "isolate, clear and cleanse" the listed buildings, the article 1 stated that classification may intervene to

"valorize" them: "*the spirit of the law was no longer based on the conflict between a monument and its environment, but rather on finding a necessary complementarity, the reciprocal effects between the monuments and its surroundings*" [12].

At the heart of the act, there was the institution of a "radiant" protection thus added to the "punctual" one. This new procedure submitted to the authorization of the *Service des Monuments historiques* each construction project located in the "field of view" of a building classified or proposed for classification" and concerned indeed, "*any other building visible from the first or visible at the same time that it and located in a radius not exceeding 500 meters*".

Because of a poor drafting of the text, the notion of field of view gave rise to many difficulties of interpretation. The article 1 defined "a priori" a protection zone corresponding to a square of 125 meters on each side, a circle with radius of 79.61 meters. Under these conditions, the range of such servitude seemed highly limited; its scope was indistinguishable from many of some protected areas established under the Act of 2 May 1930. In fact, the Administration has always taken a broad interpretation of the text, substituting to the concept of perimeter that of a radius (500 meters long) of the circle drawn around a monument. However, this definition apparently clear not only posed problems of interpretation but, in many cases, also proved inadequate and insufficient. This, because of the automatic nature of the law, primarily based on geometric criteria (later it will be defined as "beasts and villain" round).

However many buildings near monuments were saved, even if only in an embellishment perspective, rather as accompanying elements, such as "*l'écrin qui met le bijou en évidence*" [13]. In fact, texts and interventions were taking into account the environment of the monuments (and only the major ones) only if they had artistic, legendary, historic and picturesque values. Once again, such an instrument was the result of a "*monumental idea of heritage*". Keeping the framework allowed a better valorization of the monument.

Later, it was the projects for Paris first and then everywhere in France, which created a new awareness. Medical investigations, relayed by the hygienist movement, had highlighted many unhealthy islands at the center of *Vieux Paris*. An important part of the Marais was slated for demolition.

The Minister of Culture André Malraux alerted by an opinion more sensitive to its surroundings and aware of the need to preserve the evidences of a past more and more weakened by the imperatives of modernity - in collaboration with the minister of Construction Pierre Sudreau - decided to take action. They did pass the law of 4 August 1962 known as *loi Malraux* that introduced the concept of *secteur sauvegardé* [14].

The 1962 Act radically changed the approach regarding the *patrimoine*. This text did much for the development of the concept of heritage, determining the expansion to areas before excluded. The sectors definitively dragged the question of the protection of the monument to the space now taken into account for themselves, as forming a whole, beyond reference to any element composing them. The decree to implement the law, which later was incorporated into the *Code de l'Urbanisme*, therefore officially linking the two kinds of legislation, heritage protection and planning, was published in 1963. It created the *Commission Nationale des Secteurs Sauvegardés* within the Minister of Culture, gave the power of veto over planning applications in the sectors to the *Architecte des Bâtiments de France* (ABF). It also introduced the *Plan de Sauvegarde et de Mise en Valeur* (PSMV) : a kind of detailed master plan, preceding the *Plan d'Occupation des Sols* (POS) which was not introduced until 1967 (*Loi n° 67-1253 du 30 décembre 1967 d'Orientation Foncière*).

Conservatives and passionate enemies of vandalism, who saw in this tool - innovative and strongly different from the previous protective measures - the answer to their prayers, greeted this revolutionary law enthusiastically. Its main purpose will be to extend the concepts of conservation and valorization to the historic districts, taking into account every aspect - social, economic and financial - connected to them, and involving residents in restoration operations to relieve them from otherwise unaffordable expenses.

Despite good intentions, however, the plans later called "of first generation" extremely ambitious and seductive, often proved to be unenforceable due to a series of difficulties related to their implementation: such as, for example, the hostility of the Municipalities that, almost never really involved in decisions and forced to undergo a number of charges, often slowed down the process. As to the timing of plans' approvals, initially estimated at 18-24 months, they were in many cases even increased tenfold. The negative impacts that these rhythms have led to the overall quality of interventions are evident; they are often restricted by regulations made longer appropriate given the evolution of times, urban and social needs and attitudes. In addition, these plans were generally characterized by extreme choices that have marked the historic fabric: a number of demolitions, the widening of road sections and the realignment of the fronts built to allow, according to the conceptions of the time, an automotive circulation *à grande vitesse* (fig. 2).

Entrusted to the *Architectes en Chef des Monuments historiques* not possessing the necessary skills for the development of real projects of urban renewal, the plans of the first decade of experimentation,

in full contradiction with the premises made by the legislator, were designed in order to be "exemplary". Globally, they translated an idea of protection too selective, more careful to the quality of architectural objects than of the urban landscape in its entirety. Later, following the change of mentalities, to the numerous "exercises in style" and/or interventions geared to the *façadisme*, followed recovery actions less invasive but more forced; clutches of the new in the ancient not always carefully screened in their figurative forms.

In the early '70s, the French policy of protection of historic centers has been radically called into question. The first plans were reviewed in the light of new guidelines based on an overall view and on interventions less aggressive, driven by a greater respect of minor architecture and public space. The evolution of the doctrine, legislation and planning policies has enabled to produce a new generation of plans, more alive to the historical and urban dimensions. The Ministry of Public Works abandoned the classical system of the *îlots opérationnels* (until then used to quickly start with operations but with very bad results), financing less individual restoration operations and increasing urban recovery actions.

Following the law of 31 December 1976 (*Loi n° 76-1285 du 31 décembre 1976 portant réforme de l'urbanisme*), also the *loi Malraux* has undergone a substantial redefinition, finally becoming a planning tool in its own right. The presentation of the PSMV (now private by the adjective "permanent") has become comparable - in terms of content and procedure - to that of the local urban plan (*plan local d'urbanisme*, PLU) introduced by the Law n° 2000-1208 of 13 December 2000 on solidarity and urban renewal (*loi relative à la solidarité et au renouvellement urbains*). The PSMV replaces the PLU in the defined perimeters while being different in some features, such as an increased graphics precision and the high level of in-depth analysis on architectural heritage and on the morphological characteristics and historical evolution of the urban fabric.

In the early '80s, the process of decentralization has allowed to reconsider the division of powers between the different administrations. The State has maintained the responsibility of the national policy for the protection of cultural heritage - of which it is still guarantor - despite the growing involvement guaranteed to Municipalities, Departments and Regions.

In the same spirit of sharing powers between the Central Administration and local authorities for the safeguarding and valorization of their local heritage, French heritage policy has thus been enriched with new tools. In particular, the Act of 7 January 1983 on Architectural, Urban and Landscape Heritage Protection Zones has provided for the possibility of establishing the *zones de protection du patrimoine architectural et urbain*, in the vicinity of historical monuments and more generally in all the quarters and sites meriting to be protected and valorized for aesthetic or historical reasons. "*It is important to remember that the ZPPAUP instrument was based on an original pact between State and Municipalities*" emphasized the former Minister of Culture and Communication, Frédéric Mitterrand, during the installation of the Committee of reflection, consultation and proposal for ZPPAUP in September 2009.

This mechanism has benefited from a growing interest of people towards heritage preservation and at the same time from relatively flexible regulations allowing "innovation" by adapting to very different situations. It has been motivated by the opportunity of taking into account a variety of different places (built or natural, large or small, communal or intercommunal), provided they were equipped with an heritage "asset" as affirmed by the circular n° 85-45 of 1 July 1985 on ZPPAU: "*Heritage is itself a concept that evolves over time and concerns, for example, the personality of a region. A regional policy can allow this perception: here history and archaeology predominate, then the industrial 19th century, elsewhere rural architecture of vineyards or mountain pastures, sometimes mines and mills of the 20th century founding the collective consciousness*".

However, such a freedom of action has at times makes fail some. Actually, several delimitation engaged in the '80s for the establishment of ZPPAUP have been unsuccessful due to lack of knowledge and understanding of the method. A number of documents of this period seem reluctant to assert specific characteristics of ZPPAUP that remain, in the operative approach, still poorly defined. For the establishment of some dossier, the *chargés d'études* have actually chosen as source of inspiration other planning documents - the *plan d'occupation des sols* or the *secteurs sauvegardés* - widely experienced but having different objectives. In addition, most municipalities did not benefit before any inventory or any protection regulation.

The heritage prescription were often limited to the opinion of the Architects of France's Buildings (ABF) on the monuments surroundings (*abords*) or historical sites. Everything had to be invented: based on a from a historical and cultural study of the territory, ZPPAUP should be designed for a shared management taking into account both the value of *patrimoine* and the necessary adjustments to their revitalization.

Even if some early results may seem disappointing and objectionable, the ZPPAUP has gradually become an instrument very much appreciated by Municipalities and supported by heritage associations (such as the *Association Nationale des Villes et Pays d'art et d'histoire et des Villes à secteurs sauvegardés et protégés*). The number of created ZPPAUP (about 620 and approximately 400 study in mid-July 2010) can give an idea of the success of the tool.

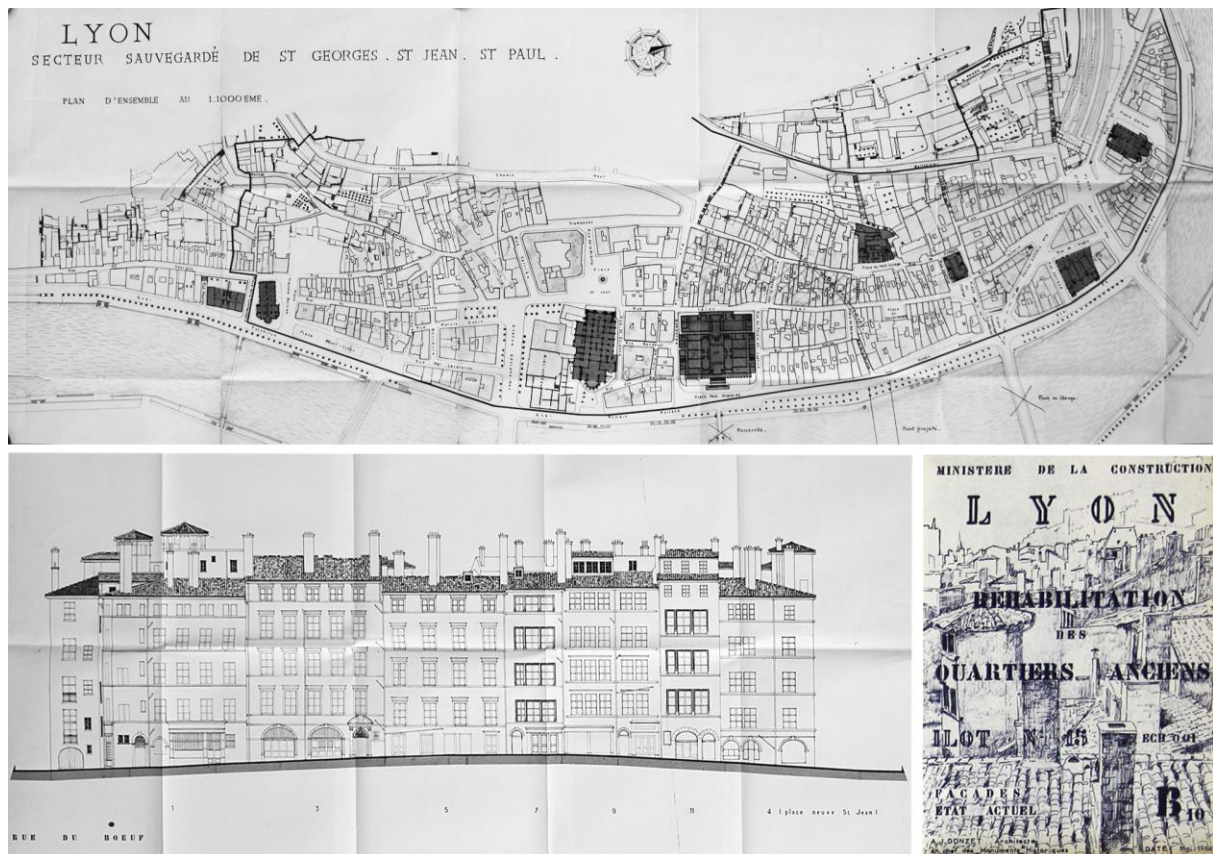

Fig. 2: The plan de sauvegarde et de mise en valeur (PSMV) of Lyon by André Donzet (1964)

The law of 8 January 1993 has then extended this instrument to natural landscapes' protection by defining the *zones de protection du patrimoine architectural, urbain et paysager* (ZPPAUP). The simplifications has made more "attractive" these instruments, especially in rural areas. The order n° 2005-864 du 28 July 2005 related to *secteurs sauvegardés* and its implementing decree of 2007, have further cut down the procedures for the preparation and adoption of the safeguard plan, clarifying its relationship with the local level of planning (fig. 3).

More recently the article 28 of the on National Commitment for the Environment - also referred to as the Grenelle II Law (*Loi n° 2010-788 du 12 juillet 2010 portant engagement national pour l'environnement*) - has created new conservation perimeters, called *aires de mise en valeur de l'architecture et du patrimoine* (AVAP), which will replace the ZPPAUP within five years (i.e. by 13 July 2015). One of the reason for the change in the name is that of giving greater priority to sustainable development, although many consider that these new areas offer less in terms of control and financial support than the ZPPAUP.

If the new instrument has no significant break with the old - as "*the greening of heritage law was not accompanied by a disruption of the legal mechanisms. Clearly, the legislature favored continuity to achieve its purposes*" [15] - the passage from ZPPAUP to AVAP is for all people concerned an immense challenge. While many municipalities are engaged in this transition, some will have neither the legal and financial means nor the time to transform their zones in AVAP before deadline. Several municipalities will have no choice but to subscribe their heritage policy: the regime about historical monuments and sites registered under the Environmental Code will be restored. To avoid the risk that in 2015 some areas lose their protected status, the Minister of Culture Aurélie Filippetti decided to proceed with the establishment of a new law with the intent of make a new simplification of procedures in order to better protect. A component of this *projet de loi* will concern the urban development areas: "*50 years after the Malraux law, protection zones should not suffer from lack of funds*" [16].

3. The 2013 French vision for protected areas: simplify to better protect

As foretold by the Minister, 100 years after the promulgation of the 1913 Act on historic monuments, a *projet de loi sur les patrimoines* has been presented to the Council of Ministers at the end of 2013. Heir to a long normative stratification that has given it some complexity, the legislation in the field of heritage needs to be simplified and modernized, without compromising its fundamental principles. Exceeding the strict powers of Ministry of Culture and Communication, it prior requires a close cooperation with other ministries, representatives of local authorities and associations.

Fig. 3: Some examples of ZPPAUP showing the huge application field of the instrument: the Belsunce quarter in Marseille, the towers of Villeurbanne, the reconstructed town of Havre, the *Marché aux Puces* in Saint Ouen

The revision of heritage code will update the existing law in the field, in response to recent developments (particularly in terms of planning). It would facilitate the public access to different forms of heritage, raising the risk of weakening the legal protection of heritage (additional delay in transforming ZPPAUP in AVAP, which posed a threat of loss of protection of these areas). The primary objective is to meet the new demands posed by a sustainable development of the territory while responding to essential questions: why do we need to safeguard? How to reconcile conservation and innovation? Which are the economic, social and cultural benefits that may result from a conscious and conscientious exploitation of cultural heritage?

The main changes will concern five priority topics: protected areas and historical monuments, museums, archives, architecture and preventive archaeology. In particular, with regard to protected areas and historical monuments, the Ministry of Culture intends to integrate heritage issues in the planning documents. Today, if these heritage issues can be dealt with under Article L123 -5/ 7 of the Town Planning Code and in the *plans de sauvegarde et de mise en valeur* (PSMV), the *zones de protection du patrimoine architectural, urbain et paysager* (ZPPAUP) and the *aires de mise en valeur de l'architecture et du patrimoine* (AVAP), they remain related to the PLU without being integrated. Following the new provisions, the number of categories of protected areas should decrease from 10 to 3. It would thus exist the "historical sites", the "classified sites" and the "abords".

All these areas would be brought under a single statute, appointed by the still provisional title of "old city". Unless these areas already have a PSMV, they will need to develop a "heritage PLU", which will replace the current one. In case the PLU become intercommunal (law n° 2014-366 of 24 Mars 2014 *pour l'accès au logement et un urbanisme rénové*), it is possible to consider a switch from "heritage PLU" to "heritage PLUI" without major impact on the content of the document.

The Ministry of Culture said that these changes do not amount to a withdrawal of the State that will continue to support the communities involved in the preparation of these documents, whether heritage PLU or PSMV. The documents will be forwarded to a national commission, after regional review. Other discussions are also underway on the listed sites, which if they have not changed since the early 20th century could be reclassified. Regarding the "abords", whose perimeter is currently 500 meters, the ABF propose to transform them into "intelligent" perimeters – i.e. variable depending on the characteristics and requirements of the site - which would be subject to public inquiry.

This project has created some concern in heritage associations, in particular with regard to the establishment of "heritage PLU". Indeed, the choice left to the local communities for future "historical cities" (which will bring together *secteurs sauvegardés* and ZPPAUP/AVAP) between "heritage PLU" and PSMV could lead them to move towards a less powerful tool: less protective but more tempting because less expensive. It would therefore necessary to create a "real" heritage PLU having goals and a development process based on that of protected sectors or AVAP. A reform of the Town Planning Code shall be conducted at the same time. It is important to consolidate existing and make it a springboard for more ambitious protections. The establishment of the planning document should be made with the endorsement of the State and not only through a formal legal control. The "heritage PLU" also raises the question of the capacity of the territories to be professionals. Support, expertise and training should be offered to local communities.

On the other hand, as the ancient centres concentrate hundreds of thousands of vacant housing, it is very important to develop specific fiscal advantages aimed at their revitalization and at recovering their

social image, as already experimented by the Urban Renewal Programme (*Projet de Rénovation Urbaine*, PRU) established by the law n° 2014-173 of 21 February 2014 *de programmation pour la ville et la cohésion urbaine* or by the National Program for Sustainable redevelopment of Old Areas (*Programme National de Requalification des Quartiers Anciens Dégradés*, PNRQAD) created by the law n° 2009-323 of 25 Mars 2009 *de mobilisation pour le logement et la lutte contre l'exclusion* (fig. 4). Ultimately, the future "historical cities" need to be outfitted with tools promoting and helping the public awareness, such as the label "*Villes et Pays d'Art et d'Histoire*".

It would not be the first time that an attempt to simplify the legislation and avoid overlapping generate an administrative chaos and stop ongoing procedures. We hope that this is not the case (fig. 5).

4. Conclusions

The French experience in the field of architectural and urban heritage preservation, held by its reputation in the cultural and social domains represents a legitimately recognized reference in Europe and in the world [17]. In the course of time, France has developed a legislative apparatus of the most comprehensive and articulated, especially in relation to protected areas

The idea of "heritage safeguarding" strictly combined with that of "quality of life" is now at the center of its cultural concerns: in a globalized world, every society clings to its reference points, even if they are called to evolve. This approach indicates how the inclusion of heritage should not be built up exclusively through the protection, but by integrating the heritage issue in procedures for development. Titian affirmed in his *Allegory of Prudence* (1565) that "*From experience of the past the present acts prudently lest it despoil future action*" but be prudent does not mean being timid, but to assume its own status as an intermediary between the world passed away and another that installs, without breaking the thread of life of the town which exists only because it is a living space, not a decoration [18].

This is the key point of French politics. Its ambition is to build a perennial great project for heritage through the implementation of stable, innovative and dynamic policies, able to reconcile protection, citizenship and evolution of functions and uses, at an enlarged urban scale.

Abstract

With the construction of three coverings in the Valle dei Templi of Agrigento, the management of the Park Agency is carrying out an experimental action which can produce innovation in the context of archaeology. The “Architecture X Archeology” workshop explored the state of the art in terms of works protecting archaeological landmarks, with the goal of identifying new modular and flexible types which are adaptable to the diverse needs of archaeological sites. The Park, which covers 1,300 hectares, preserves an extraordinary monumental and landscape patrimony. Though visited by millions of tourists, the archaeological sites are not appropriately equipped for tourist use. To better use this enormous cultural resource and to make it an active agent of the regional economy, it is of strategic importance to equip it with new facilities which are appropriate for today. For this purpose, the workshop has seen professors and students of Politecnico di Milano, Palermo University, and of Tokyo University involved in the construction of experimental prototypes for the protection of archaeological finds and excavation sites. The shelters produced during the workshop —other than having a functional and aesthetic value— form the first nucleus of a park of modern architecture within an archaeological park. The work shows the willingness to systematize the great potential value which the interdisciplinary prospect of integration between architecture and archaeology offer to both disciplines in terms of research and analysis.

Keywords: Archeology, Architecture, Innovation, Digital Fabrication, Shelter

1.INTRODUCTION

“Architecture x Archeology” is a co-joint workshop held at the Parco Archeologico Valle dei Templi di Agrigento, together with Tokyo University, Politecnico di Milano, and University of Palermo, with the aim to design and build three pavilions for covering and safeguarding archeological excavations, and for protecting archeologists from atmospheric agents such as sun and rain.

The workshop offered an up to date study about shelter structures for archeological sites. It aimed at producing modular and flexible structure adjustable to different scenarios and needs. The workshop was divided in to two parts: the first preliminary part -45 days- took place at each respective university of the players involved. The second phase -7 days- took place on site.

The first preliminary part introduced issues relating to the complexity of designing within archeological sites, applications of computational design, structural stability, and practical solutions for quick physical materialization within limited time and budget. The second part explored culture and nature of Akragas (old name for Agrigento) which served as a pretext for further exploring design for archeological sites.

Three teams, each comprised of 6 to 10 members, ultimately produced three full-scale shelters to test out their ideas, methodologies, proposals, and materials. Despite differences in use of software (Rhinoceros, Grasshopper, BIM, Autocad), principal material (wood, bamboo, stones, micro-perforated polycarbonate), fabrication method (CNC routing, manual sawing), and budget (from 1,000 EUR to 6,000 EUR, including all costs) it was possible to make comparisons and analysis during the process and later in three distinct outcomes.

1.2 Functional Program: Shelters

Due to the complexity of the touristic fruition of Agrigento's archeological site the workshop focused only on shelter for covering and safeguarding archeological excavations.

This theme represents an unsolved issue of many open air archeological sites in Italy. In fact, archeological excavations need a particular protection against atmospheric events that may bring back the excavations to their original conditions.

Moreover, the shelter theme represents a complex theme because it induces a substantial modification of the site aspect. In case of construction -besides technical problems such as anchoring the structure to the ground- the site will be inescapably changed by the addition of a new volume on the site. In this sense, the team were asked to see their respective project as a shape that merges and connects to the landscape, and not as an opposing element. The three teams tested different technical and material solutions, all respectful of the historical heritage.

The experimented solutions were of three types:

- 1) Shelter with a light structure easy to move and disassemble.
- 2) Shelter with a medium-light structure easy to move and disassemble.
- 3) Shelter with a medium-light structure fixed to the ground.

2. Archeology and Architecture

According to architect-archeologist Sebastiano Tusa, the relationship between archeology and architecture has always been characterized by several, interlinking factors including historical perspectives, technological aspects, issues relating to restoration and the link with the local territory. No matter how tight this relationship has been, it has not always been linear and calm, both of which are necessary qualities for advancing the state of the art in this area. Differences due to background, epistemological divergences, academic contradictions and reciprocal individualism have produced a fracture between architecture and archeology - not only concerning research and analysis, but also the design of new facilities, restoration, and the transformation of the asset into a more fruitful experience: it seems logical to say that it is time for architecture and archeology to start talking to and understanding each other.

2.1 Sicilian Context

Architect Giuseppe Guerrera – former director of a master course on architecture and archeology offered at the University of Palermo – reckons that Sicily is not rich of primary resources, it does not have an industrial reality big enough to sustain the Sicilian economy and, finally, the tertiary sector is not in very good shape, in spite of its strategic position in the middle of the Mediterranean Sea. Thus, maybe the real resource for a concrete economic and social development is not mass tourism, but cultural tourism, a sector on which regions like Tuscany and Umbria have prospered. If Sicily is to become a region capable of supporting a successful tourism industry, it is necessary to design and build adequate structures that are currently lacking: it is mandatory to update our heritage and natural sites for a better fruition.

2.2 Architecture for Archeology

Archeological sites could be one of the most important touristic resources of Sicily. However, archeological sites, even though they are visited by millions of visitors every year, are lacking adequate and up-to-date infrastructures. In addition, this present lack of infrastructure creates obstacles to archeologists and researchers in further excavations. In order to effectively exploit Sicily's cultural and historical heritage, new facilities that respect the historical context yet remain open to the future need to be built. As the first in a series of workshops, the projects designed will form the basis of a catalogue for actual construction, and will contribute to strengthening the collaboration between the academic world and the Archeological Park of Agrigento.

3. The Site and its needs

Covering an area of nearly 1300 hectares, the park preserves an extraordinary monumental and natural heritage that includes the ruins of ancient Greek city of Akragas and its surrounding landscape. Listed in 1997 as a Unesco World Heritage, the Valley of Temples is home of one of the largest

archeological complex of Mediterranean area, immersed in a outstanding rural landscape punctuated by centuries old olive and almond trees. Agrigento is a major tourist centre due to its extraordinarily rich archaeological legacy.

Though visited by millions of tourists, the archaeological sites are not appropriately equipped for tourist use. To better use this enormous cultural resource and to make it an active agent of the regional economy, it is of strategic importance to equip it with new facilities which are appropriate for today. It is necessary to plan and build adequate structures which are now missing, and to adjust the cultural and environmental assets for better use.

The construction of the shelters—in addition to posing technical problems related to anchoring to uneven ground, and to the dispersion and/or collection of rain water— transforms the site in that it inevitably adds a new element to the archaeological landscape. The projects have been interpreted as a shape to be managed in continuity with the landscape, something which does not conflict with it but rather merges with it. The projects have in part attempted a dialogue with the context—they listened to and answered it—and in part—in the most extreme manner—attempt to merge and cancel themselves in it in order to disappear.

4. Shelters case studies

Three case studies are described in the following sections. Due to the complexity of the site and the limited timescale, the workshop primarily focused on the design of shelters for covering and safeguarding archeological excavations. This particularly composite theme is at the center of many harsh debates in Italy and beyond. This is due to the substantial aesthetic change that they can bring to a site as well as the technical problems.

The workshop witnessed a true debate between the various participating schools, both in the design and in the construction. BIM, parametric software and digital fabrication techniques alternated with handmade sketches and craftsmanship skills pushed to the extreme. The three shelters went from the search for a dematerialized and wooden architecture—in contrast with the solidity of the Greek temples—to the use of materials found within the Valley, from the stripping of river reeds to the collection of rocks used as an integral part of the shelter structure.

The work shows the willingness to systematize the great potential value which the interdisciplinary prospect of integration between architecture and archaeology offer to both disciplines, both in terms of research and analysis and also in terms of how the planning pertains to the execution of avant-garde interventions.

It is on the basis of these considerations, that this complex, fascinating, and contemporary issue, regarding archeological areas and parks, was explored during the workshop. This signaled the beginning of a fruitful collaboration between Parco Paesaggistico e Archeologico della Valle dei Templi, Polytechnic of Milan, Tokyo University, and Università di Palermo. The collaboration consisted of both taught sessions throughout the academic year and collaborative work before and during the workshop. Functionaries of the archeological park provided students from Japan and Italy with reference books, technical drawings, aerial photos, and cadastral maps of the site. The preliminary research and design activity conducted co-jointly by professors, tutors, and students was used to achieve a mature design during the workshop. Students were asked to focus on a reciprocal and beneficial dialogue between architectural and archeological issues.

4.1 AkragaShelter, Milan Politecnico

The Polytechnic of Milan has realised a project named AkragaShelter, that sits by a temple built to honour the sacred spring dedicated to Demeter, wife of Zeus. A special and holy place, where architecture and nature combine and unite themselves in an empathetic way.

The small pavilion, about 20 sq.m., was built to protect some portions of the temple, now dismantled and aligned on the ground, waiting to be reassembled. However, this system could serve the Valley of the Temples Park also for other needs. Due to the sacredness of the place and the impressive archaeological site, the team opted for a simple design solution which makes use of materials including wood, corrugated fibre glass and rocks collected on site.

As the design work was shared with the Kengo Kuma Lab, which also developed its own pavilion, the team referred to some aspects of Japanese culture, Zen mysticism, as well as the historical context, Greek classicism.

The reference to the Greek temples of Agrigento is expressed in the project through the use of massive columns realised in galvanised steel gabions filled with local stones which serve for anchoring the shelter to the ground. This reference is highlighted by the slope of the roof, with an angle of 22.5°, identical to that of Temple of Concordia. Moreover, the wooden roof evokes the typical gable roof of the Greek temples. Concerning the reference to Japanese culture, the shelter gets inspiration from the Ise Shrine, the most important Japanese shrine, made of Inoki wood (cypress). In particular, it looks at the temporality and reversibility of Ise—which is disassembled and reassembled every 20 years— and at the shape of the roof summit, surmounted by a V-shaped ventilation duct for water collection.

Fig.1: Digital model of the module, and database associated to it.

Fig.2 Sketches of the structure

The roof structure is covered by a white corrugated fibre glass which gives a soft atmosphere to the shelter when lit up at night. An effect similar to a Japanese lamp made of rice paper.

AkragaShelter was designed with a parametric and associative model. The shelter – which is modular and flexible – was conceived as a module that can be built in different areas of the park. Four variables have been taken into consideration for making the model: 1) the variety of sites with ruins in the park, 2) the different orientations of the sites, 3) the different size of the ruins to be covered by the shelter, 4) the uneven level of the ground.

Each variable was considered as a parameter in the digital model. The digital model designed can adapt its global geometry and that of its components to different variables. The height of every pillar is adjusted to ground conditions. The ground was modelled as a cloud of points built by importing data through a laser scanner survey. Length and width of the roof came as a result of the dimensions of the ruins. Every component of the shelter is hierarchically associated to the geometry of other components in a tree of associative relationships.

Once the shelter is digitally modelled, it is possible to simulate the real condition of the site and associate its geometry to a database from which it is consequently possible to extract: amount, dimension and specifications of construction elements. Finally, the team built a small architecture, simple and respectful of the surroundings yet functional and elegant, perfectly integrated in the natural environment of the Valley of the Temples.

This experiment shows the possibility in the use of this modelling strategy in a very simple geometry. Here the advantage is in the adaptability of the parametric shelter to different environmental situations.

4.2 Molecular Shelter, Tokyo University

While respecting the local context, the molecular shelter design reinterprets a concept borrowed from Japanese traditional culture. In fact, the shelter takes inspiration from the bracket system found in traditional Japanese temples where the roof plays a prominent role.

The eaves, which extend far beyond the walls and cover verandas, have a practical function because they protect the building by carrying the rain as far as possible from its perimeter. The roof's weight is supported by complex bracket systems called "tokyō". The shelter meets the requests of the Park Agency that asked for a shelter with a roof as large as possible, designed to carry as far as possible the rain from the excavations, and to minimize the surface area of column base. The columns size was checked by professor engineer Jun Sato through structural analysis software to optimize them to the thinnest possible size.

The traditional bracketing system was reinterpreted in the design by keeping it extremely essential both structurally and esthetically. Moreover, this system presents an intrinsic elasticity, which lessens the impact of lateral forces by acting as a shock absorber. The partial inclination of the roof is reminiscent of the "Tempio dei Dioscuri", so to have a direct reference to existing forms in the landscape.

The shelter – being made of multiple units – is light, easy to fabricate and assemble in a reasonably short time, movable, adaptive to the site, and modular. The structure serves also for hanging archeologists' working tools.

Fig. 8: The Park Agency asked for a shelter with a large roof, designed to carry as far as possible the rain from the excavations, and to minimise the surface area of column base.

The whole structure of the shelter is made by a joint system of four small struts bind along the x-y direction beams with M6 screws. The screws add on resistance against rotational movements due to horizontal external forces. Being modular, the system can extend. If requested by a particular site condition, columns can be positioned at different point of the grid. The structure weighs around 100kg, and can be easily moved by few people. The shelter is anchored to the ground by four concrete blocks of 20 x 20 cm.

The shelter is made of local pine trees, that were cut and assembled with M6 size screw * 5000. It took five days to assemble, and the final cost of the pavilion amounted to 1600 euro.

Concerning computational aspects, programming was developed with Rhino, Grasshopper, Python. This enabled the exchange of information between Tokyo and Agrigento and optimized the calculation which enables parametrical changes. In particular, the use of parametric software proved to be essential for testing different size and arrays of the grid structure, structure thickness and weight, material length and number of the elements used. As for the fabrication, hand-made easy fabrication system was used which demanded only simple holes by drilling and screwing instead of sophisticated CNC machines hard to find on site. Moreover the Tokyo team preferred to realize its project just by taking advantage of the local craftsmanship.

4.3 River Reed Shelter, Palermo University

River Reed shelter reflects on the idea that the millenarian culture of Greek temples is strictly related to the immensity of its surrounding landscape. It is thanks to this relationship with the landscape if the ancient culture can transmit its values to future generations despite the fact that the maintenance of current archeological park, it is not a shared value promoted by local politics. While the two previous shelters were designed during the preliminary phase, the Giardini in Campo follows in the category of readymade experimentation since it was designed and built during the workshop construction week.

The shelter responds to the following issues: it protects from heavy rain, hail, rain-off and erosion; it provides shade during excavations and to the general public. Thanks to use of local materials, it offers a high degree of integration with the landscape, moreover it is reversible and economical.

The shelter takes inspiration from archetypal shape of the two pitch rural houses in Sicily: the roof height and inclination can be adjusted to different needs.

The project aims at a bare essentiality. Nevertheless, it solves decisive issues such as the immediate possibility to adjust to uneven ground conditions. Moreover, the team decided to use a camouflage technique thanks to which the shelter almost melts into the landscape. This was partly possible thanks to the use of river reed collected in the Valley itself.

The river reed (*Arundo donax*) is a constructive element that characterizes the local construction culture. The reed is inextricably linked to the river Akragas which gave its name to the Greek colony. The reed has been used for centuries for fencing rural plots, as material for simple roofing, and as constructive material in sandwich walls. Very common in this area, the river reed is flexible and can be found at nearly zero costs. In the past 50 years river reed was replaced as a building material by

Fig.12 The team decided to use a camouflage technique thanks to which the shelter melts into the landscape.

synthetic materials which has resulted in an overpopulation of reed in the majority of Sicilian rivers and it has caused damage to the ecosystem. In order to optimize the structural performances and to minimize the size of the structure, the shelter is made of a 5x5 cm width profile in Corten steel.

The structure has been designed to be packed in flat boxes which are easy to move and it weighs just 103kg for a module of 9 s.qm. The reeds are prepared in advance and are assembled with the Corten structure in a easy way. The structure could be easily disassembled by archeologists themselves.

5. Conclusions

Conceived and finished in a very condensed period of less than 45 days, both computational design and digital fabrication enabled the speed and the challenges undertaken in each of the shelter.

The Japanese and Italian students interacted profitably, both with the local authorities and with the park functionaries and architects. The architectural design meeting took advantage of the scientific supervision of Kengo Kuma and Jun Sato as well as the contributions of subject matter experts like Giuseppe Guerrera, former director of a master course about Archeology held at the University of Palermo. The union of these synergies—university, public functionaries and craftsmanship—represents a unique moment of exchange and growth which opens new paths to explore.

The three shelters produced during “Architecture X Archeology” —other than having a functional and aesthetic value and were built only for temporary use— form the first nucleus of that which Director Parello imagines to be a park of modern architecture within an archaeological park.

Abstract

Light Emitting Diode (LED) or Solid State Lighting (SSL) represents a promising technology for future lighting application; compared with other light sources, the LED lights allow efficiency comparable with those sources actually best performing, longer life and increased flexibility as it can be regarded as an effective "point source". On the other hand, the design of a LED based luminaire has to take into account many specific aspects of this technology such as photometric characteristics variation with the junction temperature, current vs. input voltage forward variation, environmental conditions (ambient temperature, humidity, and wind), and other aspects related to the heat dissipation (heat sink design and integration), control (current driving and power supply) and lighting fixture design for which is of a crucial importance the integration of different parts of a LED luminaire considering existing standard requirements.

In order to achieve the final target of developing a LED based luminaire in exterior lighting application, it has been firstly analysed and revised a set of up-to-date and trendy LED-based luminaires today commercially available and their principal characteristics have been listed; the behaviour of the main components of a LED system has been analyzed and their relationships have been taken into account. The first results of design process have been reported and the proposal of some prototypes fully described.

Keywords: LED, Hybrid Design Methodology, LED based luminaires design, LED system components design, Energy saving.

1. Design case studies, market analysis and trend

In the first phase of the design project some case studies were chosen to examine the different categories of LED outdoor lighting systems existing on the market. The case studied were classified in different categories of application:

- 1) Lighting for residential areas, parks, gardens and urban streets;
- 2) Lighting for parking lots and city large streets;
- 3) Lighting for extra-urban streets.

To this study were added: a specific study of some LED headlamps available on the market with different powers, a repertoire of retrofit devices and an analysis of some devices based on traditional

light sources competing with LEDs because still widely used. A comparison with these devices was carried out in order to define design strategies to overcome the LEDs weakness and to enhance their benefits.

The analysis was conducted on two different levels. A first level of systematization was carried out cataloguing and indexing the devices in relation to some identifying features, some of those useful to compare their potentiality in terms of market competition.

The features were:

- name;
- producer;
- site of production;
- type of source;
- degree of protection;
- orientation;
- electrical power;
- light efficiency;
- technical specifications;
- photometric simulation files;
- catalogues.

A further and more detailed analysis, was carried out on a limited selection of products, considered more interesting in relation to the specific business context and market related to the company that funded the research project. In this second step a detailed report of data and graphs was carried out. The analysed features were defined in relation to the needs of the business market, in order to be able to build a strategy database, covering several sectors. The analysis could be continuously updated in order to drive the company's innovation strategy and the new products development, both from the technical and design points of view. The repertory obtained is easily implementable and linked to instructions for updating to obtain a durable strategic instrument for the future of the company beyond the end of the project. As result of the survey performed, all the gathered informations have been organized, for each luminaire, as reported in figure 1.

Fig. 1: Example of luminaire record.

After the activities of selection, cataloguing and characterization, a trend scenario was carried out. Besides the products on the market, some design concepts developed by designers or by design students were considered at an international scale. This study allowed for foreseeing the advanced functional and aesthetic trends useful to define the evolution paths of technological opportunities, users needs and design ideas.

The result of the analysis on a specific target of devices with a power of 250 W shows a prevailing aesthetic uniformity in terms of design and of the LEDs geometrical organization in the projector.

In contrast, the analysis of the more advanced concepts associated to lower power devices, smaller, lighter and more free from technical limitations, has provided some clues to the evolutionary trends that could be transferred and implemented on devices with high power. Inspired by these design trends, though the necessary technical and technological considerations, our research aimed for giving new design solutions to develop new products oriented to emergence on the mainly uniform market.

2. Design evolutionary framework and corporate identity strategy

The innovative formal and technical solutions emerged from the evolutionary framework were:

- modularity of the projectors starting on a basic module composed with various geometries in order to be flexible and adaptable to different contexts with different lighting requirements;
- use of new LED assembly geometries, alternative to the conventional rectangle. There are various examples of compositions. One of the most interesting is a continuous bend organization in which LEDs are mounted on a continuous bended profile (see Mira 380 by Hei Solarlight, Pilled by KXdesigners, SoleCity by Philips, PALO ALTO by Vibia). This kind of "bendy" sign could be interpreted as a characteristic identity of LED technology, which specifically allows this type of geometric arrangement. An opportunity to propose a recognizable character to associate to the LED devices connecting this new language with the values of innovation and sustainability, which should strengthen the image of these products on the market;
- in parallel with the previous bendy tendency oriented to harmonic continuous morphologies without interruptions, in other examples, emerges also the exaltation of a polilinear segmented geometry, with the contrast between the net vertical and horizontal lines (see Plan by Schröder group, Archilede and UFO by Guzzini);
- optimization of the structural supports and reduction of matter, oriented to reducing both the economical and environmental impact. The essential and minimal shape, resulting from structural optimization, seems to facilitate the integration of devices in different context, new or ancient. Geometries are clean and coherent with the contemporary in contrast with the approach of many companies of imitating morphologies and details of old lampposts for the historic contexts. At the international level this approach is now considered as "historical fake";
- use of systems of reflection, refraction and diffusion to increase the LEDs efficiency and to overcome the spot effect that characterizes them, providing more homogeneous and continuous lighting conditions;
- tendency to integrate LED lighting systems with renewable energy sources, like PV systems and microwind, connecting the LEDs energy saving potential with other solutions for environmental sustainability;
- tendency to transfer morphologies from biology to propose new morphologies different from the conventional ones as well more compatible with nature and able to communicate the value of sustainability included in LED technology (such as the Philips's concept evoking a flower that opens and closes).

From this evolutionary framework the requirements of the various project proposals were developed, reaching to the definition of 4/5 devices corresponding to different target of market and fields of application e.g. parks and green areas, main streets and urban minor streets.

The analysis developed shows the need to impress the design of new devices on real users needs, deepening the differences, in terms of visibility and quality of light between traditional light sources and LED sources, in order to design systems that enhance the potential of new technologies exceeding their limits: many of the LEDs barriers to diffusion could be overtook by a good design.

Some fundamental restrains, that constitute a barriers to market, can be recognized in the high initial costs and the reduction of the useful life due to design errors in terms of dissipation (higher junction temperature), assembly and power. The benefits to highlight are, however, a better visibility of objects and walking people, durability, low maintenance costs, reduced energy consumption, possibility of dimming, colour rendering and greater visibility of road signs.

Among the several proposals developed, the research project has been closely related to various types of roads with specific lighting requirements (ie. road lighting class).

From the survey on the state of the art, it can be derived that the LED lighting market, particularly for outdoor use, suffers from a general morphological and linguistic uniformity that interprets, in an automatic way, a source that is often perceived as cold and artificial: as if the appearance was sacrificed by the virtue of energy saving and technological innovation.

The study of design emerging trends leads, moreover, to identify two parallel and often conflicting approaches: a first one that continues the path of minimalism and "smoothness" of the forms that become "universal" because seem abstracted from all contexts, and a second one inclined to "naturally complex" forms that find in the "parametric design trend" the ultimate expression of affinity between mathematics and nature under a new digital aesthetics.

In the design phase of the research it was decided to combine these two approaches through a "bio-inspired" approach which refers to the "intelligence of biological systems" to define a new line of products more efficient in terms of optimization, adaptability and flexibility: an identity strategy, based on the integration between the concept of sustainable innovation with a nature-inspired approach, was defined.

A "new generation" of devices was conceived, by intersecting high LED technology with innovative complex morphologies, bio-inspired textures and organizations as well as structures taken by nature, with the aim to approximate the artificial dimension to the biological one.

The ultimate goal was to shift the perception of these systems from a "cold" and "technological" image toward a more natural one, more compatible and similar to man and to his biological nature.

The design concepts developed for the research project described below outline a new scenario of possible development paths characterized by a perspective of design for sustainability that intersects technological innovation and scientific evolution. In these "design concepts" nature was interpreted as a conceptual reference for designing systems that are more compatible with nature, but also as a communicative potential to sensitize the stakeholder on the environmental issues facilitating the assimilation of ethical messages. The nature is conceived, so, even as conceptual and communication tool to demonstrate an interest in issues of sustainability.

In this project, a bio-inspired design approach was applied through the adoption of a specific bio-inspired methodology particular called Hybrid Design Methodology [1] developed within the Hybrid Design Lab [2], a design lab dedicated to bio-mimetic design born in the Second University of Naples in 2006. In the Hybrid Design Lab the complex qualities drawn from biological world are transferred to the design of innovative products and services as a kind of "new genetic code". A code that can be extended from a single product to composite systems, defining new forms of relationships between production systems and user system.

3. Methodology and outcomes

The bio-inspired design methodology used in the project is an evolution of the "hybrid design methodology" geared to the specific characteristics of the LED lighting sector. The design process steps were:

1. analysis of the evolutionary scenario and trends;
2. definition the project brief as a list of "design problems" to compare with biological references. The issues identified were: modularity, light efficiency, reduction of environmental impact throughout the life cycle, energy efficiency, structural efficiency, lightness and reduction of materials, economic sustainability, adherence to the user requirements, adaptability to different contexts, aesthetic and formal quality;
3. check the solutions currently available, using the present scenario, the information coming from the state of the art but identifying the related limitations;
4. preparation of a list of biological systems in which it is possible to find answer to "life problems" similar to the "design problems";
5. interpretation of the nature model from a "design" point of view;
6. translation of the nature model into design concepts;
7. selection of the "hybrid concept" more suitable to be developed;
8. development of the design and technical details.

The application of methodology allows to obtain a selection of strategies inspired by nature applicable in the field of LED streetlights. The strategies were:

- structural optimization;
- aggregation;
- modular;
- organization of space;
- organization of light;
- mimicry.

Fig. 2: References of the "Hybrid Design" approach specifically applied to the research.

Inside these strategies two families of design concepts were developed:

1. One's Parametric: this concept was based on the principle of modular organization in some biological structures like: the cobweb, the cells of a honeycomb structure of a leaf, the eye of an insect, the ribs that strengthen the wings of the dragonfly.

These all are the result of shapes repeated several times that creates a rhythmic composition and a modular organization that seems to be born to perform specific mechanical, physiological or optical needs. The texture present in many species of diatoms, for example, in the form of hierarchical holes on the shells is an interesting nature model as the structure of Amazonian Victoria leaf that seem to respond to the need of differentiation in terms of strength, flexibility and shape. This strategy was interpreted as an evolutionary response to the flow of specific forces on a surface.

2. One's Mehndi (Diatom top, Diatom01, Diatom0): these concepts are different versions of the same "type" inspired by the complex patterns of diatom shells. Diatoms are unicellular algae that have always been a great object of biological studies and research. Many species of diatoms exist in nature and the variety of shapes and ornamentations is very wide. These perforated patterns have in nature many motivations like filtering, structural optimization and lightness. In the design concepts this nature model was transferred to obtain heat dispersion, structural optimization and material reduction.

The founding principle of the project consists in a proposal of a minimal base model adapted to be inserted in both historical and contemporary contexts and in places with different "degrees of artificiality".

The new product collection includes some possible solutions inspired by textures of nature, which lighten the structure, in order to optimize the structure but also to dissipate the heat with a great advantage in terms of increasing the efficiency of the LEDs, thus of saving energy.

Textures can also be customized, according to the architectural character of the place of installation, to the trends changing and to the different aesthetic languages characterizing different cultures. For example, the propensity of Arab culture decorations to choose very complex patterns or Scandinavian preference for minimal morphologies.

The choice of materials and surface effects allow to choose different colours promoting the opportunities of integration in different contexts, according to a predetermined colour palette and the opportunity of customizing finishes and colour effects.

Fig. 3: Hybrid Design: One's Parametric luminaire concept developed for street light application.

4. Light source and optic

From the technological point of view, the growing efficiency of the Light Emitting Diode (LED) technology involves the possibility to use LED based luminaires in wider application fields. If from one side LEDs allow a greater efficiency, flexibility and longer life than traditional light source, on the other side their application presents new problems to take into account to guarantee their correct operation.

Comparing a traditional source luminaire vs. LED based luminaire, it can be noted the presence of some parts that specifically characterize LED luminaire type. In particular, in a LED based luminaire, there are components such as a heat sink, secondary lens, Printed Circuit Board (PCB), driver, etc... that are not usually considered in the design process of a present luminaire or they are present with different form or function: just considering the light source itself, the traditional luminaire was often assembled with a single light source of considerable size whereas LED based luminaire is characterized by an array of light source that can be approximated as "point sources".

Within this perspective it raises the necessity to a suitable approach for defining the behaviour of every single component as well as for the whole assembly, to analyse not only reciprocal relationship, but also the influence of environmental condition or the operating condition of the application field.

The main parts of a LED luminaire system that is hence necessary to consider can be summarized as:

- **LED**, as the light point source;

- **secondary optic**, that provides for optimizing and redirecting the luminous flux emitted by the source in precise directions;
- **heat sink**, that has the function to dissipate the heat power produced by the LED source;
- **power supply** and control system, that provide for electricity supply, flux control and system regulation under several operation conditions.

The Light Emitting Diode represents the core of the system and at the same time the most fragile element of a LED system as it acts as "basic point" for the choice and the design of all other components.

A LED is a chip of semiconducting material impregnated, or doped, with impurities to form a junction positive-negative (PN); the main feature of these devices is to allow current flow in one direction, as a normal diode, to which is added the ability to emit light.

The main characteristics of a LED can be summarized as reduced size (usually 5 x 5 mm), longer life time (greater than 50000 hours), higher efficiency (up to 160 lm/W or more [3]) and a high Colour Rendering Index (CRI) (greater than 90 for white light LED [4] [5]); these features allow to use the LED not only in retrofitting operation but, above all, to develop new and innovative products.

Considering a scenario where can be detected a market situation made of an impressive and massive LED sources availability, it is fundamental to correctly select the LED that fits the design targets and requirements necessary for each lighting application such as defined during the "design process" previously considered. Above all, the main aspects to consider for the choice of a LED light source can be summarized as:

- type and its field of application;
- efficiency;
- commercial availability;
- life time;
- luminous flux emitted;
- unit cost.

In the following table, the LED considered during all the phases of the research project have been reported with their main parameters.

Manufacturer	Model	Color	CCT (K)			Flux (lm) @ 25 °C	Thermal resist. (°C/W)	Viewing angle (°)	LED junction temp. (°C)	Drive current typ. @25°C (mA)	Drive voltage typ. @25°C (V)

Getian	High Power LED	Cold White	6000	6500	7000	6500		115		3200	33

Tab. 1: Main parameters characterizing selected LED.

Another aspect that has been evaluated during the development of the LED luminaire for the specific road lighting application, is the application of existing regulations and standards; in this field many technical standards claim for the enhancement of the vision quality and the reduction of light pollution. Thus, it rose up the need to integrate a lens system able to provide for the necessary photometry to optimize the luminaire and adapt it to the specific requirements.

This "secondary optic" is mainly divided into two types:

- **Total Internal Reflection (TIR) lens;** they are constituted by a full body, realized using polymer with a high transmission factor of the light, with a characteristic shape of a revolution paraboloid with central emptying. The area without material along the central axis has the function of directing the high intensity radiation of the central portion of the photometric solid. The area with material works by exploiting the phenomenon of total internal reflection to redirect the light; each reflection involves minimal absorption that must be adequately considered to reach a high luminous efficiency;
- **Reflector lens;** they are built using polycarbonate with a high thermal resistance and with an internal surface treated with burnished aluminium oxide in order to achieve the higher reflectance. At any reflection, a light absorption greater than the TIR lens occurs but, between two reflections the light runs through an empty space with negligible absorption; therefore only a little difference in efficiency is observed comparing TIR and Reflector lens. Nevertheless, the reflector lenses offer a lesser control of the radiation; a part of the light rays are emitted directly (without modification), causing an expansion of the beam.

For application where a careful control of the luminous beam is required, such as road light application, a new type of secondary optics have been developed, called “free-form”. The free-form lens can be classified as a TIR lens, and its importance is related to the possibility to accurately design its internal and external shape for precisely controlling of the light beam of LED source.

In our design application, the use of free-form lens has been considered within the design of lighting fixtures to achieve the desired photometry as well to improve the optical efficiency; ie. it is important not only to consider the efficiency of the apparatus in terms of how much light is emitted from but also how much light effectively illuminate the task area.

Presently, on the market are available many lenses type for different application fields and LED source; each manufacturer makes available all necessary information for a correct selection of a lens for a specific application.

For our process, the design of the correct lens type for a specific application, has been made by a suitable selection among those commercially available; whereas the lens adopted has not been defined by a photometric point of view, a laboratory measurement where carried out by a simplified system set up at the Built Environment Control Lab of Department of Architecture and Industrial Design of Second University of Naples, for the photometric characterization of LED based sources. The facility is provided with photometric bench within a dark room, equipped with both traditional luminance meter and videoluminancemeter (LMK) that acquires luminance map of a suitable target upon which falls the luminous flux emitted by the LED and LED & lens system under consideration.

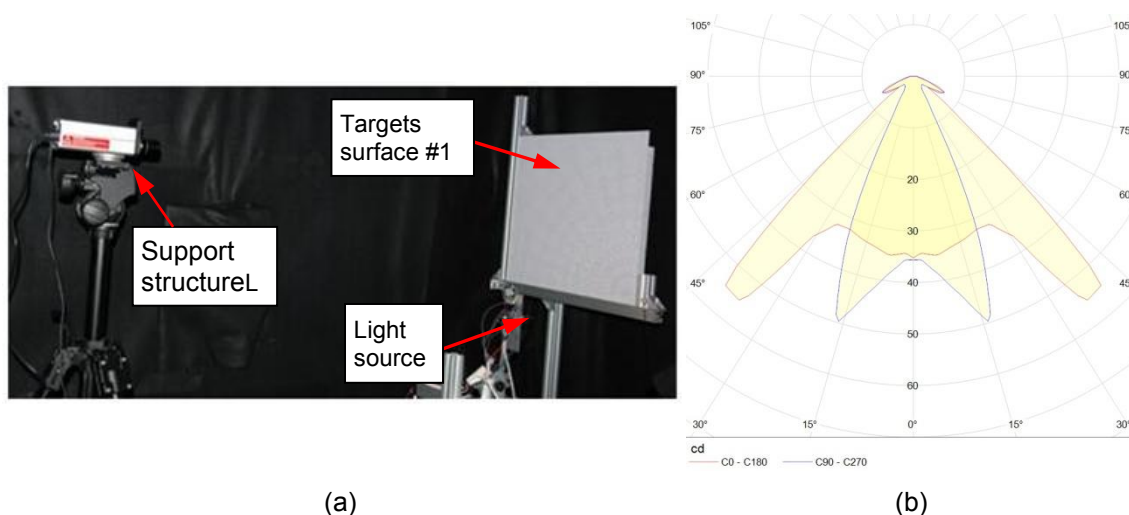

Fig. 4: Facility layout (a) and candlepower distribution of LED Cree XP-E equipped with a free-form lens for street lighting (b).

5. Thermal management

Considering the working principles of a LED, it can be seen that about the 70% of the power supplied is converted into heat and that its life time and efficiency strongly depends from the operation temperature of the p-n junction; the major cause of failures in LED devices is due to improper thermal management. For this reason, the thermal management of a LED system assumes a critical aspect in the LED system design process and represents a topic ("heat sink" design) for many researches.

For the optimization of the system LED & Heat sink, a preliminary simulation tool able to identify the maximum thermal resistance value for the heat sink, with a predefined junction temperature, has been developed. The value of the maximum thermal resistance, so calculated, was used as input value into the catalogues of different manufacturers for the choice of the optimal heat exchanger, in terms of the total size, shape and characteristics of the fins.

To analyze the thermal behaviour of the LED & Heat sink considered, laboratory measurements were carried out using some T-type thermocouples, for different point acquisition, and an infrared thermal imager [6], for the characterization of the temperature distribution on the surface of the LED system. Various combinations (optimized and not optimized) of light sources and heat sinks have been considered and tested; for each combination the experimental junction temperature values have been compared with those simulated.

Before starting the thermal acquisition it has been checked that the system achieved electrical and thermal stabilization. Figure 5a shows an example of the LED system investigated and figure 5b shows a typical thermal acquisition.

Fig. 5: Coupling of LED & Heat sink investigated (a) and its thermography (b).

For the present design project, the cheapest solution for a correct thermal management of a LED system for road application was considered: a fin aluminium heat sink that exploits natural convection heat transfer.

The choice of the heat exchanger type was made based on two considerations. The first consideration originates from a market research, the second one from the study of the datasheets and the catalogues of heat sinks manufacturers.

The market analysis was aimed to define some manufacturers of heat sinks and to analyse characteristics used in competitor devices for road applications.

The survey gave indication about the shape, material, fin type and surface finishing; the research results indicate, as the most used for road luminaires, the aluminium heat sink with straight fins and surface of anodised natural colour.

The study of the datasheets and the catalogues of heat sinks manufacturers gave information about the size, the shape, the thermal power dissipated and the efficiency of the products available on the market.

In the table 2 are listed some of the combinations investigated with indication of the type, thermal resistance and characteristics of the heat sink and the LED light source coupled; for each combination, the junction temperature has been evaluated and reported.

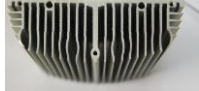

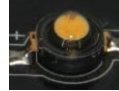

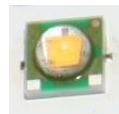

6. Field test

The last step of the design process is the photometrical characterization of the luminaire to know how the light is emitted: it represents a crucial aspect of the development of the luminaire. The luminous intensity distribution measurement is very important also to verify the data obtained through simulation during different design steps or to evaluate the effectiveness of a design choice.

The presence of a protection glass, the assembly process or other parts essential for mechanical or protection reasons can modify the original photometry of light source. Therefore, it is fundamental to measure the luminous intensity distribution of the whole luminaire; to this aim, a "test room" was prepared as showed in figure 6, where has been reported a picture of the experimental apparatus realised for the evaluation of the luminous distribution of luminaire.

Marks were placed on the room floor defining a "reference system" to use for measurements. The light source was placed at 3.5 m from the floor to respect the hypothesis of considering the light luminaire as a "point source" from all marks; a modular structure was used for supporting the luminaire and for aligning it to the reference system.

The luminous intensity distribution is simply calculated applying the "inverse square law" starting from the illuminance measurements in correspondence of the marks; the illuminance values have been gathered using a multi-heads luxmeter (Konica Minolta, Illuminance Meter T10).

LED system	Heat sink	R (° C/W)	WxLxh (mm)	Fin thickness (mm)	Pitch (mm)	LED source	T _J (°C)
System 1		1.4	150x95x40	B = 3 b = 2	variable		79.9
System 2		1.5	150x110x40	1.5	4		52.9
System 3		5.9	34x54(diam.)	a1 = 1 a2 = 5	3		55.6
System 4		2.0	170x40x35	2	7		58.4

Tab. 2: List of some combination LED & Heat sink analyzed.

During photometric measurements, also temperature values and electrical parameters have been acquired and stored to have a full knowledge of operation condition. A luminaire commercially available was used to calibrate the experimental apparatus, comparing experimental data with luminous intensity distribution provided by manufacturer.

Fig. 6: Facility layout for photometrical characterization of luminaire.

Knowing the geometrical position of each mark respect to the light source and the illuminance value on them, the luminous intensity distribution and the luminous flux of the luminaire have been obtained; from experimental data, a EULUMDAT file can be created by a suitable software [7]. EULUMDAT is a standardized file format utilized to provide information about photometric distribution and power supply of a light source and to exchange those information among simulation software.

The EULUMDAT files, obtained for the luminaires considered, has been then used in a lighting simulation software [8] to evaluate the respect of the performance requirements and to compare various lighting solution and different luminaires.

7. Conclusion

In the present paper, the issues related to the development of a LED based luminaire in exterior lighting application have been faced. In order to understand the behaviour of a LED system, the specific aspects of this technology have been analyzed and their relationships have been taken into account, while to the aim to increase the overall efficiency, the "design approach" has treated the LED system as an "unique" device with different parts and contributions interacting each other.

The analysis of the LED-based luminaires available on the market and some case studies has been developed showing a prevailing aesthetic uniformity in terms of design and LEDs geometrical organization.

In this research a "new generation" of devices was proposed, by intersecting high LED technology with innovative complex morphologies, bio-inspired textures and organizations and structures taken by nature, with the aim to approximate the artificial dimension to the biological one.

From technological point of view, the main components of a LED system have been identified and analyzed.

The LEDs as light source have been analyzed and their main characteristics, compared with traditional light sources, have been summarized as well as the main aspects to consider for the correct selection of a LED source for a specific application field, have been suggested and listed.

In order to achieve the desired photometry as well to improve the optical efficiency, the different type of secondary optics have been examined and a simplified system has been set up and used for the photometric characterization of LED based sources.

To understand the thermal behaviour of a LED system, a preliminary simulation tool has been developed and several experimental acquisitions have been performed to know the punctual temperature values and its distribution on the surface of various combinations LED & Heat sink. For the present work, a fin aluminium heat sink that exploits natural convection heat transfer as cheapest solution for a correct thermal management of a LED system for road application, has been considered. Finally, an experimental facility has been used in order to measure the luminous intensity distribution of the luminaires developed. From the experimental data, the EULUMDAT files have been derived and a lighting simulation program has been used to evaluate the respect of the performance requirements and to compare various lighting solution and different luminaires.

Acknowledgement

The authors wish to thanks the company TELENIA Srl for the strong support provided during all the phases of research project and the availability of luminaires and hardware for performing in-situ measurements.

Abstract

The utilization of SSL (Solid State Lighting), better known as LED, in internal and external application of lighting and displays is becoming nowadays more important. Their utilization is growing as an alternative to more traditional technologies due to their tangible features such as luminous efficacy comparable to the traditional compact fluorescent or HPS lamps, possibility to use CC forward current, wide opportunity to integrate renewable FV systems and operate in a way to ensure "smart" control and management operations to reduce energy consumption.

In this paper is presented a simplified system set up at the Built Environment Control Lab of Department of Architecture and Industrial Design of Seconda Università di Napoli, for the photometric characterization of LED based sources. The facility is provided with photometric bench within a dark room equipped with both traditional luminance meter and videoluminancemeter (LMK) that acquires luminance map of a suitable target upon which falls the luminous flux emitted by the LED and LED & lens system under consideration. Starting from luminance map (ie. luminance of each pixel of CCD matrix), target reflectance and considering the application of cosine square law for a point source, it can be easily derived the luminous intensity distribution of the source considered.

The methodology developed has been checked vs. a set of led and lens assembling system commercially available, giving useful information on the reliability and accuracy of results.

Keywords: LED, Videoluminancemeter, Luminous intensity evaluation, Luminous flux evaluation, Luminance map acquisition

1. Introduction

In the lighting field, the photometry of a light source represents the starting point for an accurate lighting system design. Without this information it is not possible to know how the light is emitted into the space, if a light source can be utilized in an application or compare two lighting design solution.

With this purpose, during years different instruments and apparatus have been developed and standardized to allow the quantification of the luminous intensity distribution and the luminous flux of light sources [1, 2, 3].

With the growing use of Solid State Lighting as light source, it becomes more and more important to characterize the whole system, light source and fixture, than the single source. This leads to a greater use of the goniophotometer respect to the photometer spheres but, the advantage in the use of goniophotometric measurements contrast with its maintenance and purchase costs.

To have the possibility to conduct photometric characterization of a LED based luminaire during all phases of its development, a simplified and less expensive system at the Built Environment Control Lab of Department of Architecture and Industrial Design of Seconda Università di Napoli has been developed and set up.

2. Aim of the work

The growing interest in energy saving and environmental pollution has affected all fields of technology. A lot of researchers, both in industrial and scientific fields are working to develop products more efficient or management strategies that permit to reduce the use of fossil fuel. In lighting field, the development of Solid State Lighting (SSL) has provided light sources more flexible than traditional, with higher efficiency and longer life. However, to maximize the performance and the efficiency of a Light Emitting Diode (LED) based luminaire, the knowledge of its luminous intensity distribution is fundamental.

To this aim, at Department of Architecture and Industrial Design "Luigi Vanvitelli", an experimental simplified apparatus for evaluating the photometry of LED or LED and lens systems has been set up. In this paper, the experimental facility and the methodology are described. The luminance values of some targets have been acquired, using a videoluminancemeter and a traditional luminance meter and then the measurements have been compared. Taken into account the definition of luminance, it is possible notice that its value depends by direction between target and sensor and then by their relative position. In order to make independent the acquired luminance values from this parameter, the videoluminancemeter and the traditional luminance meter have been arranged in the same geometrical position respect to the targets. Finally, the experimental luminous intensity distribution and the experimental luminous flux have been compared with light source manufacturer data to estimate the reliability and the accuracy of the methodology.

3. Experimental set-up

A schematic view of the set-up is shown in Fig. 1. The system consist of a dark room, a supporting structure, a light source, a DC power supply, a Peltier cell, an heat sink, a data acquisition unit, a videoluminancemeter and two surfaces with targets.

The light source under consideration (a) is placed on and thermally connected to a Peltier cell (b) and all is fixed to a supporting plate (c) and an heat sink (d). Using the Peltier cell is possible make stable the junction temperature while the heat sink provides for heat dissipation. Through the supporting plate the light source is fixed to the supporting structure whereas the DC power supply (C) powers the LED and the Peltier cell.

The supporting structure (D) is a modular structure realized using aluminium profiles with which is possible to define easily the relative position of the light sources, the targets and the sensors; the structure is lean on a desk, it is used to keep the light source, the target surfaces, the instrumentations and all that is necessary for measurements.

The luminous flux emitted by light source falls upon the surfaces with targets (B) creating a luminance map; using a luminance meter (A) the luminance values are captured.

The targets have been realized upon the surface of a white cardboard. The C- γ reference system and a pitch of 10° for C planes and 5° for γ angles have been considered to identify the position of the targets on white cardboard; in correspondence of the targets, the luminance values have been measured. White cardboard permits to have appropriate and uniform photometrical characteristics for all measurement points.

In the present set-up two surfaces with targets have been used: targets surface #1 has been placed in vertical position in front of the light source at a distance of 0.50 m from the source and targets surface #2 (it also in vertical position) has been placed on the side of the light source, at a distance of 0.50 m from the source and orthogonal to targets surface #1.

The luminance meter (a traditional luminance meter or a videoluminancemeter) is placed on a professional photographic tripod equipped with a head that offer a precise movement in 3 directions; in this way, it is possible to vary the height and align the sensor to the cardboards.

In order to reduce as much as possible the external and the stray light and to control the environmental temperature value, all the facility described has been placed inside a dark room equipped with an air-conditioning system. The dark room has been realized inside a box 3.0 m x 3.0 m (plan) x 3.0 m (height) whose walls have been coated with black textile attached to a rigid trestle.

Finally, current and voltage supply of LED and Peltier cell and temperature values have been acquired and stored using a multi-meter FLUKE NetDAQ 2640A.

Thermocouples T-type (accuracy ± 1 °C) have been used to measure temperature values in five different points of the systems: two (T1 and T2) have been placed on the surface of the PCB as close as possible the LED source, one (T3) on the surface of Peltier cell, PCB side, one (T4) on the other surface of Peltier cell and last one (T5), for environmental temperature, in proximity of light source.

The evaluation of the luminous intensity distribution, in direction α , is evaluated considering the light source as a point source and the surface of cardboard as Lambertian, by the equation:

$$I_{\alpha} = \frac{\pi \cdot L_{\alpha} \cdot d^2}{\rho \cdot \cos(\alpha)} \quad (1)$$

where I_{α} is the luminous intensity value, L_{α} is the luminance value of the measuring point (target in direction α), d is the distance between light source and measuring point, ρ is the reflectance value of the surfaces with targets and α is the angle between the normal to the measuring point surface and the direction of the incident light.

Fig. 1: Schematic view of the experimental set-up.

4. Metodology

The methodology developed is based on the so called “indirect measurement”. Indeed, differently from the direct measurement, the luminous intensity distribution is not calculated directly from the measurement of illuminance value at a definite distance and direction from the light source, but the illuminance values are derived from luminance values acquired on a diffusely reflective surface placed in the path of light. To can consider the light source as point source with a negligible error, the diffusely reflective surface has been positioned in the far field.

The methodology proposed starts from the photometrical characterization of the surface upon which the light emitted by light source analyzed falls, the geometrical definition of the relative position among the light source, the videoluminancemeter and the targets, and through the acquisition of the luminance values in correspondence of the targets, the luminous intensity distribution is calculated using equation (1). The photometric characteristics (reflectance) of the two cardboards, have been measured with a spectrophotometer Konica Minolta 2600d considering three survey points for each cardboard; the results of measurements are reported in Table 1.

The measurements allowed to evaluate the reflectance values considering different type of illuminant and the specular component included (SCI) or excluded (SCE).

As it can be seen from the table 1, a very small difference between reflectance values obtained considering or not the specular component, for different points and different illuminants has been observed. As previously said, in this paper the cardboards surface (and then targets surface) has been approximated to a Lambertian surface. As a consequence of this hypothesis, the reflectance can be considered constant in all direction and thereby the luminance value acquired on a target is the same regardless of viewing angle.

	Measuring point	Illuminant A		Illuminant D50		Illuminant D65	
		ρ (SCI)	ρ (SCE)	ρ (SCI)	ρ (SCE)	ρ (SCI)	ρ (SCE)
Target surface #1	1	72.17	71.94	71.99	71.78	72.17	71.95
	2	72.30	72.06	72.51	72.29	72.65	72.43
	3	72.35	72.11	72.56	72.33	72.52	72.32
Target surface #2	1	71.46	71.24	72.19	71.96	72.08	71.86
	2	72.28	72.05	72.32	72.11	72.58	72.37
	3	72.03	71.79	72.49	72.27	72.70	72.49
Mean reflectance		72.10	71.87	72.34	72.12	72.45	72.24
Overall mean reflectance		72.19					

Table 1: Reflectance values for cardboard used to realize the target surfaces.

This results permit to consider, for the use of equation (1), an overall mean reflectance value of 72.19 % for all targets.

Using a videoluminancemeter is possible to capture, at the same time, the luminance values for all points of the target surface; while, using a traditional luminance meter, it is possible to acquire only the luminance value of a point at a time.

The figure 2 show a typical luminance picture of the light source photometry upon white cardboard acquired with the videoluminancemeter [4]. Luminance data measured can be stored as a colours map, where different colours correspond to different luminance value, or in table form, where each pixel of picture is coupled with a luminance value; luminance value are expressed, for both colours map and table form, in cd/m^2 .

The measurement points, employed to obtain the luminous intensity distribution, are marked with rings on the surface of cardboards. For each measurement point (target), the luminous value is deduced as the mean value of luminance values of the white cardboard surface enclosed inside the ring.

Fig. 2: Typical luminance colours map for targets surface #1 (in front of the light source).

4.1 Videoluminancemeter acquisition vs. traditional luminance meter acquisition

As described earlier, the measurement of the luminance value represents the critical aspect for the determination of the luminous intensity distribution of the light source analyzed.

In order to have a better information about luminance values, for some measurement points, the luminance has been detected with both the videoluminancemeter (LMK) [4], equipped with a TT25 lens (focal length: 25 mm, $f_1' = 2.7\%$, accuracy = $\pm 4.7\%$) and the traditional luminance meter (LS110) [5] (acceptance angle = $1/3^\circ$, accuracy = $\pm 2\%$, ± 1 digit of measured value); the luminance values on the targets have been acquired posing, one at a time, the two instruments in the same position and keeping constant the light source power supply conditions and the temperature inside the dark room. The difference among the luminance values evaluated with the two instruments has been compared in terms of percentage differences and, in function of the C-planes and the γ -angles that identify the measurement points taken into account, the results are reported in table 2.

According to the data in table 2, it can be noticed that the percentage difference presented among the LMK and the LS110 values of luminance ranges from -1.65% to -5.71% ; taking into account that the percentage differences reported in table 2 are negative, it can be stated that the LMK luminance are always lower than the LS110 luminance.

The maximum difference has been calculated: on targets surface #1 for the measurement point C40- $\gamma 42.5$ (LMK luminance value is 7.44 cd/m^2 , LS110 luminance value is 7.76 cd/m^2 and a percentage difference of -4.16%) and on targets surface #2 for the measurement point C70- $\gamma 47.5$ (LMK luminance value is 5.66 cd/m^2 , LS110 luminance value is 6.00 cd/m^2 and a percentage difference of -5.71%).

Percentage difference of luminance values acquired								
Targets surface #1					Targets surface #2			
	C0	C40	C50	C80		C60	C70	C80
$\gamma 0^\circ$	-3.69 %	-3.69 %	-3.69 %	-3.69 %	$\gamma 47.5^\circ$		-5.71 %	-1.65 %
$\gamma 17.5^\circ$	-3.75 %	-2.89 %	-2.99 %	-2.72 %	$\gamma 52.5^\circ$	-1.95 %		
$\gamma 27.5^\circ$	-3.59 %	-1.66 %	-3.50 %	-1.89 %	$\gamma 62.5^\circ$		-2.48 %	-2.25 %
$\gamma 42.5^\circ$	-2.79 %	-4.16 %	-3.44 %	-2.33 %	$\gamma 67.5^\circ$	-2.43 %		
					$\gamma 77.5^\circ$	-3.69 %	-4.08 %	-3.67 %

Table 2: Percentage difference of luminance value acquired with the videoluminancemeter (LMK) [4] and the traditional luminance meter (LS110) [5].

4.2 Methodology developed

In the first step of the methodology, all parts of the facility have been placed inside the dark room on their supporting systems, their relative position have been checked and their alignment has been verified.

The second step of the methodology covers the acquisition of the luminance values of all targets marked upon the surface of the two white cardboards by the videoluminancemeter (LMK) equipped with the TT25 lens. Before starting the acquisition it has been checked that the light source achieved electrical and thermal stabilization [6]. The luminance map acquired have been processed using the LMK management software to obtain the luminance mean value for each target.

In the third step, the photometrical values (luminous intensity and luminous flux) have been deduced. The luminance values deduced in the second step and the geometrical data about the position of each target have been used in the equation (eq. 1) to evaluate the luminous intensity in different directions. According to its definition, the luminous flux in a direction can be calculated as the product of the luminous intensity and the solid angle centred in this direction; the total luminous flux will be obtained as the sum of all the luminous flux calculated for all direction. In this study, it was supposed that all light emitted by light source falls on a imaginary single half-sphere (where the source is located at the origin) and it was chosen to branch the half-sphere into 648 zones enclosed by the lines $\Delta C = 10^\circ$ and $\Delta \gamma = 5^\circ$ from which the solid angle was derived; the luminous intensity values have been measured in the middle of such zones.

In figure 3a is showed the layout of the experimental facility with the relative position of the luminance meter, the targets surface #1 and the light source, while in figure 3b is showed a detail of the light source equipped with its PCB, the electric cables, the thermocouples, the Peltier cell and the supporting plate.

Fig. 3: Facility layout (a) and a detail of the light source (b).

5. Results and discussion

To get information on the reliability and accuracy of the methodology, the experimental results have been compared with data made available by the manufacturer in terms of luminous intensity distribution and total luminous flux.

To calibrate the facility and the methodology a led X-Lamp XP-E [7] (luminous flux: 35.409 lm and input wattage: 0.3 W) made by Cree has been used as light source. The experimental results were obtained considering: a power supply of 0.3 W, a forward current of 105 mA, a junction temperature of 25 °C and a dark room temperature of 21 °C; all electrical and thermal parameters have been acquire and stored for all duration of the test.

In the figure 4 the experimental (continuous line) and manufacturer (dashed line) luminous intensity distributions are plotted for three C-planes, C0, C70 and C90; C70 represent the plan on which the maximum experimental value of the luminous intensity has been detected.

In particular figure 4 show :

- a different distribution for experimental and manufacturer luminous intensity highlighting that the manufacturer data display a distribution almost identical for the three C-planes considered, while the experimental data exhibit a distribution as a function of both the target position (γ -angle) and of the C-plane considered;
- a good agreement between experimental and manufacturer data for γ -angles between 0° and 30°, where the percentage difference ranges from 2.77% to -5.50% and for γ -angles between 60° and 80°, where the percentage difference ranges from 6.67% to -4.79%;
- for γ -angles between 30° and 60°, the experimental data are lower than manufacturer data with a percentage difference ranging from -4.56% to -18.52%;
- the experimental data are generally lower than that declared by manufacturer.

Comparing the value of the total flux of $\Phi=31.487$ lm, derived from the experimental luminous intensity distribution, with the value declared by manufacturer $\Phi=35.409$ lm, it can be derived a percentage difference of -11%.

6. Conclusion

In this paper a simplified methodology, developed and set-up at the Built Environment Control Lab of Department of Architecture and Industrial Design of Seconda Università di Napoli, has been described and information on the reliability and accuracy of its results have been obtained.

Information about the photometric characteristic of the targets surfaces have been evaluated using a spectrophotometer. The measurements show a very little difference in reflectance values; consequently, an overall mean reflectance value of 72.19 % was considered for all targets.

In order to have a better information about luminance values, the luminance values for some targets using two instruments, the videoluminancemeter [4] and the traditional luminance meter [5], have been investigated. It can be notice that percentage difference ranges from -1.65% to -5.71%; it is always negative underlining that values acquired with the videoluminancemeter [4] are lower than those acquired with the traditional luminance meter [5].

Information about reliability and accuracy of the methodology have been extracted using a single LED as light source and comparing experimental data with data made available by the manufacturer. Differences have been observed in terms of both shape and absolute values of the luminous intensity

distribution. Measurements highlight that the percentage difference vary at varying of the position of target; a maximum percentage difference of -18.52% was found. Finally, for the total luminous flux calculated from experimental data and that declared from manufacturer, a percentage difference of -11% has been evaluated.

Fig. 4: Cartesian luminous intensity distribution for C0, C90 and for C70 (plane of I_{max}).

Applications of Augmented Reality to understand an archaeological site: problems and future development.

Mara CAPONE,¹

⁽¹⁾ DiARC Department of Architecture, School, University of Naples Federico II, Naples, Italy
E-mail mara.capone@unina.it

Abstract

To understand heritage plays a key role in the experience of visitors and it becomes critical when sites are partially buried or in ruins. To understand an archaeological site we have to reduce the communication gap linked to archaeological finds, giving to visitors all additional information to decode the sign. One way is to merge the real and virtual word together using AR applications.

We present the results of our experimental research about mobile Augmented Reality (AR) applications for the ancient site of Cuma.

This paper resumes recent advances in AR and shows some of the problems linked to the right collimation between the real world and 3D models. We have analyzed some different merging techniques in particular we compared the techniques that are based on the use of markers (QR code) and more complex ones based on the recognition of the site's geometry, markerless.

We have tested AR technology using an *open source* software that allows us to mixed real word to digital word, we have activated our channel and we have created a link to MatchMed, the database that we have developed in our research. Scanning some different QR codes we can: link directly to MatchMed, active the channel and see the labels at geo-located Points Of Interest, POIs, that give us access to all the information contained in MatchMed or start up the 360° navigation in the rebuilt temple which overlay visible reality by the devices' webcam of tablet or smartphone.

Keywords: Augmented Reality, Virtual Archaeology, 3d Modeling, 3d Database, ICT.

1. AR Applications to understand an archaeological site

To understand heritage plays a key role in the experience of visitors and it becomes critical when sites are partially buried or in ruins. To understand an archaeological site we have to reduce the communication gap linked to archaeological finds, giving to visitors all additional information to decode the sign. One way is to merge the real and virtual word together through AR applications. The most applications can be placed in the field of so-called Mixed Reality (MR), in the scale that goes from the Real Environment (RE) through Augmented Reality (AR), Augmented Virtuality (AV) to a full Virtual Environment (VE) [1].

Recent advances in AR technology let us to overlay virtual content, such as labels, images or 3D models, directly onto the video feed with the correct position and perspective using the localization tools of smartphone or tablet such as the map or GPS or some others systems.

There are a lot of very interesting applications for art, history and in particular for archaeology.

ARCHEOGUIDE is the first Augmented Reality Guide for Archaeological Sites, it is an application that includes the use of portable devices capable of providing guided tours with audiovisual information and limited interaction. It can be considered the first experimentation that uses outdoor tracking, mobile computing, 3D visualization, and augmented reality techniques to enhance information, presentation, reconstruct ruined sites, and simulate ancient life [2].

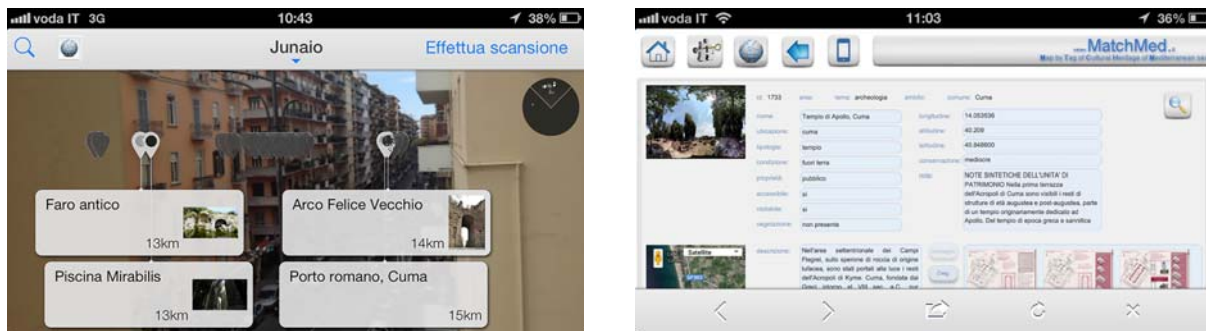

Fig. 1: AR application based on the use of POIs and the access to our database MatchMed. PRIN 2009, research group led by A. di Luggo, Napoli Federico II.

Actually, thanks to the advances in ICT and AR technology, we can choose between a lot of Augmented Reality systems that allow to give some additional information during the visit in archaeological site.

There are a lot of AR browsers that allow to unlock digital information from places, products and sights around the viewer, to visualize information in a completely new way. Now even non-developers can create their own Augmented Reality “channels”, a drag-and-drop and easy-to-use content management system for AR. These systems combine GPS, image recognition, visual search and a robust cloud-based architecture to recognize and attach digital information to nearly any object or environment in real-time. In order to make possible the creation of augmented elements into the real world, devices can use one or more of the following technologies: optical sensors, accelerometers and gyroscopes, GPS, solid state compasses, RFID and wireless sensors.

There are some different AR applications that help to bridge the gap between recreation, education, and scientific research in archeology linking augmented components into the real world. The easiest application and the most common is based on the use of the augmented geolocated view. In a geolocated view, the augmented reality system uses the GPS, accelerometers, gyroscopes and compasses in order to place a lot of POIs, Point Of Interests, according to the user's location and direction. Once all the data received from this hardware are analyzed, the output will be used to place some POIs on the screen. Using POIs we can design a specific communication project or access to a database where there are all information about an archaeological site. Using this system we can visualize text information, multimedia documents such as PDF and videos or simple images.

Another kind of augmented reality system is based on the use of the optical sensors to “catch” what is happening in the environment, analyzes the input information and overlays the augmented information over the real physic world. We can overlay images, texts or add interactive 3-D content to the real scene. We think that the most interesting application for the archaeology are all the applications that allow to visualize the reconstructive hypothesis overlapping on the existing findings during the real visit, thus our goal is to choose the best way to visualize 3D Model using the advanced of ICT.

We can use two different methods: overlay a 2D image on another or visualize in real-time a 3D object in an exact point of the real space. The first approach is based on the overlay of a virtual image on the real image from camera devices, in this case we have to determinate the right point of view in the real space from that we can see the image correctly overlapped on the real scene. Using this approach we have to localize this point of view in the site and we have to design the way to do that.

2. AR : different methods used to augment a view with 3D data

This paper resumes recent advances in AR and shows some of the problems linked to the right collimation between the real world and 3D data. We have analyzed some different merging techniques in particular we compared the techniques that are based on the use of markers (i.e. QR code, ...) and more complex ones based on the recognition of the site's geometry, so called markerless.

AR technology let us to mix reality with texts, Images, Movies and 3D objects.

Using high resolution cameras, internet access and positioning sensors of smartphone, it is possible to visualize these additional information in Points Of Interest (POI) in relation to the context in which the user is located. The information about the real world that surrounds the user can become interactive and digitally manipulable.

While smartphones are able to provide geo localization through GPS, the lack of accuracy does not allow for precise and robust alignment of the augmented 3D data with the camera image. There are some different approaches to solve the camera pose estimation problem [3]:

Fig. 2: Cuma, Temple of Apollo. Design of AR experimental applications based on the use images: the virtual image is overlapped on the real image from camera devices.

1. Using the localization tools of devices (accelerometers, GPS, and digital compasses) for obtaining the camera position and orientation;
2. Using the images to extract the camera pose from them ;
3. Using both the localization tools of devices and information from images.

The first approach allows to measure directly the orientation and camera position avoiding the high computational, but the overlay of 3D model to the real scene isn't very accuracy, so it is not very used when the accuracy is required, such as in 3D virtual archaeological reconstruction visualization.

The second system is based on photometric information from images of the scene to measure the pose of the camera. There are two kind of vision based approaches: marker based tracking and markerless tracking.

In the marker based tracking we have to pose fiducial markers in the scene to recovery 3D camera position, in this way the appearance of markers in images may be considered as a reference for image scaling, or may allow the image and physical object, or multiple independent images, to be correlated. By placing fiducial markers at known locations in a subject, the relative scale in the produced image may be determined by comparison of the locations of the markers in the image and subject. This application is based on principles of photogrammetry, the fiducial marks of a surveying camera may be set so that they define the principal point, in a process quite the same of conventional collimation.

There are some systems to do that, based on QR Code, ARTag, ARToolkit [4] or Visual Markers.

QR Code is a type of matrix barcode used by all AR browser to link to information system, images or 3D data. The browser supports URL redirection, which allows QR codes to send metadata to existing applications on the device.

ARToolkit is a computer tracking library for creation of 3D augmented reality applications that allows to overlay virtual images on the real world. To do this, it uses video tracking capabilities that calculate the real camera position and orientation relative to square physical markers in real time. Once the real camera position is known a virtual camera can be positioned at the same point and 3D computer graphics models drawn exactly overlaid on the real marker.

ARTag is a fiduciary marker system to support augmented reality. It can be used to make it easy to make virtual objects, games, and animations appear to enter the real world. Like the earlier ARToolKit system, it allows for video tracking capabilities that calculate the real camera position and orientation relative to square physical markers in real time. Once the real camera position is known a virtual camera can be positioned at the same point and 3D computer graphics models drawn exactly overlaid on the real marker. It thus addresses two of the key problems in Augmented Reality: viewpoint tracking and virtual object interaction [5].

For Visual Marker we intend the use of image as marker. There are two different AR Visual Markers Systems: the Image matching systems and Image tracking. The image matching systems are based on optical sensors that are able to recognize an image that appears in the scene and will trigger an

Fig. 3: Metaio experimental markless system based on geometry of the site.

Fig. 4: AR application using SLAM tracking (based on their own proprietary algorithms). A city model elaborated by Metaio to demonstrate how it is possible to map large physical spaces in real-time, with simple, non-stereo HD cameras and Smartphones.

event (i.e. an 2D image, a text ...) unlike the image tracking system is able to know the camera pose too. This camera pose estimation will allow the system to overlay a 3D object just where the target is, in the right perspective that we could visualize if it were a real object in the real physical world. In real-time applications, however, unpredictable motion makes sequential approaches uncertain and fragile introducing some errors in visualization of the resulting reconstruction models. The most important problems are caused by the difference between the viewing device's angle that could be slightly different from that assumed for the augmentation of the natural user's view.

These marker methods allow a good control of small 3D objects in a small environment but it doesn't allow us to get good results when the goal is to introduce a building in an urban context or to represent the reconstructive hypothesis in an archaeological site, in fact it is very difficult to use marker based technologies for outdoors applications.

Markerless methods are based on the geometric features of the place that allow us to reconstruct 3D model of the real scene without introducing any artificial elements.

Markerless outdoor augmented reality solutions are generally based on using of projective invariant. [6] or on Structure-from-Motion (SfM) [7] or on the related online approach of Visual Simultaneous Localization and Mapping (SLAM) that are able to estimate camera position and the 3D structure of the imaged scene together.

All the images are the 2D projection of a 3D scene, therefore the use of 3D information is fundamental in AR application for different tasks involving both planar surfaces and full 3D solid objects.

In the first case, the target is planar, its projection in the camera frame is planar too. This allows a complete modeling of the relationship between target object and its projection in the image in terms of a simple homography matrix. It will be easy to extract 3D information from the homography, allowing a 3D pose estimation of the target in the space. Many interesting applications in creating augmented content are based on the use of the planar facade extraction technique to use as a 3D frame of reference for augmenting the scene [3].

The case of 3D solid is more complex because 3D objects appearance significantly change according their instant pose. If the camera moves around a cube the target projected image changes showing the different faces according the relative position between camera and object and the solution becomes more complex. Iterative methods are usually applied in order to estimate the correct pose of the target. The general idea is to find the pose matrix that minimize the so-called re-projection error,

Fig. 6: Streetmuseum is a new augmented reality iPhone app created by the Museum of London that allows you to browse historical photographs in various parts of the city. It is an outdoor georeferenced application where 2D historical image overlays to real image.

the difference between the projection of the 3D model of the target in a given pose and the image captured from the camera.

Using a SLAM Simultaneous localization and mapping, technique used by robots and autonomous vehicles to build up a map within an unknown environment, or to update a map within a known environment, there are some applications that exploit a set of images of the same scene captured from different point of view in order to rebuild the 3D structure of the scene and to make it easier to determine where the 3D content should be positioned and visualized in the 2D image of the scene.

There are a lot of experimental systems that allow to research the best solution for each problems, for this reason it is very important knowing the power of different browsers to choose what is the best for our needs. Our goal is to find a system that allows us a real time interaction with 3D model of reconstruction hypothesis of temple of Apollo visible in the right scale in the archeological site, this isn't a very simple outdoor application.

One of the most important problems that we have to solve are the 3D model size, the technology to use to visualize 3D model in perfect overlay on the archaeological finds and the possibility to visualize the reconstructive hypothesis in motion.

The extensive use of 3D models in Augmented Reality App is one of the most interesting news of recent years, to do that we need a 3D model that can be displayed in that virtual 3D world that exists over the real one that we can see through our device's camera.

Some mobile App lets us visualize 3D models in Augmented Reality, integrated in real time in their actual size and environment. Generally 3D models can be exported from any 3D software such as 3ds Max, Sketchup, Maya, SolidWorks, Cinema 4D etc...

The problems that we have to solve are linked to the size of 3D model that is defined from the total number of polygons in a 3D model. Usually this numbers unit is counted in triangles. A high-resolution model with a lot of polygons is called "high-poly-model" in comparison to a "low-poly-model" with a small polycount. Sometimes these categories are not clearly distinguished. They are dependant on the device and from the use of the models. In case of real-time applications mainly low-poly-models are being used. They render faster and increase the performance of an application. Thus, when we design a 3D model we have to use as few polygons as possible but many as necessary.

Another problem to solve is the correct use of the texture, in fact if we use many texture, especially large ones, the performance of mobile phone will also decrease and the texture sizes must not be larger than 2048x2048 pixels.

3. Augmented Reality (AR) applications for the ancient site of Cuma

We have tested AR technology using an open source software, Junaio, that allows us to mixed real word to digital one, we have activated our channel and we have created a link to MatchMed, Map by Tags of Cultural Heritage of Mediterranean sea, the database developed in PRIN 2009 by Federico II research group led by A. di Luggo.

Scanning some different QR codes we can: link directly to MatchMed, active the channel and see the labels at geo-located Points Of Interest that give us access to all information contained in MatchMed, or in a point of observation, appropriately marked in the site visualize the 3D model of reconstructive hypothesis or, activate the 360° navigation in the rebuilt temple which overlaps on the visible reality through the camera of the device, tablet or smartphone.

Fig. 7: AR experimentation: Archeological site of Cuma. We have used a free AR browser, Junaio. Scanning QR codes the visitor can access to MatchMed database, can access to geolocated view mode or visualize the 3D model. Download Junaio, it is possible to try from this image.

Fig. 8: AR experimentation on Archeological site of Cuma. Design of 360° navigation in the rebuilt temple which overlaps on the visible reality through the camera of the device, tablet or smartphone.

For placement of the QR codes in the archaeological site we designed Plexiglas panels that can be considered interfaces between analogical world and virtual one, where we are going to impress the image of reconstructive hypothesis and we are going to localise the QR codes.

Using the principles of Descriptive Geometry, and in particular of linear perspective, we have sized panel, built the image, defined the position of the observer and the localization of the panel in site so that the image of reconstructive hypothesis overlaps perfectly to reality.

The project for the installation of the panel has been developed based on principles of perspective projection, intersection of the visual pyramid with a plan, where mathematical observer is considered a single fix point unlike the human observer who has two eyes in continuous movement.

The perspective projection that represents the hypothetical reconstruction of the temple has been built using the digital model, simulating the process of image construction.

The size of the panel and the position of the observer relative to the panel have been defined considering a 50° visual cone and the possible positions of the panels relative to the model is been defined to obtain an image of the reconstructive hypothesis in vertical perspective projection.

After we have checked if POV, Points Of View, was in a right position related to the site and the image represented on the panel coincided with the image of the existing findings.

The project involves the installation of Point Of View, an element that signals the position to be taken by the visitor to align the real world to the virtual representation, and the plexiglass panel on which are printed the perspective image of the model and the QR codes to access digital content.

To create the conditions that *artificialis perspective* looks like *naturalis perspective* the observer will have to look with one eye and the gaze should be fixed as far as possible, to make easier this vision mode, a target will place on the panel in Vo, the orthogonal projection of the point of view on the panel.

In this way the panel with the image and QR codes becomes an interface between the analog world and the virtual world.

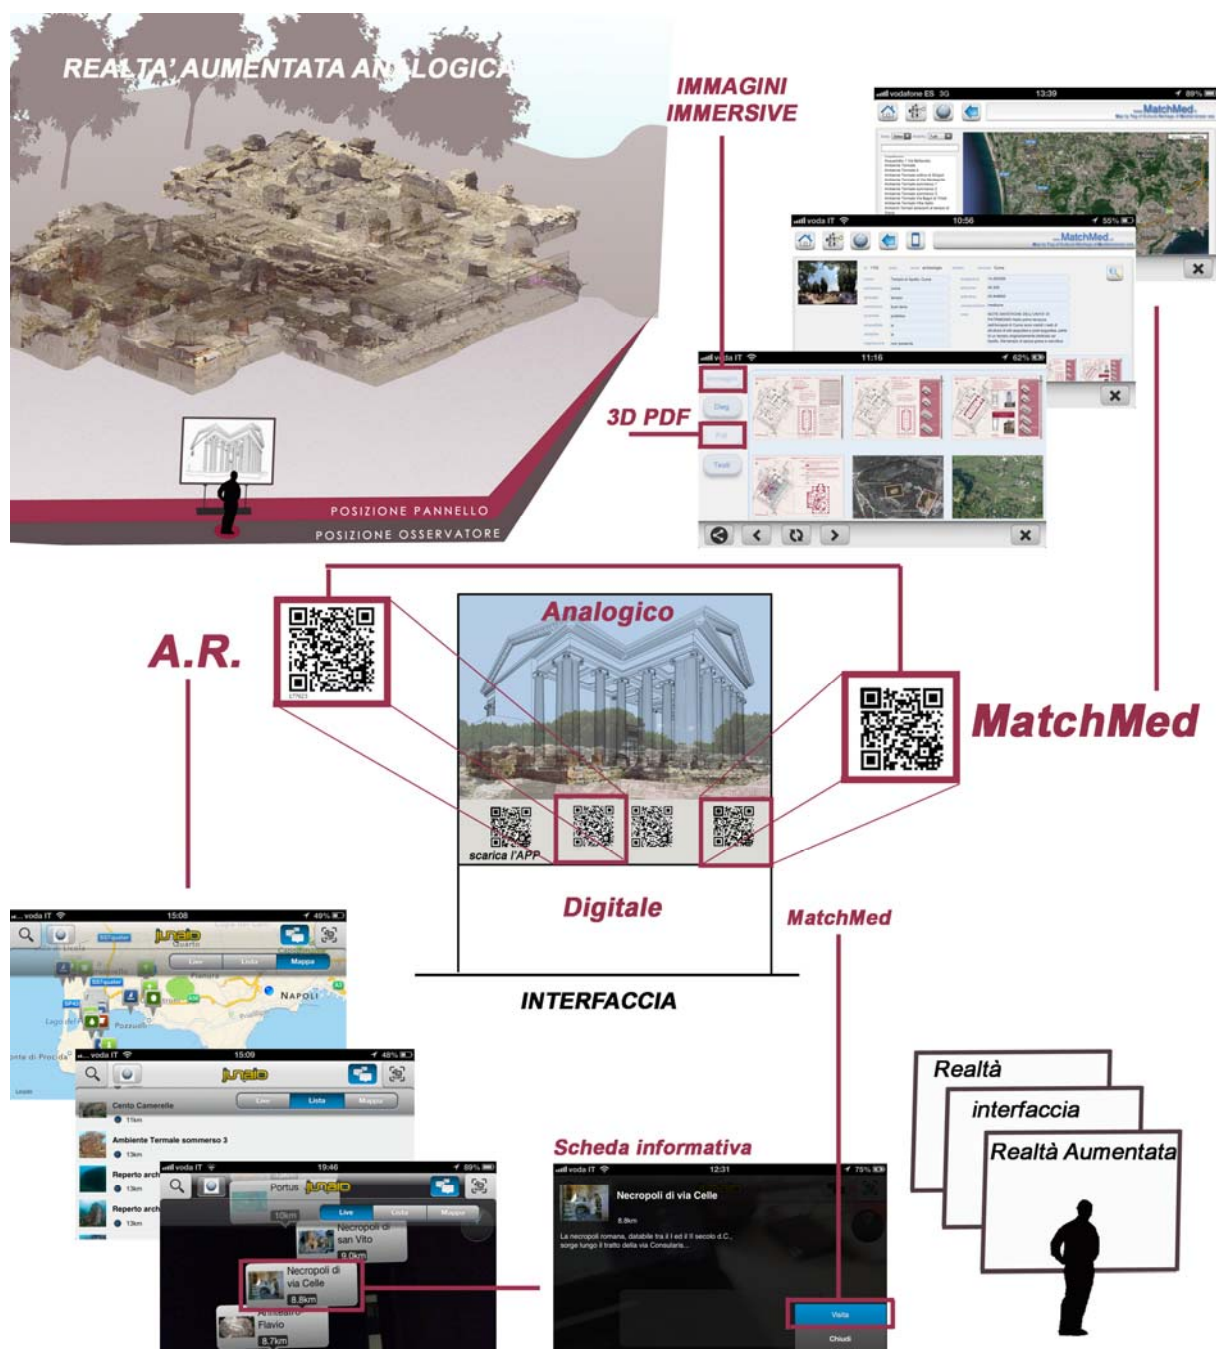

Fig. 9: AR experimentation on Archeological site of Cuma. Design of Point Of View, an element that signals the position to be taken by the visitor to align the real world to the virtual representation, and the plexiglass panel on which are printed the perspective image of the model and the QR codes to access digital content. It is possible to try from this image using Junaio and scanning QR Codes.

Fig. 11: Augmented Reality System based on Visual Markers and Markerless

4. Augmented Reality trends and future developments

The research has shown some technological problems that have stimulated to find solutions that can hybridize the analog world and the digital one, as the panel that has the function to communicate explicitly the presence of a digital platform and to promote the access to it.

The most important problem to solve is the determination of camera position, in fact if the pose of camera is correctly determined the virtual objects can be rendered onto the virtual camera in right location and perspective to provide the illusion to be present in the place. When the real camera is correctly located the system allows to locate the virtual camera in the same position and so 3D model can be visualized perfectly overlapped on the real world.

To find a solution in our case studio we have defined a new paths of research mainly oriented to develop systems where the alignment between real world and virtual world achieved through the recognition of three-dimensional geometries present on the site, so now we are working on the hybrid markerless systems.

In the near future we will probably be able to localize camera position using only the natural environment features but now we generally use systems based on markers, such us QR Codes, ARToolkit or ARTag.

A very interesting new trend is to use 2D Visual Markers that can be designed in very different ways for very different applications. This method is based on a marker that is an image, using a AR browser, scanning this image we can visualize a 3D object and we can interact with 3D object using the visual marker as an interface.

Some interesting applications about the use of visual markers are developed especially in the art. In Leon Keer's works AR gives birth to a new dimension to 3D street art.

AR is an "illusion" that could be associated to visual illusion create by the Anamorphic street Art of Keer. In both cases the problem is quite the same, especially when we want visualize a perspective image overlapped on the real world and so we have to stay in a fixed point to visualize correctly the illusion. In Anamorphic paint we have to find the right point of view to see the transformation of 2D image in a 3D picture and in AR applications we have to find the right point of view to see the overlap of the perspective image to reality that we can see by smartphone camera.

AR LelystArt. is an Anamorphic street art where art is combined with Augmented Reality, in this case to see the AR animation you have to download the Junaio App, search for 3d street art and scan the marker (caution sign).

In this case the marker isn't a QR Code but it is a part of paint.

In Wisma Atria Singapore too, the anamorphic painting created on a wooden platform in front of Wisma Atria Shopping Centre, scanning the painting in the centre of the image with the Augmented Reality application of Junaio snowfall will appear on the screen of our smartphone or tablet. (snowfall 3d animation created by Joost Spek / 3d picnic)[8].

These examples show a new way to active the additional information linked to an image or to a site using a visual markers instead a QR Code.

Fig. 11: AR LelystArt. Anamorphic street art made by Leon Keer and AR content made by Joost Spek/3Dpicnic. visual markers it is a 2D marker. It is possible to try from this image: download the Junaio App, search for 3d street art and scan the marker (caution sign).

Fig. 12: Wisma Atria Shopping Centre, scanning the painting in the centre of the image with the Augmented Reality application of Junaio snowfall will appear on the screen of our smartphone or tablet. (snowfall 3d animation created by Joost Spek / 3d picnic)

Very new approaches, based on natural features, are markerless Augmented Reality systems where each part of the real environment can be used as a target to determinate camera position and to place virtual objects in a correct way.

The news is not only allowing to use real objects as a target, but also overcome some limitations linked to markers systems.

First of all markerless augmented reality systems rely in natural features instead of fiducial marks and so it's not necessary to introduce any markers in the real environment.

Furthermore, another advantage of the markerless systems is the possibility of extracting from the environment characteristics and information that may later be used. However, tracking and registration techniques of markerless augmented reality systems are still more complex than markers systems.

Techniques developed for online monocular markerless augmented reality systems are based on features of normal image or object to be tracked, like the edges, corners, or textures, and so they could not be invasive like marker-based systems. [9].

For the Temple of Apollo, we are experimenting an Hybrid System. The idea is to use the markerless technology but in this case there isn't any natural features of the environment that we can use because the geometry of archaeological finds are very difficult to recognized. Therefore we are thinking to put 3D objects on the place, 3D Visual Markers that could be used to correctly localize the camera and to visualize 3D model in the right scale and in the right point in the real space.

These objects will be designed such as art installations, they could be considered like landmarks in the archaeological site and they are a part of a more complex Communication project consisting of MatchMed database, Plexiglass pannel and POV Point Of View.

The concept is to design a cultural brand a of AR Virtual Archeology developed by our research group, These 3D Visual Markers will became another interface to go inside AR virtual world, another analog "door" to go inside AR world.

Abstract

The need to read the material, with the specific aim of going back to the ancient structuring geometries, makes it necessary to pay more attention to the local culture and to the identity expressions connected with the shape and the material and aiming at penetrating into the sense of history which is of fundamental importance in the interventions in small and large scale.

There are some works, halfway between sculpture and architecture, which testify the use of shapes and models belonging to the cultural traditions of their local areas, but, at the same time, they are connected with different cultures. They are proper *architectures inside architecture*, which means they are architectural structures in a small scale and they also show the great creative skills of Sicilian artists.

The great variety of the elements taken into consideration shows a coherence of language, the expression of a way of doing architecture, even in small scale works.

In order to better emphasize these structural similarities, the research will make use of epistemological processes, supported by a peculiar perceptual discretion sensitivity in which, the survey through sensitive instrumentations and the representation through virtual models establish a dialogue which is preliminary to any preservation actions with a scientific base and necessary to remember instead of forgetting.

Keywords: Survey, Geometry, Representation, History, Fragments

1. A diachronic analysis for the recognition of an identifiable language (*R. Valenti*)

The cognitive journey of the present study is taken through time and space and its specific aim is interpreting mutation and persistency giving reason to a recent past which has borrowed from the characteristic forms of the territory.

In particular, the carried out research supports a culture of intervention based on an epistemological approach pointing at a dialogue with the place where the re-cognition of elements is fundamental for the decoding of the language necessary for any conservation intervention on small and large scale.

If architecture has to be considered not only as a creative process but also as a conforming act of the matter related to the context, interest is concentrated on the ways it has been structured and shaped. Hence, the story about the places goes through the reasoned knowledge of the old geometry in search of models which in time have, transversely, delivered the identity content.

The primary task often comes from a wider circulation of architectural-constructive references which, once stored in the local cultural knowledge, have become identity and have been subjected to time contamination.

Starting from here, the topic we are dealing with focuses on those architectural phenomena which on a smaller scale are contained in a more articulated system – within the spatial volume or simply as

grafts on the closing surface and delimitation of the total form – as elements of functional or decorative definition.

Actually these pieces of “architecture in architecture” which in its formal composition draw on the rules of the making and of the representing architecture are real jewels, extensively protected in the investigated territory; partly survived to the catastrophic events related to the earthquake which severely damaged the south-east of Sicily determining a deep fracture with the past, partly being the result of the wish for a carefully-planned reconstruction according to the tastes of the time.

The variety of examples clarifies the language coherence, implementable and verifiable through the redesigning of the visible which helps us perceive the invisible, that is, what time and nature have strongly wiped out.

The diachronic analysis performed through the instrumental survey is based upon the discernment and cataloguing of all those elements which on a smaller scale, even if widely spread on the Sicilian south-east area, present the assonances which can be considered an identity language originating from the imported cultures assimilated into the peculiar context with particular emphasis on the matter. There are a lot of examples where it is possible to detect the models used outside the island, both in the geometric and sculptural shapes referred to the pre-and post-earthquake period. The earthquake hit in a “ruinous” way some areas of the Val di Noto in 1693 preserving only some architectural “jewels” dating back to the XIV and XV centuries.

There are a lot of examples where it is possible to detect the models used outside the island, both in the geometric and sculptural shapes referred to the pre-and post-earthquake period. The earthquake hit in a “ruinous” way some areas of the Val di Noto in 1693 preserving only some architectural “jewels” dating back to the XIV and XV centuries.

The investigation is expressed through a cognitive journey which, first of all, is based on a particular perceptive awareness; the control occurs later, gradually, while the pieces are analyzed from the geometric and symbolic point of view in order to undertake the necessary comparisons.

“Small scale pieces of architecture” have been chosen: parts of religious and civil buildings. They are characterized by the sculptural plasticity of matter with particular reference to the use of materials, of geometry and of communicative expressiveness which, for centuries, have represented a shared recognizable code. A coordinate system for the collective identity and sense of belonging.

A spatial code which, according to Salvatore Settis, sharpened in Italy from the Middle Ages to the Renaissance, moulding the memory lane; a code which makes it easy to read the context, experienced not only through highly expressive manifestations and reflecting social and political concerns, but also through all those key features which, though located in relatively close areas at the time, present a uniform interpretation conveyed through the relatively contemporary culture. Examples are the remains of Palazzo Migliaccio in Syracuse and of the Loggia of Palazzo Platamone in Catania, where the bichromatic tone of the stones with its geometric horizontal pattern prevails, similar to the engraved stone in the archivolts of the “bifora”, the double lancet window, of palazzo Maciotta Mergulese in Ortigia.

This last one, excellent manifestation of the “Chiaramontano” style, is an example of sculptural façade, a proper arrangement of figurative elements with a recurrent geometry. In particular, the thin twisted columns of the “bifora” and “trifora” are expressions of a transversely recurrent language.

Fig. 1: Palazzo Migliaccio, Ortigia. Palazzo Platamone, Catania.

Fig. 2: Portal of St. Mary from Josaphat, Paternò (Catania). Graduation thesis by E. Paternò. Supervisors R. Valenti, S. Giuliano.

We find them full height in the Renaissance period “in the airy structure of the open loggia with twisted columns” of Palazzo Abela in Syracuse, a XIV century building probably redesigned in the XVII century by Andrea Vermexio, with relatively different proportions from the model of the end of the XIV century; Carlo Broggi re-proposed them faithfully at the beginning of the last century in the project for the “Umberto I” Civil Hospital in Syracuse.

If we travel through time and space towards the province of Catania, in Paternò, a small example of religious architecture such as the Santa Maria de Valle Josaphat Church, built in Norman Age, in 1072, by the count Ruggero’s wife, Adelitia, is part of the hill and in the façade presents a portal with a pointed arch supported by thin twisted columns, very similar in terms of elegance and slenderness to those of Palazzo Montalto, with a more elaborated moulded shape.

The cloister in late Gothic style of the Santa Maria del Gesù monastery erected between the end of the XV century and the beginning of the XVI in Modica consists of a triumph of twisted columns. The geometry of these elements presents a large variation of the twisted column from the traditional screw vertically zigzagging around the geometric pattern, previously mentioned for the loggias and archivolts, whose geometric spiral genesis is purely perceptive.

Though having a more massive structure, they call to mind the complex composition of the columns of the XIII century cloisters of St. Paolo fuori le Mura and San Giovanni in Laterano in Rome and those of the cloister of the Benedictine Abbey of St. Pietro and St. Paolo in Königsutter, Germany.

Fig. 3: Zig Zag geometric pattern. Jesus St. Mary courtyard, Platamone building’s balcony, Maciotta Mergulese building’s mullioned windows.

Fig. 4: Architectures' fragments. Aediculas: St. Antonio Abate's Church, Cassaro (Siracusa). Via Capodieci, Ortigia (Siracusa).

"The use of twisted columns in the medieval cloisters probably has a Solomonic meaning which refers to the Porticos of the Temple of Solomon, a meeting place of prayer for the Apostles after the Crucifixion of Christ" [Tuzi 2002, 68]. Solomonic is also one of the most mysterious pre-earthquake remains in Ortigia, embedded in the staircase of a building in Via Capodieci, found in the basement. It is a small aedicula which contains the symbols of Christianity, a real example of "small scale architecture" both for its plastic intensity and for the representative project design.

The survey and the drawing pattern of this fragment and in particular the two highly expressive twisted columns delimiting it deal with the cultural debate about the Solomonic columns. Their presence in Sicily is diffuse, probably thanks to the Spanish influence, in the iconology apparatus of religious buildings built after the 1693 earthquake, especially on the external façades which anticipate the complexity and the richness of the interior altars.

The present research, which follows the relief approach on a time crossing basis, has launched a fertile program, establishing a dialogue in favour of conservation interventions in accordance with the criteria of the "circular journey" of memory.

2. The character of an identifiable mark (*S. Giuliano*)

In a reference context regarding the epistemological process aiming at the identification and conservation of architectural characters, a certain role can be performed by the study of the XVIII century altars, paying attention to the relocation of the main protagonists, the artists, from the city to the little nearby urban areas.

The survey, carried out mainly at two levels of analysis, is the starting point for the fulfillment of the investigated phenomenon. The first level of analysis deals with the conceptual survey, coming from archives, historical sources and iconography. The second, on the other hand, is material, in close contact with the investigated object, corresponding to the architectural survey, which in the present study about altars has been conducted with 3D laser scanner technology.

Both the material survey and the conceptual survey represent the two essential non-separable ways in constant osmotic and dynamic relation which allow a grounded understanding of the artifact.

In order to carry out the research, it was considered worthwhile to define a historical, sociological and cultural framework of the events occurred in Sicily, especially in the city of Syracuse. Starting from the end of the XVII century, in fact, there is an artistic renovation connected to an earnestness for reconstruction as a consequence of the catastrophic earthquake which struck the Val di Noto in 1693.

In this flourishing period the Val di Noto enjoys the presence of a multitude of stonemasons, skilled in the art of building, and expert carvers, who arrived just after the earthquake. Among the most significant of them we mention Pietro Paolo Battaglia, head of a household of masons, Pompeo Picherli and Andrea Palma, who took the role of architects.

Since the XVIII century architecture reached its peak in Syracuse. A lot of reconstructions and completely new constructions were made.

Fig. 6: Altar “a tosello”. A. Pozzo, treatise. On the right survey from identity representative altars.

The XVIII century altar in Syracuse has its own precise feature. It is an architectural object growing in its own space, neither inside nor outside, but annexed to the newly built church, conceived as a single unit.

To ease and enhance the research it was considered appropriate to prepare a typological catalogue of altars present on the territory of Syracuse and consequently to relate them to the “canonical” models theorized and built by the Baroque architects in Rome.

The first type of altar observed in the territory is the so called “a tosello” or wall-mounted altar, characterized by its position against the backwall. These can often be detected in the side chapels of churches.

The reference model for this type of altar can be found in the “Chiesa del Collegio” in Rome, as it is drawn by the Jesuit Andrea del Pozzo in his treatise.

We find other similar but relatively minor examples in Buccheri and Palazzolo Acreide, little towns in the province of Syracuse, and also in the side altars dedicated to Mary Magdalene in the church of the same name and to St. Gaetano da Thiene in St. Paul’s Church, respectively.

The altar in Buccheri presents a lower order with a multicoloured marble antependium and an upper order which on the contrary has a pair of columns rotated 45 degrees surmounted by a trabeation and a broken tympanum. The altar in Palazzolo presents the lower order in multicoloured marbles as well. The upper order, instead, presents a pair of twisted columns lying on corbels.

The second type of altar present in our research is the one with an “ascending triangle” pattern. This is a characteristic architectural feature in “full survey”, culminating with an aerial canopy on thin pillars supported by sculptural figures.

It is usually found in the centre of the apsidal area. This type of altar can be, probably, assimilated to that of the Blessed Sacrament Chapel by Gian Lorenzo Bernini in St. Peter’s basilica in Rome, whose “tronetto” or throne is completely inspired to the Bramante’s St. Peter in Montorio.

Fig. 7: SS. Sacramento’s altar drawing by G.B. Bernini. SS. Sacramento’s altar orthoimage, St. Paul’s Church, Palazzolo Acreide.

Made of wood, with decorations in golden stucco, it is the “ascending triangle” altar of the Blessed Sacrament of St. Paul’s Church in Palazzolo Acreide.

It is characterized by a dark wooden antependium, widely decorated with golden stucco, with three upstands on top which inlay the aerial canopy, without any accompanying sculptural group.

In this case, too, the altar is placed in the centre of the apse in the side aisle of the church.

Sicilian architecture has, as everyone knows, a privileged relation with decorations.

This study on altars, carried out from an architectural and sculptural point of view, cannot exclude the decorative features connected to the use of marbles and to the technique which had spread throughout the island since the XII century.

“If the purpose of Baroque is that of stimulating imagination, what imagination conceives must become real. The task provided by the technique is that of realizing everything is asked and wished for” [Argan 1975]. As such, the technique of altar architecture developed a lot. The specialization in every discipline and the consequent presence of professional figures is noticeable, among them the marble workers. They had great technical skills but, probably, poor artistic creativity. The inlay drawings in the antependia of the wall-mounted altars, in fact, despite their apparent variety in the same context, are extremely repetitive.

The pattern of the two dimensional inlays, only a few millimeters thick, could be perfectly defined on paper with indications about colours, being then reproduced from life on paper and transferred onto white marble slabs which constituted the stand of the inlays.

The craftsman, once decided how many parts he would divide the figures into, with the chisel obtained the socket for the thin inlays of polychrome marble, leaving in relief the parts which had to remain white according to the drawing. The slabs, so carved, were anchored with iron or bronze cramps.

The inlay technique is accompanied by the marble intarsia widely used in the decoration of the altar antependia. The underlying plan in white marble in the marble intarsia disappears from the composition, regressing to a simple support. The pattern was obtained from the combination of different marbles and stones.

Fig. 8: Typological abacus of altar frontals.

The strong creative development in the use of multicoloured marbles in opposition to the heavily ornamented baroque style slowly disappears from the third decade of the XVIII century, being gradually replaced with a higher geometric control of the structure. The marble slab is exalted for its own intrinsic features: colour and grain variations.

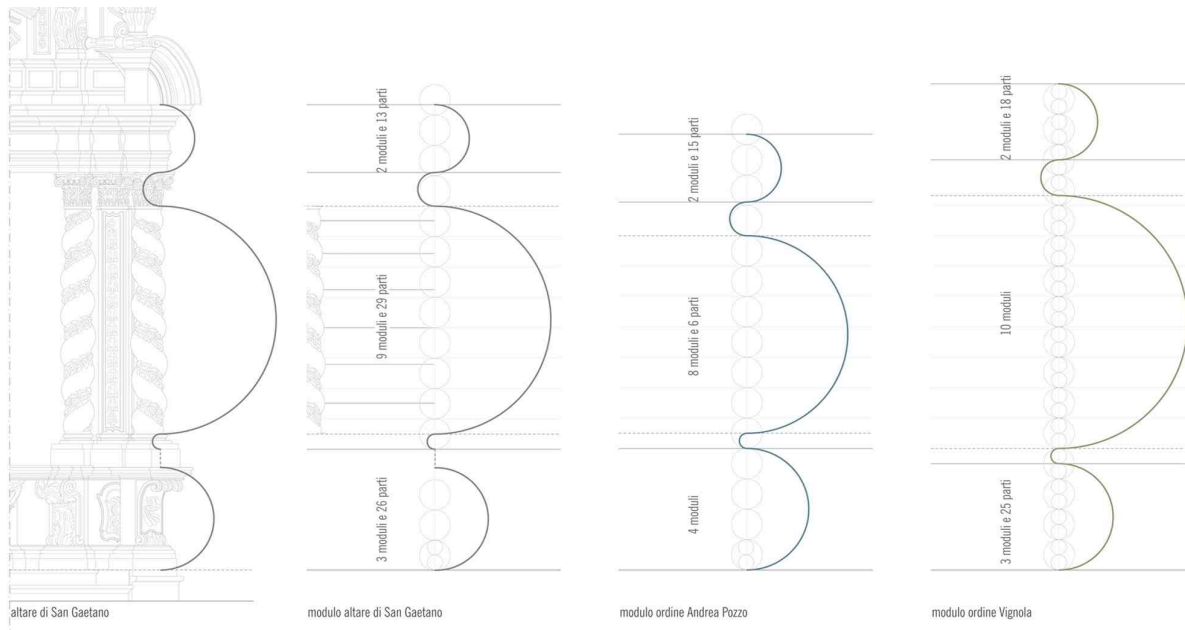

In order to satisfy and improve the knowledge on the investigated phenomenon, it was essential to carry out the morphological and dimensional analysis of the “small architecture” taken into account. Each of them is based upon “simple” geometric rules.

The graphical analysis highlighted the frontals of the altars inscribed in rectangles with golden or diagonal ratios. In the plan, especially on the “tronetti” level, geometries arranged on the circumference were also detected.

The decorative pattern and the architectural order characterizing the examined objects disclosed a strong and meaningful similarity to those codified in Vignola’s and Pozzo’s treatises, both in the proportions and in the juxtaposition of the classical mouldings.

Another recurring pattern detected by the research is the overlapping of pedestals: the lower one which represents the table or “mensa” and the upper one which completes the canonical order with column and trabeation in its most diverse forms of baroque pomp and fantasy.

Those are all compositive morphologies within a general framework of a research focusing its interest on a specific aspect – directed to the peculiarity of the Baroque period – emphasizing the scenic effect of architecture referred to a particular context in the Syracuse area.

Abstract

The Alcalá City University Campus is known for the new use and the restoration of much of the old buildings that belonged to the XVIth Old University, and others historical buildings from de XVII, XVIII an XIX century. This recovery process is rewarded with recognition (1998) of the Council of Europe as a World Heritage Site by UNESCO. An interesting example of the modern practices on dynamic conservation of the historical heritage of the is the new Learning and Research Center (LRC) on the ruins of San Diego headquarter, built in 1859 on the site of the 1445 Franciscan convent of Santa Maria de Jesus. The aims of the new LRC are to preserve and document the archaeological remains from each one of the previous cultures. It intends to add value to the existing Heritage through a new project which involves not only an intensive use but a transdisciplinary complex including urban, architectural and functional changes which have been solved through a comprehensive rehabilitation project. Construction of the new building respects the most important archaeological remains that have been well documented and protected for later use and display. The new building is built into the skin of the head quarter of the nineteenth century. The overall performance respects the ancient remains discovered, clean the building of unwanted performances and adds the new architectural elements necessities for the today use.

Keywords: rehabilitation, architectural heritage, reuse.

1. Background

The University of Alcalá was founded by Cardinal Cisneros in 1499 and is one of the oldest Universities in Europe. It operated continuously until 1836, when it was relocated to Madrid. [1] The academic activity in Alcalá de Henares restarted in 1977, when the University inherited a great number of religious and military historic buildings that were unused. This meant an important investment in human and material resources in order to restore the appalling conditions of large architectural heritage. UNESCO recognized this work in 1998, when the university was awarded the title "World Heritage Site". The preservation task continues. It also plays an important role within the education programs and it is a symbol of identity [2]. The last heritage intervention is the new LRC, which occupies part of Prince Headquarters [3]. It is located in San Diego Square in Alcalá City Centre, next to the University's foundational building, the College of San Ildefonso (1499) (Fig.1).

The Prince Barracks is a military building built in 1859. The plot had been previously occupied since 1453 by a building and orchards that belonged to the Convent-College of Santa Maria de Jesus (Franciscan Order). The convent became a military building and the Franciscan complex was demolished to build the new barracks after the government's confiscation of church properties in 1837.

Fig. 1 : San Diego place. On the left, the new LRC in the old Prince Barracks 19th-century. In the front, the University's foundational building, the College of San Ildefonso, 15th-century.

The building responds faithfully to the types of military architecture of the nineteenth century, consisting of large double bays constructions organized around courtyards [4]. The building presents itself to the public space with a sober brick facade, repeatedly perforated with large windows framed with limestone, also used in its perimeter plinth and cornice lines and imposts. Inside, the elevations are even soberer, with windows and doors cut on revoked lintel walls (Fig.2).

In 2005 the military abandoned the building and it was transferred to the University. Since then, various partial intervention projects took place, due to the building's large size. The demolition work of the first bay, which was followed by an archaeological study, started in 2009 [5]. The excavations revealed the remains of a primitive 13th-14th-century church, the remains of the 15th-century Franciscan convent church, the Chapel of San Diego (from the same age) and the walls and flooring of the convent. Excavations confirmed that the convent suffered looting and demolition. Its ruins were used to build barracks, especially masonry and stone remains. These remains have been graphically documented, and protected with gravel filling. Establishing their status and location has been key to the design of the new building. Interfering with the new foundation has been avoided and free space has been left to recover the remains and incorporating them into the new intervention (Fig.3).

2. Project

The LRC project has been developed by the University through the Intervention on Heritage and Sustainable Architecture Group (which belongs to the Architecture Department) and by the University's Technical Office. The project development has combined various goals, such as maintaining the pre-existing building (more on the compositional issues than concerning the formal language) through the introduction of a complex functional program within a given volume.

The Heritage rules of Alcalá assigned the building the maximum outdoors protection, so maintaining the façade and its formal and material characteristics was mandatory. The intervention basically consisted on rebuilding the interior space, maintaining a balance between the pre-existing conditions, the conceptual interpretation of the disappeared elements and setting a new program of needs through the use of contemporary materials and figurative codes within a logical and coherent project [6]. It is important to consider that the interior of the building had been continually modified over decades by the military, which did not preserve, except for the entrance hall, any relevant characteristic or original elements. In the 1870 cadastral plan, just 10 years after the completion of the building, there was no longer a clear distribution of the interior space, but a random partitioning system.

Beyond preserving the outer limits of the building as it was required by the law, we tried to emphasize some of its key features: the entrance hall access as a transition element between the public space of the city (the square) and the public space inside the headquarters (the courtyard); the placement of different levels of slabs in accordance with the original levels and the maintenance of the height of the windows to conjure up the ancient user's relationship with the outside space. Although the building was always very compartmentalized, much importance it was given to the restoration of the inner perception of the construction, whose urban perception it always was unified. Unnecessary divisions were eliminated as they interrupted the visual perception of this sober, austere and repetitive architecture.

Fig. 2: Prince Barracks building, including 1870 site plan and 1859 front drawing.

The global operation, very austere as well, it was performed using a contemporary contained language and limited to a structure of columns and slabs, and a roof structure to which the services are attached. A lift core and a longitudinal stair, which runs linearly across the building, are the only elements that cross and connect the different levels. The inclusion of some patios allows a unified vision of the building from different angles. In the formal aspect we tried to avoid ambiguous postmodern elements as well as an archaic mentality. At the same time we didn't force the uncritical incorporation of a disruptive language, as often happens in current interventions [7]. The goal was to balance the perception of the original volume of the building (a quality that we considered essential to it) and the functional requirements of the new building uses without giving up a modern prospective that doesn't compete or block the understanding of the space.

The facade of the San Diego square' and the interior courtyard facade are treated in different ways. In the exterior the original character of the building has remained, restoring the gable roof. The facade has been cleaned with water and sandblast, keeping the own signs of aging of bricks and stones, provided they didn't compromise the future integrity of the masonry. The only contemporary intervention was limited to the design of the new doors and joinery. At the southern end of the roof, matching the San Pedro and San Pablo Alley, a discreet glass gazebo was located that offers a view of the towers of the sixteenth, seventeenth and eighteenth centuries, which shape the skyline of the city.

All functional actions affecting the building facades have been concentrated on the courtyard, where the emergency stairs towers highlight. They consist on two prismatic metal framed which force the contrast between the intervention and the pre-existences. To keep the austere appearance of the military building the rest of the facade has basically been chopped and revoked and the fascia lines and stone plinths have been cleaned up. Skylights have been inserted in the roof to illuminate the upper floor.

The courtyard, minimally adequate with a protective concrete floor with a stamped finish, it is seen as a continuous and abstract surface on which the emergency stairs' towers stand. When adaptation works to advance the rest of the block will take place in the future, the yard might be easily modified, given the lightweight of the performance.

Fig. 3: Prince Barracks archaeological excavation. Including ground plan of the 15th-century Franciscan convent church.

Fig. 4: LRC project. Ground plan (with archaeological remains), longitudinal section by the main space and transversal section W-E by the main entrance and the courtyard.

The interior distribution of the barracks' original volume takes into account both the archaeological remains and the existing organizational structure of the military building. The passage from San Diego's Square into the first courtyard has been cleared, keeping the old hallway access. This will grant access to the barracks, and the various courtyards in the future on an independent basis. Those spaces could even be connected to city's public space.

The ground floor is divided into two parts by the entrance hall. The left wing of the building has been left as an area reserved for the future location of the University Art Museum, which has an important collection of Contemporary Spanish and Latin American paintings. The museum will be located on the remains of the fifteenth century chapels found during the excavation phase, which were cataloged and are protected until they could be recovered when the museum will be built. To allow more flexibility in the layout of this museum area, the space was created using a large spans structure without intermediate columns. This has allowed for avoiding interferences between the new foundation and the archaeological remains, and to free space inside (Fig.4-5).

The entry to the LRC occurs from the vestibule on the right side of the ground floor. From the entrance hall, past the access control desks, we reach the loan desk. The cataloging spaces and the technical floor are located behind it. The entire LRC program is developed on the upper levels, organized by floors and sectors. The organization in U of the old barracks, which was already present in the old three volumes set up (a central volume, coincident with the facade of S. Diego square, and two perpendiculars to this side) has been explicitly maintained by introducing service cores, communication cores and emergency halls, which physically divide the building coinciding with the same three volumes.

The central volume, more limpid and wider than the others, houses the large workrooms, and reading rooms. This multipurpose space offers books consultation as well as individual study spaces and, mainly, collective study spaces, much in demand by students since Bologna Plan was established. Only the first floor of the southern volume attached to the main building it is occupied, in continuity with the great central space. The ground floor is intended to services.

Fig. 5: LRC project. Longitudinal sections by the main space, by the courtyard and transversal section E-W by the main entrance and the courtyard.

The side volumes, perpendicular to the central one, house the library staff's work zones (right wing of the building) and other spaces such as silence rooms, researchers and graduate offices, some classrooms and rooms for seminars and research groups. The books deposit is located on the mezzanine, connected to all levels by an exclusive lift.

3. Construction

The building construction blended the new edification, built between the main structural walls, and the pre-existing elements, the facade walls and the archaeological remains located at foundation level. The stresses of the new construction were very restrictive in terms of static charges, distances between structural elements and fire load. The starting point was to embrace a very simple and sincere constructive solution, with very little differences between structure and finishes and where structure and facilities are exposed.

The foundation was made using micropiles attached to the interior face of the building's facade. The micropiles perforated the current foundation reinforcing it and reaching the firm below the water table. The pile caps were made above the ground floor, which cheapen the cost and created platforms under the ground floor windows. The use of this foundation technique has also prevented damage of the archaeological remains scattered around, which otherwise they would have suffered.

Given the resulting loads, the vertical structure was made with reinforced concrete columns erected on the capping beams and attached to the internal face of the building's facade. On the LRC's ground floor, adding an intermediate structural axis matching one of the old building's foundation lines, allowed us for thinner slabs. In the future museum's area, scattered with archaeological remains, we avoided this foundation line using deep beams made with self-compacting concrete. Above them, the centerline of vertical structure has been recovered from the first floor on. On the penultimate floor, due to the external walls section decrease, and matching the vertical line of structure, (widely separated from the walls) the used of steel columns of reduced section lighten the structure.

The floors were made with a mixture of flat concrete slab (25cm thick), in the transit zones, and a rib slab made "in situ" on the reading and study areas, performed with a linear recoverable formwork. A beam that longitudinally crosses the building, and that has been suitably perforated to allow the passage of the services joins both slabs. The stability of the external walls is ensured by the use of metal connectors and resins.

The original side gable roof is recovered. A 14 meters long laminated wood and metal trussed is the only structure that rests on the original walls. A perimeter concrete beam consolidates the stone cornice. A 12cm EPX insulation sandwich panel and an interior board made by recycled OSB particles forms the roof wrought. The outside is coated with a waterproof dry sheet, corrugated sheet and recovered tiles (Fig.6).

Electrical, lighting and fire facilities run through a general line along the inner building perimeter, and they are distributed between the ribs. The electrical facilities run through the lighting trays. The upper slab is perforated to allow their accommodation in manholes from where the worktables will be electrified.

Fig. 6 : LRC construction. From left side to right: foundations, protection of archaeological remains, internal construction and roof.

The air-conditioning system is designed with a four hot-cold tubes structure that is distributed through fan coils. A condensing boiler's heat generator is combined with a high efficient VRV system for cold. Conventional systems are supported by solar panels and pretreated air in a heat exchanger. The system has been designed thinking of the future integration of a geothermal pump fed by pipes buried in the backyard. The placement of insulation in facades has been omitted, taking advantage of the high thermal inertia of the perimeter walls. The calculations made in simulation programs give the building an A qualification in energy efficiency.

4. Conclusions

The new LRC is the latest accomplishment regarding the recovery of historic buildings for teaching purposes that follows the University of Alcalá tradition. Because of its volume and implementation in the historic city center, this latter embodiment could be considered as an effort to pursue a new type of intervention matching the current economic, social and cultural circumstances. This renovation has given a greater prominence to the architectural space, managing a limited formal and constructive repertoire, also expressed with a limited use of materials. It is an intervention in stark contrast to previous ones, traditionally more focused on the formal and aesthetic recovery, with a profuse use of finishes and materials traditionally associated to rehabilitations (hardwoods, stone, glass, plaster and stucco). The result is a wide space that can be run with the flexibility demanded by the constantly changing university needs and uses, of low maintenance, low energy consumption, and built adjusting costs to the current Spanish economic situation (Fig.7).

Abstract

Several European directives invite Member States to take measures in order to reduce both energy consumption and pollution associated to existing buildings, especially those of public services. The energy and economic impact of several retrofit actions on an existing historical public building is evaluated in this paper. The study is aimed at both proposing a general operational methodology as well as highlighting a best-practice for the Italian territorial context, which has several historical buildings needing restoration.

The analysis has been focused on the Abbey of San Lorenzo ad Septimum, that is located in Aversa (southern Italy) and hosts the Department of Architecture and Industrial Design of the Second University of Naples.

First of all, the current energy demand of the building during winter has been estimated. At a later stage, three different retrofit actions were simulated and analyzed: 1) utilization of thermostats to regulate the target of indoor air temperature; 2) increase of thermal insulation of the external opaque walls; 3) reduction of both thermal transmittance and air draught associated to the fenestration systems.

The influence of each action on the building performance has been carefully evaluated in terms of both primary energy consumption and operating costs, with the main aim of estimating the potential benefits associated to the proposed measures.

Keywords: Historical buildings; Building simulations; Energy Saving; Energy efficiency; Retrofit actions.

1. Introduction

Even if a significant part of the Italian building stock was realized between the 1950s and the first part of the Eighties, as a result of the urban growth following the second world war, over 3,900,000 buildings were built prior to the 1920s [1]. Moreover, a lot of these constructions are characterized by historical-artistic values and therefore protected as Cultural Goods; the Italian cities show a beautiful mixture of admirable examples of buildings, characterized by significant historical-artistic value as well as including mosaics of ages and styles.

According to the Italian Legislative Decree 192/2005 [2], no energy retrofits are mandatory for historical buildings in order to postpone the energy performance to the cultural integrity. However the energy consumption of the civil sector in the European Union is about 40% of the total energy demand, with it generating 40-50% of the total output of greenhouse gases [3]. These figures imply that, with initiatives in this area, significant energy savings can be achieved, thus helping to attain objectives on climate change and supply security.

A survey of the references in the scientific literature illustrates a substantial lack of studies specifically focused on building retrofitting and refurbishment actions [3].

In this paper, the energy and economic impact of several retrofit actions on an existing historical public building is evaluated; measures compliant with architectonic features and respecting the historical heritage were considered and analyzed.

The study focused on a portion of the Abbey of San Lorenzo ad Septimum, that is located in Aversa (southern Italy) and hosts the Department of Architecture and Industrial Design “Luigi Vanvitelli” of the Second University of Naples.

The analysis is aimed at both proposing a general operational methodology as well as highlighting a best-practice for the Italian territorial context, which has several historical buildings needing restoration.

The primary energy consumption and operating costs associated to the current operation of both the heating system and lighting appliances of the Abbey during winter were evaluated based on field survey and manufacturers’ data. These estimated values were compared with those achievable by adopting several retrofit actions on both the heating system serving the Abbey as well as the building envelope; the primary energy consumption and operating costs associated to the mentioned hypothetical measures were evaluated by using the whole-building dynamic simulation software TRNSYS 16 [4]. The performed comparison among the current status and the possible future scenarios allowed to evaluate the potential benefits in terms of primary energy saving and operating costs reduction and, therefore, assess the feasibility of each proposed retrofit action.

2. Description of the historical building

The Department of Architecture and Industrial Design “Luigi Vanvitelli” of the Second University of Naples is located within the Abbey of San Lorenzo ad Septimum. The abbey complex was built at the end of tenth century along the consular street named “Via Campana” and represents the result of three centuries of history. The church was raised around the year 1080: it has a nave and two aisles and shows several stratifications. The bell tower was rebuilt around mid-fifteenth century as a consequence of the earthquake of the year 1456. The main renaissance cloister has several round arches positioned over Doric columns; it acts as the connection among the different parts of the abbey complex: towards the north, there is the church; the garden is located towards the south; westward there are the minor baroque cloister and the eighteenth-century portion designed by the architect Ferdinando Fuga; eastward, there is the nineteenth-century portion that was completed during the period when the abbey was a College and Real School of Arts. Additional details regarding the historical building can be found in [5].

In this paper, only a part of the whole Abbey of San Lorenzo ad Septimum was investigated. In particular, in this study attention was focused on three main parts of the historical building composed of three floors per each:

- the nineteenth-century portion;
- the west wing;
- the east wing.

Figure 1 highlights the portions studied in this paper on the map of Abbey of San Lorenzo ad Septimum.

The nineteenth-century portion hosts 2 classrooms and 1 library, with a total volume of 5432 m³ and a floor area equal to 302 m²; the west wing hosts 5 classrooms, with a total volume of 7188 m³ and a floor area equal to 517.69 m²; the east wing hosts 5 classrooms and 6 bathrooms, with a total volume of 4483 m³ and a floor area equal to 474 m².

The current thermal transmittance of the external opaque walls ranges from 0.699 and 1.484 W/m²K, while the current thermal transmittance of the windows is equal to 3.47 W/m²K.

3. Heating and lighting systems: state of art

The portions of the Abbey of San Lorenzo ad Septimum investigated in this paper are currently heated during the winter by using a water system. Hot water is produced by a diesel-fired boiler; according to the manufacturer data, the thermal efficiency of the boiler η_B can be obtained by using the following equation:

$$\eta_B = -0.001 \cdot P_{th,B} + 0.957 \quad (1)$$

where $P_{th,B}$ is the thermal output of the boiler.

Hot water is heated up to a preset temperature and circulated towards several fan-coils distributed throughout the building by means of pumps and insulated tubes; 96 fan-coils are installed with a nominal heating capacity ranging from 2.6 and 3.0 kW (at medium fan velocity) per each and nominal electric consumption (at medium fan velocity) in the range of 27÷45 W per each. At the moment, the

building is not equipped with thermostats to set the target of the indoor air temperature and switch off the heating system in case of the target temperature being reached.

The lighting of the investigated parts of the Abbey is currently obtained by means of 621 fluorescent sources with a nominal electric consumption from 55 W up to 200 W per each.

The primary power consumed by both the heating system and lighting appliances P_p was calculated based on the following equation:

$$P_p = \sum_{i=1}^{96} \frac{P_{th,FC,i}}{(\eta_{em} \cdot \eta_{dist} \cdot \eta_B)} + \sum_{i=1}^{96} \frac{P_{el,FC,i}}{\eta_{el}} + \sum_{j=1}^{621} \frac{P_{el,L,j}}{\eta_{el}} \quad (2)$$

where $P_{th,FC,i}$ is the nominal thermal output of the i -th fan-coil (obtained from manufacturer's data), $P_{el,FC,i}$ is the nominal electric power consumed by the i -th fan-coil (obtained from manufacturer's data), $P_{el,L,j}$ is the nominal electric power consumed by the j -th fluorescent lamp (obtained from manufacturer's data), η_B is the thermal efficiency of the boiler obtained from equation (1), η_{el} is the average electric efficiency associated to electricity production in Italy including transmission and distribution losses (assumed equal to 0.461 according to the Italian scenario [6]), η_{em} is the emission efficiency taking into account the thermal losses associated to the use of fan-coils as terminal units (it was assumed equal to 0.960 according to the Standard UNI/TS 11300-2 [7]), η_{dist} is the distribution efficiency taking into account the thermal losses associated to the circulation of hot water through the building (it was assumed equal to 0.925 according to the Standard UNI/TS 11300-2 [7]), and the indexes i and j represent the number of fan-coils and lighting appliances, respectively.

The total primary energy E_p consumed by both the heating and lighting system was calculated by assuming that both fan-coils and lighting appliances operate for 10 hours per day from November 15th up to March 31st (academic holidays and weekends excluded).

The operating cost OC associated to both the heating system and lighting appliances was calculated based on the following equation:

$$OC = UC_{diesel} \cdot \frac{E_{p,B}}{\rho_{diesel} \cdot LHV_{diesel}} + UC_{el} \cdot E_{el,FC} + UC_{el} \cdot E_{el,L} \quad (3)$$

where UC_{diesel} is the average unit cost of diesel (assumed equal to 1.41 €/liter according to the Italian market), ρ_{diesel} is the density of diesel (assumed equal to 850 kg/m³), LHV_{diesel} is the Lower Heating Value of diesel (assumed equal to 44.4 MJ/kg), UC_{el} is the average unit cost of electric energy (assumed equal to 0.20 €/kWh_{el} according to the Italian market), $E_{el,FC}$ is the electric energy consumed by fan-coils, $E_{el,L}$ is the electric energy consumed by the lighting appliances, and $E_{p,B}$ is the primary energy consumed by the boiler. The value of $E_{p,B}$ was calculated by means of the following formula:

$$E_{p,B} = \frac{E_{th,FC}}{(\eta_{em} \cdot \eta_{dist} \cdot \eta_B)} = \frac{\sum_{i=1}^{96} (P_{th,FC,i} \cdot OT_{FC,i})}{(\eta_{em} \cdot \eta_{dist} \cdot \eta_B)} \quad (4)$$

where $E_{th,FC}$ is the thermal energy output associated to all of fan-coils and $OT_{FC,i}$ is the operating time of the i -th fan-coil.

Under the above-mentioned hypotheses, the current primary energy consumption and the operating costs associated to the operation of both the heating system and lighting appliances during the heating period are equal to:

➤ $E_p = 3.02E+05$ kWh

➤ $OC = 37548.20$ €

4. Retrofit actions

In order to both save primary energy and reduce operating costs, the following three retrofit actions were proposed and analyzed:

- 1) utilization of thermostats to regulate the indoor air temperature with a target of 20 °C;
- 2) addition of insulating panels to increase the current thermal insulation of the opaque external walls to be compliant with the Italian Law [8];
- 3) substitution of current windows to reduce the current thermal transmittance to be compliant with the Italian Law [8].

In order to estimate the energy primary saving and the operating cost reduction associated to the proposed actions, the portion of the Abbey of San Lorenzo ad Septimum described in Figure 1, the whole-building was simulated using the dynamic simulation software TRNSYS 16 [4]. This software allows to calculate the thermal load to be balanced taking into account the external climatic conditions, the thermal transmittance values of both the walls and windows, the air change due to air infiltration, the internal loads due to people and lighting appliances, the target for the indoor air temperature, etc. This simulation tools is widely used in literature for evaluating the energy performance of buildings upon varying the operating scenarios [9-12].

The simulations were performed from November 15th up to March 31st, with a simulation time step equal to 1 hour; both heating and lighting systems were considered as switched off out of school time. In the following sections, the above-mentioned measures are described in more detail and the results associated to the above-mentioned three retrofit actions are shown and discussed.

4.1 Retrofit action 1: simulation results

As above-mentioned, currently the heating system of the Abbey is not equipped with thermostats to set the target of the indoor air temperature and switch off the heating system in case of the target temperature being reached.

The installation of a thermostat in each room is proposed as first retrofit action. In order to evaluate the potential benefits associated to this measure, the investigated portions of the building were simulated. The simulation was performed by assuming:

- thermal transmittance of both the walls and windows equal to the current values;
- air exchange rate due to air infiltration ranging from 0.40 up to 0.48 volumes/h (calculated according to the Standard UNI 12831 [13]);
- internal loads due to people compliant with the current academic timetable by assuming the students as seated at writing;
- internal loads due to lighting appliances compliant with the current academic timetable by assuming that 75% of the nominal electric consumption is transferred to the indoor air as heat;
- target for the indoor air temperature equal to 20°C.

Figure 2a highlights the hourly variation during the heating season of the sensible thermal load associated to the whole part of the Abbey under investigation, while Figure 2b reports the hourly variation of both thermal load and indoor air temperature for a single particular classroom during a typical day of operation. As can be derived from Figure 2a, the maximum sensible thermal load is equal to 137 kW, while Figure 2b illustrates the operation of the heating system that is switched off in the case of (i) the indoor temperature becomes equal to the desired target (20 °C) and (ii) out of school time.

Figure 3a highlights the hourly variation during the heating season of the operating costs of both diesel (consumed by the boiler) and electric energy (consumed by both lighting appliances and fan-coils) associated to the whole part of the Abbey under investigation, while Figure 3b reports the hourly variation of diesel cost and electric energy cost for a single particular classroom during the same typical day of operation considered in Figure 2b. As can be derived from Figure 3a, the total operating costs can reach a maximum of 36 €/h, while Figure 3b demonstrates that the operating costs are mainly due to the boiler operation and they are relevant mainly from 8 a.m. to 10 a.m. and from 5 p.m. to 7 p.m..

Figure 4a highlights the primary energy consumption associated to the current status of the building (calculated as described in the section 3) and the primary energy consumption obtained from the simulation after the introduction of the above-mentioned retrofit action 1. The latter value was obtained by integrating the primary power calculated with the following formula over the whole period of operation of heating and lighting systems:

$$P_p = \frac{P_{th,LOAD}}{(\eta_{em} \cdot \eta_{dist} \cdot \eta_{reg} \cdot \eta_B)} + \frac{P_{el,TOT,FC}}{\eta_{el}} + \frac{P_{el,TOT,L}}{\eta_{el}} \quad (5)$$

where $P_{th,LOAD}$ is the total sensible thermal load (obtained from simulations), $P_{el,TOT,FC}$ is the electric power consumed by all of fan-coils, $P_{el,TOT,L}$ is the electric power consumed by all of fluorescent lamps, η_B is obtained from equation (1), η_{el} is the average electric efficiency associated to electricity production in Italy including transmission and distribution losses (assumed equal to 0.461 according to the Italian scenario [6]), η_{em} is the emission efficiency (assumed equal to 0.960 according to the Standard UNI/TS 11300-2 [7]), η_{dist} is the distribution efficiency (assumed equal to 0.925 according to the Standard UNI/TS 11300-2 [7]), η_{reg} is the regulation efficiency taking into account the losses associated to the on/off operation of the heating system associated to the control of indoor air

temperature (it was assumed equal to 0.920 according to the Standard UNI/TS 11300-2 [7]). As it can be derived from Figure 4a, using thermostats allows to save the primary energy consumption by about 62%. The percentage difference reported in this figure was obtained as follows:

$$\Delta E_p = \frac{E_{p,current} - E_{p,retrofit}}{E_{p,current}} \cdot 100 \quad (6)$$

where $E_{p,current}$ is the primary energy associated to the current status of the building, while $E_{p,retrofit}$ is the primary energy consumption achievable after the retrofit.

Figure 4b compares the operating costs associated to both the heating and lighting systems before and after the retrofit action 1: the introduction of thermostats reduces the total operating costs for both diesel and electric energy by about 67%. The percentage difference reported in this figure was obtained as follows:

$$\Delta OC = \frac{OC_{current} - OC_{retrofit}}{OC_{current}} \cdot 100 \quad (7)$$

where $OC_{current}$ is the operating cost associated to the current status of the building, while $OC_{retrofit}$ is the operating cost achievable after the retrofit.

4.2 Retrofit action 2: simulation results

The current thermal transmittance values associated to the opaque external walls of the Abbey range from 0.699 and 1.484 W/m²K. Starting from 1 January 2010, the Italian Law [8] specifies the threshold values of thermal transmittance for the external walls of the renovated buildings depending on (i) the climatic zone where the building is located and (ii) the wall type (external wall, ground and roof); the threshold value of the thermal transmittance for the external walls associated to property renovations in Aversa is 0.34 W/m²K.

The retrofit action 2 consists of using both the thermostats to regulate the target of indoor air temperature (at 20°C) as well as insulating panels [14] with thermal conductivity equal to 0.023 W/mK in order to achieve the threshold value of thermal transmittance suggested by [8]. Taking into account that the Abbey is characterized by several typologies of external walls, different thickness of insulating panels were proposed for each wall typology.

Figure 5a highlights the primary energy consumption associated to the current status of the building (calculated as described in the section 3) and the primary energy consumption obtained from the simulation after the introduction of the above-mentioned retrofit action 2 (calculated from the simulation results by means of equation (5)); as it can be noticed, the primary energy consumption is reduced by about 70%; by comparing Figure 5a and Figure 4a, it can be noticed that the addition of insulating panels allows to lower the primary energy consumption by about 8% with respect to the only use of thermostats (retrofit action 1).

Figure 5b compares the operating costs associated to both the heating and lighting systems before and after the retrofit action 2: the use of insulating panels reduces the total operating cost for both diesel and electric energy by about 75%; by comparing Figure 5b and Figure 4b, it can be noticed that the addition of insulating panels allows to lower the operating costs by about 8% with respect to the only use of thermostats (retrofit action 1).

The percentage differences reported in Figures 5a and 5b are calculated by using the formulas (6) and (7), respectively.

4.3 Retrofit actions 3: simulation results

The current thermal transmittance values associated to the windows of the Abbey is 3.47 W/m²K. Starting from 1 January 2010, the Italian Law [8] specifies the threshold values of thermal transmittance for windows of renovated buildings depending on the climatic zone where the building is located; the threshold value for windows associated to property renovations in Aversa is 2.10 W/m²K.

The retrofit action 3 consists of three main measures:

- using thermostats to regulate the target of indoor air temperature (at 20°C);
- adding insulating panels [14] on the opaque external walls to achieve the threshold value of thermal transmittance suggested by [8];
- substituting the current windows with new ones characterized by thermal transmittance values compliant with [8].

Thanks to the higher quality of window-seal associated to the new windows under consideration, a reduction of air exchange rate due to infiltration from $0.40 \div 0.48$ volumes/h up to $0.12 \div 0.14$ volumes/h was also assumed.

Figure 6a highlights the primary energy consumption associated to the current status of the building (calculated as described in the section 3) and the primary energy consumption obtained from the simulation after the introduction of the above-mentioned retrofit action 3 (calculated from the simulation results by means of equation (5)); as it can be noticed, the primary energy consumption is reduced by about 74%; by comparing Figure 6a and Figure 5a, it can be noticed that the substitution of the current windows allows to lower the primary energy consumption by about 4% with respect to the result associated to the retrofit action 2.

Figure 6b compares the operating costs associated to both heating and lighting systems before and after the retrofit action 3: the substitution of windows reduces the total operating cost for both diesel and electric energy by about 79%; by comparing Figure 6b and Figure 5b, it can be noticed that the substitution of the current windows allows to lower the operating costs by about 4% with respect to the result associated to the retrofit action 2.

The percentage differences reported in Figures 6a and 6b are calculated by using the formulas (6) and (7), respectively.

5. Conclusions

Three different retrofit actions were proposed to reduce both the primary energy consumption and the operating costs associated to the operation of both heating and lighting systems during the winter associated to a portion of the historical building hosting the Department of Architecture and Industrial Design “Luigi Vanvitelli”.

A general methodology (applicable to case studies different from that one investigated in this paper) to evaluate the potential energy and economic benefits associated to retrofit actions on existing building is proposed and described.

With respect to the proposed measures, the analysis highlighted that the utilization of thermostats allows to achieve the most significant reduction of both primary energy consumption and operating costs if compared to the other proposed retrofit actions; the utilization of insulating panels allows to achieve a more pronounced reduction of both primary energy consumption and operating costs with respect to the substitution of windows.

Urban planning and administration in a provincial city in the early 20th century

Maria Paola GATTI,¹ Giorgio CACCIAGUERRA¹

⁽¹⁾ Department of Civil, Environmental and Mechanical Engineering, University of Trento, Trento, Italy
E-mail mariapaola.gatti@unitn.it; Giorgio.cacciaguerra@unitn.it;

Abstract

Between the end of the 19th century and beginning of the 20th century, the urban plan of a number of European cities underwent major transformations.

The birth and proliferation of innovative industrial enterprises caused the previous socioeconomic structure generated by an agricultural economy to evolve.

In the space of just a few years, factories, housing for workers and numerous public and private buildings for the new society were built.

For the first time, the evolution and expansion of cities were planned on paper before implementation.

The projects drawn up by the planners were no longer on individual building scale, but covered large areas, to the point of considering the evolutions in terms of the entire local authority area.

The road network in the existing city was amplified and new buildings were built, often demolishing part of the historic town. New single-function districts were added alongside the consolidated nucleus. During this period, a series of analytical, design and regulatory tools were developed to allow cities to be developed congruently.

We therefore felt it would be interesting to follow the transformation of Rovereto (Trentino) where, in just under 15 years, the presence of a large number of troops and the introduction of industrial activities created a modern rational urban aggregation in place of the previous small-town dimension.

Keywords: urban transformation, expansion of cities, modern architecture.

1. The urban transformation of Rovereto at the turn of the 19th century

During the closing decades of the 19th century, many European cities adopted an urban planning scheme and began a complete reorganisation of land use, driven by social pressures, the need for new residential areas at the edges of the existing city and the necessity to confirm and transform the consolidated urban nucleus. The social and economic changes induced by the development of industrialisation and the parallel regression of subsistence agriculture led to often unplanned expansion of the suburbs which ended up modifying the consolidated image of the city closed within its medieval walls. The search for areas to allocate to the new buildings led to proposals to gut the historic city centres, demolish the city walls, separate districts according to social class and introduce factories into the city. By modifying the rules of the market, the social transformations attributed ever growing importance to income from the land which became the mainstay of the capitalist society.

During this period, cities and towns were provided with new infrastructure - drains and sewers, aqueducts, power mains and tramlines. For the first time in urban history, the resulting high degree of "urban disorder", scale of the activities and maximisation of profit by landowners made it necessary to define compulsory land regulation and planning tools, necessitating the drafting of building regulations and planning schemes.

The procedures and timing of the growth process differed in the various European urban agglomerations. Some cities expanded spontaneously, others according to established plans, irrespectively with sometimes positive, sometimes negative results.

In the case of small towns, far from the driving forces of the industrial mentality, the evolution came later and in the majority of cases took place in the total absence of any form of planning, with new buildings springing up alongside the historic city centre in an attempt to take as little land as possible away from agriculture. There are only a few cases of small provincial towns which grew consciously according to planning schemes and careful economic evaluations, in many cases based on policies drawn up on the basis of nothing but good sense and proving highly valid, to the point where they could still be adopted today.

One such case is Rovereto, a small city in the province of Trentino which, between 1890 and 1915, underwent major social and economic transformation. From a small market town at the centre of a number of agricultural villages with the same characters, it was transformed into an industrial and military centre.

From the second half of the 19th century, Rovereto based its growth on planning schemes drawn up by "city engineers" appointed by the municipality to coordinate and control urban growth. In the majority of cases, these planning and regulatory tools received only partial approval, but they nevertheless guided the subsequent transformation processes.

In the 19th century, more than in other cities or towns, in Rovereto (situated on the frontier of the Hapsburg Empire) attempts were made to reactivate the urban development process promoted by the Venetians in the 15th century (from 1418 to 1509) by introducing silk production. In just a few years, this modified the centuries-old economy, bringing a vitality which was maintained for a number of centuries. In the second half of the 19th century, Rovereto went through a further period of economic stagnation, partly caused by the agricultural crisis, combined with the crisis in the industrial sector (in 1873, the whole of Europe and the United States were experiencing the first economic depression of the industrial age). New activities were introduced in an attempt to revive the economy and urban development. Growth was hampered by central government, which considered it inappropriate to invest in a frontier territory where the Italian and German cultures had always existed side by side... an area which, after the loss of the Lombard Veneto, was becoming an ever more important part of the defence strategy as the Adige valley was one of the main axes of penetration from the Italian regions.

As in all municipalities in the Hapsburg Empire with a population of more than 10,000 inhabitants, in compliance with Law no. 206 of 26 November 1824¹, a building office² was set up to regulate public and private building activities. This was responsible for regulating and coordinating public and private building, including through preparation of the city's expansion plans.

In Rovereto, the city engineering department was run first by engineer Folinio Cristiano Chiusole³, then by engineer Gaetano Gerola and later by engineer Ettore Gilberti. Working in the city from 1904 to 1922, it was Gilberti's job to give concrete form to the plans drawn up by his predecessors and advance new proposals for expansion with the public and private buildings required by modern society.

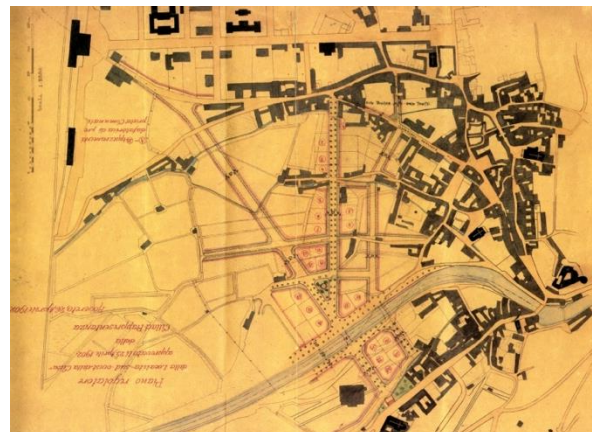

Fig. 1: Planning scheme covering the entire surface area of the municipality drawn up in 1902 by the city engineer Edoardo Gerosa.

Fig. 2: Detailed plan of the expansion to the west of the historic city centre, drawn up in 1902 by city engineer Edoardo Gerosa showing the planned route of the new connecting axes.

The urban transformation took its cue from the solicitations of enlightened politicians and rich landowners who, with the declared aim of obtaining new resources (sometimes through highly speculative operations), began by financing the modern infrastructure, then planning strengthening of the banks of the Leno torrent and straightening the course of the Adige river and constructing new road and rail axes. This was followed by construction of hydroelectric generating stations (for example, on the Flora and Ponale) to supply the city with electricity, gas (the 1872 plan shows the gasometer already in operation), aqueducts, drains and sewers.

In 1857, city engineer Chiusole drew up the first expansion scheme, including a connection between the existing nucleus and the railway and defining the city's first middle-class district around the road axis. The new district, to the west of the historic city centre, was organised around a linear axis (more than 15 m wide and about 800 m long) extending from the railway station to the new square where the various roads met - the axis of the medieval city and the axis of the 18th century expansion. The plan also included a hypothetical second link, proposing straightening an existing road to connect the church of Le Grazie with the Capuchin Monastery, then crossing numerous private smallholdings to join with an established road axis in the historic city centre (now Mercerie street).

From 1868, Gaetano Gerola intervened on the extensive land front, dividing the territory into large regular lots and assigning them to the modern activities at the service of the community - prison, magistrate's court, law court, schools (teacher training college, swimming school, kindergarten), a number of hotels (the Glira and the Venezia) and meeting rooms. Further roads were also proposed, including one which started from the southern edge of the historic city centre to join Borgo Santa Caterina with Borgo San Tomaso, constructed only 40 years later (Dante street was not in fact constructed until 1901-02).

During this period, the city administration located the areas assigned to industry in two different areas, one parallel to the Leno torrent between the historic city centre of Rovereto and Borgo Santa Maria, in part occupied by the spinning mills and factories built since the 16th century, and one "less artisan" near the railway which occupied agricultural land.

Given the scale of the transformations, in 1896, city engineer Edoardo Gerosa was appointed to draw up the first planning scheme covering the entire municipality. The division of the south west sector was the same as that adopted in engineer Chiusole's expansion plan, but this scheme proposed a more detailed land organisation, utilising only a minimum part of the existing routes. The expansion zone extended from the historic city centre to the railway station and was structured round two main highways (a sort of V), joined by narrower secondary roads. As well as tracing out the layout of the north south axis, the plan also proposed constructing a small park near the bridge. From there, a 25 m wide road went as far as Borgo Santa Caterina where it joined the existing road system, occupying part of the land owned by the Capuchin monastery. As well as providing guidelines for development of the city's south west sector, Gerosa also defined those for the areas to the north. In general, the planning scheme proposed creating wide roads defining large lots, those to the north destined for large industry, those to the south for small industry and workers' housing.

The urban development of Rovereto continued, adopting schemes for medium sized areas, including the plan drawn up in 1902 which proposed a new road joining the old Borgo Santa Maria with the railway and the new districts, without passing through the historic city centre (San Marco district).

To guarantee a fluid and continuous road network, it proposed reconstructing the bridge which had collapsed when the Leno flooded in 1798. Following preparation of the urban planning scheme, the city administration acquired the land along the new 25 m wide road axis (Dante street), subsequently proposing its division into medium to large sized lots (23 to be precise, including 5 on the left bank of the Leno). The lots to be allocated for public works were then identified and the remaining were sold to local businessmen to construct private single and multi-family housing.

To better coordinate the city's expansion, in April 1893, the city administration decided to update the building regulations⁴. For those wanting to construct new buildings or convert existing ones, the revision introduced the obligation to present the building authorisation with the inclusion of a general plan indicating the parcels in the area, the existing and planned roads and the buildings. The building dossier (signed by a qualified engineer and the building firm) had to be accompanied by the plan, the vertical section and a "*detailed and precise drawing*" of the main façade, and also the side façades "*if not identical*". Art. 15 of the regulation suggests that the municipality reserved the right to indicate the precise line and level for both new and converted buildings. The next article (art. 18) prescribed that, in the case of new or reconstructed buildings in "*narrow or winding streets*", an "*appropriate widening or straightening of said streets*" must be considered. The regulation then specified provisions on the dimensions (the height of the building, the rooms, the minimum surface area of the rooms, etc.), the quality of the spaces (lighting and ventilation index of the rooms) and numerous technical requirements (for example, the quality of the materials) to be respected during construction.

Despite the planning tools, for many years modernisation and development of the city remained a paper exercise as the agricultural and economic crisis of the 1870s affecting the entire empire limited the city administration's plans. The greater economic stability of the last years of the 1800s and

appointment of a young enterprising engineer allowed Rovereto to give concrete form to the economic plans and urban expansion projects drawn up for the city until that time.

In 1903, after engineer Edoardo Gerosa had retired, a competition was announced for the position of head engineer of the municipality of Rovereto. The notice, published in both German and Italian newspapers⁵, required a diploma in civil engineering and a "good" level of proficiency in architecture. In fact, the city administration was looking for an engineer able to stimulate "quality" urban growth, according to the aspirations of the period, equipping the city with modern infrastructure and functional buildings of significant architectural worth. Unlike other provincial capitals in the Tirol, Rovereto was not therefore looking for a mere technical bureaucrat, but an eclectic curious designer, able to attract capital to build a new city able to rival Trento, always the most important city in the province of Trentino, seat of the church and an imposing military fort.

The political and administrative municipality of Rovereto wanted to have no doubts as to the quality of the man running the city engineering department. The notice therefore established a trial period of two years before definitive appointment which necessarily involved taking German citizenship. Despite the fact that it was not actually specified, this suggests that the governing authorities encouraged the appointment of people from outside, perhaps to combat the numerous acts of favouritism common at the time.

Many Italian engineers asked for clarification on the competition and a full thirty responded to the notice by sending in a formal application, attaching their scientific and professional curriculum vitae. Applications to take part in the competition came from engineers from Turin, Milan, Ferrara, Udine, Venice etc., but the selection never got underway. In fact, the competition dossier has never been found among the documents kept in Rovereto's historic archive and the minutes of the council sittings show that the commission was never even appointed.

After many months, the city administration decided to cancel the competition and enter into private negotiations. Burgomaster Malfatti contacted certain academics at Milan Polytechnic who indicated Ettore Gilberti⁶ as a suitable engineer to occupy the post of city engineer, not least because he understood German⁷.

Contact was made first with professor in architecture Sebastiano Giuseppe Locati⁸ (letter of 22 June 1904) and the academic Camillo Boito (letter of 23 July 1904) who both considered the young student Ettore Gilberti suitable to occupy the post of head engineer of Rovereto. In particular, Boito praised Ettore Gilberti's technical abilities: "*... not only does he compose and draw with great grace and a lively imagination, he is also a precise and well-grounded engineer. He is well familiar with constructions and has no lack of practical experience, as on a number of occasions he has built certain modest buildings in his native Friuli. ... appointing Gilberti would not therefore be other than commendable. ...*". Gilberti himself wrote a series of letters to the mayor of Rovereto. Before he had graduated, the municipality of Rovereto decided to take Ettore Gilberti on for a trial period of one year. (letter of 29 July 1904). Negotiations were rapid. Just six days passed between Boito's letter, the council's resolution and Gilberti's formal acceptance.

During the assembly of 9 August 1904, the representatives of the city resolved to appoint Ettore Gilberti provisionally (municipal notice of 20 August 1904) as head of the city engineering department, according to the provisions of the internal staff regulation from the city magistrates. In September, a few days after graduating, Ettore Gilberti was appointed head of the city engineering department of Rovereto and straight away became the technical interpreter of the objectives defined by the politicians to transform Rovereto into a modern city, built in homogeneous districts, flanking the already well-established garrison economy based on contracts and services and responsible for building barracks and forts with the economy of industry and banks.

Gilberti's perspicacity in resolving both urban planning and architectural problems soon emerged as right from his first assignments he dedicated the same attention to designing both the building and its surroundings, considering appearance, structure, technology and functions on both scales. This is clear from his designs and his early projects in particular consist of a considerable number of illustrations defining the immediate surroundings and the building on various scales, right down to the interior design.

Right from the start, Ettore Gilberti's thinking on urban planning is clear, together with the approach he would take in his work to transform and expand the city. He was called on to demolish the insalubrious districts, amplify the drains, sewers and aqueducts, introduce a public and private lighting system, widen and straighten the narrow tortuous streets, improve connections between the consolidated urban nucleus and the railway and establish the main routes crossing the city suitable for the new mechanical means of transport.

The city engineer of Rovereto tried to provide a rapid response to the numerous requests and although these did not always coincide with the political and social demands, they were nevertheless well received by the community. Gilberti certainly did not stop at the knowledge learnt at university. Through constant consultation of French, German and Italian journals, he developed the urban planning and architectural proposals he felt to be most appropriate to resolve the issues, without

becoming a follower of particular schools of thought. For example, he was always against complete gutting of an area, preferring selective demolition and trying, on the other hand, to define architecture able to create a greater sense of space. Ettore Gilberti immediately realised that what was currently happening in numerous German and European cities could not be implemented in Rovereto without completely eliminating the fine fabric of the city and its structures. His way of working makes it clear that the thinking of Gustavo Giovannoni (1873-1947) already existed in embryonic form. Modernisation of the existing buildings and public spaces could not take place by proposing radical demolitions altering the plan of the city and modifying the spatial distribution of streets and squares. Ettore Gilberti criticised the rigidity, technical narrow-mindedness and generic nature of the expansion schemes. For him, the urban planning tool could not be subordinated exclusively to resolving the technical problems of traffic, but must also consider the spatial characteristics of the city and thus its architecture.

The spatial conception of Ettore Gilberti was based on the concept of an interconnected organic composition of sequences of buildings, a refusal of the isolated building, of straight lines, uniform storeys, geometric plans and abstract building regulations. It was founded on the other hand on consideration of topographic details, the dimensional relationships between the buildings, asymmetry and variety to be evaluated through use of a three, rather than two-dimensional design process. These ideas can all be found in the urban planning proposals drawn up for Rovereto.

For example, in his first assignment in Rovereto (conversion of the Pergher house as premises for the Banca Cattolica), to improve hygiene conditions and the road system in the neighbourhood, he proposed shrewd selective demolition, without complete gutting. The local engineers had drawn up various solutions, but the city council and ornamentation commission systematically turned them down as they felt they had too great an impact on the volumes and appearance. Gilberti proposed eliminating the original portico to create a modest recess in the building, together with an airy formal articulation with light coloured marble and pilasters reaching the roof, further widening the road and thus eliminating traffic jams.

Gilberti's formal solution was approved as fully satisfying the requirements of aesthetics, form and spatial rationality expressed by the city administration and the clients. By maintaining the alignment of the existing façades, the uniformity of the row of buildings was retained, while at the same time widening the road and adapting it to form part of the new road system.

This practice was adopted in other projects (Casa Caracristi, the covered market and Casa Suster, constructed in various periods) in various districts in the city centre. Gilberti adopted the principle of minimal demolition and worked predominantly at architectural level, defining buildings with the maximum possible volume, without being spatially invasive as they set out to retain the existing as far as possible. To best satisfy the clients' requirements, in his plans, functions and forms, Ettore Gilberti adopted the language then in vogue, although to reduce construction costs, he used new materials and innovative building techniques.

Fig. 3: Selective demolition in the historic city centre - modernisation of Casa Pergher

Ettore Gilberti completed the expansion schemes drawn up by engineer Gerosa, proposing modifications determined by assumption of the detailed plan for a large part of the projects. He also developed new and innovative plans completely independently. Working in synergy with politicians, above all Podestà Malfatti, he used the urban planning tools to try and obtain funding to construct infrastructure and public buildings.

The mayor and the engineer set out first and foremost to increase the council's land holdings, but they were aware that the practice of expropriation (now consolidated in Italy for public utility and included in Milan's urban planning scheme by Cesare Beruto in 1884) to open up roads and squares was not simple to apply. Above all, they did not fund the construction of public works. In Rovereto, they tried to proceed on the basis of the development scheme drawn up by the city council with acquisition of agricultural land which, after changing the designated use, was sold to private individuals who were required to develop it within a certain period. If they did not, the land was re-acquired by the municipality. Development was subordinated to the preparation of what we now call urban planning schemes. In some cases, such as for example the middle-class residential area of Via Dante, the expansion scheme drawn up by engineer Gerosa was "enhanced" by a modern-style compensatory action. To finance creation of a park, Gilberti in fact entered into a public-private partnership in which the city administration granted an increase in the volume of an existing building (the design for the extension was drawn up by Ettore Gilberti) in return for acquiring free of charge a large plot of land which was later divided up into residential lots (Gilberti himself tried to buy a lot). The council-owned parcels to be sold were indicated on the city maps.

In the plan for Via Dante, Ettore Gilberti was responsible for designing a school, a number of single-family houses (Villa Tacchi and Casa Tomasi) and a multi-family house (Casa Feller) which immediately became the headquarters of the military command. The city engineer also took on design of a number of residential buildings for workers' housing (Casa Fedrigotti), adopted as an example by Italian and Austrian designers.

The establishment of numerous industrial activities in the city of Rovereto led to the identification and allocation of numerous areas for the construction of workers' housing by the city council, public utility associations and institutes and consortiums formed by workers and businessmen. Taking advantage of a number of legal provisions (Law no. 37 of 9 February 1892 concerning points for new buildings for workers' housing, Law no. 21 of 31 July 1892, Law no. 144 of 8 July 1902) defining minimum size parameters, providing for substantial tax benefits and making state grants available, in the space of a few years numerous residential blocks of workers' housing were constructed in Rovereto. In Rovereto the municipality in fact used these laws to erect buildings which immediately after construction and with minimum adaptation were used as barracks, thus respecting the requirements of the Vienna War Ministry which obliged local authorities to build troop quarters. For these municipalities, this obligation considerably impoverished their modest coffers, not least because the rents of the military structures were established by central government with Law no. 93 of 11 June 1879 and Law no. 100 of 25 June 1895.

Fig. 4: Urban equalization: increase of the volume available to build public works.

Ettore Gilberti's concreteness and dynamism can be seen from the lot division scheme for the first residential neighbourhood, conceived with a typically middle-class mentality, which wholly re-proposed the Via dei Colli development in Florence, designed by architect Giuseppe Poggi. After close analysis, Ettore Gilberti decided to locate the district on the hill of Rovereto which enjoyed maximum exposure

to the sun. The development was conceived not just as a residential area, but also as an urban park with a sinuous road destined to become a promenade for the middle classes.

Following acquisition of the Antonini agricultural premises by the city council, Ettore Gilberti drew up a plan tracing out a winding route starting from the 19th century square, then becoming a sort of walk in nature. It also provided a more direct connection with Noriglio, until then accessible only by crossing Rovereto, and also a direct connection with the pellagra hospital built in 1898. The engineer designed the main infrastructure, then the mains water supply, drains and sewers and the public and private electricity network. When the parcels of land were sold, a number of lots were bought by city councillors (Red, Pinalli etc., and by Gilberti himself). The purchase deed included a clause committing the city administration to undertake design of the building. This was signed by both the buyers of the land and the municipality and specified the dimensions, form and technologies of the building. The contract also established the duration of the construction work, with penalty clauses for delays in consigning the building.

The city engineering department, or rather the head engineer, was responsible for drawing up the architectural design and an extremely detailed quotation, which became the construction costs, including the technical expenditure and profit made by the municipality⁹. The buildings had to be constructed according to the regulations laid down for municipal buildings and on the basis of a detailed metric estimate, correlated with an analysis of prices and contract specifications.

The private individual, after signing the convention, deposited the established sum in a savings bank. Through a call for tender (with discount bidding), the municipality awarded the contract and the building work began. Subsequently, the city administration drew the sums required for construction freely from the amount deposited (direct payment for materials and labour). If the building was consigned within the time limit established in the contract and in accordance with the design drawings, the private individual was obliged to accept it, renouncing the right to raise objections as to the quality of the materials or execution of the work, acknowledging the municipal supervision as sufficient to safeguard his interests and guarantee the compliance of the private parties involved.

Fig. 5: Land division plan for the construction of the middle-class residential district of Via dei Colli.

The plan and buildings themselves were fully coherent with the taste and expectations of Rovereto's middle classes and from then on, despite the city council's denial, Ettore Gilberti began taking on a number of design projects, many in his native city.

Another important urban planning operation promoted by Ettore Gilberti and backed by podesta Malfatti was the appointment, in 1907, of the brothers Karl¹⁰, Julius¹¹ and Rudolf Mayreder to draw up the city's urban planning scheme. The brothers had previously been responsible for the urban planning schemes of Vienna (1892-1893) and Baden (1904). Together with his brothers, the academic Karl was attracted by the theories of Camillo Sitte (1843-1903), to the point where the Mayreder brothers adopted Sitte's theories in their design work.

Unlike many other city engineers, Ettore Gilberti felt the need for a "systematic" urban planning tool which defined long-term urban growth for the entire municipal area.

The plan proposed the straightening and (where possible) widening of streets in the historic city centre to adapt them for mechanical means of transport, and then the partial or total demolition of a number

of buildings, followed by redevelopment with modern buildings. As in Gerola's plan, the expansion zone was located to the north west of the existing urban nucleus, as was the primary road network, while the system of secondary roads was denser, defining the housing blocks which, as well as having a smaller surface area than in the previous plan, were also of a regular shape and more or less constant surface area. The plan was not approved, but it became the basis for subsequent interventions promoted by Ettore Gilberti.

While confirming the importance of the east-west connections, this plan suggested defining new north-south axes as the existing and/or planned roads were fragmentary and discontinuous.

The meeting with the Mayreder brothers was important not just for definition of future development in the city of Rovereto. It also enabled Ettore Gilberti to learn about the urban planning theories which were gaining ground in Austria and northern Europe and the new architectural languages which were spreading in the eclectic Vienna.

2. Conclusions

All this demonstrates that the 19th century growth of Rovereto was extensively planned. The urban planning hypotheses guided subsequent phases of development as the general planning scheme drawn up in 1908 by the Mayreder brothers was never approved at political level. It also shows that the urban expansion was the result of a strategic plan with major effects on the economy. The growth of a city cannot therefore take place without programming of any sort, in the absence of any form of development plan and without coherent and well-thought-out planning of public works.

Today as last century, urban planning schemes can, and maybe must, be the starting point for planning both the old and new parts of the city. The proposals in the plan must be evaluated with respect to real feasible projects, evaluating their feasibility in the smallest detail, including with respect to the economic commitment required. We therefore need to go back to the urban planning scheme combined with the architectural plan, hypothesising a rational and well-considered consequentiality based on the actual needs.

Planning should not create long-term expectations. It should rather ensure that building work can begin immediately. Correct timing can also lead to the rapid implementation of measures to contrast the economic crisis - now as in the past.

Today as yesterday, it is therefore necessary to promote integrated inter-sectoral visions of urban policies, enabling best use to be made of the endogenous dynamics generated by local resources, giving priority to the dimensions of sustainable development not exclusively linked to economic growth objectives, but rather to growth models based on a better quality of life and local well-being.

Planning must consider the transformation right from the start, successfully minimising future expectations.

It is also clear that it makes no sense to manage the city through the indices and parameters of urban zoning. Today as in the past, the most appropriate solution seems to involve removing management of the consolidated city from the urban planning discipline and giving it general strategies and more construction-type rules, aimed at the quality of the interventions and completion of a precise urban form, rather than the abstract quantity of buildings which can potentially be constructed.

We note ever more often the need for change to transform and improve our cities, but we continue to think separately - urban planning on one hand, architecture on the other.

Perhaps the time has now come to think of reintegrating the figure of the architect with the planning complexity of the city as urban planner, designer and composer.

The figure of Ettore Gilberti represents an amalgam of the two figures. He was a good urban planner, working with both the old and new, and also a good architect.

In architecture, Ettore Gilberti in fact managed to interpret the tastes and inclinations of the middle-classes, creating spaces and buildings for their use and on their scale.

At architectural level, he was responsible for a great number of designs for public and private buildings, adopting a range of languages, but always paying enormous attention to the functional and distributional characteristics.

Although he never achieved an autonomous architectural expressiveness, in his buildings he made confident use of pilasters, string courses, projecting window reveals, portals with imposing columns and broken-apex pediments and neo-renaissance loggias, designing buildings which are in many ways monumental, animated by well calibrated divisions with pictorial effect, although in most cases only superficial.

He made fluent use of neoclassical, eclectic and liberty styles. Buildings which were appreciated in their time and which have continued to function, demonstrating their functional and above all technological validity.

⁵ The announcement was published in the *Giornale degli Affari*, an insert with the Milan edition of the *Corriere della Sera*, in February 1904.

⁶ Ettore Gilberti (Udine, 1876-1935) studied first at Padua, then at Milan where he graduated in 1904. While still studying, he had already undertaken a number of design projects.

⁷ As explained in a letter sent by Gilberti to one of his high school professors, he began studying German during his military service. In fact, his knowledge of the language was elementary and the archives contain no letters written by him in German.

⁸ Sebastiano Giuseppe Locati (Milan, 1861 - Milan, 1939) studied at the Brera Academy under Professors C. Boito and C. Formenti, graduating from the higher course in architecture in 1881. In 1894 he graduated in civil architecture at Milan Polytechnic. From 1899 and 1935, he was professor of decoration and architecture, architectural composition and practical architecture at the University of Pavia.

⁹ For example, the Villa Red cost 39,785.24 crowns to build and was sold at 41,350.75 crowns, with a profit of 1,565 crowns.

¹⁰ Karl Mayreder (1856-1935) first studied at Vienna Polytechnic's School of Building (1872-1877), where he was first pupil of Heinrich von Ferstel, then assistant to Carl König. He began his academic career teaching at the Technical University, becoming full professor of urban planning in 1899. Between 1923 and 1925 he was also rector. As a freelance professional, he founded a studio with his brothers Julius and Rudolf Mayreder, taking on both urban planning and architectural projects. Between 1894 and 1902, Mayreder was appointed as city planner and drew up the urban planning scheme for Vienna.

¹¹ Julius Mayreder (1860- 1911) studied first at Vienna Polytechnic's School of Building (1872-1877), then at the School of Arts and Crafts and finally at the Fine Arts Academy where he studied under Friedrich von Schmidt. He practised first in the studio of architect Victor Luntz at Vienna, the studio of professor Nordio in Trieste and then in the studio of architect Adolf Lang in Budapest. He later worked in the studio together with his brothers, often working completely independently.

A SPECIAL LAW FOR SANA'A

The old city of Sana'a (Yemen): Proposal for a special fund for its conservation

Arch. Nabil Al-Makaleh, Arch. Abdulhakim AL-SAYAGHI

Social Fund for Development - Yemen

Arch. Renzo RAVAGNAN, Dott. Massimo Khairallah

Centro Italo-Yemenita per la Conservazione dei Beni Culturali

rravagnan@hotmail.com

Abstract

Yemen has been facing a continuous political and economic crisis since 2011, and though the efforts UNESCO and other international bodies have made in the last 30 years, the state of conservation of Şan'ā' is still a major issue today. The situation has worsened to the point that Şan'ā' is at risk to be soon included into the UNESCO *List of World Heritage in Danger*, while the Old City of Şan'ā' was registered in 1986 as a worldwide recognition for the importance of its old centre. As a matter of fact, Sana'a counts more than 8,000 historical buildings, and is one of the most authentic and meaningful examples of urban development in Southern Arabia.

A practical effort to face the situation can be the creation of a special law for its heritage management and conservation, taking example from the Special Law created for Venice in 1973, its special fund and dedicated team of experts.

The paper presents the perspectives of a similar approach in Şan'ā' and discusses the possible outcomes of the creation of an independent body for the technical and financial management, control and operational dimension of the interventions. This organization will operate with a team that could plan and implement projects in a short time, to ensure the quality of operations and their compliance with current legislation and regulations, including financial transparency through public and verifiable budgets and auditing reports. It will take advantage by the added value of a skilled local team that can carry out the restoration and preservation according to traditional materials and building techniques.

Keywords: heritage management, Yemen, traditional materials and techniques, architecture.

1. Introduction:

Recognized worldwide for its importance as one of the most authentic and meaningful examples of urban development in Southern Arabia, the historic centre of Şan'ā' was listed in the UNESCO World Heritage Sites in 1986. The traditional structure of the city is characterized by urban and architectural elements that have succeeded in preserving their essence over centuries.

Today, however, the city is more than ever at risk, because its uniqueness, favoured by some geographical and cultural isolation, is threatened by neglect, uncontrolled modernization, improper interventions, lack of a comprehensive vision, lack of technical and urban management experience, and poverty. In addition, the 2011 political upheavals shifted the attention of the authorities towards the political instability and the related security problems, thus reducing the already limited resources

available for the conservation of its heritage. As in the city of Zabid, also Ṣan‘ā’ could soon fear an exclusion from the UNESCO list of World Heritage Sites.

The present document seeks to indicate a possible operating model for the preservation of Yemeni cultural heritage, which could allow the gradual recovery of the urban fabric, also thanks to the creation of a body with competence to oversee the development of the program. This model has been identified in the 1973 Special Law for Venice.

Fig. 1: View of Ṣan‘ā’. Pier Paolo Pasolini wrote about this city: «Yemen, architecturally, is the most beautiful country in the world. Sana'a, its capital, is a wild Venice on dust without Saint Mark's and without the Giudecca, a city-form, whose beauty lies not in its perishable monuments, but in its incomparable design... it is one of my dreams»

2. Urban heritage conservation approaches

The concept that the urban heritage to be preserved cannot be identified with individual buildings or monuments, but, on the contrary, that single buildings and monuments are more significant because they are placed in a specific context is well recognized in the culture of restoration. This principle can be well applied to the city of Ṣan‘ā’, whose charm is given by the complexity of its houses.

The negative example of some Italian historical centres, abandoned by their inhabitants not only because of reckless town plans that have favored the spread of bad neighborhoods, but also because of objective problems of mobility and absence of some facilities now necessary, leads us to believe that we should find some practical solutions on a case-by-case basis. If we want the life in Ṣan‘ā’ to continue to pulsate, we need a clear and unified vision, a broad-spectrum planning, a capacity of capillary action, qualified staff and appropriate legislation to regulate the activities. All what is needed should be combined with respect for its beauty, history, constructive traditions, and spirit of the community. With respect to its morphology, its horizon, its scenery, its vision.

3. The historical evolution of Ṣan‘ā’

Yemen, with its 24 million inhabitants, is one of the most populous countries in the Arabian Peninsula, but it is also the youngest and poorest. For this reason, its literacy and school enrolment rates are quite low. Although only 30% of the population resides in urban settings, Ṣan‘ā’ has suffered a strong and rapid process of urbanization and modernization in recent decades. Ṣan‘ā’ is located in a mountain basin at an altitude of 2300 meters, in a semi-arid and mountainous region. It is the political and administrative capital and the most important cultural centre of the country. Its origins date back at least to the 2nd century AD, when the Sabaean King Sha‘ir Awtar surrounded the existing Ghumdan fortress with walls, making it a "fortified city", as its name indicates. However, the oldest documents give us very little information about the events that led it to become the capital of the Himyarite Kingdom. From the 7th century, the conversion to Islam of the population was very rapid, so much so that, according to what is handed down, in the 6th year of the Hegira (628 approx.) the Prophet Mohamed himself ordered the construction of the Great Mosque (Jami’ al- Kabyr) in the historic centre. Umayyad and Abbasid caliphs controlled Yemen through governors based in Ṣan‘ā’, until in the 10th century when a local dynasty was constituted, the Zaidi imams, who ruled a territory that was extended up to the region of the mountains.

At the centre of important caravan routes through which the trade of incense, myrrh, spices and products from the East took place, the city expanded and had periods of great prosperity. Later, it lost relevance from the 15th century with the first Ottoman rule, mostly due to the constant attacks suffered by both occupants and the Zaidi for its possession. The second Turkish conquest, in 1849, was severely hampered by the imams and when finally at the end of World War I the Ottomans were forced to leave the country, again two imams ruled the city, isolating it from external contacts, along with all North Yemen, thus condemning the culture and the economy to a state of stagnation and backwardness. The South, meanwhile, was occupied by the British, who left it only in 1967 when the People's Democratic Republic of Yemen was born, with Aden as capital. In the North, in 1962, a revolution ousted the last Imam of the al-Mutawakeliah Kingdom and established the Yemen Arab Republic, with Ṣan‘ā’ as a capital. In 1990, after years of conflict and tension, the reunification of the country was achieved.

Ṣan‘ā’ currently has about 2,000,000 inhabitants, compared to 427,500 people estimated in 1986. This frenetic increase in population - caused by massive internal migrations after the unification and by the return of more than a million people from Gulf States after the Gulf War in 1990 - has been accompanied by a dramatic increase of the urban area. The real estate boom, that the city lived up to 2011, put at serious risk the integrity of the historic centre and its delicate balance. The use of inadequate construction techniques and non-traditional materials such as reinforced concrete, combined with uncontrolled urbanization, has affected many buildings, but also destroyed some historic sights of the city.

4. The architectural heritage of Ṣan‘ā’

What makes the historic city of Ṣan‘ā’ special is its architecture: in its 8,000 houses, different styles and materials are mixed up with charming harmony. A typical building, tall until five, six, or seven floors, is constructed at the lower levels with basalt blocks, which support upper structures in brick. The oldest bricks are manufactured with local mud and dried in the sun. The exterior walls are decorated with elaborate friezes, white chalk plasters and stained glasses of alabaster. This typical tower-houses are interspersed with minarets and create a unique setting. The area of the ancient walled city shrines true architectural gems inside. Even the constructions from the medieval period, as well as the alleys and small squares, remain largely intact.

Another unique feature is the urban orchards and gardens, whose attractively vibrant green lightens the massive masonry buildings. Many of these were unfortunately destroyed to make way for new buildings.

Fig. 2: Detail of the decorations of the buildings. Photo Credits: Marteen de Wolf

There are 48 mosques, 11 public baths, and 10 specialized market areas (such as for clothes, grain, salt and spices, silver and gold, and cattle). There are still a good number of caravanserais. Only one of the eight main doorways of the city is intact: Bāb al-Yemen in the South. A medieval citadel overlooks the Eastern district, and on the Western side there is a big riverbed (Al Sāila), mainly dry during the year.

Nevertheless, the real uniqueness of Ṣan‘ā’ lies in its being an ancient city that is still densely populated and tries to integrate itself with modernity. This delicate step requires considerable effort as for maintenance and urban planning. All this must be held together with some contemporary effort to keep the city alive.

5. The international actions

The interest of the scientific community was triggered by the particular architecture of its buildings and by the city morphology, but also by its unique construction techniques.

Although steps taken so far for the conservation of very old buildings that are significant to the Islamic culture have been a lot, they have not always proved to be effective. Some first interventions date back to the 1970s, following Pier Paolo Pasolini’s concerned call for the salvation of the city from rapid urbanization, which urged uncontrolled after the fall of the Imams’ kingdom.

The international campaign for the preservation of the historic City of Ṣan‘ā’ resulted in its inclusion in the list of World Heritage Sites in 1986, and led to significant works for the preservation of its historic centre, such as the paving of most of the historic city.

Unfortunately, other maintenance and urban renewal activities, such as the creation of the domestic water system in the buildings of the old city, were not made with the same care. Consequently, the newly realized sewer and water systems of the city are jeopardizing the stability of the city because of infiltrations and moisture. Moreover, works of modernization have often seen the use of inadequate materials and modern buildings are not always in harmony with the context.

Also for this reason, as is clear from several studies conducted over the years by researchers and as shown by the inventory made by UNESCO, the problem is organic and general. The planning of the single interventions must be integrated into the planning of the city and the work needs to be

constant and attentive, but above all it must be realized in the city as a whole and not just in a few isolated buildings.

In 2008, when the effects of the political and humanitarian crisis were not so acute as they are today, UNESCO, in collaboration with the governmental authorities, presented a very detailed report on the status of the principal risks and damage that has been created to the ancient core. Those data were collected thanks to a project for the inventory of the heritage, which led to the creation of some GIS mapping (Geographic Information System) and contributed to the training of Yemeni young architects and students in architecture.

Many years of efforts by UNESCO and the Aga Khan Foundation of Architecture have failed to produce a firm commitment for protection by the side of the national authorities. However, it must be considered that a capillary action in the historic centre requires a considerable financial burden and management, with which Yemen cannot cope without the help of international organizations. The city has benefited from a number of monumental restoration works, funded by foreign archaeological institutes and other bodies, but these are isolated cases, while it is essential, before it is too late, to implement the plans that have already been identified in the past by UNESCO and GOPHCY (Organization for the Protection of historic cities in Yemen).

6. The Yemeni conservation law for the preservation of historic cities, areas and monuments

A step long advocated by all the conservation actors in Yemen has recently been taken in August, 2013, when a law was passed regulating the conservation of cities, areas and sites of historical interest in Yemen (No. 16/2013). Among its objectives, this proposes to "give effect to the commitments laid down in the conventions and treaties signed by the Republic of Yemen on the subject, including the Convention for the Protection of the World Cultural and Natural Heritage (UNESCO)" (Chapter 1, Art. 3). Besides, it establishes penalties for lawbreakers and for those who contribute to the degradation of the sites of interest. In addition, it arranges the creation of "agreements with international organizations for the protection, conservation and preservation of historic cities and sites of interest in Yemen" (Chapter 2, Art. 6).

Until now, the absence of a legislative framework had made it impossible to perform activities and to implement recommendations and plans in collaboration with international organizations such as the Italian Cooperation or UNESCO. Its existence, today, allows us to open the challenge for their implementation concretely and with new vigour.

Fig. 3: View of the transformations taking place in the Old City of Şan‘ā’. Source: UNESCO - World Heritage Centre / Arab States Unit. 2008

7. The “adapted” restoration

In order to be included in the guidelines developed by UNESCO in the field of conservation, providing a holistic view of the city and making it possible from the financial point of view, a conservation action has been hypothesized. It will work in view of the “adapted” restoration mentioned by Jaques Feiner in his 1997 work. This scholar has developed an analysis of the architectural styles and types of buildings in Şan‘ā’, where he also advanced proposals for the conservation of the city, which combine the conservation of the heritage with the right to use public and private spaces, typical of every city, in accordance with its traditions.

He proposed to intervene on buildings throughout restoration works that, though keeping their traditional character, would make them habitable with comfort, and to promote ancient knowledge by involving local workforce specialized in the use of traditional materials and techniques.

In this way, it would be possible to proceed, simultaneously with the restoration of buildings that are abandoned or in ruin, with the revitalization of the urban fabric in the historic centre, with a boost to employment and with generation of income. Not only: if it is true that, as pointed out by Bonnenfant, the use and maintenance of local materials are more expensive than today’s ones such as cement, by contrast, ancient building systems are the only ones capable of ensuring the functionality of the structures without compromising their stability, being conceived and developed for the climate and geological conditions of the region. They are the only ones capable of conserving its humanity, force, vital energy, identity, in addition to beauty, without excluding that the generalization of their use could help make costs more affordable.

SWOT ANALYSIS (Strategic Planning)

Strenght	Weakness
<ul style="list-style-type: none"> - Unique urban architectural context - UNESCO World Heritage Site since 1986 - Creation of a body responsible for the protection of the World Heritage - Recent creation of a legislative framework - Definition of Conservation & Development Plan for the city - Sites mapping elaborated by international bodies 	<ul style="list-style-type: none"> - Lack of maintenance of the buildings - Execution of works that are undermining the stability of buildings - Prevalence of work executed with non-suitable materials - Low level of local awareness - Rapid disappearance of local knowledge - Lack of education of the staff responsible for the protection of historical heritage - Difficulty in prosecuting abuses committed
Opportunities	Risks
<ul style="list-style-type: none"> - Unique city where old and new can still be integrated - Support by international institutions and private organizations concerned with the conservation of Şan‘ā’ - Presence of local and traditional maintenance and conservation techniques - Existence in the city of still expert workforce 	<ul style="list-style-type: none"> - Rapid uncontrolled urbanization - Boost to modernization - Economic crisis and political instability - Complex bureaucracy - Low effectiveness of previous interventions

Fig. 4: Chart on the swot analysis. Source: IVBC.

The extraordinary nature of this urban environment has long been recognized at international level, but it does not enjoy the same wide recognition yet by the side of the local community. The objective difficulties in which the country has fallen since 2011 with the political crisis have made it difficult to intervene, and in some cases they have even compromised the *status* of its heritage. However, there are some presuppositions for the realization of effective conservation actions, given the now historic presence in the country of international organizations (UNESCO, foundations, scholars, private institutions), who over the years have contributed to advance new researches, to increase the information, and to grow the awareness on the part of the authorities.

8. The "special law" model for the creation of an independent operating body

In view of what has been illustrated so far, a situation of urgency has emerged, in which the risks of the conservation of the historical, artistic, cultural, urban and architectural heritage of Ṣan'ā' are extremely high.

As anticipated, the intervention model judged adequate and exportable is the same as the one already tested in Italy with the Special Law for Venice n. 171, in 1973. This law was the result of the great fear caused by the 1966 catastrophe, when an extraordinary high water flooded the entire city of Venice. The event, of extraordinary proportion, but not isolated, activated a very in-depth reflection on the need to intervene on Venice and the lagoon area, in order to avert the danger of the disappearance of its inhabited centres within less than a century. The newness, as well as the key aspect that for us seems interesting to borrow from that law, was the combination of a new specific regulatory framework with the provision of dedicated funds and the creation of a specific body responsible for their management.

Along the lines of what happened at that time in Italy, here we propose the creation of a unitary body that could be designated for the implementation of specific actions on the old buildings of the historic centre, according to a plan agreed with all concerned bodies and in full compliance with the guidelines in the field issued by the Yemeni authorities over the years and by UNESCO.

The need to establish a body independent from GOPHCY and the city government comes from the urgency to intervene operationally in short terms, and from the necessity to access to international funds directly.

Therefore, it is necessary to create an international competent and working team that is independent from other local authorities and institutions, while operating in synergy with them. Such a team should include specialized operators both for the planning and for the conservation and restoration systems of the buildings, beside skilled labor force that can carry out activities according to tradition.

The use of local staff and the respect of traditional building techniques will improve the economic situation by creating job roles, while the access to international funds, facilitated by this procedure, will allow them to intervene in short time even when the public or private funding would not be sufficient.

9. The intervention plan

9.1 Creation of the International Committee for preservation of Ṣan'ā'

The special initiative for the conservation of the historic centre of the city of Sana'a involves first the creation of an operating core, as described in the previous paragraph, known as the *International Committee for preservation of Ṣan'ā'*. The start-up of this team including technicians and local or international experts corresponds to the first phase of the intervention.

9.2 Building Capacity

In order to broaden the Yemeni participation and to create new skilled professionals, a period of training of the local staff will be essential, through training courses for young graduates in engineering and architecture, or possibly upgrade courses for some GOPHCY experts.

9.3 Functions

The tasks of the Committee can be summarized as follows:

- updating of the mapping of the deterioration of the buildings;
- identification of conservation priorities;
- definition of the general and particular criteria of re-qualification and conservation works;
- planning and evaluation of any proposed projects;
- collection, management and disbursements of national and international funds;
- preparation of tender notices for the provision of funds for restoration;
- evaluation and acceptance of requests for intervention by the side of owners;
- monitoring of the compliance with the established rules during and after the interventions, even for the granting of money;
- evaluation of the guarantees offered by the companies that will operate on individual buildings.

The Committee would have the functions of planning and supervising the restoration work on the identified buildings. In addition, they would play control functions on the successful completion of the projects, by proceeding with the report of any abuse or violations. This body would have financial control, acting as a guarantor for the proper use of financial resources, thanks to flexible management free from the most expensive bureaucracy. It would ensure the full compliance of the activities with the UNESCO and GOPHCY guidelines.

9.4 The first group of interventions

The action plan has the great advantage of being able to make use of studies and mapping of the buildings of the historic centre already carried out by different agencies operating in the city. After updating the survey on the state of conservation of the buildings, they will proceed to the selection of about 70 buildings, according to criteria of urgency, of advance of the state of degradation, or of relevance and interest of the building. The first funds could then be used to test the efficiency of the working group and to measure the interventions.

9.5 Impact on the social fabric

The program will generate a virtuous mechanism of protection, able to safeguard the city, to send a sign of activity recovery and, at the same time, to create a team of technicians and skilled labourers, reliable and recognized by the institutions for conservation and restoration. The works will require the intervention of small teams of artisans or of individual workers. In this way, the value of the intangible heritage, that is, the culture and knowledge of the Yemeni builders, who are the last custodians of a millenary tradition at risk of extinction, would see its significance recognized. As indicated in all guidelines, the restoration and enhancement of traditional knowledge are part of the activities that permit to respect the authenticity of a site. This is because the heritage is more than ever linked to the life and evolution of the city. These results meet the main objectives of the Convention for the Safeguarding of the Intangible Cultural Heritage that intends to protect the cultural elements and expressions, and to promote (at local, national and international levels) awareness of their value as vital components of the life of a population.

9.6 Collection of funds

Alongside with the establishment of the Committee, the collection of funds will be started, illustrating in detail the promoted activity. Possible funders may be:

- Arab Fund
- Social Fund for Development - Yemen
- Italian Cooperation
- UNESCO
- American Friends of Yemen
- Gulf Cooperation Council (GCC)

9.7 Subjects of funding

Funds may be directed to:

- acquisition, and conservative restoration of properties to be devoted to residence, or to social, cultural, productive, commercial and craft activities, which are essential for the maintenance of the socio-economic characteristics of the settlement;
- construction of primary infrastructure works;
- provision of resources for the execution of restoration and preservation works of private real estates.

9.8 Initial budget

We are confident of being able to start the program with initial funding of 5 million euro, considering that each building renovation is planned to cost at least € 50,000.

20% of the amount will be initially absorbed by the creation of the operational structure, including training courses. As regards the headquarters and logistics they will be able to use, at least in part, public structures. A certain portion should also be addressed to the awareness and diffusion campaign of the project at the population.

9.9 Conclusions

The historical and cultural heritage of Şan'ā' is now in serious danger. The urgent need to protect this World Heritage Site recognized by UNESCO is not only limited to preserve the value of individual buildings. Today more than ever, there is a need to preserve the complexity and the vitality of a thousand-year-old city. In other words, we must act quickly, so that Şan'ā' can maintain its authenticity.

It is impossible to leave the burden and responsibility of the Yemeni heritage only in the hands of government and community bodies. The international community has the duty to support them in the fulfilment of the responsibilities that they have already decided to assume: as a matter of fact, at

present, they are not able to realize plans of similar scope and delicacy because of financial and management difficulties.

The creation of an independent body will allow: planning and implementing projects within a short time; ensuring the quality of the operations and their compliance with the current legislation, regulations and detailed plans that will be processed contextually; guaranteeing financial transparency through public and verifiable balance sheets and financial reports.

It is an urgent and necessary action, which will have the benefit to generate a small local economic system, as a "secondary" effect. In addition, all this will enhance knowledge, providing a recovery opportunity for an urban fabric that is weakened by poverty and unemployment.

The case of the XVII century “Teatro Farnese” in Parma: integrated conservation, between conservation and valorization.

Federica BORGHI, Federica OTTONI

Department of Civil Engineering and Architecture, University of Parma, Parma, Italy.

federicaborghi.re@libero.it

federica.ottoni@unipr.it

Abstract

The project of reutilization and valorization of the ancient Farnese Theatre in Parma represents an excellent case study in order to apply the principles of the “integrated conservation process” defined by R. Di Stefano in 80's. Thus, the first guarantee for conservation of historical heritage is not only in finding and applying the most suitable techniques of structural and formal restoration, but, most of all, in identifying the most appropriate use of it.

Actually, the great wooden Farnese theatre, built in the XVII century by Farnese family in the magnificent Palace of Pilotta, in the historic centre of Parma, and severely damaged over the centuries, had hosted performances only nine times since its construction and now it remains “museum of itself”, constituting the scenographic, and unique in the world, entrance to the National Gallery.

This paper aims at presenting the study carried out on this masterpiece in order to revitalize it. Starting from an historical and structural analysis of this monument and recalling the interesting and cultural debate on its possible “reuse” as theatre, the project of reutilization herein proposed has dealt with structural, functional and safety issues, together with the theoretical ones of restoration.

At the end of a path in balance between structural and functional improvement and preservation of built heritage, the monument can increase its cultural and economical value, gaining a new life.

Keywords: cultural valorization, restoration, wooden structures, XVII century theatres, integrated conservation

1. Introduction

The Farnese Theatre, one of the greatest seventeenth century theatre in Europe, is located into the magnificent Palace of Pilotta, in the heart of the historic centre of Parma, in northern Italy.

It was built for want of the duke Ranuccio I Farnese and it hosted only nine performances between 1628, when it was inaugurated, and 1732^[5].

It was opened again in 1913, when the city celebrated the centenary of Giuseppe Verdi, but in 1944 an air raid destroyed it.

Between 1957 and 1965 the theatre was rebuilt, implementing an historic restoration, and from 1986 it constitutes the scenographic entrance to the National Gallery.

Soon after its rehabilitation, the debate on the renaissance of the theatre as a place for performances started and it's still open.

The paper aims to show how, with a few technical and functional solutions, directed to optimize the use of the theatre, its cultural and economic value can be enhanced, so this monument, unique in the world, can be brought to a new life.

2. The object of the study

2.1 The structure of theatre

The majestic Palace of Pilotta is formed by many great masonry buildings erected around three courtyards. Thanks to its dimensions, beyond measure compared to the historic urban context, it dominates the city centre. The early structure was built at the beginning of the XVII century in order to become the new residence of the Farnese's entourage^[5]. The construction site lasted for three centuries, but the enormous building is still uncompleted. The theatre was projected by the architect and scenographer Giovanni Battista Aleotti between 1617 and 1618, taking the place of the pre-existing chamber of weapons^[5]. The volume of the room is enormous: it is 87,22 m long, 32,16 m large and 22,16 m tall. The fourteen bleachers shape a "U" sector for the audience, crowned by two loggias: the first one is in Doric order, and the upper one is in Ionic order.

The wooden structure existing today is the exact copy of the original one, which was destroyed by the bombing occurred in 1944. The historic restoration was realized reproducing the metric surveys, with the support of ancient photos and reassembling the few fragments saved. All the load-bearing structures and the bleachers themselves, the loggias and the wooden decorations were rebuilt, following the original project. The floor and the stage was also rebuilt maintaining the original declivity and the structural damages of the walls were restored^[2]. All the wooden surfaces were processed with fireproof paints, therefore the colour of the wood became light ocher^[2]. Originally, these surfaces were almost entirely painted. To distinguish the few original elements from the new ones, the latter were left unrefined. Finally, the roof was repaired. To cover the 32 metres span, the architect G. B. Aleotti had realized a composed truss, made by reticular beams which elements were connected one another by joints; the whole structure was stiffened by ties. The new parts of the roof reproduced the original one, but many metal ligatures were added all over the trusses in order to reinforce them. Originally, the structure of the roof wasn't visible because a canvas representing "Jupiter and the Olympus" hid it^[2]. Therefore, the present look of the theatre reproduces the original one, but the aesthetical aspect is heavily different: most of the decorations and the paintings are lost and the decors are missed.

Fig. 1: The Farnese Theatre before the bombing occurred in 1944.

Fig. 2: The Farnese Theatre after the restoration realized in 1957-65.

2.2 The use of the theatre today

After the restoration of the structures, many proposals were moved for the use of this fascinating place.

Till now, occasionally the theatre hosted theatrical and musical performances, and also a few art exhibitions.

Nowadays, the theatre is a museum of itself. The entrance is set up by a Corinthian wooden portal, miraculously surviving the bombing. Reaching the parterre, a gorgeous view appears: the wooden bleachers constituting the cavea, crowned by the two orders of the “serliana” loggias; the proscenim characterized by the giant order; the triumphal arches at the two sides of the stage with the equestrian sculptures on their top; the beautiful wooden trusses supporting the roof. Unfortunately, the access to the bleachers and to the loggias is presently forbidden because of safety reasons.

Under the bleachers, along the north-west side wall of the theatre, some remains of the many sculptures are exhibited. Behind the stage and partially under it, part of the itinerary of the National Gallery takes place. A gangway connects the parterre to the stage; from it a footbridge, installed in 1979 in the occasion of an important exhibit and since then become permanent, brings into the heart of the National Gallery. So the theatre, where the exhibit starts, and the gallery are parts of the same great museum.

Fig. 3: A view of the theatre today, shot from the stage.

3. The historic debate around the opening of the theatre

Soon after the bombing, when the opportunity to rebuild the theatre was verified, a lively debate on its renaissance started.

Some proposals were moved to adapt the theatre to the needs of the modern shows, or to convert it into a cinema^[2]. Thanks to the Office for Conservation of Monuments and to the Ministries of Education and Public Works, it was decided to realize a conservative restoration^[2]. In 1957 the restoration began: the lost elements were integrated, differentiating them from the original ones, and the evidences were replaced in their own location.

The restoration was completed in 1965 and, the later year, a great concert was organized to inaugurate the “new” theatre. The technical committee, appointed to verify the accessibility of the audience, approved the opening of the theatre only in case of exceptional events, like that one, and to let the public use only the orchestra in order to preserve the wooden structures. The vigilance committee demanded the opening of four fire exits, but this structural intervention was judged unacceptable for the preservation of the monument. So, the concert was cancelled a few days before the date. The cancellation of this great event caused a great polemic with a nationwide echo.^[2]

This was the dilemma: was the best solution to keep the theatre as a monument or to destine it to performances of extraordinary artistic and cultural appeal?

In 1967, the City Council unanimously decided to use the theatre for great events.

4. The project for the reopening of the theatre

In 2011 the Municipality of Parma achieved the authorisation from the Ministry of Culture to use the theatre to host an important concert, once the static safety of the structures and the flow of the people in case of emergency were guaranteed.

Therefore, the project here presented analyzes the load resistance of the structures and proposes a solution for the arrangement of the public, suitable, as possible for an historic building, to the current safety legislation.

4.1 The analysis of the static safety of the wooden structures

In order to verify the stability of the structures, first of all, the existing metric surveys were checked and completed with the measuring of the precise dimensions of every element which constitutes the wooden cavea. These data were essential not only to calculate the payload of the structures, but also to verify if the bleachers fit the rules to host the audience and to design a suitable arrangement of the seats. The cavea is formed by fourteen bleachers, spaced out by stairs and crowned by two loggias, only in part accessible and reachable from the two spiral staircase situated at the sides of the main entrance. All these elements are wooden made as the load-bearing structure, which is formed by reticular beams leaned against the perimetral walls of the theatre. The bleachers are made by fir-tree boards 3,5 cm thick, which shape seats 50 cm deep, stiffened and bound by wooden strips put far 70 cm one from another. Steps are 50 cm large and 24 cm tall and they are made by the same kind of boards which formed the seats.

The assessment of the load resistance was carried out on the stairs because in this area the weight of the structure is the greatest, as well as the load prescribed in the event of crowding. First of all, the features of the materials like the woody type and the degradation of the wood structures, were inspected, in order to define the parameters for the assessment work. Considering the moisture of the material and the surroundings, the reducing coefficients were identified. The distributed load was evaluated to be $q_k=4 \text{ KN/m}^2$ for theatres. Thanks to these data, the load-bearing capacity of the structures was checked through a finite elements numerical model. Also the connections of the structures, joined by bolts, were verified.

The results of all these evaluation showed that the load-bearing structures are safe, both the bleachers and the loggias: the safety index obtained is 1,8. Therefore, the structures are considered resistant and safe in anticipation of the reopening of the theatre to the public.

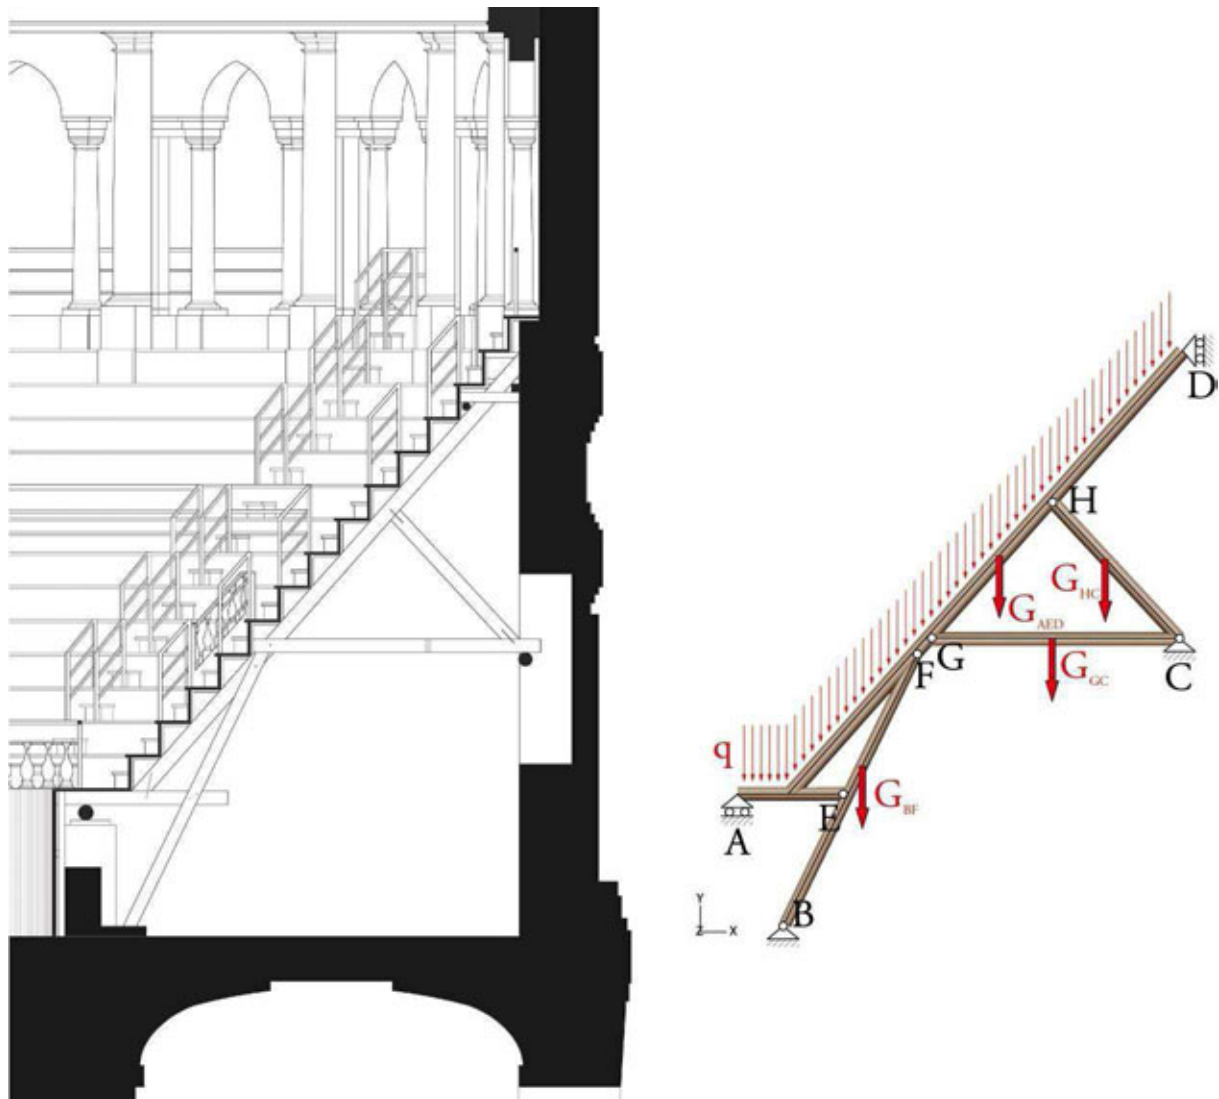

Fig. 4: The cross section of the bleachers realized to calculate the load-bearing capacity through a finite elements numerical model schematized on the right.

Fig. 5: A view of the load-bearing structures under the bleachers.

4.2 The issues concerning the opening of the theatre

Once the security was proved, a functional plan for the cavea was studied with a view to the reception of the audience, identifying the most suitable solutions both to preserve the monument and to guarantee the safety of the people, as the legislation requires.

In order to respect all these aims, the design proposal is to define the seats using removable cushions, so the wooden structures won't be damaged. Following the safety norms, disregarding them only where necessary, the seats will be divided into sectors delimited by parapets and separated by passages, both along horizontal and vertical axis. In this way, in case of emergency, people will be directed from each sector to the allocated exit and the structures will not be stressed too much. The bleachers will be vertically gathered into two sectors separated by a passage, large as one seat, to let the people flow. This passage is narrower than the legislation requires, in order to respect historic restrictions. For this reason, the maximum seating capacity will be halved, in order to guarantee the safety: only six of the fourteen bleachers will be used. This arrangement allows to furnish 571 seats. The insertion of a parapet at the top of the cavea is necessary for the safety and a second one will be placed in the middle of the bleachers in order to avoid the audience to fall down. Presently, the stairs which lead to the bleachers have no parapets. In order to preserve the wooden structure and to maintain its original appearance, all the parapets, projected with a minimalist design but with dimensions appropriate to the current safety legislation, will be placed only for the last of the performances.

In case of emergency, the stairs already existing will be used to the flow of the people, including the two spiral staircase at the sides of the main entrance, which lead to the first loggia. Into these staircases it will be necessary to install hand rails which can be permanent. The access to the stairs which lead to the small terraces over the triumphal arches will be forbidden, in order to preserve the few frescos surviving the bombing. To protect also the paintings between the columns, barriers will be placed over the upper loggia.

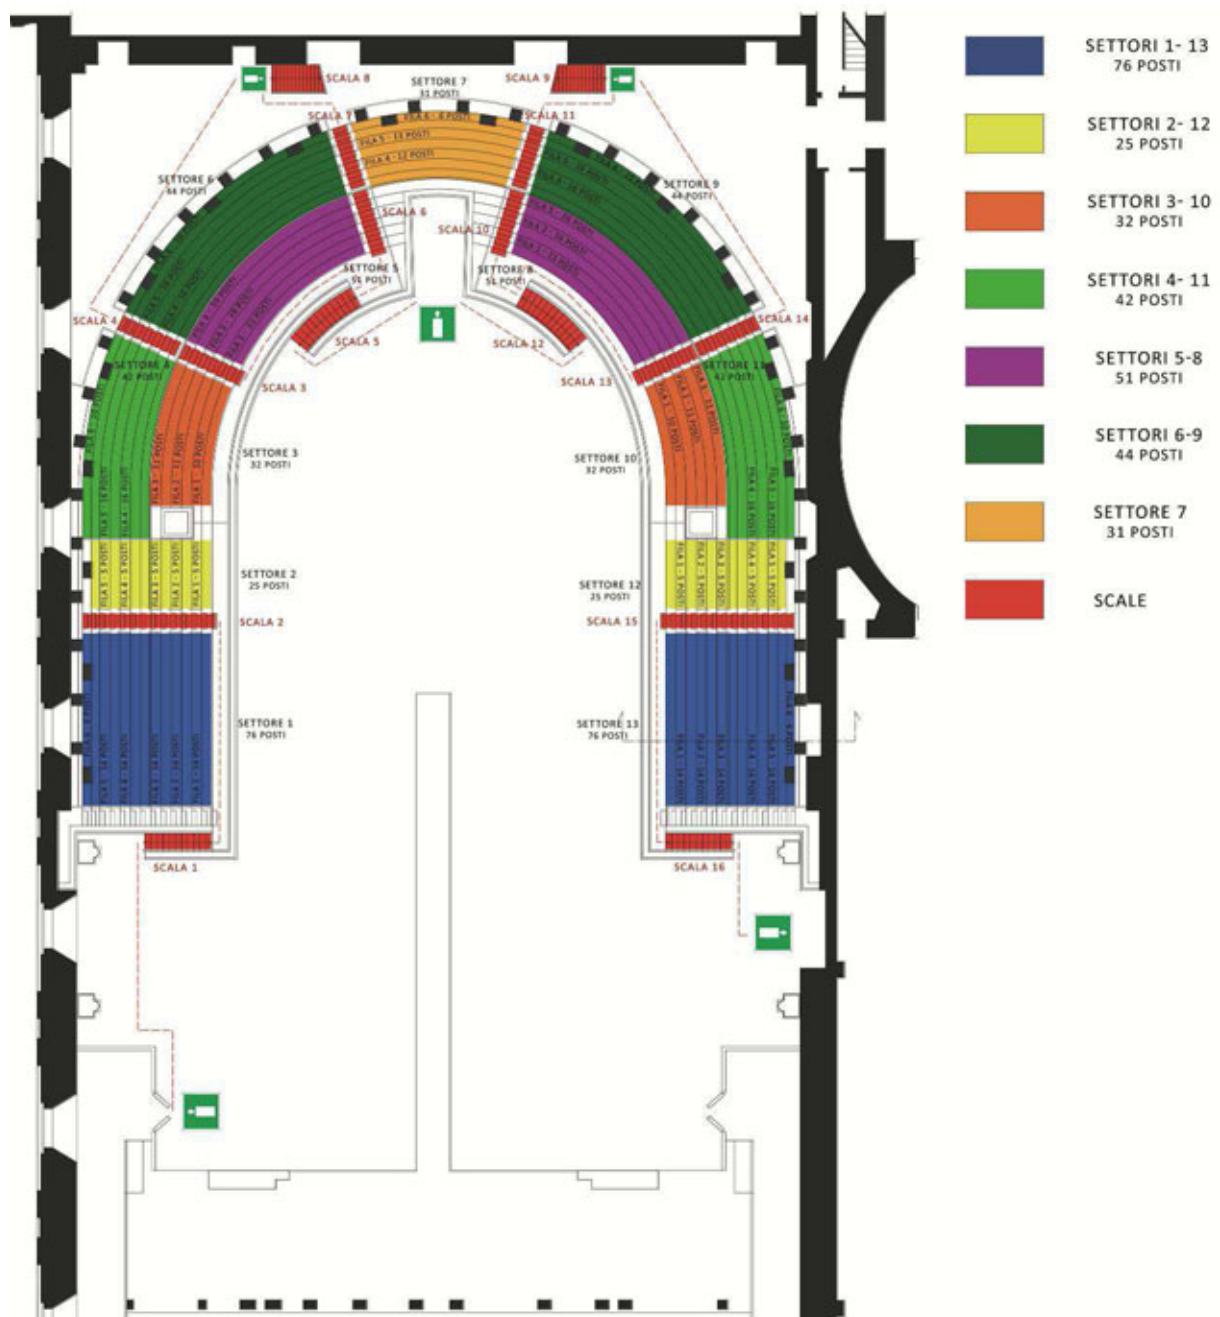

Fig. 6: The partition of the seats into sectors and the ways to the emergency exits.

5. Conclusions

One of the aims of restoration is to hand down the monuments in their best possible conditions^[1].

The structural consolidation and the preservation of the materials are necessary to the survival of the building, but sometimes it couldn't be enough: in order to optimize the intervention, it should be supported by the functional and economic valorization of the monument^[4]. Conferring the most suitable function to the building means to maintain it lively and often to increase its economic value: in this way the conservation is guaranteed. The "integrated conservation process", defined by R. Di Stefano in 80's, encourage this kind of restoration intervention, which integrates the material conservation with the cultural and economic valorization^[3].

The successful conservative restoration realized on the Farnese Theatre assured its structural and material conservation. Nevertheless, it risks to be wasted if the theatre is considered only as an archaeological evidence to be shown to the visitors. Bringing back the theatre to its original function, would allow to bring much more interest on it and to increase the visitors a lot. In this way, not only the life of the theatre, but also a great income, will be assured for long: these are all guarantees to the safeguard.

The project here proposed proves that simple interventions which don't interfere with the historic meaning and the conservation of the monument, can increase a great deal its cultural and economic value, ensuring it a long life.

Fig. 7: The theatre crowded on the occasion of the centenary of Giuseppe Verdi in 1913.

Università degli Studi *Mediterranea* di Reggio Calabria

e-mail: marinella.arena@unirc.it

Abstract

Most of the Italian architectonic patrimony is made up of little villages well integrated with the territory. This research is directed towards three Micro_Cities on the Sicilian Ionic coast showing: three examples of integration between site, architecture and space fruition.

On the Strait of Messina the landscape has delineated some “great rooms”, i.e. spatial surrounding, looking out over the sea. The Micro_Cities that we have chosen are part of this complex system.

The area to which these “rooms” belong is closed at the back by Peloritani Mountains, on lateral sides by Cape Sant’Alessio and Cape Ali and the ground is inclined in the direction of the coast line.

The research analyses, with the same method, Mandanici, Forza D’Agrò and Ali.

This study mixes the usual investigations on the surveys with the unconventional analysis related to the fruition of the space.

The method, innervated by an essential structure, is an open path that directs you to the perception and comprehension of these sites.

The whole village centre has been analysed with conventional surveying by hand while the architectural highlights have been surveyed by laser-scanning techniques.

The representation of each Micro_City also comprehends:

- a. site plans and some re-elaborations that take into account the texture and the local factors;
- b. territorial cross sections that illustrate the relationship between the village and the landscape;
- c. navigable 3D models;
- d. graphic re-elaboration of the data related to the fruition of exterior spaces by local population.

*Scappavano arrampicandosi all'Antinmare
con gli strumenti del loro mestieruzzo,
come se lassopra (...) sperassero di trovare sabbia,
acque salate e barche da varare.*
Stefano D'Arrigo

1. Introduction

The definition of “historical centre” or of “minor historical centre” has been much discussed in the international and Italian cultural panorama from 1950's to the present day. The term *minor* has, often, had a dimensional meaning related to the number of inhabitants or the extension of the centre; in other cases it has assumed the sense of less importance from the artistic and cultural point of view. In 1987 the “Charter of Washington” gives a broad definition of the old town centre: “Aggregation housing whose meaning is irreplaceable in the historic and cultural field of humanity”.

The whole of Italy is scattered with little towns perfectly integrated with the territory, so its history and its culture is strictly linked to them.

Manieri Elia subdivided the minor towns in two big categories those that have the hypotactic structure and those that have the paratactic one. The former ones, in the late Middle Ages, are in a pre-mercantile state and their structure is organised all around the architectonic highlight, such as a castle, a church or a palace. The latter ones, that have a paratactic structure, are those where “the village is articulated in a rich set whose parts are related in many different ways”. In Sicily the first centres often have their roots in the Greek or Roman Era. They have continued to develop from Byzantine and Medieval Eras up to the 1700 Century.

Fig. 1 Pictures of Forza D'Agrò, Mandanici and Ali

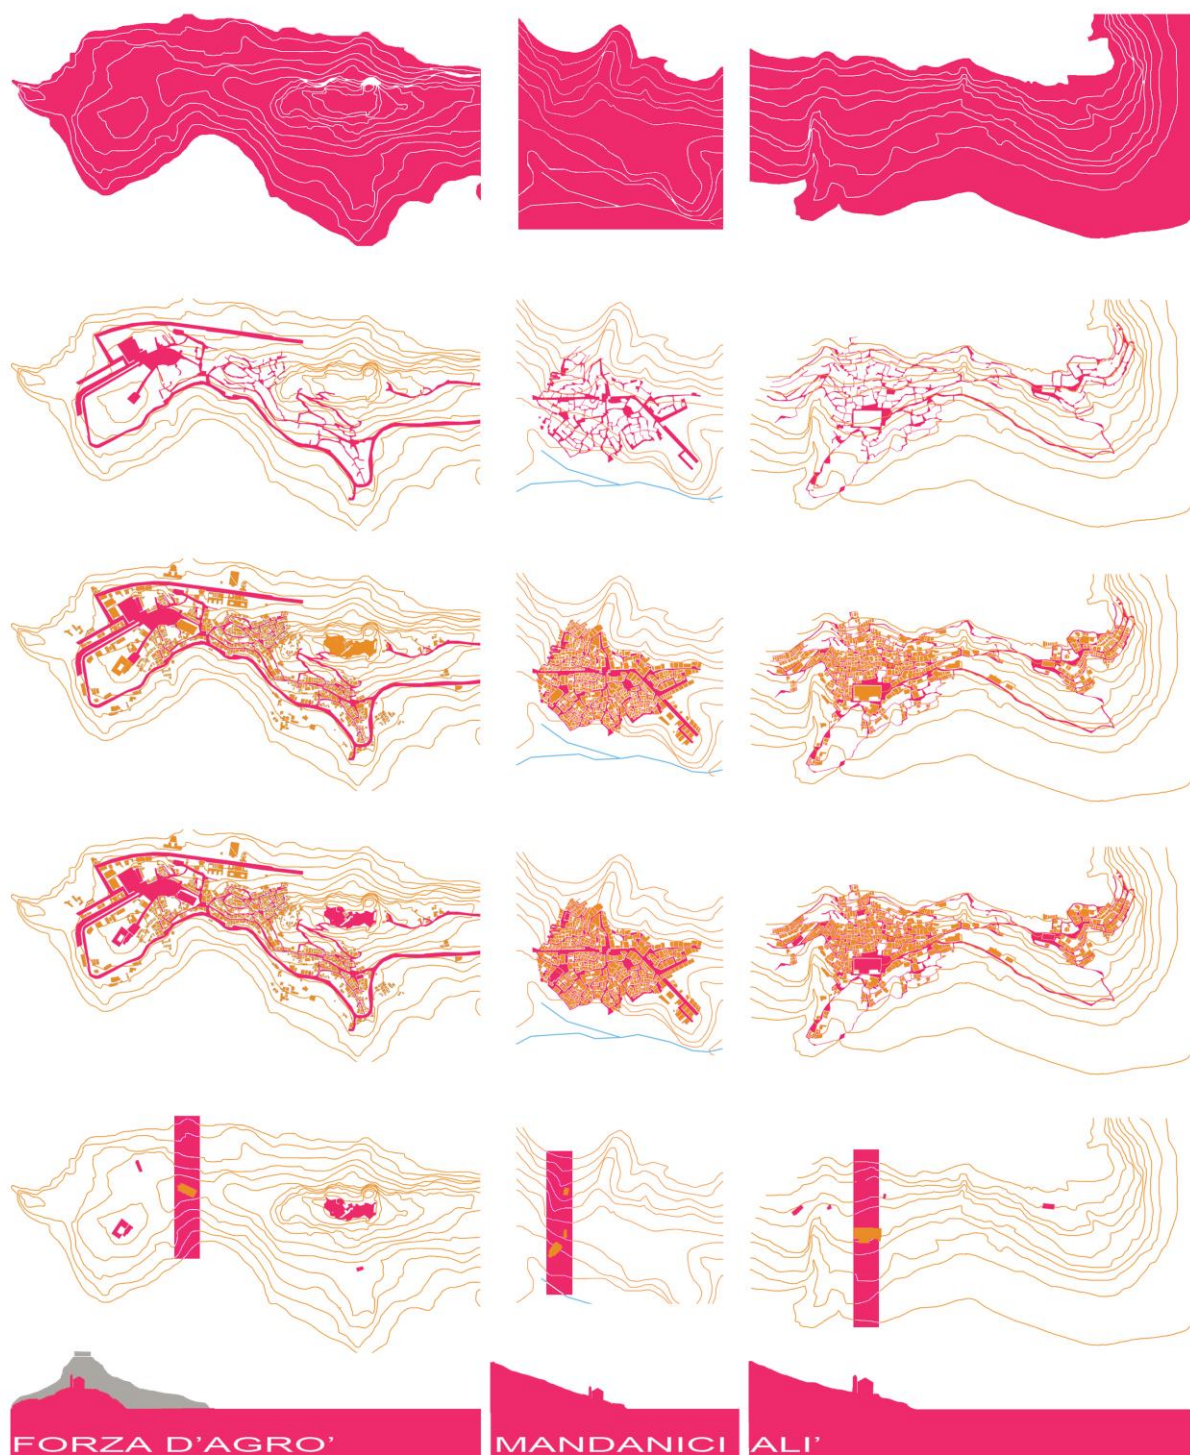

Fig. 2 The structure of Forza D'Agro, Mandanici and Ali.

In fact, during the period of the Industrial Revolution, some of these little centres were abandoned and the population went to the big cities where there was more chance of finding work. It could be useful, in this paper, to use a different term to indicate this kind of minor town. The word *Micro_Cities*, in my opinion, emphasizes the complex structure of these villages that have been real cities and that could become so again. Each centre has its peculiarity, its historic and geographic characteristic. In the past our society studied these centres to understand the anthropologic and economic phenomenon, to solve the hydrogeological instability and to study the architectonic highlights.

Not much research has analysed this centre with a global approach. So now it is interesting to try to carry out new research that takes into account the actual economic and cultural conditions.

Now we are in the Era of Informatic Technology where most relationships and communications are virtual. So these little towns could become attractive again. Moreover their peculiarity, their small

dimension and their disseminate quality of heritage, make them almost invisible to the new media that prefers big cities.

In the Age of Images, where everything is possible, where everything has already been seen, these little centres seem to be invisible. This research tries to compare three little towns in the area of the Peloritani Mountains.

The three centres that overlook on the Strait of Messina have the same historic and geographic context in common. The way chosen for this research tries to link together material and immaterial heritage.

The latter could support the deep knowledge of these places and could modify people's perception of the sites. Changed awareness, could be useful for improving economic and demographic recovery of these towns.

In fact every hypothesis of re-use could be useful to "make innovation preserving at the same time not only the warp of the stones but also the specific weft to human relationships".

This research, from the disciplinary point of view, tries to conjugate conventional and unconventional representations, seeking for a new approach to the communication of the material and immaterial heritage of Micro_Cities.

Fig. 3 The pattern of land parcels of the three centres.

2. Field of investigation

The area of the Peloritani Mountains extends between two slopes of the north-eastern part of Sicily. The slope that overlooks the Strait of Messina is the Ionic one. Here the foothills of Peloritani Mountains define large and complex spatial fields. Every field could be defined as a real room overlooking the Strait.

The "back wall" part of this room is made up of the foothills which are coloured by the Mediterranean Maquis shrubland.

The lateral walls, amazing and very recognizable, are the Capes which at the same time define the space and determine the view. The ground is sloping, and going down towards the coast. The ceiling is the blue sky of southern Italy while the last wall is a large window which overlooks the sea and the Strait.

The area belonging to the three towns, which have been analysed, extend from Cape Sant'Alessio to Cape Ali. Here the territory is dotted with little villages¹ some of which are hidden in the folds of the ground, invisible from the sea and main roads; others however occupy the ridges and are the most important element of the landscape. In fact they can be seen and at the same time they have a view all around.

¹ Excluding the coastal centres, that have been built recently because of the increasing tourism, the other centres that are important to the comprehension of the site are: Savoca, Casalvecchio, Fiumedinisi, Allume, Sciglio, Forza D'Agro and Ali.

This area is characterized by the deep, hard tracks of the four torrents, named Agrò, Savoca, Pagliara and Nisi. These torrents after a short tortuous stretch widen towards the coast and show a thin trickle of water in the stony bed.

The straight lines of highway and railway reaffirm the direction of the old *Roman Strata*, while the paths that ascend the foothills, steep and tortuous, follow the traces of the old Byzantines and Basilian roads which join the two slopes of the Peloritani Mountains².

The very steep ground has a dark yellow tinge, its many folds generate ridges and the sharp valley line. Only the use of long terracing allows cultivation of citrus and olives trees. The villages that belong to the Ionic slope of the Peloritani Mountains, rise near the torrents, and are linked to the Basilian cult developed on the oriental side of the Sicily during the XII century.

The mode in which these centres have developed is called "comb". The towns were built in the Era of the Greeks or Romans were located near the coast while the towns that originated from the late Middle Ages, had a defensive role. Moreover the latter had some links with defensive structures on the coast, as is the case of Forza D'Agrò and Ali.

The research tries to identify the connections between the cities that have developed along this part of Ionic Coast. Mandanici, Forza d'Agrò and Ali are only three of numerous centres which belong to this particular landscaped field. Before proceeding with the analysis of comparing these Micro_Cities it could be useful to make a short description for each one.

2.1 Forza d'Agrò

The profile of Forza D'Agrò draws the south wall of this landscaping field. It is a sharp sign where the bell towers and the high facades of the churches carve, with their stony mass, the inconsistent blue of the sky.

The centre rises on a ridge and, like the others, has a difference in level from the lower point to the higher of almost one hundred metres. I.e. the Cathedral of Santissima Annunziata is located at the altitude of 360 MSL while the Norman Castle is perched at the altitude of 426 MSL.

The structure of the centre today goes back to 1300 but the most important architecture, like the Augustinian Convent, was built in the second part of the XVI Century. The Norman Castle was built in the XI Century but its present shape was determined by restoration carried out in the XVI Century. The Cathedral, which is the structural core of the centre, was built in the XV Century and then rebuilt in a new position in the XVII Century.

2.2 Mandanici

From the green lemon trees, olive trees and the Mediterranean *macchia* (or Maquis Shrubland), little houses pop up. These, very close each other, show little projections and deep hollows with their facades orientated towards the solar radiuses. The facades have different inclinations and trace the infinite facets of an urban organism.

Mandanici is a little village hidden in a fold of the Peloritani Mountains along the course of Dinarini Torrent.

Its history is, probably, connected to the Greek Chalcis colonies while the most important monuments are built in the late Sicilian Baroque style.

Mandanici rises on very steep irregular ground, there is a difference of about 70 metres between Santa Domenica Cathedral, built near the Dinarini Torrent, and the Church of the Carmine in the upper part of the city which dominates the site.

The shape of the ground and the local rural economy have caused the fragmentation of the soil, giving rise to a dense urban tissue, with buildings of 2-3 levels that are built on little land parcels measuring 25-40 square metres.

The urban paths have been shaped by the slope of the terrain and by the direction of the flow of meteoric water. Many of them are no wider than 2 metres and often the inclination of the soil generates steps. The extent of building and the small dimension of the passages with time have created many underpasses.

² "This system is similar to the Basilian centres localized along the torrents, many of them were related with a non-secondary viability. In fact we can suppose the existence of an important street along the ridge of the Dinnamare Mountain, where a set of orthogonal axis were connected ascending the beds of the torrents going down on the opposite slope. This system, cutting the Peloritani Mountains obliquely, made a link between the costal streets of the Ionic side and the Tyrrhenian ones. The net of the Basilian centres is at the centre of this system. SS. Pietro and Paolo of Itala, SS. Pietro and Paolo of Agro, S. Salvatore of Bordonaro, S. Filippo Grande, S. Maria of Mili, and S. Maria of Mandanici, were built to control these important streets of connection." Reported in *Vie di comunicazione e potere in Sicilia* (sec. XI-XIII) by Lucia Arcifa

Fig. 4 The plan of Forza D'Agrò, Mandanici and Ali

2.3 Ali

The “great room” overlooking the Strait is closed on the northern side by Cape Ali. In the upper part, on the slopes of the Sant'Elena Hill, between the dense terracing of olives trees and citrus trees lies the village of Ali, at an altitude between 400 MSL and 490 MSL.

The village can boast very ancient origins but its present structure dates back to a period of expansion and richness: the middle of the XVI Century. In this period the Cathedral, dedicated to the cult of Saint Agata, and the Convent of the Capuchin were built.

3. The method

The research analyses Mandanici, Forza D'Agrò and Ali, with the same method,

This study mixes the usual investigations on the surveys with the unconventional analysis related to the fruition of the space.

The method, innervated by an essential structure, is an open path that directs you to the perception and comprehension of these sites.

The whole village centre has been analysed with conventional surveying by hand while the architectural highlights have been surveyed by laser-scanning techniques.

The representation of each Micro_City also comprehends:

a. site plans and some re-elaborations that take into account the texture and the local factors. In fact every building has been indicated with a colour, a cover system, a specific detail; so a sort of

“emotional plan” which suggest experiences and sensations, which the architectural drawing does not always allow, has been made.

b. territorial cross sections that illustrate the relation between the village and the landscape

c. navigable 3D models;

d. graphic re-elaboration of the data related to the fruition of exterior spaces by local population.

Fig. 5 The scans of the Cathedral of Mandanici, Santa Domenica, of Forza d'Agrò, Santissima Annunziata, and of Ali, Sant'Agata.

The method used in this research forms a parallel between the three Micro_Cities and, at the same time, identifies the common elements which are related to the shape of the terrain, to the sense of the site, to the inhabitants, to the local traditions and the historical phenomenon that have happened in this particular geographical and cultural field. To create this parallel, after the analysis of each centre and after completing the survey and the representation, only a few themes were enucleated.

The analysis uses the drawing as a tool, to simplify the reality, to reduce the unnecessary information and, at the same time, to optimize the communications emphasising the crucial data. A preliminary analysis, maybe the most direct and evident, this is possible by comparing a panoramic photo of the three centres. Immediately you can sense the hypotactic structure hypothesized from Manieri Elia. In fact the Micro_Cities are all organized around their cathedrals. The latter, real urban out of scale, draw the profile of the centres and orientate their structure. Both the Cathedral of Forza D'Agrò and the Cathedral of Ali dominate the village with their mole. The dimensions of the cathedrals have necessitated the construction of large terraces of ground to level; so their mole and height appear more evident.

The other element around which these villages are orientated is the system of defence. This is represented at Forza D'Agrò by the Norman Castle and at Ali by the bastion located near the coast.

All the centres have a great religious building very close to them. The most ancient is the Basilian Monastery in Mandanici, erected in the XI Century, while the Augustinian Convent in Forza D'Agrò and the Convent of Capuchin in Ali were built in the middle of the XVI Century. (Fig.1)

From the orographic point of view the analysed centres, and many of the fifteen Micro_Cities which populate this area, are located in the range of the 400 metres above the sea level. The maximum rise is about one hundred metres and normally the cathedral is placed in the flattest area of the site. The three centres have a very dense urban pattern. Nevertheless the urban tissue of Forza D'Agrò appears frayed because it is organised all around the Rocca of the Norman Castle.

The tissue, made by little houses two or three levels in height, is much frayed, with real little parcels measuring 35-45 square metres. Mandanici has land parcels almost square; in fact most of them are no wider more than 3-4 metres and have the same depth. Forza D'Agrò and Ali have land parcels a little bit larger, the frontage is about 4-5 metres and the depth is 9 metres.

The paths, which belong to the town, draw a cobweb which is spread over the ground and leaves many thin signs. Tortuous, interrupted alleys define the shape of irregular rounded blocks. The blocks, like mosaic tesserae, form the shape of the town and underline the orography of the site. In fact the principal streets follow contours while the secondary paths cut them obliquely to reduce the slope. Blocks and paths, sometimes, seemed to converge in the central square making a radial pattern.

The central square is, usually, very big and its shape is determined by the union of two streets: it's the case in Forza D'Agrò and Mandanici. The paths are often a sort of cul de sac and, in the central part of the village, especially in Mandanici and Ali; there are many underpasses created by the saturation of the land parcels. Many streets are, indeed, long staircase, which are necessary to overcome the slope of ground. (Figs.2-3)

The research, which is still in progress, has investigated different aspects of these three centres. Here only a few notations and drawings have been reported and they are limited to the core of these centres: the central squares and the cathedrals. (Fig.4)

The instrumental survey has been limited to the latter which have, obviously, many common elements like the orientation, the typology with three naves, transept and dome; the squared bell tower, and the façade morphology. A well-defined survey was the first step to analyse concordances and discordances. For these reasons the three Cathedrals were surveyed with laser scans. (Fig.5)

These three Micro_Cities have a special link to the site. The reasons are clear when the history of their foundation is analysed. In fact some of these cities developed along streets that connected some important centres in the past: it is the case of Mandanici. In other cases the centres had had a defensive role, as is the case of Forza D'Agrò and Ali. These, besides, have found a balance which has allowed them to develop over many centuries. If the centres are observed from the exterior these things are all evident.

They, as living organisms, offer themselves to solar radiuses and enlarge their mesh towards the landscape and the Strait. The position, perched on the slopes of the mountains, permit every house to find at the same time the Sun and the scenery.

From the outside the villages are sunflower fields where each facade turns to take sunlight and is also well placed on the slopes of the ground.

The towns, inside, are a labyrinth made by a complex fragmented space. The perspectives are interrupted and the capacity to orientate is supported by vacuous elements only. The curtain embroidered behind a glass door, the chair in the shadow of a balcony, the white smoke of the stoves, the washing swaying in the air, the flower pots on the road, the old men who always sit on the same sunny bench.

Every element, alone, is inconsistent and illusory but these data, all together, give significance to the space which became the scenery of the community made of men and woman. This is what the emotional plants show. In these drawings every land parcel, every house, has its texture. Sometimes the texture is realistic, a colour or the grain surface or a detail; sometime information is aleatory, mutable or incoherent. (Fig. 6)

Abstract

With this paper, part of a research project, that takes a holistic approach and about memory and the preservation of the tangible and intangible heritage of Aljezur, south of Portugal, whose territory almost preserved at its majority, is however too coveted for its tourist potential, we want to warn about the contradictions of a law that supposedly protects and promotes the maintenance of a unique landscape and ecosystem, but also allows its disfigurement, authorizing projects that, contrary to logic, common sense and good taste, contribute to its destruction, defacing places that for centuries remained virtually untouched and protected its inhabitants, changing the landscape and introducing new paradigms of experiences in a community where always respected each other without sealing paths, without create real boundaries, proposing, under the guise of development and a new concept of tourism, in rural areas, the destruction of one of the most protected and untouched places in the heart of the municipality of Aljezur. A once magnificent place where for centuries stood merely an ancient and ancestral farm - with its housing – Monte – with its traditional language - and its agricultural support small scale buildings, begins to resemble a new village whose architecture appears under the guise of sustainability and tradition, since is in *taipa* (adobe or sun dried bricks), integrates characteristics of other places, anywhere, other than where it goes lifting, disfiguring landscape, in contravention of the vernacular architecture contradicting the memory and also the maintenance and preservation of material and immaterial heritage which is the opposite of what will be sustainability.

Keywords: Aljezur, Vicentina Coast, Heritage, Traditional Architecture, Sustainability

“Alas! How little does the memory of these humans inhabitants enhance the beauty of the landscape...” (Henry Thoreau)

1 The Project

This paper is an integral part of a research project named - *Aljezur "between vision" of the place and memory* - which aims for the cultural analysis and the protection of tangible and intangible heritage of an territory which is an integral part of the Southwest Alentejo Natural Park and Vicentina Coast. Incorporating various disciplinary valences that promote a close and critical view regarding heritage, memory and the preservation of the cultural identity of a depressed and aged county that urges to boost. Thus, according to our research supported by a multidisciplinary team, and for a continuum of several articles published and presented at various seminars, national and international conferences, for nearly three decades. We assume not only an EMIC approach and a systematic participative observation, but also an attentive reading of all documentation and legislation that have been published on the present territory, particularly since it was considered protected landscape in 1987, and later Natural Park in 1995.

We intend to contribute to the wider debate within the academic community and also the civil society, regarding the necessary and compelling regulated protection and ethically sustained of a natural landscape and also of its urban territory. In the sense, that it assumes a symbolic, social and material impact. Not just for those who reside there and experience it in everyday life, but also for all who seek it in search of an alternative to mass tourism and concrete, that have mischaracterized the rest of the

Algarve region, which political power and the local authority, seek to offset not understanding or ignoring the potential of an extraordinary material and immaterial heritage that may become irrelevant very soon, since it will be destroyed in its essence.

In this context, we wish to emphasize the contradictions, excesses and some legislative permissiveness that have allowed a slow degradation of a territory of the Algarve coast. Integral part of a vast area of landscape legally protected for over 25 years, but whose beauty and unique location has been constantly a special target for greediness based on touristic and real estate pressure among political powers.

Assuming that the underlying concept of “natural heritage” is all that is inherited from previous generations, maintained or preserved in the present and bestowed for the following, the concept of “natural heritage” can thus be very close to natural heritage and includes a pressing need of safeguarding the biodiversity and the ecosystems, but can not ignore the role of man and all those inhabitants that always have protected it [1].

2 Aljezur, a case study

Fig. 1 NETO, Maria João Pereira (photos). Traditional architecture in Aljezur. On the left an urban house, while on the right an rural house (“monte” house)

We will focus our approach on a recent and very controversial intervention of rural tourism with the terminology of countryside accommodation [2], in accordance with Portuguese law in the municipality of Aljezur, southwest of Portugal, in what is still called by local Vale Palheiro (Haystack Valley) located until 2013 in one of the most beautiful, untouched and protected places of the Natural Park of Southwest Alentejo and Vicentina Coast, part of footpaths of the so called Rota Vicentina: “a long distance path along the Sw coast of Portugal. Comprising the Historical Way and the Fishermen’s Trail, totals 350 km to walk, between the city of Santiago do Cacém and the Cape of St. Vincent, the most south western point of Europe”[3].

According to the path’s website “besides the implementation of the path, the project also foresees its integration into the region’s tourist offer and local community and its exposure at national and international level. Conceived as a public structure. The Rota Vicentina intends to establish itself as a defining characteristic of the region, becoming viable via the most natural of human practices – walking – and contributing unequivocally towards to the sustainability of rural areas through the promotion of economic activity, stimulation of existing activities and services, maintenance and enhancement of local culture and traditions, encouraging new business creation and promoting the destination out of season”[4].

We believe this to be an example of good practice that associates nature tourism with protection of the immense cultural and natural heritage of a privileged territory, and that when monitored does not destroys its core heritage. However, not being our scope to focus our approach on existing controversies interventions, targets of previous analyses and duly published [5], we do not want also to obviate the reference to the proximity of the major urbanization called “*Esparta*”. For us, one of the biggest attacks on common sense, good taste and aesthetic sensibility that have occurred in recent years, in the country, having generated authentic architecture and urban aberrations, which led to adulteration and wounded a perennial way the balance and beauty of the unique landscape. Disfiguring the “*spirito locci*”, as advocated by the ICOMOS Declaration of Quebec, in October 2008.

However, we can understand it, even with all criticism, given its approval on the verge of the legislation that fully integrated the territory of the protected landscape in 1987, later Natural Park in 1995. Thus, and resuming our reasoning, we intend in this context, to report a new and immense attack on the integrity of a unique heritage, disfigured in its essence through a tourism *project in rural*

area [6]. Authorized at the threshold of the review of the new Park Land Use Plan [7] would come to prevent any intervention of this nature on this or in another place so preserved, against all logic and common sense, and being highly contested by the inhabitants who still resist and did not leave the municipality.

As we have been analyzing, despite several appeals to common sense and dialogue leading to equilibrium between the main actors and agents of the process by some members of the civil and academic community in which the project coordinator is included, we continue to watch to proliferate in recent decades of a mindset that insists on resistance to change assuming a semi autistic position, but sometimes contradictory, highlighting, but also rejects the categorization, classification and asset preservation of a unique and unrepeatable scenery but simultaneously planned, managed, discussed and performed by "bureaucrats" who are unaware of the realities and aspirations of local people that since there is the Park were prevented from making small changes to their homes or agricultural support in defence of nature and the overriding need to protect the leading, or greatly contributed to the abandonment of traditional and ancestral agricultural practices.

Remains a failure to dialogue between the local government, the central power and the county's population. Aljezur is a council already very depressed not only by unfavourable demographic situation with an aging population, but also in their socio-economic aspects. However its inhabitants stoically resist, trying to survive against all odds: impositions and restrictions promoted by a legislation, which sometimes led to the abandonment of cultural and survival practices: a way of life deeply rural only for allegedly not complying with the laws that supposedly "defend" a rich heritage that has remained untouched or little changed in its essence for centuries. But on the other hand, allow or tolerate an assault situation for landscape balance in a privileged region, as we consider the exemplary case that today we bring to this conference.

Also worth noting: the analysis of the legislation that has been published over these three decades that emphasizes the need for application or maximization of gains arising from the classification of the territory, as well as the possibilities of finding alternatives to a sustainable development model that does not only assume the tourist seasonality, leveraging the advantages of sustainable and ethically responsible tourism [8]. Based on the balance in the preservation of natural and cultural heritage that enhances the added value of their insertion in a Natural Park. This case can highlight initiatives such as the Route Vincentian that fits in sustainability logic and new opportunities that can enhance protecting nature in its essence.

Fig. 2 NETO, Maria João Pereira (photo), 2010. Palheiro Valley in Aljezur

3 Aljezur and the Vale Palheiro

Aljezur is a municipality located in the southwest of the Algarve, the most southern region of Portugal. And has always been a predominantly rural area whose population for centuries depended on the products of the sea and land. Although in more recent contexts, the fish, with the advent of tourism, was particularly disposed to southern Algarve, to the nearest markets in tourist areas. During the 60s

of the twentieth century, agriculture had experiencing an increasing abandonment and the county was hard hit by high emigration crisis that was reflected in its demographic structure that has marked his aging in a continuous process. The economic and social history of this municipality is going to reflect on the history of this case study: the Vale Palheiro and surrounding land that stretched almost to the sea, were owned by a single family of aristocratic roots and rural land tenure, about 150 years ago. Family whose origins and history is mixed with the county itself.

Fig. 3 NETO, Maria João Pereira (photos), February 2013. Rural house in Palheiro Valley.

With the progress of time and the distribution of property by successive processes of inheritances, the land map has been changing, the country has changed and the countryside has been slowly dying. The legislation has arisen in order to protect a landscape of extreme beauty and virtually unspoiled, has been not sufficiently understood or provides confidence by those who resisted. Having been overtaken his goodness or subdued by the prohibitively excessive that even restricting the passage of cattle on the banks of streams or planting and harvesting in areas where for centuries had planted and produced a bit of everything from rice to sunflowers, not forgetting the wooded component and the cork production [9].

The Palheiro Valley has been an agricultural property that dominated part of a wonderful territory where even the sixties, early seventies of the twentieth century withdrew cork (today there are oaks, protected by law and which is extracted cork in the area) and rice fields were extensive and spread - by long valleys to the sea. Consisted of traditional hill, perfectly integrated into the landscape [10] and with her mingling, the residence of the farmer, the tenant (non-owner), and an agricultural support, a warehouse and the cattle.

Fig. 4 NETO, Maria João Pereira (photos), February 2014. Overview of the Vale Palheiro, in Alzejur

The direct descendants of the most recent owners, a branch of the family that held the ownership of much of the land that ended up near the Atlantic, sold it to a enterprise in the capital, which quickly presented a project for Tourism in rural areas.

In reality, this project hides itself under the supposed sustainability perspective, because the buildings Certain that they were was intervening in one of the most sensitive areas of the Natural Park, where since the promulgation of the 1987 Decree nothing could be constructed or altered for being illegal, including an enlargement of a window. Any intervention in the area had to pass the scrutiny of the highest authority: those responsible for the Natural Park and in the majority of cases they were rejected.

Fig. 5 NETO, Maria João Pereira (photo), February 2014. Ancient distillery house in the hill, Palheiro valley in Alzejur

Fig. 6 NETO, Maria João Pereira (photos), February 2014. Palheiro valley in Alzejur

The new owners, a company based in Lisbon, purchased most of the properties around, and suddenly, to the consternation of many began to be built a small private village. A supposed rural tourism space on its legal designation of country houses altering paths and subsequently applies to local authorities to be fenced.

This behaviour contrasts with all the logic of community local tradition, which always respected the private property, allowing the free movement and land crossing. This pathway was one of the roads that the older generations made to go to the near beach of Monte Clérigo. More severe, this intervention is destroying and is digging one of the most beautiful and untouched hills, destroying oaks, terrorizing migratory birds, cows, other indigenous animals and damaging the local flora, protected by law. Which is impacting in the calm landscape and its patrimonial value by a deafening roar of machines and trucks that bring the raw materials to the place where supposedly elaborates the adobe bricks.

At the present time, early 2014, the aforementioned project was too quickly approved by the ICNB (National Institute of Nature Conservation), compared to what would be usual in March 2010 [11]. This project has just been launched in the summer of 2013 and encompasses about 44 acres and a total of 700 m² of construction. Where besides the owner habitation (on that was once the traditional hill, and

now highly modified) are included six units of housing, stables and an arena next to the stream bed, in a flooding area. Also included in this project is a building to support the honey production and a distillery, which is strategically placed in what was once a beautiful and untouchable slope, which was destroyed and excavated to give origin to a huge building completely deranged from everything else, in a place where there never was any construction.

are allegedly made in adobe and earthen architecture, even though they included steel and concrete, as we have observed and recorded photographically during the last months. If this is an untouchable place then it should be impossible to be changed according to the present legislation. So, this construction constitutes by itself a huge wound in the landscape and a deep imbalance in cultural and intangible heritage of Aljezur and in the whole Natural Park. It is in our understanding and that of many of the older inhabitants of the county and the true guardians or keepers of its memory, a real plague and an aberration: because it disfigures the park landscape; because it does not suit the local architectural language and tradition of this region [12], taking two or more floors and mixing traditional architectural raw materials with iron and concrete; because it contradicts everything that has been previously denied, for nearly three decades, to those who resided or worked there and which always succeeded in preserving the essence of this place; because it contradicts the law itself, as it is based to achieve the project for rural tourism – countryside accommodations.

Finally, because it contradicts one of its key articles: "the developments of tourism in rural areas referred to in subparagraphs a) to c) the following paragraph shall preserve, restore, and enhance the natural heritage and landscape architectural, historical, their locations and regions where located through the reconstruction, rehabilitation or expansion of existing buildings, in order to be assured their integration into the surrounding ... " [13]

According to the law "countryside accommodations are the properties situated in villages and rural areas which are integrated, for their design, building materials and other characteristics, in the typical local architecture". In this paradigmatic and exemplary case study, it is assumed the opposite, in the name of development and private investments. Thus, we consider this one of the saddest and most exemplary cases of (un)sustainability and disregard for local culture, and a huge heritage attack to one of the most beautiful and until now protected natural regions of southern Europe. Paraphrasing Ghandi: "Earth provides enough to satisfy every man's needs, but not every man's greed."

Havana: urban configurations and heritage conservation

Jorge PEÑA DÍAZ, Joiselen CAZANAVE MACÍAS

Faculty of Architecture, CUJAE, Havana, Cuba

jorgep@arquitectura.cujae.edu.cu, joiselen@arquitectura.cujae.edu.cu

Abstract

Against the background of contemporary global urbanization, Havana must be regarded as a completely exceptional case. The current urban situation defines several urban configurations that epitomise the seven most important components of the specificity of the urban for the Cuban Capital as a whole while at the same time each of these configurations synthetises the specificity of the urban situation of its parts. Heritage conservation is a key factor of the current urban situation.

In recent years, Havana has gained increasing attention especially in terms of urban development. However, the main interest remains strongly focused on the *Habana Vieja* quarter, which was declared a UNESCO World Heritage site. The government-led development program to renovate the old city has achieved relevant successes despite Cuba's difficult economic situation. However, *Habana Vieja* only constitutes a small part of Havana's heritage of urban architecture. Our analysis shows that Havana's historically and architecturally significant area is much greater. Due to the great diversity and richness of its urban structure, the city at large is a unique example of our global heritage. This heritage is nonetheless threatened in different ways. The paper elaborates on this issues and on what strategies has been defined and how planning has reacted to these different specific situations.

An Exceptional Case

Against the background of contemporary global urbanization, Havana must be regarded as a completely exceptional case. While at the global level, urbanization is progressing undiminished and the creation of overflowing urban landscapes and megacities is seen in diverse locations all over the world, this development seems to be bypassing Havana almost without a trace. The Caribbean metropolis has experienced comparatively little growth in the past 50 years. With its approximately 1.4 million inhabitants in 1958, Havana was one of the large metropolises of Latin America. A rapid urbanization process and an intense construction boom marked it. The skyscrapers along the Malecón, which today form a still-incomplete skyline, bear witness to this fact. Today, Havana has a population of around 2.2 million, with the demographic development having stagnated since 1980 and the population aging at a fast pace¹. The suburbanization process has been halted, and even today, the city's outer limits are clearly discernible².

The reason for these developments is mainly to be found in the nature of the Cuban Revolution, which primarily aimed to improve conditions outside Havana. Accordingly, revolutionary Cuba pursued an explicitly decentralized development strategy. The main aim of policies was directed towards developing rural areas as well as small and medium-sized cities. The further development of the nation's capital, by contrast, was only given secondary priority³.

In recent years, Havana has gained increasing attention especially in terms of urban development. However, the main interest remains strongly focused on the *Habana Vieja* quarter, which was declared a UNESCO World Heritage site. The government-led development program to renovate the old city has achieved

relevant successes despite Cuba's difficult economic situation⁴. This favourable situation contrasts with the attention to other areas. The paper elaborates on these issues and on what strategies have been defined and how planning has reacted to these different specific situations. The sources of these analyses are three projects that have been carried at the Centre for Urban Studies of Havana: The projects SeDUT, Atlas Urbano de La Havana, and Sustainable Urban Rehabilitation for Centro Havana. The two former have been developed in collaboration with several Swiss Institutions such as the ETH-Zurich and Metron among others. They used mapping as a research tool and were instrumental for the identification of seven urban configurations. Each of them was given a symbolic label addressing its key features namely The Blue Strip, Deep Havana, Central Havana, Hidden Havana, Industrial Cities, Satellites of Modernity and National Havana. The latter project deepened in the systematisation of heritage components with a wide scope in one of the most complex municipalities of the metropolis. Historic, Urban and Architectural heritage components were identified and registered within the so-called Atlas of Cultural Heritage for Centro Habana⁵. This new knowledge was used in order to define activating projects able to revert the negative situation. The key common issue linking the three projects have been the attempt of understanding specificities of the urbanisation process and finding approaches able to inform current planning tools.

Urban Configurations and Heritage

Havana's current urban situation defines several urban configurations that epitomise the seven most important components of the specificity of the urban for the Cuban Capital as a whole. At the same time each of these configurations synthetises the specificity of the urban situation of its parts. Heritage conservation is a key factor of the current urban situation. Although in most of them heritage components are present in three of these configurations heritage and its conservation, are key components of the current urban situation. Nevertheless they play different roles.

The Blue Strip and Deep Havana represent the antipodes of the urban situation: On the one hand there is the Blue Strip. It is the shiny area that concentrates the best qualified zones and the places that constitute the branding of the city e.g. the best-off neighbourhoods, most of the hotels serving the international tourism, and in general most of the main facilities operating in hard currency within a dual system. The main metropolitan functions such as Banks, Media and Government facilities are concentrated here. Moreover main recreational attractions are within this area: the modern Downtown Vedado, the beaches and the historical centre. On the other hand there is Deep Havana. It summarises the rupture of the balance between centrality and periphery-generation shown by its location south of the Harbour and in the gravitational centre of the city. Nevertheless although close to the central areas and with hot spots of centrality within itself it is still perceived as far, disconnected and downgraded. The area has been somehow neglected and almost no tourist related nor foreign joint ventures related to foreign investment take place in there. Qualification of public spaces and services is generally low.

The presence of the Historical Centre within The Blue Strip evidences the successful impact of the heritage preservation measures carried out in this area during the last three decades. After being included in the World Heritage List _ along with the colonial defensive system _ the area was benefited by a comprehensive program of recovery. Its transformation capacity and positive impact became more visible during the 90's. A set of special economic and political measures granted the capacity to obtain the economic means to both recover the most valuable zone of urban, architectural and historical value of the country. The set to value of this heritage has been the key engine of this process. It has turned a downgraded area into a highly appreciated part of the city by both Cuban and foreign visitors as well as by locals. The program has been in general terms successful in avoiding gentrification and a clear social orientation characterises it. The program has been registered as an international Best Practices initiative and within Cuba is regarded as a model that should be further developed and adapted to other areas beyond the colonial historical centres⁶. The fact that these programmes can be considered one of the most significant actions over the built environment along the last five decades in the whole country makes it explicit the professional, technical and organisational potentialities embedded within the Cuban society to deal with and protect its heritage in a clever way. Additionally it has been proving how tourism, private initiatives, State-lead programmes and other stakeholders can align themselves in order to increase the wealth of the Cuban Society using heritage recovery as a key component of the strategies they have forged.

Threatened Heritage: Other configurations

Cuban policy of decentralization ensured that the existing urban structure was preserved. Only few new housing projects were constructed in Havana, and these (e.g., Alamar) were added to the city without destroying existing neighborhoods. Unlike in almost any other city of comparable size, the historic quarters of

⁴ Schmid and Peña Díaz, "Deep Havana."

⁵ Rey Rodríguez, Peña Díaz, and Sánchez, *Centro Habana. Un Futuro Sustentable*.

⁶ Cazanave Macías, "Pautas metodológicas para el diseño de espacios de intercambio social accesibles por adultos mayores. Caso la Habana Vieja."

Havana were not destroyed by urban transformation processes, but were preserved. Havana can therefore be regarded today as a museum of urbanism: All phases of its historical development, from the colonial and republican periods to the metropolitan phase of the 1950s and the revolutionary period, can be traced with extraordinary clarity in the urban landscape. Havana Vieja only constitutes a small part of Havana's urban heritage. Havana's historically and urbanistically significant area is much greater. Due to the great diversity and wealth of its urban structure, the city at large is a unique example of our global heritage.⁷

Chateloin⁸ has demonstrated the existence of urban zones with cultural and historic value (ZUVHC). Roughly one fifth of the total built up area of Havana is considered within this category. Such representation reinforces the exceptional character of the trace of urbanisation in Havana since most of these areas have not suffered transformations since they were built. The most important of these ZUVHC is the Historic Centre La Habana Vieja i.e. the above-presented case. Nevertheless two other configurations show a different status quo regarding both the comprehension of the value of this heritage and the actions in place to preserve it. They are basically Havana Central and Hidden Havana.

Havana Central embraces most of the area that in the XVIII century was beyond the City Walls. During this Century the area became the logical space to accommodate further growth and already in 1862 the extramural population doubled in size that living within the walled area⁹. Military requirements associated to the peculiarities of the defensive system (City Wall, Campo de Marte, the presence of the Shipyards) among other features, had forced before the allocation of settlements in a separate fashion from the city core. Consequently suitable space had been preserved for the inescapable expansion. The axes of today's Paseo del Prado _the eastern border of the configuration_, Reina Street and Carlos III Avenue in the Northwest and Monte _Southwest_ were key elements of the consolidation of this area between the 18th and 19th Centuries. The continuation further west of the latter was known as Calzada del Cerro in reference to the crossing of the neighbourhood it articulates. The area of El Cerro _South Western part of the configuration_ was first the space for the settlement of the non-Spaniards. "Its existence is associated to the development of the national identity of the Creole (criolla) Oligarchy. There they found a space for development with certain autonomy and differentiated from the space of the Spaniards¹⁰. This neighbourhood had an impressive splendour and fast decay took place all within 19th Century"¹¹ constitutes together with current Centro Habana key pieces of this configuration. It also engages the southern area of the historic core of Old Havana. This area lacks the concentration of monumental buildings and spaces of representation of the colonial period. Its development is much connected to the port and the former shipyards. Presently the impact of the recent impressive physical renovation and social programs is not still as visible as in the northern part. It used to be a much more modest zone where working class people lived amid a much less significant architecture. It also reaches further south the areas of the Municipality of Habana Vieja just beyond the UNESCO area around the bay, the northern part of Cerro and most of Centro Habana.

The Blue Strip frames it in the north and Deep Havana in the South. It is therefore just in-between the populous gravitational centre south of the bay and the privileged coast-oriented northern fringe. The back of the Malecón along the San Lázaro Street is its northern frontier. It extends towards Infanta in the west and Via Blanca cuts it the south between the Sports City (Ciudad Deportiva) and the Fishing Port (Puerto Pesquero).

The specificity of this configuration resides in the contrasting paradox given by the confluence on the same spot of three conflicting elements: its privileged location _accompanied by high levels of centrality_ coexists with the enhancing concentration of heritage assets both of material and immaterial character framed by high levels of deterioration of both the physical and social tissues. The latter aspect has been affecting the possibility of its heritage to be recognised by average citizens. It is not rare either to hear in the voice of both practitioners and certain academics expressions such as "we should make tabula rasa of all this area and start from scratch again". This situation shows the contested character of this area. Nevertheless there is not any comprehensive program in place to deal with this complex situation. Consequently even though there have been important punctual actions supported by the state and isolated private initiatives seems to have understood the value of centrality, the lack of coordinated action threatens the possibility of keeping this valuable piece of heritage.

The second of these configurations is Hidden Havana (HH). HH has been labelled a configuration with their cores in the foundational areas of three former towns on their own: Regla and Guanabacoa in the east and Marianao in the west. The urbanisation process of Havana engulfed them only in the second half of the 20th Century. In 1939 Marianao was still considered the second largest city of Cuba and Guanabacoa was fifth in

¹⁰ Llanes, 1898-1921: *La Transformación De La Habana a Través De La Arquitectura*.

¹¹ Coyula and Rigol, "La calzada del cerro esplendor y ocaso de la habana neoclásica."

the list. Presently both areas are deeply embedded in the understanding of the identity of Havana with very specific blends such as the coined image of African-origin religiosity and both cultivated and popular dancing music being generated within the remnants of the former colonial structure. Both parts of this configuration have made room for spontaneous settlements in their edges.

The western section of this two-pieces configuration defines the identity of the west-south section of Havana. It goes beyond the current limits of the municipality of Marianao and includes westwards parts of La Lisa. It stretches eastwards beyond the margins of the Quibú River including its precarious settlements with sonorous names _such as Los Pocitos_ to Street 44 in the Buena Vista neighbourhood and connects with the areas of the Parque Metropolitano de La Habana and the East-West Highway. 19th Street marks the northern limit with the back of the Blue strip . This limit continues along Ciudad Libertad and the margins of the Quibú River and the southern end of La Coronela. A conglomeration of Industrial facilities flanks its southern border including the former Oriental Park presently turned into a large storage and large retail zone. The dumping site and the large space-needed connection of the east -west highway and 114 street close to the only sugar mill of the city territory definitely marks this frontier which extends with a similar character to the west.

The territory in the west contains the nucleus of an area that developed since colonial times in the western side of the Almendares River in connection to summer recreational facilities. It obtained the category of independent municipality only in 1878. The 51st avenue constituted the backbone of the urbanisation process in the area. Nevertheless the area north of this street towards the coast remained almost empty until the very end of the XIX Century. The periods after the first and second World Wars witnessed an accelerated process of urbanisation under different models defining the current shape of the territory.

This piece of Hidden Havana used to be part of a larger space that reached the northern coast of Havana where the notorious Clubs and Nightlife hotspot of the 30's and the 40's of the 20th Century were located. Nevertheless it presents itself today as a separated piece that lost its connection to these branded areas on the north. In spite of the fact that the territory is crossed by important streets that presently connect for example the international airport (114-25th-190) with the protocol area close to the sea in the west and the former Headquarters with Vedado towards the east there is no connection between Marianao and the beaches that keep the same name of the former town and present municipality: Playas de Marianao even though they are now in Playa. The partly empty surface of the military airport at former Columbia Headquarters, which was built by the American Army during the 1898-1902 occupation of the island, constitutes today a major border that definitively separated this configuration from the adjacent coastal development. Paradoxically the urban transformations made around it constitute icons of this part of the city: the obelisk dedicated to Dr. Carlos. J. Finlay and the 31st avenue containing a concentration of medical facilities. .

Morphologically this configuration contains a gridiron structure with different sizes in specific areas. Shared walls buildings concentrate in the oldest areas along the 51st street. An assemblage of different urbanisations resulting from private initiatives during the first half of the 20th Century make the most of it. The presence of the Quibú River imposed derelict space_ leftovers of the frantic speculative urbanisation process that shaped the territory, which has been occupied by small slums. Hence, In spite of the weight of the area in the collective memory of the citizens this it is perceived today as one of the most deteriorated ones and stands for low quality living.

The eastern piece of this configuration embraces two former cities: The ultra maritime town of Regla and the city of Guanabacoa, capital of the Cuban Music. They define the second and complementary segment of this configuration. The relation to the harbour and the sea coin the character of these areas even though the storage and shipyard facilities belonging to the harbour do block the direct access towards the opening of the bay. The identity of this area makes also reference to the strength of religion_ particularly that of african origin_ and the cultural elements that surround it as well as the omnipresence of popular music. The presence of babalawoes for example is an important reference in the collective memory when referred to this place. The connection with the sea has also an influence in this fact since the shoreline is used in the religious rites. Other areas such as the Colina Lenin offer space for these practices due to its open air and hilly character. The procession of the Virgin that takes places every December 4th agglutinates Catholic church followers and Yoruba religion practitioners adoring simultaneously The Virgen of Regla and Yemaya each one group. On the other hand this was the area where personalities of the Cuban popular and classical music were born and developed such as Rita Montaner, Bola de Nieve, y Ernesto Lecuona among others.

The historical nucleus of Guanabacoa was declared National Monument in 1990, which defines a protective framework. It has started a promising process of rehabilitation. This area has been however surrounded by several "repartos" (urbanisations) such as Chibás, La Jata, Nueva Habana and others. These repartos do not make reference to the morphological composition of this colonial core. They are in general references to the international architecture movement that so much impact had in housing models all over Latin American in the late 40's and 50's. Notwithstanding the conservation process is very weak even though there have ben several studies. These results have not been implemented and the attempts to create a municipal group to take care of the heritage components have been unsuccessful. As a result " the conservation of this

historical centre is severely threatened since several of the most singular buildings are close to be lost”¹². There is growing concern because in the absence of a quick reaction the beauty and value of this exceptional part of the heritage can be definitely lost by the “fickleness of oblivion”¹³. This concern can be extended to the neighbouring Regla. Although there are signs of a better understanding of the value of its heritage the absence of a comprehensive program of intervention is also part of the situation.

Final words

In summary it has been possible to show the singular situation of urban heritage through three different cases. The example of Habana Vieja (Old Havana) shows the implementation of a successful model in dealing with heritage conservation in a holistic manner. The connection between tourism and local development strategies has achieved a synergetic interaction. Besides the singular economic setting defined for this historical centre these programmes have been supported by a specialised planning office whose role has been directly related to the regulation and fostering of sectorial and individual initiatives while safeguarding the heritage of the territory under its control. Nevertheless this successful model has not been extended to other areas of the city where Heritage also plays a significant role. Hidden Havana and Havana Central show it in a clear way. The lack of further development of such initiatives could be associated to the particularities of the urbanisation culture and model put in place since 1960, which favoured the creation of new areas instead of the maintenance of the already built ones. In a context of little expansion and a concentration of historical zones a more thorough approach is demanded.

Moreover studies and proposals such as that of Rey¹⁴ and the studies conducted by several local institutions have created the conceptual and methodological basis for the consolidation of a policy to deal with the heritage of this kind of areas. While these lines are typed the National Congress of the Cuban intellectuals Association (UNEAC) has just closed its final session. A commission of this congress addressed specifically issues related to the city as an intrinsic component of Cuban culture. Its report calls for the definition of comprehensive policy framework to save the city as a whole from deterioration and oblivion. It is a relevant contribution to the intensive debate that the update of the economic model of Island Nation has recently opened. It has put the cities as a protagonist of such a crucial process. These lines are a modest contribution to this debate.

The memory of change

Maria Ines PASCARIELLO

Department of civil construction environmental engineering, School of Engineering, Federico II University, Naples, Italy
mipascar@unina.it

Abstract

"As far as we know, the construction of the world starts from the worlds that we already have; the construction is a reconstruction. However, how the real worlds that we recognize as such really are, is an entirely different matter? Even under very restrictive assumptions, it is possible to find innumerable interpretations, all equally legitimate". In Nelson Goodman's definition, relativism appears as a theoretical concept, in which a single object can be viewed from different perspectives, all resulting from the cognitive orientation of the individual yet considered equally valid. The activity of analysis or the project of urban architecture is influenced by both a myriad of aspects of life of spatial, political and socioeconomic nature, as also by their impact on the perception that the individual has of the constructed environment.

As a subject of study, Naples can be related through an indefinite number of perceptions that are evidently equal in the level of volatility and conflictuality of the city, ever changing. Often alternative visions of the urban environment and its elements are the starting point for analysis, survey and representation of the space: from many points of view the city relates, represents and subdivides.

The continuing transformation represented by the collective structure of the city to which is entrusted the vision of urban form and an invariant design primarily connected to strategic locations, capable of providing the framework on which to prefigure images of themes and actions at all scales.

Keywords: Urban environment, multicentric vision, disclosure.

1. The reading of the city

The activity of analysis or the project of urban architecture is conditioned by both a myriad of aspects of the living of spatial, political and socioeconomic nature, as also by their impact on the perception that the individual has of the constructed environment. Like that of the anthropologist, an architect's description, which starts from relativistic assumptions, can contribute to define many-sided perceptions in order to better understand certain aspects of the human spatial experience and their unique characteristics. Moreover, it is here that the architect must differentiate himself from the typical limitations of the definitions of anthropological relativism, to formulate judgments, evaluations and priority of the perceptions in order to establish a productive dialectic that can give shape to the future urban built environment.

Naples provides a unique opportunity to study the way the architect can use the vast opinions and perceptions that define a city and how they can in many ways determine the route, which, in the spirit of Goodman's relativism, are all true: the frequency and range of the past, present and future of its space.

As a subject of study, Naples is a place that can be related through an indefinite number of perceptions that are evidently equal to the level of volatility and conflictuality of the city. Often alternative visions of the urban environment and its elements are the starting point for the analysis, the survey and the representation of the space: from many points of view the city is related, is

represented, is fragmented; the urban area, analyzed small parts at a time, is characterized by a plurality of urbanized nuclei of which settlement identities differ.

Large and small residential areas, historic centers, mixed areas punctuate a territory in which prevails a polycentric structure, where solids and voids alternate in their variable role of forming the positive and negative space of the urban fabric. The "solid" intended as that part of the city composed of districts and of the social and housing multiplicity that design the scene, on which to apply actions of analysis, projects and survey; the "void" represented by the structure of the collective city to which is entrusted the urban form of vision and an invariant design above all connected to strategic locations, capable of constituting the framework on which to prefigure images of themes and actions at all scales.

Solid and void define space, the humanistic space of the classic culture, the one enriched by time and defined and limited by objects.

Significant component of the very identity of the city, it is the added value, the aggregative, collective value, of socialization and wealth; it is the flexible space, able to continually redefine itself and to be immediately related to the physical structure of the city; it is the system of voids, in their more diverse extensive and intensive declensions, to constitute the irremissible invariant of each city, the structural backbone of urban space: the texture of open spaces, together with pedestrian walkways, squares, cloisters and mobility networks, establishes as the essential form and fundamental point of view of territory and city. There are numerous structures of relationship between solid/void that contribute to emphasize the specificity of contexts and Neapolitan districts and to make the identity of the urban structure be recognizable; Naples appears as an extraordinary kaleidoscope, dense of ideas, criticisms, opportunities in which to succeed in recognizing a multiple partition in the urban structure that allows to read the city through a more attentive point of view. Especially in recent years, the urban voids have been mostly considered as breaks or remains to be conquered from amongst the solids and not as material capable of generating the necessary quality of urban space. If the void structure of any planimetry of the city is extruded and volumetrically moulded as if it was solid architecture, an original figure will emerge from each void, a figure completely new, which allows to highlight the criticisms and opportunities that are connected.

Observing then the urban form of the void, appears clearly the necessity to put at the centre of each presupposition, analytical, descriptive, projective, the character of permeability that each urban space assumes like a material capable of strengthening the network structure of the city; it is the void, in this sense, that must ensure the continuity between the different systems - historical, formal, morphological and configurative - and, together with the services and infrastructures, that must construct the netlike structure of the city.

Recognizing a system of centrality in this sense means detecting concentrations of urban monuments which express the multiple vocations of the city both past and present, invariable in the challenge proposed by the changeability of the contemporary city and its constant metamorphosis.

The reading and interpretation of the complex Neapolitan area have requested the use of several survey instruments, the comparison with different scales of reference, the contribution of various disciplines, above all survey, privileged instrument of knowledge that enables to explicate a method of approach to space and an expressive language, of which the critical and cultural foundation is Descriptive Geometry.

This discipline helps the eye of the observer to get used to grasping, from the space in which from time to time it is inserted, configurative characteristics and morphological aspects, to understand the volumes and surfaces which compose the space, disarranging them in the mind and rearranging them in the representation; to distinguish the intersections between the planes and surfaces that border the space; to identify geometric genesis and to critically describe the significant elements.

For this the equipped-eye of the observer, the eye of the one who practices the art of drawing, the eye of the one who knows the Methods and Principles of the Representation, discomposes the space of the architecture and fragments the architecture in representation often simultaneous or overlying, which help its analysis and comprehension; once the observer has taken possession of the space and its intrinsic characteristics, he becomes a designer and reassembles the fragments of architecture in one or more images that summarize the space and express its forms and contents according to the logic and rigorous language of Descriptive Geometry.

The representation that results from the survey permits, through the powerful synthesis of which it is capable and the visual immediacy of communication that it generates, to obtain the image of "within eye sight" city: nothing is more difficult than to try and reconstruct an image of Naples, which is full of images, being inside it. Myopia prevents, hinders the vision.

The complexity of the urban experience and its continuous changes, direct function of the evolution of the reality and of the temporal context, requires an adequate and always up to date representation; the latter, never setting aside the methods of representation of Descriptive Geometry, must make a conscious and unscrupulous use of each method, and, at the same time, update them with the aim of producing images more suitable to the current visions. In fact the current process, of sudden and

continual transformation of the reality in which we live, no longer requires a static observer, rigidly linked to the flat surface on which to project the image, but requires rather a dynamic and interactive observation capable of adapting the graphic image to the laws of development, fruition and expansion of space.

The contemporary urban setting accustoms us, and more often, obliges us to uses and views of the reality that surrounds us which shift the interest of the observer from the strictly metrical and typological to the projective and topological, undoubtedly more complex to code and decode. If, from one point of view it is true that cultural, conceptual and imaginative enrichment of the modern world offers as ultimate limit a qualitatively differentiated product, it is also true that it involves a loss of comprehensibility in relation to the ever increasing level of information that it contains. Obviously the representation is also affected by this duality growing richer with new ideas, researches and reflections; history, geography, sociology, anthropology, economics, statistics, archaeology, architecture and engineering, the accompany the analysis at different scales of reference and in respect to a vast range of points of view and themes: different morphological characteristics, variable speeds of movement, different ways of living emerge from the analysis carried out in that way on the city, or better, they become the privileged reading keys. In particular living, anthropological constant of every territory, specializes in so much diversified forms and dimensions and the home becomes the preferable area of discovery, for technique and for art; when the man lives, builds and transforms a territory, in accordance with needs connected to living, the invariables which underlie each centrality and each nucleus inside the urban space.

There are different types of connections between the individual urban centralities of the City of Naples and among these and the major environmental systems composed by the suburbs, the coast, the area of the Vesuvius and the Phlegraean zone: from the pedestrian routes, to those in buses, trams or underground which connect each part of the city center, to the crossings designed by the new underground line, to Cumana and Circumphlegrea lines, from the Vesuvius areas to the coast, each portion of the territory is connected by a network which proposes to strengthen exchanges trade, developments and interactions.

"It is possible to arrive in a city from the sea as from the sky, from the land or even from underground, but once inside, you are captured. Naples is a prism and reflects all descriptions, returning them multiplied" [1], developing a critical analysis of the city that allows to explore a complex reality, consisting of heterogeneous parts, characterized by numerous typologies and morphologies, experienced and crossed in different ways according to the various places. The methodological approach and the resultant reading and interpretation, make evident the compulsory course that urban reality and life that it contains have crossed, that from unity to fragment: in the route from unique to multiple, contemporary reality has intensely transformed; today the fragment seems to prevail over unity, as a matter of fact, it has become the symbolic form of reality, the most immediate expression of the chaotic essence of urban living, the image of local diversity. Each fragment of Naples contains in itself the complexity and entirety of the unity, but at the same time each fragment differs so evidently one from another, in form and colors, noise and silence, lights and contrasts, dimensions and life, history and society, to form a unity of its own, a cell of the strong architectural, artistic, social and cultural connotation, extremely full of positive values, expression of the identity of one of the historically richest Italian cities.

The many stories, ideas, perceptions that have passed through Naples during the course of time, the numerous voices and identities that come from within as well as from outside the city, provide the material from which intellectual concepts, visions and descriptions can be generated.

Naples provokes, stimulates, scares and excites. Naples promotes debate with its own existence because it belongs at the same time to a recognizable world and to another world.

It is impossible to wander through this city without remaining fascinated by every detail of history, art, architecture, tradition; it is impossible to wander through the city without being struck by the neglect of large and small urban fragments.

Both positive and negative images of Naples have always been, such as in recent times, widespread, attracting national and international attention; like in the rounds of a boxing match, today more than ever, eyes of the spectators are glued on the city, waiting to see the outcome: some expect a dramatic knockout whilst others would prefer the old champion in difficulty to win once again.

Many recent representations of the city turn the eye on the probably sublime, the city as an allegory of failures, very often caricature of the failure of the urban. Even if these representations can partially reflect reality, it is too easily forgotten that cities are the most complex of all human cultural enterprises; cities evolve more or less slowly with the participation of thousands of individuals and the reasons of their transformations over time are almost infinite and sedimented in the historical process.

Naples is not a simple metaphor.

If you are willing to look, there are many visions of the city, serious visions, unusual visions...

Fig. 1: Whitin eye sight (photo by Claudia Iacomino).

We watch Naples from above and hope, always hope, that the design would be recomposed, become legible, whilst all around, tourists and passersby, from the balustrade of the Largo della Certosa play the same game: they try to recognize where is a certain square, a certain church, their home. They all search for the line, the route, the form.

Fig. 2: An unusual vision of the city (photo by Claudia Iacomino).

2. The method: Naples in fragments

In a reticular and multicentric vision of the city, where the single identities constitute an extraordinary resource of knowledge of the territory, the survey and representation permit us to describe an urban landscape which has no solution of continuity between solid and void and, often, between internal and external, but which is constellated by fragments which, like stars, dot the infinite space of the sky allowing the observer to be find his way and be able to recognize his relative position; in the same way, the fragments of architecture define and connote an urban scenario permitting the observer to recognize it and himself. This is the most important aspect of the fragments, to constitute a true constellation, made of architectures, squares, streets and urban fronts, a constellation, the absence of which is perceived as a dis-astrum.

Rational thought, foundation of every research of scientific type and, in particular foundation of architecture, is capable of unifying what is separate, by means of diversified disciplinary operations, method and applications; but only the representation can reach the extraordinary spatial construction capable of expressing, from space, contents and structures of thought: the image. It reveals itself as much in the relations between the objects of representation, separate and distinct from one another, as in the relationship between these and the observer; the represented space finds, or rather, is focused on the observing subject, that situated alone in the center of the visual experience, gathers its unity and comprehends its geometrical configurative structure.

The space of representation, however, always and in any way an artificial space which conceals but does not entirely embrace reality; points, lines and planes are abstract entities of the space which through the geometric language, are transferred in formal units commonly known by the name of images. But in the space stopped at the moment of the representation, points, lines and planes are released from their positional value in order to acquire relational value and, surveyed in their mutual relationships, appraised in their dynamic equilibrium and used in the proper level of belonging to the visual system, turn out to be reorganized in a new and inedited image.

From the reading of the urban area emerge differences in the habitat, in the ways of living the territory, various ecologies that form a network of urban and social geographies with specific identities at the macro and micro scale: there is a consolidated city, that is the historic city with its permanences in the layouts, in the architectures, in the forms; there is the city of the sea, the linear city made of crossing pathways, connecting lines, borders, profiles and margins.

The reading of the Neapolitan territory, as a whole of specific identities, has involved in these works the micro scale, intended as the local scale of the district, place of life and expression of the society that solicits the reshaping of urban livability, as a scale of the small architecture, of the architectural detail, that makes the difference in the identification of quality. The collection of the data, the study and survey data was aimed at the perception of the city, and the design of the cultural and social identities that it consists of, according to a logic of belonging to the place and to the recognition of a determined urban centrality.

The complexity of Naples appears in the multiplicity of the parts which constitute and describe its essence, a city, constituted internally by distinct and multiple potentialities: this approach which tries to unite the concrete experience, that is reality, with vision, finds its synthesis in the realizations of a possible observation of the city, in the translation of what, *in fieri*, our city should be, or we would like it to be. This vision has as preferential object architecture and represents it through images and designs that express the essence of the city without the pretension of designing each time, in every fragment, the whole; from the design it is possible to understand the context and to communicate situations, to achieve a critical reflection on the things that came before us, through survey we can compare ourselves to the things *cum modo*: what emerges of this is a way of being in reality with moderation expressing the need to give form to a complex spatiality according to a linguistic code that pursues the substance of architecture.

"Places have a meaning for us as they are tied to a stratification of and images that bring them to life, and that it not necessarily ours. The soul of places, the sense of their being is independent from us. But this soul is determined by their temporal fragility. Time modifies them and gives them an enchanted aura. Nostalgia, as a founding sentiment, takes control of it. Places that are not necessarily noble, puddles, ruins, fragments of the world are the sense of being" [2].

Everyone can identify himself in a place, retracing in the archive of memory events of distant times, only for having recognized in an architectural object the practical and emotional meaning of its function within the "existential space" [3].

In this way, is established a structure in terms of elementary organizational patterns which helps to face the reading and the rereading of some spaces of reference according to the concept of figurability. Everything that is objectively concrete has that property, determined by "shape, colour or dispositions that facilitates the formation of vividly identified, powerfully structured and highly functional environmental images. It could be called readability or perhaps visibility in a broader sense where, not only can objects be seen but are also acutely and intensely presented to the senses" [4].

The city therefore becomes the appointed place of this sensory experience, making tangible its own legibility in the architectural space as a representation of its memories, its history and its daily events; the symbolic-formal and evocative place that guarantees individuality and recognition of those meanings potentially present in the structure of the urban environment. The streets, squares, urban voids, recognizable by the wealth of their symbolic values, activities or functions, relate qualitatively with the constructed in a one to one manner although they have autonomous constructive and formal characters, independent from the shape, typology and characteristics of the buildings that define them. The square, which by its spatial connotation meets the needs of the community to have a place in which to carry out public and private activities, is the place where events and meet in a very strong way. The void-square describes itself as a place for excellence, more than any other urban space, because it relates to the whole through a representative image in which the monuments, the civil and religious buildings have determined its image "soaked with memories and meanings" [4]. Unfortunately and ruthlessly, the time variable modifies the signs of the shape: the squares, building and streets become fragments of different tales, it is as if this relationship between the space of architecture and the space of existence that the city has had since the act of its foundation fades away [5]. The matrix of the ancient city with its geometric centers of gravity, its and symbolic key points as archetypal and psychological references fundamental to man fades with the passing of the eras, eliminating those elements that render this place recognizable.

The perception of the existential space, intended as sequence of images from the a narrative, is on the other hand, independent from the time variable. Its memory cannot be lost because even the critical reading of urban shreds, like a public fountain, a façade, and section of street make its souvenir reemerge in our mind. It is possible to seize its configurative complexity through the interpretation of the fact itself, going beyond the material limit of the very object to build a conceptual grid of reference in which to insert each characteristic element of the place.

Operations which, only through the observation of the phenomenon and “the places where the conflict hides” [6] is able to reconstruct the system that helps to understand the architectural object. Measure and design are necessary aspects in the re-appropriation of the meaning of place as a space of stratifications of time that flow ruthlessly determining the fragility of things. Withdrawing time from the representation, recovering the corresponding image of the historic memory through the passage of lines and surfaces in the dimension of the drawing, is not the nostalgic vision of the reality of the past, but the true perception of the sense of being part of time.

Fig. 3: The interactive map of the “city per fragments” is a graphic and app for pc or tablet. If the users install this software and have to query information about a fragment, they are able to see on the screen an interactive sheet with photos, historical and geographic details, drawings, etc. For example, in the next pictures, some photos and drawing about fragment n° 5.

Fig. 4: Some pictures in the interactive sheet for fragment of Naples n° 5 (piazza Vanvitelli, photos by Carolina Graziani).

Fig. 5: Some drawings in the interactive sheet for fragment of Naples n° 5 (piazza Vanvitelli, survey and drawings by Carolina Graziani).

Such an appropriation of the city is possible by exploring it in the dimensions of the drawing through the theological consequence of geometric-descriptive methods, the ability to recall perceptual relationships that settle between the observer and the observed is attributed to the image of this space. The graphical representation becomes the dialogue between the parts of this relationship, which, through the symbolic code of graphic signs, builds the concrete structure of the architectural spaces; so the design will no longer be understood as intellectual opportunity, but as an opportunity of conservation of the memory of places with hypothetical forms which develop the ability to distinguish these spatial configurations, erased by time and transformed into fragments. Each fragment implies a strong urban identification and, forming complex relationships (one fragment with another and each with the whole) is declined and analyzed in the sign of the mixture: this re-proposes typical modalities of the city's historical evolution, at times covering the idea of "city in the city" in which each fragment expresses visual and physical relationships with the geographical morphology of the areas.

Even ballad singers, who are fascinated by the positive examples that emerge from the cities, need a synthesis in order to create an engaging story. Once again, the eye of the observer must settle on a simple vision to articulate the theme and complete the allegory.

This type of narrative gives multiple roles to the city, but that which prevails over all others is the role of place, of special identity, rich and varied like that which determines the complexity of the (eco) system. This type of narrative is a representation in which Naples designs an arch inside of which are important issues, containing attempts to answer the issues of the historic city, inside of which lies a rope, an efforts aimed at understanding, shaping and representing, therefore, the identity of the city as a system (either ecosystem or ecological system), bound to the place, context, history and culture.

In carefully reading the urban design, outlined in the fragmentation of the design and unavoidably more partial, summarized in the representation of the elements that, in various degrees, characterize the urban form, the city becomes the site of multiple narrations that compete against one another to emphasize a model, that, in this case is a tapestry and as such is built piece by piece rather than expressing itself a priori and gathers and recomposes the fragments that bit by bit are added.

Research derives from these assumptions, like the common whole of a grammar.

To study is to discover identities, represent them, give form to inedited urban centralities that cross the city and define areas capable of offering connecting spaces, useable and perceptible, linear and continuous, articulated and fragmented, made of courtyards, squares, facades, volumes, from the most variable geometry, dimensions, physical and perceptive, the most diverse at all levels, that follow one another, intertwining and opposing one another to the point of becoming a sequence of visual plans, suspended or subtending, that look out upon the image of the city and its territory.

Together with the fragments of architecture which they contain, the urban pieces, which are analyzed here, constitute the results of the collective work, and at the same time, the sum of the individual researches and experiences of a group of architects who investigated different urban episodes following an unambiguous approach beyond the scale and dimension of the object of study, with the aim of representing the punctual qualities of the single fragment and, operating in perceptive relativism, give life to a composite story of architecture and city.

Abstract

European culture acknowledges that the Italian peninsula rules supreme as regards the representation of beauty. In the collective imagination of cultured men of learning, modern Italy is a source of powerful and centuries-old religious tradition and renewed humanist culture. The fact that in the fifteenth and sixteenth centuries the main towns in Italy were crucibles of an international artistic revolution are all elements contributing to the country's fame and fortune.

This is why knowledge about Italy plays an important role in the education and training of any "cultured person" and from the sixteenth century onwards, thanks to the journeys made by diplomats and the religious, a sojourn in Italy became crucial if they wanted to complete their studies.

Actually, these journeys did not influence only these 'tourists', they also played a crucial role in changing the taste and preferences of people in their native countries. In fact, there was an 'outward bound' effect on the person who made the trip, and an 'inward bound' effect which spread thanks to the souvenirs the travellers brought home with them. The final result was also influenced by the travel diaries and art collections which were gradually put together.

The study will analyse these objects of desire from a new perspective, focusing more at length on technical objects testifying to the state-of-the-art of the architectural artefacts.

Keywords: Gran Tour, souvenir, drawing, engraving, model

1. An educational journey to Italy

At a certain point in history, just before the Renaissance, the cultural "migration" to Italy - which had always been a prerogative of the religious - began to fascinate and include seculars, albeit in small numbers. When this desire became overwhelming, and the journey could no longer be postponed, it was spontaneously embarked upon in solitude, even at the expense of one's personal safety.

Albrecht Dürer was one such traveller. In fact the artist from Nuremberg arrived in Italy in 1495 and remained for almost a year; he moved from one place to another in the north-east of the peninsula in an attempt to revive the golden age, or, paraphrasing Edwin Panofsky, to make it "regrow". Around the first half of the sixteenth century and for the next two and a half centuries until the beginning of Napoleon's campaigns which wrecked havoc in Europe, this educational journey changed from being an intellectual experience to being a sine qua non intellectual journey, one which gradually became part of the education of a European gentleman.

Historical chronicles report that it was Elizabeth I who launched and institutionalised this cultural adventure. She was probably convinced that genuine knowledge and experience in the field would make her subjects better people, whether they were part of the future ruling class or the offspring of the Anglo-Saxon aristocracy. They were advised to stay for a period of time in Austria, Belgium, France, Germany, Italy, the Netherlands, Switzerland and Hungary. Italy was the preferred country and its major cities were depicted as being the high point of this long journey. In fact, in the mind of the British sovereign they represented the 'crucible' of an absolutely crucial artistic revolution and, as suggested by Attilio Brilli, it was here that "young people came into contact with Europe". Rome in particular was considered a universal city, Caput mundi, "a mother to all, rather than a lady", an

expression attributed to Giambattista Piranesi. This acknowledgement was primarily due to the undisputed supremacy that it held over all other nations, as well as the extraordinary mix of pagan and Christian aspects which were one with its myth, a myth which involved the whole country.

The English were by far the most numerous to undertake the journey. What began like a torrent with small tributaries soon became a river. However, the river was soon flooded with travellers from France, Flanders, the Netherlands, Germany, Sweden, Russia, Poland and other European countries. Nevertheless, it was the British who wrote the first code of the Tour; in fact, apart from establishing the most important regions, they also determined which sites had to be visited during the journey, the right itineraries and educational goals. This meticulously drafted work was very successful in the eighteenth century when the community of grand tourists became the biggest, free and itinerant academy that western civilisation has ever known.

Obviously such a well-organised plan made their study programme more gripping and intriguing. In some cases it had much broader contents and they had much more to learn, for example, the history, building techniques and materials used in architecture. Furthermore, the innovative input of this 'academy' did not fade when the goal had been reached, instead it spread its beneficial effects to other fields such as diplomacy where it helped reinforce the role of ambassadors and triggered a change in the political rapport between the courts of the old continent. One consequence of this change was that a new foreign army crossed the natural border of the Alps undisturbed.

This time, however, it involved a very special army, totally different to previous armies. In fact, this army didn't come to fight, but small groups silently exploited all available paths to reach the Italian peninsula; it politely communicated with the local inhabitants in a variety of different-sounding languages. Moreover, one of the main characteristics of this army was that it was made up of representatives of the European aristocracy, well-to-do members of the middle class, intellectuals, students with grants, antique dealers and painters, or rather a new group of painters which Lord Elgin, the Abbot of Sant-Non, Lord Ponsonby, etc., considered reporters who documented the sites as well as their own emotional reactions. We will be impressed and fascinated by this army only if we are ready to use our imagination and see it for what it was: an army which for many years gave its members the feeling they could self-generate endlessly and, stimulated by the overriding desire to "see better", travelled in search of an idealised and mourned paradise, oblivious of the hardships they had to endure.

They patiently and tenaciously faced the long journeys either in a carriage, postal vehicle, on horseback or by ship - all 'expensive' in more ways than one and often adventurous. Nevertheless, for those who undertook these journeys they were a source of exciting experiences which the travellers related in minute detail, mainly verbally, but in some cases summarised in letters or on the pages of travel diaries, and as such have survived to the present day. In one way or another these experiences have passed into history and today when we talk about them we consider they are experiences acquired during the Grand Tour, an term invented to describe only this particular intellectual adventure which, after the end of the Seven Years' War and the advent of a period of peace, saw the sun set on this golden age.

Travelling through the countryside described in the texts of classical authors, this army of the most brilliant intellectuals in Europe looked for practical evidence of the education they had received at home; they visited the cities which were the symbol of culture and, prompted by the same enthusiasm, also went to small but important towns in the north, archaeological sites in central and southern Italy; they improved their Italian while some individuals with a more humanist spirit brushed up their Latin and Greek, whilst all of them tried to have novel aesthetic experiences.

The continental Tour was defined by a recent research as "a real institution which rolled into one a journey (as a prize), initiation into society, a further education course, the baptism of the senses, a managerial training programme, and devoted pilgrimage". In practice it is a sort of transversal culture class which is important to understand how people saw the historical and archaeological sites in Bella Italia, but also assess the way in which these landscapes were interpreted.

Obviously the indifference and hostility displayed by Erasmus of Rotterdam for the cult of beauty - which led him to say "Rome no longer exists, it is nothing but ruins and rubble, traces and remains of its ancient misfortune" - can be considered an exception probably due to his lack of artistic education which made him visually insensitive, like many learned and erudite men of letters before and after him. In fact, starting in the fifteenth century many illustrious men and artists from countries beyond the Alps travelled to Italy to "drink" at this spring: apart from Albrecht Dürer and Erasmus of Rotterdam, we can cite Philibert De l'Orme, Miguel de Cervantes Saavedra, Michel Eyquem de Montaigne, Jean-Louis Guez de Balzac, George Berkeley, Johann Joachim Winckelmann, Johann Wolfgang Goethe, Gaspard Monge and later John Ruskin, and many more. Some were so enthralled by the art and life in Italian cities they crossed the Alps several times, others becomes residents, still others Italianise their name and never returned to their native country, for example Gaspar Adriaensz van Wittel, father of the architect Luigi Vanvitelli, a talented artist who left numerous pictorial images including many paintings of the Roman countryside, Rome, and the banks of the Tiber in the city.

The Grand Tour didn't affect only to those who actually did it; it became a key factor in changing the tastes and preferences of people back home. In fact, this cultural phenomenon has an 'outward bound' effect on the person who made the trip, and an 'inward bound' effect that spread like wildfire thanks to the objects the travellers brought home with them. The final result was also influenced by the travel diaries and art collections which were gradually put together. In fact, the diaries allowed people who didn't personally make the journey to experience this adventure, while the collections were a sort of status symbol for the European upper class and a way to portray Italy to anyone who saw them.

As mentioned earlier, educational journeys stopped for a while with the advent of Napoleon's campaigns; they started again with renewed vigour after the Congress of Vienna when the European continent could once again be travelled by civilians, especially the British who really wanted to travel abroad to develop and improve their minds.

However, the trauma of the Napoleonic wars not only interrupted the list of illustrious individuals who participated in this cultural institution, it also marked its demise, or rather the demise of the Grand Tour as an aristocratic institution. In fact, journeys in the nineteenth-century were radically different: the habits and ways in which they were conducted are more similar to modern journeys rather than journeys in the eighteenth century. The first locomotives and the fact tourists travelled in groups was irrefutable proof of this change. The continental travels of European nobles confirmed that luxury was an adjective used for the Grand Tour and its participants when, as we know, Italy was the star attraction of their educational itinerary, the last leg of their return journey home. The impatience that marked their outbound journey to the "land of the classics" was replaced by the haste of those who felt they had completed their pilgrimage and therefore rapidly passed through the Swiss, Austrian, German and Flemish cities on their route. However, whatever their nationality, and notwithstanding the city in which they ended their educational experience, their travel notes were always full of long and vivid memories of Italy. At this point please indulge me if I use a rhetorical phrase since one example says it all: the words by the English writer William Beckford in his letter dated Ostend 21 June 1780, in which the warning voice of the Bear-leader echoes ironically: "Ghent is not the most likely place to recall his attention; and I know nothing more about it, than that it is a large, ill-paved, plethoric, pompous-looking city, with a decent proportion of convents and chapels, monuments, brazen gates, and gilded marbles. In the great church were several pictures by Rubens, so striking, so masterly, as to hold me broad awake; though, I must own, there are moments when I could contentedly fall asleep in a Flemish cathedral, for the mere chance of beholding in vision the temple of Olympian Jupiter.

But I think I hear, at this moment, some grave and respectable personage chiding my enthusiasm – "Really, sir, you had better stay at home, and dream in your great chair, than give yourself the trouble of going post through Europe, in search of places where to fall asleep. If Flanders and Holland are to be dreamed over at this rate, you had better take ship at once, and doze all the way to Italy." Upon my word, I should not have much objection to that scheme; and, if some enchanter would but transport me in an instant to the summit of Ætna, anybody might slop through the Low Countries that pleased".

2. *The industry of memory: souvenirs*

During this 250 year period the European elite considered the tour– which towards the end coincides with the age of Enlightenment – as a journey of discovery and curiosity; it satisfied their desire to escape fuelled by the appeal of classical culture and boosted by the spirit of observation of Bacon's "new science", or sometimes the historiographic mentality of the French or Germans.

As mentioned earlier, the members of the "itinerant cosmopolitan academy" considered Rome and Italy as much more than the one of the obligatory 'stops' on the Grand Tour; they were considered the *communis patria*, the magical circle in which to be reborn to new life, or rather, the place where you could find your real self or change "to the very bone", in the words of Goethe - perhaps the most representative member of this academy. So for these individuals, Rome and its hinterland were places of unique incomparable beauty full of *mirabilia* which conveyed "a sense of peace", to use Goethe's words; they were places where if you stopped while walking you would see "all sorts of panoramas, buildings and ruins, gardens and scrubs, broad horizons and gorges, small hovels, stalls, triumphal arches and columns [...] which would require a thousand etchings to describe them all"; again citing Goethe, these are places "in which you learn to take pleasure, learn and do".

This sense of inner peace, absolute well-being and rebirth described by the German poet prompted several enterprising travellers to launch expensive excavation campaigns. After many thrilling and exhilarating finds, and aware of the fact that the best journey in Italy is actually to live there permanently, they began to want to own some of the excavated objects as a memento of the endeavour they had accomplished. In practice, this is initial spark that led to the collections of archaeological artefacts put together by the grand tourists. This kind of activity was originally carried out by learned individuals well introduced into the top ranks of the Roman ecclesiastical hierarchy: in fact, when asked by the individuals in question, these priests used to ask the pope for permission to collect historical artefacts. However it very quickly became a passion that gripped an increasing number of tourists, we could even call it a "sickness", a fever which infected everyone, including Italian nobles

and the middle class. Even poorer travellers succumbed to this temptation and bought historical artefacts for themselves and/or on behalf of their patrons of the arts.

Eighteenth-century Rome was also the city in which the popes started their own archaeological collections and created others open to the public. But that's not all. In keeping with the legacy of the great renaissance popes concerning the protection and safeguard of historical heritage – which began with the bull “Etsi de Cunctarum” by Pope Martin V in 1425 – the edict by the camerlengo, Cardinal Annibale Albani, dated 10 September 1733, forcefully reiterated the rules which in Rome regulated the trade and export of archaeological artefacts, and in some cases the right of first refusal and ensuing purchase by the papal collections. In his act Cardinal Albani writes “the conservation of which [artworks] not only inputs considerably into sacred and profane knowledge, but also encourages foreigners to visit, see and admire the city [...] creating great advantage to the public and private good”. Reading it today this excerpt is very moving and exciting because it is the first real written acknowledgement of the importance of artistic heritage as a way to publicise the city and increment its economy; an awareness which, more than any repressive action, has left a mark on the consciences of the Romans, I'd even go so far as to say, on the most humble who are only either marginally or not involved at all, but above all do not understand its importance. The words of the camerlengo are not, therefore, a coincidence but a lucid consideration. This approach was reiterated by the next cardinal Silvio Valenti Gonzaga on 5 January 1750; it was a bull which was to remain the legal tool on this issue for roughly a hundred years.

In short, the Eternal City was not ready to be plundered and reacted strongly. This strong reaction, based on traditional government deeds, was boosted by the long-sighted vision of several representatives of the “Republic of transnational Arts and Sciences” located in the capital, for example the archaeologist Antoine Chrysostome Quatremère de Quincy, who dared – even though he was a Frenchman – to fight against the plundering perpetrated by the Armée française in Italy; he illustrated his position in his “Lettres à Miranda” (1796) containing of the most moving and eloquent pages about the “Museo Italia”.

In the above-mentioned situation, very few people could legally trade ancient Roman artefacts. Then new ideas began to flourish: historical artefacts were no longer seen as a saleable common heritage and as a result sales began to drop. Tourists with the right contacts were able to continue for some time due to the enormous sums of money they were willing to spend to obtain the authorisation they needed to export these archaeological artefacts. The Holy Father only granted these authorisations to famous people who asked for them, especially if they followed the doctrine of the Roman Catholic Church. Obviously this ‘closing down’ of exports and the ensuing transitory phase caused the market prices of these archaeological artefacts to shoot through the roof, forcing most enthusiasts and collectors to look elsewhere.

It was in this scenario that coins, books, Etruscan vases, musical scores, maps, urban plans, marble and bronze replicas of statues, and the images of beautiful views of the city and its hinterland became the objects of desire, the souvenirs in the collections. Furthermore, plaster-of-Paris replicas of architectural ornaments were also popular because, as Quincy put it, they “faithfully reproduced the work of the chiseller”. These unique low-cost objects captured the attention of scholars of architecture and building techniques more focused and sensitive towards the human and manual execution of these works.

Etchings became increasingly popular thanks to the remarkable communication skills of their graphic artists who produced extremely elegant images which, since this was the century of enlightenment, were considered modern. In fact the etching techniques, already used when Giorgio Vasari was alive, was revived and reused specifically for this purpose. The men and women of the Grand Tour eagerly bought up these works, these “views”, these illustrated stories which unlike picturesque images faithfully reproduced the landscape as it was, with all its historical, social and formal features. Etchings were very different to the picturesque genre because the artists who used it focused mainly on architectural subjects and created graphic images which provided intense aesthetic pleasure.

Obviously we too find pleasure in the architectural features of these subjects and the ability of their authors, but a lot of our pleasure is due to the graphic moderation with which they were made. This was achieved by using simple layouts and well-studied narrative registers which nearly always provided a perspective view of the architectural object in the centre, either drawn or represented in the foreground or immediate foreground. Furthermore, the image was sometimes embellished with an exceptional scenographic depth emphasised by the wise use of light and shadow, as well as outlines, while the rest of the space in the image is full of movement and life. The latter, perceived through the lens of the “scale” effect, tends to make human figures smaller compared to natural and architectural objects so that the latter appear more majestic than they really are.

It's important at this point to recall that, compared to all other artists who used this expressive medium, Gianbattista Piranesi was the one gifted with the most exceptional graphic talent and absolute control over the etching procedure. The maestro from Mojano di Mestre was accorded this accolade due to his unconventional etching technique (he considered the copper plate a “sketchbook”) and, of course,

the many artistic works he produced during his lifetime. In fact he is universally famous as one of the greatest interpreters of the city of Rome. His works and favourite subjects - archaeological sites, historical monuments, buildings and urban landscapes, as well as the hinterland around the Eternal City - are still very popular. However there are other things which make this artist unique.

When you look closely at his prints you realise that Piranesi's Rome is different to the one depicted by other master burin etchers. In fact, his Rome seems to be portrayed using the eyes of the poorer classes, a city where everything is alive and aggressive: vegetation attacks the walls, the walls attack the heavens, and men, minute human beings, live their miserable lives or merely survive in the shadows of huge architectural objects while (one example suffices) in the Rome narrated by his teacher Giuseppe Vasi the viewer has the impression that everything is immobile, that everything represented in the scene is there as if it were a static object. In the words of Maurizio Praz: "His [Piranesi's] burin etching speaks the language of Rome, while Vasi's speaks an international language, the Esperanto of landscape painting". In other words, we can say that Piranesi's Rome is the city of the centre of the Catholic world as it appeared in the eighteenth century to someone from out of town; the one depicted by his teacher is a eighteenth-century city, any eighteenth-century city, only later did it become Rome.

Apart from the rather obvious difference between the *modus operandi* of the two artists, the teacher and the pupil, the most important thing that emerges from this comparison is that the two artists each embody a different role. As an engraver Vasi bent his intellectual energy to meticulously applying the operational methods inherited from the past and was only fleetingly interested in developing new etching rules; Piranesi, instead, was fascinated by experimentation and exploited this new approach. In order to achieve the final image he developed an unusual method based on a technical device which involved superimposing several etching veils, each of which with a different visual importance. It was a conceptual rather than practical choice that Piranesi experimented with and adapted tirelessly every day to try and make graphic representations reflect what his mind saw, i.e., he simultaneously considered the subject from several points of view: as an architectural, spatial, ideal, passionate, cultural, documentary, and functional topic, as well as anything else that passed across the visual radar of his versatile mental observatory, an observatory that was so unusual his contemporaries considered it impossible.

Earlier on we learnt that copies, plaster casts, terracotta and etchings were turned into the objects of desire required to satisfy the demand of grand tourists for souvenirs. However another expressive medium was used to satisfy their demands: the model, a three-dimensional scale representation which, amongst other things, could not compete with the "mechanical" traits of other systems. This communicative tool is based on reconstruction - objects made by craftsmen. But that's not all. Since these objects are separate from the real object and all the details are well-defined, they are unique pieces, real works of art. Of course, this aspect didn't escape observant tourists, so models became one of the unique traits of the souvenir industry.

Chronicles tell us that it was Augusto Rosa who had the idea of making models of Roman monuments and selling them. We can date the invention of models to 1772 when the craftsman made cork models of the temple of Jupiter Tonans and the Flavian amphitheatre.

Naturally, the fact that the supply of original antique pieces finally ran out cannot explain the advent of cork architecture, known as "folloplastica", because a huge repertoire of etchings existed and could still satisfy the demands of both scholars and enthusiasts. Moreover, preliminary research and the actual making of the models was very lengthy, which made these physical representations so expensive not everyone could afford them. So obviously there were other reasons why models became popular. For example, at a certain point clients preferred to have a smaller reproduction of the real object, an expert reproduction of the real thing. This heralded a change of taste compared to Romanticism: education appears to have taken over from interest in picturesque renderings. Furthermore, producing physical models was an implicit criticism of traditional representation models. Enthusiasts have trouble interpreting plans, sections and elevations, while a perspective view provides surprising proportions and even the perspective itself. Whatever the case may be, the fact remains that as soon as the model appeared on the market it became the souvenir which, more than any other, attracted the attention of onlookers, even those who were not culturally erudite; it became the most sought-after object by tourists, especially tourists with lots of money in their pockets.

Giovanni Altieri, Carlo Lucangeli and Antonio Chichi were the most famous of Rosa's successors. Giuseppe Tambroni names these craftsmen in his publication "Rapporto sullo stato delle Belle Arti in Roma nel 1814", a goldmine of information about the antique industry and souvenirs. Unfortunately, although these artisans were very prolific, only very few models remain to bear witness to their skills and all, or nearly all of them, belong to European museums and institutes. However, the archival documents regarding these material representations are not always complete. In fact, apart from objective data, we know the whole story of some models, but are unaware of the history of others, while for yet other models we only know the names of the private collections where they came from.

The works of these three Italians belong to this last group. For example, we are familiar with the works by Giovanni Alteri thanks to the models of the Temple of Vesta in Tivoli, housed in Soane's Museum in London, and the Temple of Concordia displayed in the Musée des antiquités nationales in Saint-Germain-en-Laye, while the models of the Flavian amphitheatre are housed in the École des beaux-arts in Paris. We can pleasantly appreciate Antonio Chichi's works thanks to the models of the Temple of Fortuna Virilis, housed in the Musée des antiquités nationales in Saint-Germain-en-Laye, the Temple of Vesta in Tivoli, the Pantheon, the Temple of Castor and Pollux and the Basilica of Massentius, all housed in the halls of the Museumslandschaft Hessen Kassel, in Germany.

In his book Tambroni writes: "a traveller who loves Antiquity is sometimes quite happy to take with him a smaller version but exact copy of the monuments he has admired". The fact that cork was very lightweight and easy to work with made it the material of choice to make faithful and easy to transport models. However Tambroni also explains "nothing more than cork resembles the stones and bricks corroded and broken by Time"; this was certainly not a secondary consideration when the craftsmen chose their material. Chichi was an expert in taking advantage of these characteristics. The way he exploited the irregular perforated surface of the cork to replicate the worn marbles, bricks and travertine, is quite exceptional and breathtaking. So it's not surprising that individuals such as the landgrave of Hessen Kassel or that of Hessen-Darmstadt spent any amount of money to get their hands on the whole series of thirty-six models Chichi was able to produce.

Rosa's idea was remarkably successful and continued to be popular until the early nineteenth century, first in Rome and then in France, at least as regards antiquities. In fact, in Stendhal's book, *Memoirs of a Tourist*, the French author writes: "Night had almost fallen when we arrived at the studio of Mister Pelet. It's beautiful. Mister Pelet, a tireless scholar, had made cork models of the Roman monuments in the south of France. One could not see a more skilful or exact imitation. These models, all executed to the same scale, enabled me to have an idea the comparative size of those monuments for the first time; the scale of Mister Pelet's beautiful buildings is one centimetre to a metre. I saw with astonishment that the Arch of Triumph at Orange, a gigantic work, would easily pass under one of the lower arches of the Pont du Gard".

3. Conclusions

We all know that figurative narrative and literary narrative are represented in a very different way, but the synchronism created between visual and verbal images coagulates in the mind of those who see an image or read a text. Like a game of mirrors, the two works confront each other along a common axis of balance: the draughtsman looks and describes what he sees using graphic images, the man of letters describes it by juxtaposing the letters of the alphabet using grammatical rules; pen and pencil are probes to provide us with knowledge and remind us either of our material surroundings or of an imaginary image which becomes real the moment it is drawn or narrated. In actual fact, if we once again turn to the graphic image we feel that the above-mentioned consideration could be improved or at least I perceive this state of consciousness more in this kind of narrative. But let's get back to the case in point.

In graphic reality an image multiplies its values and becomes a mnemonic footprint, a documentary artefact prior to a work of art and, finally, a completed work of art. It mediates between tangible experience and the vagueness of a recollection. Obviously this role is activated automatically, whether the image is understood by those who emotionally experienced it in person, or whether it is but a graphic, real life interpretation by a professional draughtsman rather than one's own work. Actually when I come to think of it this consideration reminds us that the relationship between the tourist with a first-hand perception of the landscape and its graphic image is based on a purely temporal movement which requires a before and after, direct experience and its memory. It also contains another mostly spatial possibility that turns the drawing into a mediator between here and there - a distance that can only be virtually overcome.

Continuing along these lines we also discover that another relationship is created between the observer and the mediated landscape; in fact we realise this because we've talked about it in this paper. I'm referring to those who weren't able to see the real views. Obviously the relationship between the souvenir and the observer is based on new elements: in fact, it is not linked either to the direct visual experience or to the practical action of drawing, in other words, it does not involve the temporal movement linking the two previous combinations. This is rather unique because not only does it make the relationship special, it safeguards the graphic works against the persuasive, if not coercive action of the emotional component of direct experience. This complete freedom to express a critical opinion is something tourists also do, especially the ones who are not experts in interpreting graphic works and just want a souvenir. Since the cultural background of the art of drawing is still only based on its realism, this allows individuals with a smattering of culture to express their opinion with "solid judgement" (paraphrasing Goethe), bearing in mind only the appeal of the works and, as a result, the expressive skills of the authors.

The etchings to which Goethe refers in his conversations with Johann Peter Eckermann, and before that in his famous book *Italian Journey* – the ones his father Johann Caspar had displayed in the hallway of his home after returning from Italy – are works which belong to this category of drawings, executed to please a learned public, but also able to make people, especially more sensitive individuals, reflect on the transitory nature of human life. However, given their technical features they are also highly cultural drawings and therefore valuable communication tools for architectural scholars, both then and now. In fact, they bear witness not only to the continued existence of the ancient structures (illustrating their state after the repeated ravages of time and the plundering performed by man), but also to new artistic architectures. These two aspects are the main culprits responsible for the “traumatic” state in which “seeing” tourists – the ones with an artistic education - find themselves in when they are in Italy. A state of intellectual frustration because they realise they lack knowledge, a state that prompted Goethe to write one of his most meaningful passages in which he declares his love for the Eternal City: “Now I am here at my ease and, as it would seem, shall be tranquillised for my whole life. For we may almost say that a new life begins when a man once sees with his own eyes all that before he has but partially heard or read of”.

Multiple factors are responsible for the popularity of the other souvenir illustrated in this paper - the model - amongst the European gentry who undertook their educational journey. Apart from being a handmade object acknowledged as a work of art and a tool that satisfied the tastes of tourists because it allowed them to embrace a complex ensemble “at a glance”, this expressive medium caught their eye because it was particularly effective as an educational tool.

Its importance in this fundamental role is due to the fact that the final result was easier to make than any graphic representation since the latter are much less intuitive and require greater specific knowledge in order to be interpreted; an education that tourists almost always lack. This is due to a basic trait of the model coupled with its material three dimensions which remain the most important: simplification of its elements. When this process is implemented during the construction of the model it helps those who see it later to appreciate the characteristics of the architectural object, especially the characteristics which are emphasised and which in the real object are jumbled together with its countless other attributes. In other words, the model is very abstract and this abstraction involves many of the traits of the real object such as: size, materials, colour, and ratio between the parts. A sectioned model allows us to examine the interior and exterior, elevation and foundations, and appreciate the ratio between the elements - something that in real life is very difficult to perceive. The less an observer has to understand, the easier his task: so the greater intuitiveness of this expressive medium is counterbalanced by a totally different characteristic: abstraction. A game of balance which tourists apparently appreciated.

I'd like to end this paper by remarking on the effect that this cultural institution had on Italy and especially on the spirit of its inhabitants.

The Renaissance gave birth to the country we call Italy: it became a real nation with its good and bad parts, contradictory ambitions and magnificent artefacts. Although we cannot say we have got past the stage of indicative evidence, I believe that there's a hidden path that runs between the concept that Italy is a modern nation and this itinerant cosmopolitan academy. In fact, the more research I do, the more I'm convinced that every European nation had contributed to the awareness that Italy can be a “real country”, and that an important contribution has come from the tourists who arrived in Italy to “get a better view”. Cesare de Seta reminds us that during the eighteenth century the country called “*Las Italias*”, described by Miguel de Cervantes with authoritative talent, developed into a country, Italy, with a spiritual unity and common conscience, considered as the motherland of the spirit, a place of the mind, and a source of imaginative creativity.

Summary: These papers begins with a reflection on the importance of handmade embroidery as Colombian cultural heritage and centralize Cartago as a site of cultural interest and recognize hand embroidery and shaft collective identity to the world. This way of thinking is reflected in the embroidery of Cartago Valle del Cauca Colombia: the methodology of this paper is divided into four (4) areas: Property heritage, cultural tourism and employment opportunity to native families in the region, heritage Cultural function of craftsmanship and hand embroidery on this native of learning a new craft in ancestral generations and local collective identity as a strategy of cultural manifesto of the town to the world.

Cartago on the national scene is displayed as a collective identity in the work of Cartago embroidery; this because it is a collective construction is definitely a cultural sign that urges a recognition, preservation, dissemination and state protection in the case of Colombia by the ministry culture. As seen above, it does project applicant based on the enhancement of the case in question, some results are reflected in invitations to present at national embroidery samples events. This paper develops through me one ideographic presentation.

Introduction: San Jorge de Cartago also known by the village of Robledo is a city founded in sixteen (XVI) century by the Spanish forward Jorge Robledo , a distance of one hundred

and eighty- system (187) kilometers from Santiago de Cali 's capital department of Valle de Cauca, with an average temperature of thirty (30) degrees Celsius and approximately one hundred twenty thousand (120,000) inhabitants seizure history of San Jorge de Cartago starts as second foundation in year 1540 , where is your current location, (is moved from the site where today is Pereira) due to the constant attacks of the natives of the region, as a colonial city inhabited by illustrious descendants of conquerors , here a palace constructs for the Viceroy of the time however this character never visited the mansion at the time of emancipation Colombian Republic eighteenth to the nineteenth century this small town plays an important role as its strategic location will make it vulnerable to constant visits of Republicans fighting for independence from Spain as the realistic who are in favor of the Spanish crown, in the first half of the twentieth century along with other nearby cities are home to violent attacks by political rivals birds were illegal armed civilian supporters of the Conservative Party fighting for the power asent Laureano Gomez after the death of liberal leader Jorge Eliecer Gaitán, in the 60's , 70's and 80 's is Cartago is prey to all guerrilla attacks from groups like the M19 , or Farc Ep and in the nineties the city suffers violent social corruption by drug trafficking, conflicts still affect socially San Jorge de Cartago , but a group of women heads of households struggling to preserve, protect , and exploit economically difundralir as a source of work, hand embroidery , thanks to this handmade craft dating back approximately one hundred (100) years ago in the region, Carthage , is recognized in the country for this job the called : embroidery Carthage by its delicacy , beauty and fine finish , in spite of having in his district six (6) well known in the region goods and three (3) of these also declared national heritage of the historic center , this historical importance is not known or reported in the country.

The city contains a group of buildings with building characteristics of republican architecture in Colombia , with an urban history dating from the sixteenth century , (3) three of them declared as National Cultural Property Interest by the Ministry of Culture House of the Viceroy or Sebastian Marisancena House or Casa de La Cadena, Guadalupe Church , the railway station and the historic center protected under Law No. 163 of 30 December 1959 containing beautiful buildings such as the Church of Santa Ana, St. Jerome Church, Cathedral of Our Lady of Mount Carmel Patron of Cartago , San Francisco church , the house of culture, among others, unfortunately by the abrupt introduction of misunderstood modern movement architecture of the city of 1957 when it is protected by law 163 are few traces of native storey houses with traditional building systems such as rammed earth and adobe, covered with straw and clay tile are today very few streets with these features that are in the vicinity of the Cathedral of the villa.

The ancestral activity of hand embroidery which passed by several generations of leading the Probordados association has national recognition , the main intention of this group is to implement the chair of Hand Embroidery area schools for free and opportunity to narrow to Cartago as a cultural tourism site of international interest.

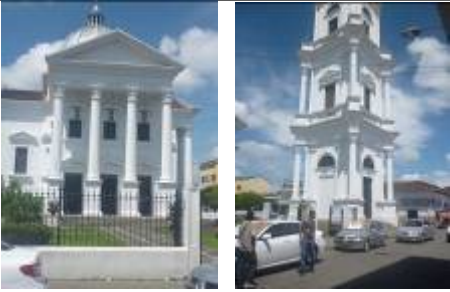

The methodology of this paper is divided into four (4) areas:

1. Heritage property:

Cartago is located 117 Km from the capital of Cali Valle del Cauca department , with a warm dry climate , the foundation and first performed in 1540[1] by Jorge Robledo today Pereira and the Second in 1691 by the architect Juan Mendoza priest where today located beside the Old river, a Town with an important role in the history of Colombia since the arrival of the conquerors; Within the Schedule of

National Cultural interest Cartago has a significant representative sample BIC are 6 properties held by the Ministry Culture of Colombia , as well :

2. The cultural heritage in terms of craftsmanship and hand embroidery on this native of learning an ancient craft in the new local generations:

Hand embroidery in Cartago Valle basically in workshops where the workforce are women heads of households* and people who work for the workshops but can not leave their homes 98 % and 2 % male, the teaching the various techniques such as kickstand, rococo, broken blade (among others) is fundamentally grounded in trust, is an office of entire families from generation to generation, in some cases close friends who can dive into the world embroidery , each piece is conceived , designed, implemented by hand.

Fig.1:Artisans Workshop Ma. Patricia Ramirez. [10]

The Bordado technique comes with the conquerors and settled in the Indian labor in the recent history of Cartago its roots back 100 years in religious communities with embroidery arts classes taught in the city with the highest number of workshops known commonly called the street of embroidery located in

between the fifth and seventh 8tva and second in tiny little shops on 4th Street between the first and second race.

Fig.2:Street embroidery.  

Some of these stores like Hats or Patricia Ramirez y Emma Ramirez Icontec have the stamp in Colombia is a recognition for quality in their work.

Fig.3:Street embroidery

Fig 4: Stores in advertisements Street embroidery.

In this query, we visited two workshops on various proposals, but the essence of the work in hand embroidery, embroidery workshop Emma with a more classic air shows his gallantry in this classic style clothing shop with a 60-year tradition casts its quality management is a solid proposal with

standard techniques of embroidery, the owner is Mrs. Emma Ramirez dedicated his life to the family business is one of the pioneers in the city at this craft show of wealth.

Fig 5: Hand embroidered detail Embroidery Emma pieces.

Embroidery Workshop Ma Patricia Ramirez venture into a new proposal in terms of art, colors and designs, bold proposals shown in accessories, clothes, bags, cultural handicrafts while renewed spirit based samples with your proposal has been exhibited in several national events handicraft exhibition as entrepreneurs in export craft fair FEREX, expotejidos, fashion circle in Bogotá, flower fair in Medellin, among others, this workshop has won awards for best artisan silver needle 2011, 2012 and 2013 with needle Gold issued by Probordados.

Fig.6: Hand embroidered garments Workshop Ma Patricia Ramirez.

In order to establish itself as a guild workshop some of Cartago Probordados join the association with an experience of 20 years * this association has three objectives: 1 - The organization of Cartago expobordados held every year at Easter, 2- Ensure the quality of craftsmanship of its members and 3.- coordinate the selling point for those who do not have their own local allies.

Fig.7: Celmira Velásquez y Patricia Ramírez Probordados Association representatives .

Probordados detects a phenomenon that threatens in question, which is the decline of the labor involved in learning, practice and embroidery that these techniques work in this regard, the association aims to lead in the department the chair of Cartago embroidery in private and public schools Probordados invites researchers and professors at the University of Ibague to promote embroidery heritage of Cartago of as Colombians, in particular an interesting dialogue between the community, the university / research and state .

Raises the following curriculum is based on the Department of Embroidery in the last 4 years of high school:

Technique	Course	Heritage	Course	Practica	Course	Practice paid	Course	Practice paid
Knowledge and appreciation of embroidery as equity. Apprehension of various embroidery techniques	Eighth secondary Semester A	Historical research techniques.	Ninth secondary semester A	Practice in small clothes	Tenth secondary semester A	workshop	Once semestre A	workshop
Past, rococó, bite tip, chain stitch, lace, shadow, French knot, kickstand.	Eighth secondary Semester B	Investigación del los bordados de Cartago como patrimonio.	Ninth secondary semester B	Internships in workshops	Tenth secondary semester B	workshop	Once semestre B.	workshop

3. Cultural Tourism employability as native families in the region and Cartago as a cultural tourism site of international interest:

Cartago suffered a serious story on behalf of drug trafficking, where I filter many areas of society today because of the resistance of the craft, embroidery, translates as the basis of the economy of the municipality where native families in the region working in the activity; the city contains the necessary ingredients to make it a place of cultural interest:

Attractions	Cultural places	Heritage Property	Heritage Intangible	Tangible heritage
Mayoralty Cathedral of Our Lady of Carmen. Island Park The Old River. Landscape and biodiversity in the region	House of Culture Viceroy's House and Historical Archive of Cartago.	Viceroy's House Churches of San Francisco, Santa Ana and San Jeronimo. Historic Center. Railway station	The craft of embroidery. the typical meals	Embroidery and techniques.

↔ Cultural Tourism:

Intangible Heritage	Exibicion	Place	Education	Accommodation
The craft, embroidery techniques	Art exhibition with hand-embroidered garments.	Visits to artisan workshops	Teaching and learning the techniques of hand embroidery.	Workshops or affiliates probordados offer hosting visitors.

According to Decree 763 of the Ministry of Culture Cartago embroidery is part of: Symbolic and aesthetic value to the value criteria of representativeness and socio cultural context and forms part of

the integrity and authenticity primarily on the traditions, techniques and management systems. The Convention for the Safeguarding of the Intangible Heritage of Cartago embroidery falls in Article 2, c) social practices and [3]e) traditional craftsmanship. [4].

4. Collective identity as a strategy of cultural manifesto of the town to the world:

What strategies proposed [9] to expand Probordados as a revenue source of Cartago, in order to promote the city as a place of cultural interest?

First day:	Day Two :	Third Day:
Santa Ana Airport Arrival The tourist meets his young host lookouts heritage are graduates of the class of embroidery.	Tour Workshops	Teaching technique embroidery.

Nights accommodation in an embroidery shop in town	Nights accommodation in an embroidery shop in town	Departure airport santa Ana.

Conclusions:

Embroidery Cartago underpin the identity of San Jorge de Cartago today, ie today Cartago is known for her masterful sample; embroidery means the identity of the place, the previous discussion shows that the embroidery Cartago must be designated as intangible heritage Colombia.

The embroidery of Cartago Valle del Cauca Colombia is a "culture of resistance" based on a trusted network based on the family relationship.

Cartago Valle has the characteristics to become a site of international cultural interest, to achieve this you must create, manage, train and reporting structure for tourism from government tourism offices to the people involved visitor personally.

Thanks to all the people who made this presentation.

In memory of my nanny Luz Angélica Playonera, thanks for the companionship and unwavering loyalty. Maria Fernanda Garcia B.

Lands of Taste. 'Still-life' ways in Southern Italy from the Antiquity to the XVII Century

Valeria DI FRATTA,¹

Abstract

The purpose of this paper is to analyze the cultural phenomena that led to the birth of the genre of still life painting in the modern era, focusing the attention on the dynamics that developed in Southern Italy from Antiquity to the XVII Century. Starting from the first evidence in the Pompeian painting, through a series of iconographic comparisons, it is possible to guess that this figurative tradition has been transposed and then extensively reworked by the modern Neapolitan painters of still life, with an outcome of such thickness as to give a particular prestige to the genre.

The historical continuity and the success tied to these themes is undoubtedly to be traced in the traditions and customs, the knowledge, the symbolic, magic and religious rituals which the people of this region has elaborated over time in relation to food, its ways of consumption, and to the seasonal works in agriculture, fishing and hunting related to it. This cultural process has undoubtedly contributed to define and strengthen the "place identity" of those people, who, since ancient times, used the visual representation of the riches of the sea, the earth and the sky not only, with a propitiatory value - as an expression of the divine grace and of the abundance bestowed upon them - but also, even though unconsciously, as an affirmation of the identifying characters of a specific environment, of its typical food and its cultural traditions.

Keywords: Still-life, Pompeii, Naples, Intangible Heritage, Collective Identity

1. Section

Food is an essential part of an heterogeneous system of symbols through which man represents himself. By transforming the shape of food and by giving it a value, the human being goes beyond the mere need for nutrition, that he has in common with other animals, and expresses his inner nature and the relationship with the outside world. Food is also at the origin of the cultural diversity, that characterizes us as a species.

Each ethnic group establishes its own identity not only through that food which represent its primary edible source, but also through special food that periodically interrupts the rhythm of the daily living, in a ritual manner and with a cadence that recalls the natural cycle of the seasons. Social relationships are formed and reinforced around these rituals.

Fig. 2: Giuseppe Recco, *Squid, sea bass and other fish, buckets of copper, a basket of oysters and two fish on a stone*, Private Collection

As a tangible sign of cultural diversity, food is a means to identify the habits and customs of a society and to distinguish the communities who live by hunting and harvest from those who practice agriculture, between town and country, or social groups.

At the origins of civilization, food was also a means to build a relationship with the afterlife: periodically offered to the Gods in order to obtain their benevolence, or placed in tombs to accompany the journey of deads. With reference to this symbolic system, it has been assumed that the birth of still life representation hails from the use to equip the tomb with a set of objects and food for the life hereafter. From the V Century B.C., in the tombs of the Greek and *Magna Graecia* area, the real food, for its perishable nature, was replaced by its representation, in painting or pottery, and, perhaps, in wood and wax, too. This substitution mechanism was extended to other ritual spheres in which the offering occurred, especially that of the worship of the deity [1].

Furthermore, great significance had, in Greek culture, the dining and the rituals associated with eating and drinking, which constituted one of the most important forms of socialization. Since the archaic age, the practices of the *symposium* and the banquet, the hospitality, the feasts, both civil and religious, were ritualized to the point that participation in them was a way to manifest the sense of belonging to the same community group. From ancient sources we learn that the people of *Magna Grecia*, even more than the Greeks of the mother country, had a particular fondness for the culinary arts, also for the abundance of food enjoyed by the region.

Indeed, we know that one of the main causes of the colonization of *Magna Graecia* by the Greeks was the finding of fertile lands, that were scarce in *Hellas*. The economy of the *Magna Graecia* cities was based mainly on agriculture, especially on the cultivation of wheat, olives and grapes, as demonstrated by the large spread of the agrarian cults of Demeter and Kore, of Athena and Dionysus.

Fig. 3: Giuseppe Recco, *Fish, squid and copper basins*, Private Collection

Fig. 4: Giuseppe Recco, *Fish and shellfish*, Musée Fesch Ajaccio

The most popular products in *Magna Graecia* were cereals, vegetables and fruits, which were eaten along with the fish and shellfish. The presence of meat in the daily meal was poor, while it was greatly used in religious ceremonies. More prevalent was, in the *Magna Graecia* society, the consumption of fish, which was, in some cities, the main base of nutrition, as we learn from the poet Ennius *Hedyphagetica* [2]. Finally, large quantities of sweets and dried fruit, such as figs, dates, almonds and pistachios, were consumed. As will be seen, these will be taken as the main subjects of the Pompeian still life [3]. With the political, social and cultural transformation that characterized the transition from the Classical to the Hellenistic period, the ritual practices connected to the banquet became ever more lavish and a distinctive sign of class. It is at this time that the still life representation, so far limited to the ritual use of food and objects during the sacred offering to the dead and Gods, acquires its autonomy. In addition to their relationship with man, things start to be evaluated for their aesthetic quality. The legitimacy of the birth of a new artistic genre, based on the representation of humble things, is even theorized by Aristotéles, who, in his *Poetica*, claims to have pleasure in contemplating the reproduction of inferior and natural beings because, through the fidelity of the representation and the realism which is able to deceive, one can appreciate the talent of the artist. This cultural attitude became deeply rooted if Pliny the Elder, yet at in Roman time, in his *Naturalis Historia*, still told the story of the Greek painter Zeuxis, whose grapes were so well depicted to deceive birds, who used to peck the painted berries being them extremely realistic [4].

The absorption of the Hellenistic culture by the Roman world dates back to the end of the Second Punic War. The victory over Hannibal led to a radical change of manners, even in the eating habits of the ruling class. A sophisticated lifestyle was imposed, also in the use of the foods. The Campania region was evidently the land of the meeting between the two cultures, the Roman and that of *Magna Graecia*. Here, more than elsewhere, it was easy to find the basic elements for the artistic elaboration of the 'still life' genre, like foods, vegetables and fruits. Although the subject had already been introduced in Pompeii, at the end of the II Century B.C., in the I Style mosaics, the emergence of the genre in the wall painting dates back to the II Pompeian Style, in the first half of the I Century B.C.. In these still lifes, the illusive and realistic representation of the objects, clearly of Hellenistic origin, is the dominant theme. At the same time, the richness with which food and the furnishings are juxtaposed, in addition to perpetuate the tradition of the ritual offering, is a synonym for abundance, wealth, ostentation of a high rank for which the rite of the banquet has become a sign of social distinction [4]. One can recognise this double meaning both on the frescoed walls of the rooms of the Roman villas, in which the opulent dinners were placed, and in the small paintings on table called *xenia*, that is 'welcoming gifts' in the Greek language, which the hosts gave to their guests as an offering of hospitality and a wish for abundance. Most of the still lifes painted on the walls of the Vesuvian villas or of other sites consists of reworkings of Hellenistic originals, also known through literary sources. Thus, the theme of grapes pecked by birds in the painting of Zeuxis, narrated by Pliny, became, at that time, so famous that it had already a lot of variants in the ancient Roman still life painting. So, it began to be defined a figurative repertory of a serial nature, which was widespread and that can be grouped into specific subject categories. The still lifes from the Vesuvian cities represent the entire repertory. As has been noted by De Caro, the subjects are linked by the concept of *utilitas* rather than the pure aesthetic value, as seems to indicate, for example, the lack of any representation of flowers. The subjects, singularly or in various combinations, can be divided into the following categories: edible elements, i.e. animals, living and dead, of the earth, the sea and the sky; the edible plants, especially fruits, vegetables and mushrooms; other edible derivatives from the previous ones, as bread, cheese and eggs; objects for the banquet and the pantry and those for the sacrifice; *negotium* instruments such as money and the tools to write.

Fig.5: Eggs, poultry, fruit and crockery (MNN 8598C), from Pompeii

Fig.6: Giovan Battista Recco, *Still-Life with a head of a Ram*, Museo di Capodimonte, Naples

Finally, more related to the concept of *ludus* than to the one of *utilitas* are the subjects with the theatrical or Dionysian masks and those with the themes of the gym and victory. The success of the still life genre in the Roman art arises from the same reasons which had earlier taken to the birth of the same genre, that are the votive offering to the sanctuaries like the lay gift of food to the guest. In the I Century A.D., the even more imaginative way to serve food to own guests became a habit, and it reached, in the Imperial Age, such outcomes to make fine food offered at banquets, not only an expression of status, but also the symbol of the culture of *luxuria* and *otium* drawn up by the ruling class of the Roman imperial society. In the Vesuvian villas, the manifestation of these excesses is confirmed by the fact that the scenes of still life come out from the rooms devoted to dinners to conquer other rooms of the house, so that the whole can inspire an atmosphere of well-being and prosperity in the host. An example is the spread, next to the small fish scene, of the paintings of fish farms, to testify to the fashion, established in the villas of the Gulf of Naples, to own private farms of fish. With the disappearance of the Vesuvian cities, following the eruption of Vesuvius occurred in 79 A.D., the documentary evidence of still life in the Ostia and Rome examples is more modest, but testify to the enduring popularity of the genre until the end of the ancient world. We learn that still life genre was still thriving after the end of the Vesuvian cities from a passage of the *Imagines* by Philostratus the Elder, who, in the late II - early III Century A.D., while visiting a gallery of paintings in Naples, describes a pair of *xenia*: one with figs, walnuts, pears, cherries, grapes, honey, cheese and milk in pots; the other with a living and a dead hare, a duck plucked, different types of bread, fresh fruit, chestnuts and figs. It is therefore clear that the genre had quite a few changes, while there was the reinforcement of the attempt of mimetic reproduction of reality and illusion of space, much appreciated by the same Philostratus [1].

The repertory of still life models, encoded in ancient times, and of whom the paintings in the Vesuvian villas represent the most comprehensive picture, must be long-lived thanks to its serial reproduction and outreach diffusion, to the point that they constitute a figurative tradition that we can find, with amazing coincidences, in the iconographic representation of still life in the Mediterranean area, during the modern age.

Charles Sterling was the first to identify the link between the Italian still life with antiquity and with the humanistic interest for the ancient world. In his exhibition of 1952, the historian considered some figurative episodes from ancient times, until to come, through the Italian Renaissance, to the specific situation of still life, as historical birth of the genre, which began at the end of the XVI Century [5]. The privileged relationship of the Italian figurative art with the classical antiquity, even for his humanistic component, was later reiterated by Mina Gregori. According to this view, the humanistic culture and the discovery through the ancient literature of the late Hellenistic interest for nature and its products, together with the environmental conditions, have undoubtedly had effects on the birth and on the features of the Italian still life [6]. Especially in Italy, during the XVI Century, the interest for the imitation of nature through empirical research and scientific observation of the nature was accompanied by the reading and translation of ancient texts. The Greek and Roman sources provided evocative descriptions of the Classical art and the ancient painting mainly dispersed. If in Aristotle, as already mentioned, it could be traced the legitimization to the emergence of new genres depicting "low things", in other sources one could recover even the models. This is the case, for example, of the already mentioned Pliny's *Naturalis Historia* or of Philostratus *Imagines*, or of the descriptions of *Naturalia* in the *Antologia Palatina*.

However, the timely recovery of figurative solutions derived from the ancient painting seems to testify unequivocally to that, in addition to the literary sources, the artists of the XVI and XVII Centuries and their employers knew some examples from antiquity, including remnants of wall paintings and mosaics, given directly or graphically reproduced, in Rome and in the other territories occupied by the Romans, according to a procedure similar to what happened with the admirable example of the *Domus Aurea* at the end of the XV Century. A significant coincidence in the iconography is apparent in particular by making a comparison between the still lifes of Pompeii and the still life paintings of the XVII Century in the Mediterranean area, especially in Naples. This identity of composition is to be found not only in the quality of mimetic representation, obtained through measures such as the refraction of light, the shadows on the laying surface, the transparency of the glass, the reflections on the objects, but also in the way in which food and objects are combined, unchanged from the classical antiquity, and first of all, in the representation of an illusory space, which, architecturally set, acts as an organizer of volumes and presences.

Fig. 11: *Silver furnishings on a table*, Tomb of Vestorio Prisco, Pompeii

Fig. 12: Giuseppe Recco, *Composition of crystals, ceramics and flowers with a page*, Fundación Casa Ducal de Medinaceli, Sevilla

In the Pompeian paintings we can find already the compositional models, that are more widely illustrated in the representation of the XVII Century still life. They range from simple structures, in which the objects are placed on a single support surface, to those with two levels, with the inclusion of a step or a shelf. In this case, it is possible to observe compositions trying to keep distinct the two plans, or to unify the whole, slanting of the elements from the upper level to the lower one. Sometimes, in the solutions with two planes of depth, there is placed a box, now to the side, now to the center of the scene, likely a simulation of an altar. Sometimes, the levels of exposure become three, recalling the ladder-shaped structure which was used in *thermopolia* for the presentation of food. With particular frequency, then, it can be found the device to open a window beyond, to illuminate the scene: in this case, the objects are all arranged on the window sill or are in part, while others are arranged laterally or on the shelf below [1].

As has been pointed out also by Gregori, the knowledge of ancient representations of fish appears indisputable for the Neapolitan painters of the XVII Century, who made it one of the favorite subjects of still lifes [7]. Thus, by comparing the fresco with *Fish and shellfish*, from Pompeii (MNN 8635) (Fig. 1), with a painting by Giuseppe Recco with a *Squid, sea bass and other fish, buckets of copper, a basket of oysters and two fish on a stone*, which appeared on the antiquarian market in Naples in 2010 (Fig. 2), or with another painting by the same artist with *Fish, squid and copper basins*, in a private collection (Fig. 3), it is possible to observe a clear alignment of themes, such as the particular of the pair of fish hung by the gills with a fishing line attached to a nail, or the detail of the fish arranged with their tails dangling on the edge of the table top. It almost seems that Recco redials on his canvases models encoded by the ancient painting of still life. Similar examples can be found, in fact, variously composed, in several paintings by the artist, such as the Musée Fesch in Ajaccio (Fig. 4) or in the D'Aziò collection in Naples.

Fig. 13: Sánchez Cotán, *Still Life with Game Fowl*, Art Institute of Chicago

Fig. 14: *Rabbit, grapes, an apple and a dove* (MNN 8644C), from Herculaneum

Thus, passing to another subject, is enough to compare the fresco from the house of *Julia Felix* in Pompeii (MNN 8598C) (Fig. 5), with *Eggs, poultry, fruit and crockery*, and the painting by Giovan Battista Recco of the Museum of Capodimonte (inv. Q1776) (Fig. 6), to realize that the two scenes show the same compositional balance between hanging items, food laid out on the counter and the construction of the space around a central pivot, represented by a silver pitcher in the Pompeian fresco and by a large copper '*rinfrescatoio*' in the painting by the Neapolitan artist. Furthermore, if we observe, in the painting by Giovan Battista Recco, it is possible to find, variously composed, the motif of the birds attached by their heads, there hanging, here arranged in a tray.

Again, the painting by Filippo Napoletano with *Fruits in a glass jar*, kept in the Palazzo Pitti in Florence (Inv. 1890 n.4804) (Fig. 7), is so comparable to the fresco of the same subject from the house of *Julia Felix* in Pompeii (MNN 8611B) (Fig. 8), which is impossible not to consider, as already noted by De Vito, that we are faced with the timely recovery of a model of the ancient wall painting, if not directly seen, at least known through figurative sources not yet known [8]. The detail of grapes hanging from the glass jar or even more the ripe fruit fallen on the floor to the left of the vase are a clue to support this hypothesis.

Then, the way to combine the fruit in the still life seems unchanged in ancient as in modern times, as we have now way to verify by comparing the still life with *Grapes, figs and pomegranates* on a black ground, from Pompeii (MNN 8623) (Fig. 9) and a painting by Giacomo Coppola from the Civic Museum of Gallipoli (Fig. 10), with *Fruits, a flower vase, a bottle and a glass of wine and salami*.

Interestingly, the recovery of the models of antiquity is not just about edible, but also about inanimate objects. In fact, we can certainly establish a parallel between the fresco of the tomb of *Vestorio Prisco* at Pompeii (Fig. 11) and the painting by Giuseppe Recco portraying a *Composition of crystals, ceramics and flowers with a page*, from the Fundación Casa Ducal de Medinaceli (Fig. 12), not only for the way in which services are exposed on the table as a sign of the high condition and prosperity of the client, but also for the singular presence of the suspended cloth in both the compositions. The presence in the background of specimens of Italic pottery of the IV Century B.C. also testifies to the keen interest in the antiquities in Naples during the XVII Century.

As a singular theme for the Neapolitan context, the representation of objects was rather more refined and established in Spain, particularly in the Castile area. Just in this region one can trace, in rather early dates, some compositional schemes, that elaborate models from the ancient Roman painting. This is evident when comparing the paintings by Sánchez Cotán, such as the one of Art Institute of Chicago (Fig. 13) with some frescoes from Herculaneum (Fig. 14), in particular the fresco of the *House of the Stags* with *Rabbit, grapes, an apple and a dove* (MNN 8644C). There is, in fact, a similar system to give depth to the scene, entering a window sill, on which the objects are arranged; similarly, we can find the same detail of the bird hanging by a hook to the beak [9]. The presence on the Spanish soil of similar subjects suggests a circulation of models across the Mediterranean, especially in the areas culturally and politically tied to the Spanish Viceroyalty. We do not know how these models are circulated, according to which paths or in what form. We know, however, that during the Spanish viceregal period, Naples was a vital cultural center also in the antiquarian field. The collecting of antiquities, already present at the Aragonese court during the Renaissance, became by the Viceroy a widespread phenomenon, especially among the robed class, to the point of becoming a social *status*, as a sign of loyalty to the crown and a symbol of ascent to the ranks of the nobility [10]. Recent studies, supported by a lot of documentary sources, have also shown that the ancient city of Pompeii was not entirely disappeared. Its historical memory, as well as the man-made attendance of the area, can be detected before the XVIII Century Bourbon discoveries [11].

Fig. 15: Luca Giordano - Giovan Battista Ruoppolo, *Autumn*, Private Collection

Fig. 16: *Dionysus – Bunch*, from Pompeii

Not currently having the tools to define the mechanisms of transmission of the models of the ancient still life painting, the success of the genre in Naples can also be explained by other reasons. Surely, next to a clientele of aristocratic extraction, it began to establish a bourgeois one, with mercantile interests. However, rather than being an expression of these interests, the nature of the Neapolitan still life, since from its beginnings in the early XVII Century, seems to transfer on canvas a popular culture that refers to the real traditions and habits of the daylife. The choice of foods, fish, fruit, vegetables, is representative of a typical Mediterranean style, shared with the Spanish paintings of the early XVII Century, but alien to the rich compositions of meats and cheeses from across the Alps, the latter being different not only for the subjects, but also for the analytical criteria of representation, extraneous from the logical construction of the space, made in the Mediterranean area. The flower theme, with its moralistic implication, seems instead to have been imported from across the Alps.

The Neapolitan still life, with the depiction of the riches of heaven, earth and sea, seems to want to recover, with propitiatory intent, the hope of abundance that, in a still agrarian and seafaring society, is strongly linked to the issue of seasonality, of the annual cycle of birth, life and death of the nature, of pagan tradition, but recovered by the Christian liturgical calendar. In this sense it can be interpreted the representation of the grapes, of classical inspiration and Dionysian meaning, in Naples, as in other places such as Rome and Spain. One example is the painting with the *Autumn*, a collaboration between Luca Giordano and Giovan Battista Ruoppolo, on the occasion of the Feast for the *Corpus Domini* in 1684 (Fig. 15). In this painting the classic reference to the myth of the seasons is reinterpreted as a religious expression of the divine grace, that bestows the variety of the world's wealth [12]. In the context of the religious feast is, thus, recovered the peasant popular culture of the Dionysian feast with a propitiatory significance and a thanksgiving that is similar to that of the ancient world, as evidenced by a comparison with a fresco depicting a *Dionysus – Bunch* at the foot of a mountain covered with vines (probably Vesuvius) (Fig.16), from the *House of the Centenary* at Pompeii.

Finally, the emotional, affective approach, that shines through the Neapolitan still life paintings is undoubtedly an expression of a familiarity with the extraordinary opportunities offered by nature in those places. An amusing description of the abundance of food that could be found in the Bay of Naples is offered, in the XVII Century, by a storyteller from Palermo, who, become a soldier for necessity and landed in Naples, when going to the market, finds there "*all the four elements*": all kinds of meat, eggs, poultry, pies and wine, cod, macaroni and cheese, figs, fennel and apples, chestnuts and dried fruits, lemons and oranges [13]. Thus, about the marine species, that were the Neapolitan favorite theme of still life, they are praised in the *Ecloghe Piscatorie* by Cesare Capaccio [14], to come, even in the XVIII Century, to provide inspiration for popular songs, such as *Lo Guarracino*, in which the wealth of fish in the Gulf of Naples is evidenced by a list of more than seventy species of fish.

The Neapolitan still-life is therefore a figurative testimony of the whole of knowledge, customs and traditions related to food practice, built up over centuries by the people of the Mediterranean. They have led to the emergence of a culture of food and dining, of a style of life which is the synthesis

between the environment, the social organization, and the religious and mythical universe built around eating. This lifestyle is not just about eating habits, but also promotes social interaction, since the common meal is the basis of social customs and festivities shared by the community and, therefore, contributes to building and strengthening the collective identity. For this reason, the Mediterranean Diet, the expression that defines this style of life, has been included in the UNESCO list for the Safeguarding of the Intangible Cultural Heritage.

Classification of the graphic legacy of Disappeared Earl of Oliva's Palace

Joaquín Ángel MARTÍNEZ MOYA

Departament d'Enginyeria de Sistemes Industrials i Disseny, Escola Superior de Tecnologia i Ciències Experimentals, Universitat Jaume I, Castelló, Spain

jomoya@uji.es

Abstract

Between 1917 and 1920 the Danish architect Egil Fischer and his assistant Vilhem Lauritzen, carried out an important graphic survey of the Earl of Oliva's Palace with the aim of later removing its most exceptional elements and shipping them to Denmark. In 1920 the Palace was declared a National Monument in order to preserve it from the devastation it was predestined to suffer. This official statement, however, did little to prevent the Palace from almost completely disappearing during the first half of the twentieth century. Paradoxically, thanks to the huge amount of graphic documentation compiled by those two architects (notebooks, sketches, plans and photographs), it is now possible to know and study this exclusive late-Gothic and Renaissance-style Palace and his architectonic elements which are an important graphic legacy of the Valencian heritage and allows us to have a better understanding of the civil architecture of its time.

In this article we'll classify all the graphic documentation that has come down to us based on its structural elements (portals, windows, coffered ceilings, vaults, arches, etc.) as a first step for further study and analysis of this unique graphic legacy that has allowed to return to Oliva this important piece of its heritage after a long trip to Denmark and New York.

Keywords: Oliva's Palace, graphic legacy, late-Gothic, Renaissance-style, heritage,

1. Introduction

The Earl of Oliva's Palace is an example of the late Gothic-Mudejar style that flourished in some parts of Spain in the mid-14th century [1], but which also includes some decorative elements from the early Spanish Renaissance.

Work on the construction of the Palace was probably started in the second half of the 14th century by the Centelles de Oliva y Nules family and was not finished until the mid-16th century. In 1449 Francesc Gilabert de Centelles Riu-Sec (1408?-1480?) was created Earl of Oliva by Alfonso V "the Magnanimous" in return for his support in the campaigns in southern Italy. Thus began the golden age of the Palace, which was to continue with his son, Serafí de Centelles Riu-Sec (†1536), who is attributed with having embellished the Palace. It was later fortified to turn it into an *Alcazar* [1].

In the 19th century, the Palace was sold by its last owners, the Osuna family. The purchasers stripped the Palace of everything that could be removed easily and, so as to be able to divide the estate up into parcels, they opened up a street that ran through the middle of the Palace.

In 1917, Egil Fischer (1878-1963), a Danish architect who was very interested in Spanish art, arrived in Oliva and bought seven sectors of the old Palace with the aim of dismantling any pieces that could be saved and incorporating them in a Spanish museum to be built in Denmark [2].

In 1919 he returned to Oliva with a team of three people, one of whom was the young student of architecture, Vilhem Lauritzen (1894-1984). Together they began working to produce the graphic documentary material on the Palace with the aim of classifying and arranging all of its "useable" elements [2].

As a result of the complaints lodged by other owners, a provincial architect sent a report to the Ministry asking for the demolition work to be stopped [2] and the Palace was finally declared a national monument in 1920 [4].

From that moment on a ban was placed on the exportation of the pieces that had been dismantled and, after many attempts to take the material back to his own country, Fischer was eventually forced to give up [2].

Both the weather and the Civil War had serious detrimental effects on the Palace. In 1950, the little that was still standing was declared to be in ruins and was demolished [2].

In 1980, in an auction in London, the Hispanic Society of America (HSA) acquired two sections of the frieze from the Hall of Arms, together with other pieces from the Palace of Oliva. This prompted a great amount of research work, carried out under the leadership of Priscilla E. Muller, who was then curator of the HSA Museum. With the help of Lauritzen, Muller managed to trace all the graphic material from the surveys carried out by Lauritzen and Fischer years before and which was now the property of his widow, Olga Fischer, who finally donated all the documents to the HSA [3].

This documentary material was finally handed over to the Municipality of Oliva by the HSA and is now stored in the Municipal Archaeological Museum.

The graphic material that has been recovered basically consists of three types of documents: plans, notebooks and photo albums.

The Archaeological Museum of Oliva has invested a great deal of time and work in ordering, encoding and scanning these documents in order to create a digital version that can be used to develop a research methodology that draws on the latest technological resources.

The aim of this paper is to classify all this graphic documentation as a first step for further study and contribute to the preservation and dissemination of this important graphic legacy.

2. Notebooks

Notebooks I and II are two 11 x 17 cm notepads, the binding is made with cardboard hardcover and navy blue cloth spine. The inner sheets have a Microdrilling in its left margin to allow to be cut out of the notebooks. They contain handwritten comments made in pencil with sketches of different architectural elements, such as portals, arches, vaults, beams, coffered ceilings, stairways, flooring, woodwork, mouldings, and so on. The sketches include annotations in Danish. There are also sheets showing measurements, lists of materials, addresses, bibliographical references and even a receipt for payment of the rent on one of the houses.

We will make a first classification of the contents of each of the notebooks depending on whether predominate graphic or written documentation. Within the graphic documentation we will make a classification by the building elements that are described graphically and within the texts we will make a classification by the content.

2.1 Notebook I

Its numbering code is MMO. APD. PC. Egil Fischer. Notebook I. LA1104. On the front cover it's glued a circle of white paper where it is hand written "I FISCHER OLIVA". The inside pages are manually numbered by pencil in the upper left corner with number 1 to 77. Pages 18, 19, 40, 56, 57, 69, 70, 72 and 75 don't exist physically in the notebook. There are also two loose sheets which are within the

columns, arches, parapet, upper frieze and pilasters. The columns, the voussoirs of the arches and severies between them are numbered.

-The General Plans: this type will include pages 39, 61 and 74. The first corresponds to a general plan of the 1st floor of the Palace with the numbering of the rooms and its orientation, the second corresponds to a partial plan of the first floor with the name of some rooms, the third corresponds to a volumetric freehand viewed of The Palace from the north-northeast. Both the general plans, as the volumetry are certainly the most value graphic material within the Notebooks as they give us an overview of the Palace and convey to us their magnificence through a single tracing.

2.1.2 Texts

We will make a classification of pages of this notebook where the texts predominate based on its main content:

-Data on the Palace: Pages 8 and 9 contain a list of the various rooms of the Palace. Page 38 contains the heights of the various structural elements of the "Gothic Room". This room corresponds to the Hall of Arms. Page 41 contains the size of a portal.

-Inventory: page 48 and 50 contain the wooden windows inventory of the Gallery. Pages 58-60 contain a numbered inventory of doors "to sell" and other windows and grills of the Palace.

-Price of materials: page 51 contains the purchase price of the new cankerworm. Page 62 contains a price list of different types of bricks.

- The Bibliographic Dating: The 52 page contains a citation of Monsignor Baudrillart's book, "Letters of the Duke of Burgundy to King Felipe V".

2.2 Notebook II

Its code numbering is MMO. APD. PC. Egil Fischer. Notebook II. LA1105. As in the previous book a circle of white paper is glued on the cover on which is hand written "II FISCHER OLIVA". In this book the pages are not physically numbered, so the numbering used is the one of the page order. It consists of 35 pages plus covers: 17 of them are for text and 18 of graphic documentation (one of them has a construction detail on the main page and a text on the opposite page), so we can say that this notebook is composed of texts and graphic documentation equally.

2.2.1. Graphic Documentation

As in the Notebook I, we will make a classification based on the graphic documentation of the architectural elements that represent and in the same order:

-Stairway: pages 11 and 12 contain the plan, elevation and details of guardrail and handrail of the starting of the first flight of a stairway.

-Portals: the most unique characteristic architectural elements in this notebook are certainly their portals. In this typology we will include page 7, detail of a doorpost and pages 13 and 14 to 22 corresponding to the covers 1 to 9. They contain portal elevation views with Gothic arches and doorposts in section view in most of them and based section view in some of them. Most of them are dimensioned. Though they are simple sketches, they provide us essential information to document these first 9 portals, except for number 8 don't exist plans of them and only in some cases there're photographs thereof (3, 4, 5, 7 and 8).

-The Kitchen: page 23 contains the plan and section of the kitchen chimney formed by a truncated pyramid shaped octagonal base that occupies the entire floor of the room. The transition from the square floor of the kitchen to the octagonal chimney starter is done through four lunettes at the corners.

-The Domes: Pages 26, 27 and 28 contain documentation of rooms 15, 13 and 17 covered with groin vault, cross vault and tube vault respectively drawn in plan and section views and bounded. Coupled with the portals is one of the most valuable documents of this notebook, allowing us to be able to reconstruct graphically these unique architectural elements of The Palace.

-The Halls: pages 30 and 31 have dimension drawings of the halls 16 and 18 (Hall of Arms) with doors and window situation. In the room 16 is shown the distribution of floor beams. Page 25 represents a scheme of the wooden structure that forms the roof of the Hall of Arms.

2.2.2 Texts

We will make the following classification of texts that appear on this notebook depending on their type:

-Citation: Pages 1-10 and facing pages except the one facing page 8 which is blank and page 7 which contain the sketch already described, containing a manuscript copy of Teodoro Llorente's book chapter, "Valencia. Volume II." about Oliva.

-Palace data: on page 14 there is a notation about the situation of windows 1 and 2 and 24 notes with general measures of the roofs of several rooms.

-Inventory: page 29 contains an inventory of wooden beams according their situation and position. The back cover contains a long list of height and width dimensions and the addition of the total volume, in the text indicates "Tarragona. Chapters".

Fig. 2: Portals 1 to 9 sketches. Elevations and sections. Earl of Oliva's Palace.

Source: MMO. APD. PC. Egil Fischer/Vilhem Lauritzen Notebook I LA1104. Pages13 and 15 to 22.

-Contacts and price lists annotations: pages 32-35 contain various contacts with their addresses, a prices list of building materials and an inventory of antiques and other annotations, some of them crossed out.

3. Photographic Albums

Within the graphical documentation recovered of the palace there are two photo albums: The Large Photo Album and The Small Photo Album. They contain general photographs of Oliva and the Palace, photographs of unique architectural elements of the Palace, photographs of other reference buildings and even photographs of the land in Denmark where Egil Fischer wanted to build its Museum of Spanish Art where incorporate the dismantled parts of the Palace [1]. These photographs are accompanied by Danish texts which we consider important to transcribe and translate in the future. This photographic documentation is invaluable for understanding the building and to be able to analyze it.

We will classify the photo albums based on the content of the photographs on both of them.

3.1. The Large Photo Album.

Its code numbering is MMO. APD. PC. Egil Fischer. Large Photo Album. It is a landscape album dimensions 30 x 38 cm hardcover and binding by two threaded screws. The color of the covers is light brown. The inner leaves are dark gray cardstock; they are reinforced with a strip of light brown cardstock glued on the back, in the bindery. Contains a total of 24 pages, on these sheets are physically attached photos, which are numbered from 1 to 108 by pen on the cardboard. There are also figure captions written by pen and text notes on some pages. We will establish the following groups based on the elements they represent:

-Pictures of Oliva: these are general photographs of Oliva and the surrounding area. There are a total of 8 pictures: 1-4 and 90-93, the latter are photographs taken from The Oliva's Palace.

-Outside Palace's pictures: in this group we include both the general photographs as the partial views of exterior facades of the Palace, consists of 10 photographs: 5-9, 11, 13, 81, 85 and 89.

Fig. 3: Diferent views of Portal 27 (*Dör 27*). Photos 33, 34 and 35. Earl of Oliva's Palace.

Source: MMO. APD. PC. Egil Fischer/Vilhem Lauritzen Large Photo Album. Sheet 9 Reverse.

-Portal pictures: the largest group is formed by a total of 24 pictures: 28-35, 39, 40, 52, 53, 61, 63-69, 72, 73, 75 and 77 which show us the most unique Gothic portals and some of them with Renaissance decoration.

-Roofing pictures: this group of pictures represents timber ceilings, coffered ceilings and vaults. There are 12 pictures with the following numbers: 25, 26, 43, 45, 46, 48-51, 54, 56 and 57.

-Photography of the galleries: in this group we include all pictures of both the main gallery as the upper gallery of the Main Courtyard. It is composed by 7 pictures: 10, 12 and 14 to 18.

-Pictures of windows: in this group we include both partial indoor photographs of the windows as outdoor pictures of them. Three of these photographs are repeated at the portal group because they contain graphic documentation of both architectural elements. There are 10 pictures with the following numbers: 71, 74 to 77, 79, 80, 82, 84 and 94.

-Frieze Hall of Arms: due to its great ornamental importance and the large number of photographs of this unique building element we have considered appropriate to make an specific group that include these 7 photos taken from this element at its original location. They correspond to the numbers 19 to 24 and 27.

-Dismantled pieces: in this group we include all the parts that have been removed from their original position: frieze, capitals, infill elements, tiles etc. There are a total of 20 photographs: 26-38, 41, 42, 44, 47, 55, 58-60, 62, and 70.

-Other buildings: the latter group are the last 8 photographs (101-108) representing buildings and other elements that keep some formal similarities with the Earl of Oliva's Palace.

3.1. The Small Photo Album.

Its numbering code is MMO. APD. PC. Egil Fischer. Small Photo Album. This is an album of dimensions 22 x 26 cm. brown hardcover and binding by two threaded screws. The inner sheets are hard, made of the same material and color than the covers; they are top with a black sheet of paper attached to each of their faces. Contains a total of 12 pages plus front and back covers. On these pages are physically attached pictures. There are also two loose photographs inside this album. On the margins of the photographs themselves there are explanatory texts in Danish. Most photographs are repeated compared to Large Photo Album and retain that numbering. In other cases they are not numbered. The numbering is pen written on the photographs themselves or on a small circular paper glued on them. There are a total of 15 photographs that are not repeated in the Large Album plus two photographs of two plans of the Palace. We only will proceed to classify these 17 photographs based on the elements they represent:

Fig. 4: Frontal views of Portal 5 (Dör 5) and Portal 8 (Dör 8). Photos 72 and 68. Earl of Oliva's Palace. Source: MMO. APD. PC. Egil Fischer/Vilhem Lauritzen Small Photo Album. Sheet 11 Anverse.

- Oliva's Photographs: Photography F, page 3R.
- Outside Palace's pictures: photo unnumbered page 3A, photo 6.1 page 4A, photo 3.1 page 5A and photo unnumbered page 13A.
- Portal pictures: photo 29.1 page 6A and photo 28.1 page 7A.
- Photographs Frieze of Hall of Arms: photo 23.2 page 6R and photo unnumbered page 7A.
- Pictures of Roofing: Photography 45.1 page 8R.
- Pictures of Windows: Photography ? page 12A.
- Pictures dismantled elements: photo unnumbered, page 4R and photo 23.2, page 6R, both correspond to pieces of the frieze of Hall of Arms. In the second one the pieces are mounted in a house as decoration.
- Pictures Denmark: photo unnumbered page 14A and photo unnumbered page 14R. The two photos match a soil in Pille Allé, Frederiksberg, where Fischer wanted to build his building with the pieces of the Palace [1].
- Photo not rated: photo A page 3R, decorative element without apparent relation to the Palace.

4. Drawings

There are 112 sheets pencil drawings of different elements of The Palace and 8 ink drawings of the construction projects for the Spanish art museum in Denmark. Each one is numbered by code: MMO. APD. PC. Egil Fischer. Notebook I. LAXXXX. The plans represent the main floor, the deck plan of the Palace, coffered ceilings, domes, arches, portals, windows, and other unique architectural elements of the main floors of the Palace. The deck plan incorporates graphical scale and in the rest of the sheets we can find some with dimensions and other ones than lack thereof. In most of the planes of the portals, windows and arches, we found a main sheet with more detail and a tracing paper that appears to be a copy of the first and where is drawn the cutting provisions for disassembly and reassembly of these architectural elements.

The classification was made according to the type of construction elements in the following blocks, ordered according to the total number of plans containing: Portals, Windows, Ceilings, Miscellaneous, Pile Allé Project Plans and Floors.

4.1. Portals. They represent the largest block of plans. Include a total of 45 plans: LA1122-bis, LA1124, LA1136 to LA1177 (except LA1172 and LA1174 that do not exist), LA1182, LA 1191 and LA1192. They represent the *Dör* 8 and from the *Dör* 10 to *Dör* 28 portals, one of them shows a detail of the portal *Dör* 7 (LA1182) and LA1176, LA1177, LA1191 and LA1192 sheets represent four other portals unnumbered and no identified. Inside the portals we can also establish different classifications depending on the decoration, arch type, number of columns that form the doorposts, etc.

4.2. Windows. This set of plans consists of 29 sheets: LA1179, LA1187 and LA1183 to LA1193 to LA1213 (except LA1200 that doesn't exist). They define 8 numbered windows: *vindue* 3 to 10 and 5 more windows unnumbered. The dimensions of the voids and their architectural ornamentation (arcs, doorposts, moldings, benches etc.) are defined on them.

4.3. Ceilings. This group encompasses sheets LA1110A, LA1110R, LA1111 to LA1119, LA1123 LA1121 to, LA1124-bis, LA1125 and LA1126, they are 17 sheets in total. All of them have identified the room number the ceiling belongs, excluding LA1110A and LA1110R. Within this group we can set 3 subgroups according to their type: Forged beamed, coffered ceilings and vaults.

4.3. Miscellaneous. In this heterogeneous group have englobed all those sheets that did not fit into the other groups. It is also made up of 17 sheets: LA1110-bis, LA 1135 LA1127, LA1178, LA1180, LA1181, LA1188 to LA1190 and LA1214. Within this group we can set three distinct subgroups: Large Tower Gallery, Arches Gallery and Misc.

4.4. Pile Allé Project Plans. There has 8 scale plans drawn ink containing the floor plans, elevations and sections of two proposals for the Spanish Museum of Copenhagen.

4.5. Plants. This group consists of a total of 4 sheets penciled (LA1106, LA1108, LA1109 and LA 1109-bis) representing the main floor of the Palace with the numbering of many of its rooms, portals and windows, two deck floors of the Palace and a last one that has drawn two floors of the distribution of a building that incorporates many of the portals and windows of the palace. It seems to be another proposal to the Spanish Museum of Copenhagen.

Fig. 5: Portal12 (*Dör 12*) and Portal 15 (*Dör15*). Elevation and section plans. Earl of Oliva's Palace.
Source: MMO. APD. PC. Egil Fischer/Vilhem Lauritzen LA1139-R / LA1150

5. Conclusions

The classification of all graphic legacy of Earl of Oliva's Palace has allowed us to depth in a best knowledge of it, while it has helped us to identify most of the parts represented as well as its location in the Palace. The fact of not being able to transcribe and translate all the texts in Danish so far, for economic reasons, makes us think that we still have an important part to analyze of all the vast information available.

It has been carried out a table for each one of the groups of building elements based on the classification made for plans, picking on them all the information found in each one of the documents available: Plans, Notebook I, Notebook II, Large Photo Album and Small Photo Album. This crossing of information has been essential to know all the information that we have each element. Attached table 1 (see Tab. 1) corresponding to the portals as an example of the work done, where we've included depending on its coding, numbers and / or page number of each document all documentation relating to each one of the portals. These documents are also linked to this table using hyperlinks, which enables us to easily find them for any work of further study.

This same work has been done for other groups: Windows, Roofing, Miscellaneous, Project Plans and Pile Allé Plants, allowing us to have a data base organized and classified all the graphic documentation as written documentation, helping us in the future research of certain aspects of the Palace.

We believe that this paper has met its main objective: a thorough classification of the graphic documentation of the Earl of Oliva's Palace which may provide basis subsequent research studies that can be performed about this exclusive late-Gothic and Renaissance-style Palace and his architectonic elements.

OFF-GRID::FARM. Multifuncional landscapes and sustainable systems for Mediterranean rural areas.

Valentina ROCCA,

Ph.D, Department of Civil Engineering, University of Calabria, Arcavacata di Rende (CS), Italy
valentina.rocca@unical.it

Abstract

OFF-GRID::FARM is a procedural method to plan sustainable and self-sufficient farms. It has been developed starting from an investigation carried out in China, Argentina, and Italy, and characterized by creativity and innovation of different case studies. Nowadays, European policies look at the rural landscape as an idyllic space easily opened to solar energy, water stream, wind, and biomass. In this context, planners must control the transformation of rural territories through innovative strategies of development and preservations. With this aim, this research offers an outlook on the potential of Mediterranean rural areas and their management, introducing the concept of countryside built in multifunctional layers. The main goal is indeed to raise awareness of farmers about the small-scale energy production from agricultural waste, in order to effectively create "off-grid" systems. Focusing on constructions, the design of farm's buildings encloses climate principles, morphology of territory and the relationships amongst activities. New ways of living rural areas can preserve their identity and educate people on food culture and energy savings, as well as can foster organic agriculture, educational and advisory programmes. OFF-GRID::FARM as a series of rules to build the future of agricultural Mediterranean landscapes.

Keywords: sustainability, agriculture, multifunctionality, off-grid

1. Sustainable Rural Systems and Multifunctional Agriculture

This is the era of continued urbanization. The energy crisis that is afflicting our planet makes us reflect about the relationship city/country, as entities not in antithesis but as elements that can be blended to form a system with new trend: the *agro-city* [1]. This is the moment for planners to reconsider current patterns of countryside development and permit a painless cohesion of artificial and natural systems, the increase of local food production and the reduction of carbon footprint. Organisms characterized by an high alimentary sovereignty, where agriculture should determine the economical vitality, the well-being of population and new sources of energy, maybe the agrarian cities will swept away by green revolutions able to take care of environment and people's health.

We have already heard talking of "sustainability", concept used to describe the possibility of a system to be maintained at a fixed level for an indeterminate amount of time. This term is usually used to describe an idyllic status of creation and maintenance for all the conditions that humanity and nature need for global harmony, and to satisfy the social, economic, and environmental needs of present and future generations. But actually, the environmental and social conditions of our planet show, with evidence, that the practiced models proposed by researchers and global institutions must have the ability to solve problems through sustainable actions: especially rules, programs and directives have to give the important solution to preserve and upgrade the environment, reduce waste and consumption of resources. In this sense, sustainability has become a fixed and binding component in political decisions because it is only in this way that it is possible to move from theory to practice. But what has been done towards the improvement of sustainability over the last years in agricultural fields?

The Common Agricultural Policy (CAP) has left its mark on the European countryside, setting development in a support role to the implementation of structural changes in the agricultural world. It has seen its structuring capacity lessened in favour of an increasingly independent policy with extended functions. In 2013 the new six-year budget and programming cycle have started as next stages in this fundamental change in the issues at stake. Rural development is gradually becoming a vector of geographical cohesion, driving the competitiveness of rural areas and supporting the sustainability of human activities and management of natural resources [2].

The process of modernization tended to replace traditional agriculture for a model of productive specialization for the market, centred on improved seeds and a technological package which included the strong incorporation of external consumables, mainly fertilizers and agricultural chemicals. Starting from the concept that the use of sustainable practices in agriculture could become the main value for a territory in terms of services for community, like management of the territory, conservation and landscape fruition, food safety and environmental control, the discipline of territorial planning could help to create sustainable systems with agricultural features, called "agro-ecosystem" [3]. They could be:

- **bioregion**: in a huge scale, it is an ecological community with characteristic flora, fauna, and environmental conditions, limited by natural boundaries;
- **eco-cities** and **eco-villages**: urban systems where it is possible minimize the use of conventional energy, promote organic food and waste reuse, preserve air and water from pollution and design a more sustainable urban element in rural areas;
- **agricultural park**: a combination of a working farm and a municipal park, located at the urban edge. It can serve as transition or buffer zones between urban and agricultural uses. It provides fresh food, and an educational, environmental and aesthetic amenity for nearby communities [4];
- **sustainable farm**: it is a self-sufficient unit located in rural areas able and close to cities, to produce its own energy and preserve the biodiversity of its territory;
- **urban farming**: it is an emerging process of growing and distributing food, as well as raising animals, in and around a city, to conceive new paradigms of health and life respect.

Multifunctional layers, that rules the land uses and practices, can change functions of ecosystems. In 2005, the Millennium Assessment defined four main categories of services provided by ecosystems [5], such as:

- Food and fiber, fuel and timber, genetic resources for crop improvement and medicine, natural chemicals and water are the material benefits that people gain from ecosystems;
- Regulating services are the benefits to sustain different components of human well-being: crop pollination, ecosystem resistance to invasion by exotic species, climate and atmospheric chemistry regulation, pest control, water purification and erosion control;
- Cultural services are intangible benefits from ecosystem through their contribution to such things as education (didactic farm) and science, spiritual fulfilment, aesthetic beauty and "sense of place";
- Supporting services are necessary for the sustained provision of all the previously described services, like productivity, soil development, nutrient cycling and mineralization of organic matter (source of soil fertility for plant growth), water cycling and the production of the oxygen.

There are no doubt that a serious study on new functions for rural areas could improve its development and to converge toward the *20-20-20 Targets*, "an integrated approach to climate and energy policy that aims to combat climate change, increase the EU's energy security and strengthen its competitiveness" [6].

2. Investigating on Farming: International Good Practices

I started to contribute to research activities on rural areas since I was a student, establishing the research unit *Imagine Lab of Architecture, City and Landscape* of the University of Calabria (UNICAL, Italy), where researchers and students can deal with territorial planning and sustainable design. In

particular, the laboratory focus on sustainable development of urban and rural areas and their interrelations, sustainable farms, use of natural resources in rural areas, eco-villages with biogas plants (located in Mediterranean Areas, Argentina and Kenya) and smart cities.

For my PhD studies, I visited China, Argentina, Indonesia and Turkey to analyse their own agricultural practices and look at best innovative processes. In all these Countries, a new consciousness on the important to preserve Earth's healthy has engaged many researches to understand the problems that are afflicting our rural lands: what is their future and what the academic world could do to sensitize people to build in a more sustainable way, to conceive good practices, to use free energies and establish a new rural/urban dialogue?

I deal with urban development planning for sustainable rural systems in the Mediterranean area, defined by new essential qualities as multifunctionality and *off-grid* prerogatives. Most of the studies I carry out fall within the purview of urban studies but inspired by agrarian urbanism. Within this field, my contributions are towards the understanding of the rational use of free energy and biomass from agricultural residues, to preserve natural resources, biodiversity, environment and local identity, and conceive systems more natural and healthy: a *green farm* as part of eco-villages and cities systems, testing ground of new policies for social and environmental sustainability, by means of implementations of urban agriculture and "zero kilometres food".

My investigation started from the idea that new strategies could be relevant only if concepts like biodiversity, sustainable agricultural practices and free energies are accepted in common life. For this, all the good practises and case studies reported have the intention of communicate the real possibility to plan from an ecological point of view, to make correct policy choices, respecting international protocols and rules, preserving the identity of rural areas and traditional resources.

In my period of research abroad, I joined the Department of Building Science School of Architecture of Tsinghua University (Beijing, P.R.C.) and the Faculty of Architecture of *Universidad Catolica de Cordoba* (Cordoba, Argentina). In very close contact with countryside realities, those experiences have enabled me to engage an eco-sustainable design for rural development, targeting rural and urban *off-grid* systems, eco-villages, sustainable communities and agro-cities. The outgoing of this research will aim at establishing a future model for developing methodologies on rational management of local resources, especially in Mediterranean rural areas, through a sustainable planning process.

2.1 Rural China and the Use of Agricultural Residues

In China, I had the opportunity to analyse the rural environment of Beijing and Shanxi provinces. I was looking for new design solutions for sustainable farms and rural villages, focusing on climate changes, renewable energy, water conservation, energy independent system, tourism, organic food and rural activities.

As the biggest agricultural countries, China's arable land is a precious resource for its development. All suitable to agriculture, mountains and dry grasslands give shape the country, but often they are covered by new cities and constructions. Also, natural disasters, soil erosion and pollution problems are changing the identity of these lands. Many factors influence the rural structure, such as economy, society, climate, culture and local energy sources: they are different for each region, due to the complexity of its geography and social economy. Local inhabitants are used to live in a very ancient way, using biomass to carry out all the common house activities, like heating and cooking. Energy consumptions depend mainly on straw, firewood and coal.

But China is also the nation with the highest percentage of worldwide urbanization, a process that is sharpening social and energy problems in rural areas. This big country is striving hard to develop a sustainable urbanization, improve a modern and efficient agriculture and promote energy saving.

As a matter of fact, a sustainable use of local resources should permit to protect the natural environment: ecological agriculture represents one of the potential alternatives to conventional agriculture and the biomass sector is identified as the main source of economic and social improvement [7].

All these prerogatives could be improve in agro-cities, already existing in China. At the moment, there are more than 500 eco-agricultural counties, with eco-agriculture demonstration zones. From 2005, the Chinese government has dispensed over 700 million Yuan to build dry farming and to plan water-saving agriculture demonstrations in arid territories, with the aid of agronomic and biological measures

Looking for new sustainable solutions for rural development, China intends to turn to all the abundant renewable energy sources and territories of unproductive lands; the attention would also emphasize the research of new promising technologies [8].

It should be said that China can not use the large amount of bio-energy storage, because of limited techniques for selection and cultivation of energy plants, low bio-energy use efficiency, difficulties in collection of bio-energy materials and so on. At the moment, China has been planning its bio-energy development strategy (2006–2015), emphasizing the desire to activate an advanced bio-energy facilities for a better use of local resources.

2.3 A Biodinamic Farm in Argentina: Sustainable Agricultural Practices

In Argentina, the modernization of agriculture gave way to a process of speculation, greater land concentration, an increase in the surface per productive unity. From 1988 to 2002, a strong decrease in the total amount of farm installations led to an increasing rural depopulation and socioeconomic desertification. The growing trend to monoculture generated negative external factors on the natural territory: exportation of nutrients, degradation of soil, and loss of biodiversity. But also in Argentina the idea of modernization is not the only possible path of action to increase productivity in rural areas; this has been showed by multiple experiences I visited.

In Santa Fe Province, Guadalupe Norte, for example, an alternative agro-ecological model has generated ecological income and employment, as well as environmental benefits. In a small area for commercial agriculture by Argentinean standards, in 1991 a family of farmers has created the *Granja Ecológica Naturaleza Viva*, an agricultural production system that use biodynamic, an alternative agricultural method developed by Rudolph Steiner in 1920s [9]. This is an holistic view of agricultural because it requests to see the Earth's environment in a more spiritual dimension and agro-chemicals are not used on the farm, to maintaining soil quality and fertility and to obtain organic food.

"Naturaleza Viva" produces more than 15 types of agricultural products on 220 ha, like yogurts, cheese, vegetable oils, flours, jams and meats, using modern industrial processes and sold at markets. The production system is based on the idea of a traditional agricultural system and it incorporates new scientific knowledge and know-how; also it has didactic scopes, to teach children and young people the importance to respect nature and human life. Starting as family business, now "Naturaleza Viva" employs 11 families that currently live on the farm and it is rapidly expanding. It is one of the most important experience of multifunctional uses of agricultural lands in a sustainable way.

2.1 Mediterranean Area: Sustainable Energy Productions in Calabria (Italy)

In every part of the civilised world, the current agricultural trend is towards more specialized actions, high input-output production systems based on modern technology. But this does not impede the use of sustainable systems in many Mediterranean areas, to preserve environment and natural resources, also producing free energies from residues.

For example, in Calabria there is the largest biogas energy plant existing in the central and south Italy, with a power of 625kW. It is part of the *Fattoria della Piana*, situated in Rosarno (RC) and it has build to cover the energy demand of the farm [10]. Livestock waste from stables and leftover from milk processing, joined with agricultural residues, are stored in two fermenters. Then they are mixed and heated thanks to an anaerobic digest process, producing biogas. The electrical energy produced is enough to cover efficiently the needs of 1.700 families, while the thermal one is used for all their internal needs. Through process of fermentation and combustion of biogas, wastes are transformed into energy and fertilizer, used for cultivation. A big farm as a self-sufficient ecosystem, able to produce energy from agricultural wastes deriving from: heads poultry, cows, sheep, 700 acres of citrus and 1000 hectares of olive tree, fruit and vegetables, green house and viticulture.

3. OFF-GRID::FARM, a process to plan in a more sustainable way

OFF-GRID::FARM starts from the concept that farms have to maintain the quality of countryside. This concept determines an approach that takes a holistic view of the whole farm as a system, focuses on the relationships between the various components under the control of the farm household and of the interactions of these components with physical, biological and socio-economic factors under the

Fig. 1: Naturaleza Viva, a sustainable farm in Argentina (Guadalupe, Santa Fe)

household's control, and aims at enhancing the efficiency of farming systems by focusing agricultural research to generate new developing planning programs for rural areas. This research proposes recommendations and farm development's program to form a sustainable agro-ecosystem research facility.

Generally, a sustainable farm has to follow criteria like: production of all energy needed for farm operations and processing of biofuels or fertilizers; requisition of carbon; production of all feeds needed for animal production; do not use chemical nutrients; to be economically viable.

A short procedure of control of the planning process permits to create systems where to put into practice sustainable agriculture, to be followed by both farmers and rural planning. But to meet these criteria, the farm must be analysed and designed as a whole agro-ecosystem. It is a system-oriented toward a holistic approach for advice, education and planning. The model covers ecological, economical and social aspects by defining indicators like energy, water, soil, biodiversity, emission potential, plant protection, waste and residues, cash flow, farm income, investments, local economy and social situation. Concisely, the OFF-GRID::FARM strategies involves different steps to conceive a sustainable farm system in Mediterranean area, considering all the factors above:

1. Identification of figures and users
2. Selection of location on rural territory

3. Planning and identification of agricultural settlements
4. Definition of the multifunctional degree
5. Size of the farm
6. Definition of farm boundaries
7. Accessibility
8. Type of Mediterranean productions
9. Identification of relations between users
10. Identification of the farm functions
11. Location of the activities' rooms with respect to the fund
12. Identification of the farm manufacture
13. Designing functional spaces
14. Water supply
15. Choice of agricultural practices
16. Energy technology installations
17. Use of biomass and typologies
18. System biogas plants
19. Production of "green" compost
20. Preparation of plant energy transformation
21. Distribution of electricity
22. Preparation of equipment for deep-freezing of products and fire protection
23. Sustainable mobility
24. Reintroduction nature and woods into the project area
25. Creation of short supply chain
26. Testing the level of business sustainability
27. Subsistence economy to business unit.

The basic concept is that anything is fritter away, but everything is reused to produce free energy and minimize the use of fuel, especially to create a self-sufficient *off-grid* organism, out of touch with the national electricity grid. Every single aspect has been engaged focusing on the main characteristics of the land, local productions and traditional dwellings. Especially the design of buildings encloses climate principles, morphology of territory and respects all the relationships amongst activities.

This way of living rural areas could preserve their identity and educate people on food culture and energy savings, as well as can foster organic agriculture, educational and advisory programmes.

The process is very complex and requires a detailed study of the background and current status. Respecting each point of the proposed program means starting a process of rational planning, in which the main actors are involved, also the main peculiarities of each local context.

The planner has the great task of grasping all main resources of places, as principal vectors of development. The methodological process will be applied in a Mediterranean farm to verify its real effectiveness, as well as the possible gaps.

4. Output and Future Perspectives Playing with Agriculture

Starting from the experience developed abroad and in Italy, I will show some outcomes with reference to different agricultural contexts.

In the *rural context*, a relevant use of agricultural residues to produce energy from biomass and create *off-grid* systems is expected, also the maintenance of biodiversity and local resources, the creation of multifunctional spaces able to improve economy and occupations in rural sector. An example of sustainability is offered in Fig. 5 that shows how to plan rural environment but also offer multifunctional layers of activities and attitude. A sustainable farm has composed by [11]: 1 - Electricity from little lakes or irrigation ditch; 2 - Forestry; 3 - Agricultural residues; 4 - Agricultural residues for heating; 5 - Collecting biomass; 6 - Photovoltaic panels; 7 - Production of natural gas; - Use of geothermic systems; 8 - Less fossil fuel; 9 - Use of biofuel.

In *Pheriurban areas*, laboratories for the experimentation of new sustainability practices could born, able to stop the phenomena of territorial disintegration, to produce processes of development and protection through improved environment.

Within cities, the *urban agriculture* could permit to product sustainable food and new green ecological tissues within cities, sensitizing communities to respect environment and practice agriculture.

As a planner, I envision a future research agenda that complements on ecological benefits for urban and rural ecosystems, by focusing on social and environmental benefits. I will try to pinpoint further significant solutions on development of sustainable villages and agro-cities in rural areas, with the hope that society will be persuaded for diverting resources from local territories to empower them, instead of impoverish. New strategies and visions for rural lands must minimize the impact of new technologies and practises on the open territory and make people aware about correct human behaviours which support Earth's life.

BETWEEN SIGN AND COLOR. THE RESTORATION SITE OF THE CHURCH OF THE VIRGIN MARY ASSUMED OF CARRÙ'

Maria Paola MARABOTTO

Scuola di Architettura e Società, Politecnico di Milano, Milano, Italy.

E-mail: maria.marabotto@polimi.it; mp.marabotto@gmail.com

Abstract

The paper critically examines the restoration of the Church of Maria V. Assunta at Carrù (Cuneo), executed in 2008, by the project and under the coordination of the author.

The conservative restoration (covered the structures, the decorations and the interior's technological upgrading) has involved different multidisciplinary expertises and skilled workers, which jointly have restored 'color and shine' to a building that has always represented the hub of religious and civil life in the Carrù's community.

The building, constructed from the 1703, is the work of Francesco Gallo (1672-1750), architect and engineer expert on military fortifications, engaged in those years in the construction of other religious buildings in Cuneo's Country.

The building was made on Greek cross plan with brick walls (exposed face to exterior, and plaster to interior), then completed with ceilings and roof in 1719. Within the various trades involved working for the decorations and furnishings. Particularly, the restored paintings was made from 1750 to 1752, then was restored from 1868 to 1900 (sails of the central dome).

The paper aims to illustrate the methodology applied in each restoration's phase (structural and technological for the roofs and the bell tower; fixing, consolidation and restoration for the frescoes's painted) by survey drawings and graphs for analysis and restoration, and still by numerous photographs taken before, during and after the work on site. During the restoration yard, is operated taking into account the best practices for the conservation of historic buildings, choosing the most appropriate solutions at every stage of the restoration.

Keywords: frescoes, parish Church, baroque, restoration.

The paper critically examines the restoration of the Church of Maria V. Assunta at Carrù (Cuneo), executed in 2008, by the project and under the coordination of the author.

The conservative restoration (covered the structures, the decorations and the interior's technological upgrading) has involved different multidisciplinary expertises and skilled workers, which jointly have restored 'color and shine' to a building that has always represented the hub of religious and civil life in the Carrù's community.

1. The historical events of the building

The church of the Virgin Mary Assumed is located in the historic center of town and was designed by architect Francesco Gallo.

In the eleventh and twelfth centuries in the municipal area there was a building of Christian worship dedicated to St. Peter the Apostle, the present church of St. Peter located along the road to Clavesana.

In the thirteenth century, inside the fortified city grew up near of the castle, is built on the current site, the Church of Santa Maria, new religious building that will take the time function of the primary site of worship. The building will undergo in the course of the centuries, several renovations. In the second

half of the seventeenth century, the church will be renewed on a design by ducal architect Giovenale Boetto, who arrived in Carrù through prestigious contacts and at the request of Conti Costa of the Trinity, lords of Carrù. The Boetto's yard realizes the arrangement of the bell tower, the choir and the facade of the church by calling workers from Lugano and Giuseppe Nuvolone for the painting. Between the late seventeenth and early eighteenth century the frequent occasions of war causing damage to the building and lead to the thought of building a new building for worship.

Fig. 1: View interior and external of the Church

The parish seat is temporarily transferred in the church of San Giovanni decollato (or Battuti Neri) in the current Via Roma; the old church was demolished, as well as some houses and the old rectory, resulting in a much larger area on which to build the new church.

Director of this great work is the Archpriest Carlo Tommaso Badino which entrusts the project to the young architect-engineer Francesco Gallo (1672-1750), an expert on military fortifications and engaged, in those years, in the work of the church of Frabosa Soprana.

The opening of the construction site of the new religious building begins 20 August 1703 with the demolition of the existing church. In the construction are used bricks and stones reclaimed from old buildings demolished and the materials arising from the demolition of part of the walls of the country.

Francesco Gallo will oversee the work of the construction of the parish church from 1704 to 1708.

After a short break in 1706 as a result of the war between the French and the Piedmontese, construction proceeded quickly in relation to the budget of the parish and the site was visited several times by Gallo. In 1708 he finished the tower, in 1715 the vault of the choir and a few months after the vault of the nave and the sacristy was built in the year following. In the summer of 1718 the masonry work had been completed and the pyramids crowning the pediment of the facade already positioned.

The facade of the parish church of Carrù is especially beautiful, perhaps the most noble and rigorous among those ascribed to Francesco Gallo. The primary geometric pattern - parastades, tympanum, hoof - is very obvious, the decorations are sketchy so as to blend in with the background, there are only a few elements emerging with force: the portal with the huge studded door, a rectangular window with a vigorous frame, the four monolithic stone obelisks. It is characterized of two superimposed orders of pilaster strips, has a considerable vertical development highlighted by its obelisks with ball.

Inside, the church has a Greek cross plan, prolonged in the central arm towards the choir, with a regular arrangement of the elements and the absolute absence of the curved line. The plant, with the presbytery covered by a vault at the basin, is formed by the succession of three rectangular spaces, each dilated by secondary chapels with a decoration of greater importance to center near the two side altars.

The decoration of the interior was entrusted, for the stucco, to Cipriano Beltramelli, active from 1725 to 1727 and, for the frescoes, to quadraturist D'Alemani and to figurist Milocco which end the work in 1751.

Fig. 2: Plant ground floor, plant of the attic and plant roof of the building. Survey drawings of the author

The first significant interventions of interior design relate to the two side chapels, to the right the altar of the Souls and left the altar of the Madonna of the Rosary. The task of the construction was given by the homonymous companies that have turned to Francesco Gallo for the design of the two twin altars and the marble worker Torre for execution. The work beginning in 1718 and ending in 1720. Between 1725 and 1727 the stucco worker Cipriano Beltramelli insert the elegant Corinthian capitals to crown of the various pilasters and columns, draws folders in stucco above the arches of the side chapels and painted faux marble the pilaster strips.

The archpriest Badino shall commission in 1729 at his own expense the scenographic major altar. It will be realized from the marble worker Giacomo Antonio Ponsanelli (1654-1735). The magnificent baroque canteen, enriched with angels and cherubs, is made with precious polychrome marbles that expand to form the geometric design of the floor in the presbytery.

The four altars of minor lateral chapels have been extensively reworked during the nineteenth and twentieth centuries, keeping only scattered fragments of the original work of the eighteenth century. The first altar on the left is dedicated to St. Catherine; facing to the right there is an altar dedicated to the Annunciation of the Virgin. Looking at the high altar, on either side of the presbytery are placed, left the chapel of St. Anthony Abate and to the right the chapel of St. Stephen.

Fig. 3: Vault of the presbytery and the first span.

The company of the SS. Sacramento has commissioned the magnificent fresco on the back wall of the presbytery and entrusts the execution to the prestigious quadraturist Giuseppe Dallamano who worked there from 1750 to 1751. During this time in the church was inaugurated the short season of the great baroque decoration, which culminated with speeches by Michael Antonio Milocco around the sixties of the century. The two important artists perform works of decided character, enriching the Church of quadratures and representations by the bright tones and explicit visual communication. Giuseppe Dallamano realizes the great stage machine of the back wall where columns, smoking censers and a sumptuous four-poster frame a spectacular triumph of the Eucharist, which was to stand out a lot more before inserting the big picture of the Assumption - a copy of the famous Assumption of Tiziano - which is covered in part (behind the canvas there was a large window which flooded the sanctuary).

Fig. 4: The bell before and after restoration.

Michael Antonio Milocco, aided by quadraturist Barelli in 1759 painted the dome of the presbytery: musical angels and joyful cherubs supporting floral garlands and glorify the name of Mary and the Eucharistic symbol. In the presbytery Milocco also works to the great fresco of the Last Supper, interesting version of a subject celebrated by many artists.

Other interventions of Milocco and Barelli are made in the 1761-62. Milocco realizes the four panels with joyful cherubs and floral inserts, painted on the serliane of the chapels of the Rosary and the Souls and grisaille scenes that narrate episodes from the life of the Virgin.

In the nineteenth century and then again in the twentieth century many surgeries are performed inside the church. The four smaller chapels are decorated with elements of minor tone with respect to the sign of the previous season Baroque. In 1839, on the back wall behind the altar is placed the large painting of the Assumption, the work performed by the carrucese Cesare Vicino, enlarged copy of the famous Assumption by Tiziano preserved in the church of the Frari in Venice.

In 1868 Turin painters Luigi Hartman, Paolo Emilio Morgari and Molineris involved in the large central dome: a starry mantle is in part raised on a vision of paradise where the Virgin on the throne, dominated by the SS. Trinity welcomes gifts of Carrù that, in female form, it offers products of the earth among a swirl of angels, saints and jubilant cherubs. In the four spandrels of the great vault the Turin painter Nicola Antonio Fava painted the Evangelists in 1900.

Above the walnut compass in the front door (carved by carrucese Giuliano Bernardo in the late nineteenth century), it was realized the balcony for the organ and choir, in carved and painted wood built around 1825 and decorated by renowned painter monregalese Francesco Toscano. In the twentieth century is also made in the presbytery of the Nativity, painted by Delle Coste, which covers a damaged painting of the same subject of Milocco.

The Count Filippo Nicolis Robilant, architect and designer of the Court, makes the design of refined walnut furniture that fully cover the walls of the sacristy, including the precious polychrome marble sink.

Fig. 5: Stone obelisks before and after restoration.

2. The restoration of the roof and bell tower

Work on the project of restoration and conservation have been divided into two phases: the first involved the roof of the building while the second phase focused on the paintings of the vault inside the church.

Externally, the building was in a state of preservation medium, but a thorough analysis of the parts that compose the structure noted a marked deterioration of the roof. During the years were not carried out the necessary maintenance work due to the considerable height of the building and the complex geometry of the roof; in addition the constant presence of birds, has increased the state of decay of the roof covering. The slope of the roof pitches, weathering and the incursions of birds have caused the displacement and disruption of brick tiles of the roof and then infiltration of rainwater that caused the exfoliation of the paintings and decorations of the vault internal church.

The surgery has restored the roof covering trying to remedy, most definitely possible to continued penetration of the roof which produced in substantial damage to the vault below. The works have provided for the insertion, between the small warping of the wooden roof and the mantle of roof tiles, a wooden plank on which were laid slabs sottocoppo waterproof. Bituminous sheets from natural fibers with corrugated profile for the accommodation of roof tiles to cover, have produced a ventilated and fully waterproof cover and protect the attic from the infiltration. It was later rearranged the roof covering in clay tiles and have been replaced gutters, downspouts and flashings.

Fig. 6: View of the roof from the attic before and during work.

The mounting of the external scaffolding has been extended to the summit of the tower and allowed the thorough inspection of the facade of the church beyond the walls and the roof of the tower. Have been restored cornices and pilaster strips of the facade as well as the stability of the monolithic stone obelisks. Work on the bell tower were: the restoration of the plaster of the walls that had serious problems of detachment, the maintenance the crown at the base of the clock and the accommodation of the cusp coverage.

3. The restoration of the internal vaults painted.

The second phase of the work - which began after the completion of the work outside - covered the interior ceiling of the building, that is, the painted surface of the entire vault of the nave. The area of the presbytery is surmounted by a dome lowered, supported by four corner pendentives interspersed with from one another by four arches paintings. The nave is divided into three bays: two smaller, the first and the third, defined on the side walls by small chapels with vault lower than the vault of the aisle; the central span, the greater is covered by another great lowered dome resting on four spandrels interspersed with arches paintings. These arcs define the two narrow and high vaulted ceilings of the chapels more; mid-wall of the chapel, through a series of columns in stucco, there is still another niche in the wall decorated with two beautiful marble altars.

The paintings that adorn the plastered surface of the vault are mainly decorative: swirls, spirals, smashed architectural, fake moldings and cartouches monochrome along with simple floral patterns made mainly in the eighteenth century by the painter Milocco assisted by quadraturist Barelli. They operate throughout the church with an impressive decorative project that began in 1759 in the dome of the presbytery and in the central nave continues in 1761-1762.

Fig. 7: The arches of the first and third span before restoration.

At the center of the vaults and domes, on portions of the side walls and the plumes are depicted holy personages, drawn from the Old and New Testament: in the spandrels above the presbytery can be recognized the four Prophets and in the spandrels of the dome are depicted the four Evangelists. At the center of the great dome is represented the Assumption of the Virgin Mary, to whom the church is dedicated, with the Trinity among a swirl of angels, saints and jubilant cherubs supporting a faux canopy decorated like a starry sky. On the side wall portions of the presbytery and nave, placed above the cornice, are depicted the Theological Virtues and the Cardinals, while on the back wall and on the arch that separates the presbytery from the first span are depicted four angels monochrome. These figures and fake architecture were much altered and repainted in the nineteenth century. In the vaults of the first and third span are depicted personifications of the Church with a cherubs that supports a scroll containing an inscription. In the dome of the presbytery are depicted numerous musical angels and jubilant cherubs that support floral garlands and glorify the name of Mary and the Eucharistic symbol.

The vault appears to be very lively and decorated, the colors are brilliant and rich overtones; there is an evident lack of homogeneity of conservation between the various parts of the painting due to the moisture infiltration from the roof and because of the likely actions of pictorial and chromatic reorganization difficult to identify. The paintings are of excellent quality, rich in detail and color, with a construction volumetric sought through a skilful use of light sources and light in general: it comes from the two windows and illuminates uniformly the decorations on the walls, while the sails and the vault they are illuminated by the central rays of divine light. The light eighteenth century is very sought and has a great yield and volumetric perspective because it comes from above and stresses the

importance of the scene represented. Before the restoration, the vault it appeared at flattened and modified by additions pictorial present throughout the decorations.

Object of the restoration was the whole surface of the roof, from the presbytery to counterfaçade to the height of the majestic faux marble and stucco cornice and the back wall in its entirety.

Fig. 8: The underarch before and after restoration.

The vault of the presbytery. The representation of the dome is not original of the eighteenth century, but is presented repainted in the nineteenth century with later interventions in the twentieth century.

The techniques used for the decoration of the eighteenth century is a fresco with dry finishing and lime. The plaster that was used as the support is formed from lime mortar and rougher, coarse and greyish river sand. The definition of the figures was performed with a preparatory drawing made with the carry from cardboard that sometimes, backlit or raking light, we see transpire from the nineteenth-century paintings. The techniques used during the nineteenth century is of poor quality compared to the frescoes of the eighteenth century, as well as the colors used - tempera with pigments from purple tones more subdued compared to the colors of the eighteenth-century paintings. The paintings are taken up in part in the twentieth century with the introduction of cherubs and angels made of fatty and oily color pigments very vivid.

The paintings were in fairly good condition. The paint film was very dusty and of low resistance, the color appeared greyish and there were gaps in some points with loss of the painting, lifting of the color and plaster and were present surface sulfation due to infiltration of rainwater from the roof.

Fig. 9: Chapel on the left. Particular the restoration of the frescoes and the degradation of the vault.

The restoration consisted in the total cleaning of the vault, without the elimination of the layers of repainting, but keeping the succession of the interventions and trying to connect them and fuse them chromatically to each other. Has been totally removed the nineteenth-century painting exclusively from the cornice of the vault that it was incomplete and dissonant with the remaining portion adjacent. Were also removed some tweaks disfiguring present on the faces of some of the angels.

Fig. 10: Chapel right. Cleaning work of the painted surface. Details

Central dome. The decoration of the dome depicting the Assumption of the Virgin Mary surrounded by a mantle decorated like a starry sky. The painting is not the original of the eighteenth century, but it is repainted in the nineteenth century with later alterations in the twentieth century. This can be seen from the engravings on the plaster, visible with oblique light, and from falls and scrapes of color that reveal other colors from richer tones and lighter typical of the eighteenth-century painting. The playing technique of the eighteenth-century paintings is a fresco with dry finishing and lime. The support of original paintings is a plaster made from a very compact mortar of lime and river sand rough, coarse grained and greyish. The definition of the representations was performed with a preparatory drawing by carrying the design from cardboard that sometimes, against the light, you see transpire from repainting the nineteenth century. The techniques of the nineteenth century is of poor quality compared to the previous one, the colors are tempera and the pigments are purple tones and duller than previous ones. The starry mantle ends with two strips of linen cloth in triangular shape, painted with the same color blue and fixed to the wall with large nails original nineteenth century. The paintings will be remodeled in the twentieth century with the inclusion of angels and other figures on blue drapery.

The decoration was in good condition. The work carried out in the nineteenth century were made with color tempera lean, very dark and dirty from dust and smoke deposited on the surface. The additions of the twentieth century have been made with colors fats that have undergone detachments, were also present salt efflorescence due to water leaks from the roof.

Fig. 11: Restoration of an under arch. Details.

The restoration began with a thorough consolidation of the paint film which was detached from the substrate in flakes of color. It 'was then totally clean the vault without eliminating the layers of paint, but keeping the succession of interventions chromatically fusing them to each other.

Fig. 12: Presbytery. Detail of the frescoes of the vault before and after restoration.

Similarly to what has been described here was through the vault and on the side walls of the vault of the first and the third bay of the nave, on the back wall of the presbytery, on the counterfaçade and in the vaults of the side chapels.

The project also involved the installation of lighting that has been totally redesigned in order to enhance and give prominence to the restoration work carried out. The next few years were made restoration to the wooden works present in the church: the eighteenth-century furniture in the sacristy custom-designed by the architect Filippo Nicolis di Robilant, the choir and the compass input.

The restoration project of the Church of the Assumption of the Virgin Mary, which was developed from 2008 to 2010 has involved different parts of the building, outside - the roof, the roof covering, the bell tower - internal - internal painted vaults, wooden works. All these interventions were carried out by implementing the best practices for the preservation of historic buildings, choosing the most appropriate solutions at every stage of the restoration. And every intervention has contributed to the larger project of recovering a complex structure, the center of civil and religious community of the city.

GIUSEPPE AGNELLO “HISTORIC ARCHITECTURE”: THE PROTECTION AND SAFEGUARD OF CULTURAL HERITAGE IN AESTERN SICILY

Iolanda DI NATALE

Department of Letters and Cultural Heritage, Second University of Naples, S. Maria Capua Vetere (CASERTA), Italy.
iolandadinatale@gmail.com

Abstract

The relation between landscape and historic centre has been widely discussed in years following the Second World War. The problems of reconstruction and urban planning pushed the protagonists of Italian culture to wonder about the relation between new and old, keeping and expansion, reconstruction and modernizing. In these years, civil organisations and association play a very important role in national debate. The Italian Touring Club (TCI) was active in the moral and material reconstruction of the country. The tourism seem to be the most suitable sector to catalyse the hope of a return to an atmosphere of peace and development. Through its official magazine “Le vie d’Italia”, the Club fought important battles for the protection of cultural heritage. In Syracuse, Giuseppe Agnello was one of the most important protagonist of this debate. Often defined as a “historic Architecture”, in reference to a particular inclination that led him to investigate the native land monuments from the III century to the XVII century. He had a depth and mature understanding of the need of knowing and protecting the local historical, cultural and natural heritage. In two reportage write for “Le vie d’Italia”, Agnello denounced the building abuses, the dangers for the local monument and the massive destruction of the coastal landscape.

Keywords: Giuseppe Agnello, “Le vie d’Italia”, Syracuse, Landscape, Historic Centre, Urban Planning, Safeguard Cultural Heritage.

1. Italy of reconstruction: the preservation of historic centres and landscape as town planning matter

The landscape has been considered among the goods deserving preservation, on the basis of its cultural and naturalistic values for several decades. An historic-critical approach that, by crossing the limits of the exclusively aesthetic, naturalistic or cultural exceptional nature, extends itself to a scheme of relations and identity resources, whose comprehension demands a deep knowledge of the never-ending interdependences among environmental frames, settling dynamics, local society lifestyles, and cultural and symbolic values linked to perception ^[1].

Nowadays, the indivisibility of the relation landscape/historic centre is clear. However, this very close relation has been very slow in establishing itself within the usual town planning procedure.

In the years immediately following the World War II, that were characterized by the problems of reconstruction, the Italian cultural world went back to wonder about the relation between new and old, keeping and expansion, reconstruction and modernizing. Architect and town planner culture foregrounds the building of contemporary cities, often by prefiguring a brand-new urban scenery, in which few selected and isolated monuments rise to the role of witnesses of the past.

This topic had already been discussed heavily at international level during the eighth CIAM Congress (United Kingdom, Hoddesdon 1951); it would been the main theme during all the ‘50s and ‘60s even in

Italy. Here, the uncontrolled building activity involves the historical centers of the city, as well as, the suburban areas. The former were affected by the Reconstruction Plans, which not involved with the bonds enforced by the Town Planning Law of 1942 (which governs "the trim and the increase in building's towns and usually the urban development in the territory"), just operated within pre-existing alignments. While, the latter, without a General City Plan, were intended a completely free from rules expansion, often assisted by proper economic actions^[2].

Exactly in those years, lots of newspapers and specialized magazines pages (such as "Il Mondo", "Casabella", "Urbanistica", "Restauro", "La critica d'arte") came alive for all the interventions on town planning problems with reference to city centres and natural beauties^[3].

Architects, historians, critics, town planners and intellectuals quarrelled animatedly, firing up the national debate. Protagonists of this *querelle* were: Ernesto Nathan Rogers, Roberto Pane, Cesare Brandi, Leonardo Benevolo, Edoardo Detti, Luigi Piccinato, Gillo Dorfless e Renzo Men. All this, while in the Italian cities, as a result of delays of regulations and speculative interests, destructions continued and the expansion kept up uncontrolled towards areas once with farming vocation^[4].

In this atmosphere, an important moment of new methodological and regulatory awareness is represented by the writing of "Carta di Gubbio" (Gubbio Chart, TN), *Final Declaration* adopted at the end of the debate arose from the National Conference "Preservation and restoration of historical and artistic centers" (Gubbio, 1960), which was promoted by Giovanni Astengo. The chart, stating the national importance of the issue, pointed out the fundamental principles of safeguard and restoration of historic centres. It reiterated also: the urgent need of an identification and classification of the areas to be safeguarded and restored; the introduction into the General City Plans (because "basis to the development of the modern city itself"); the immediate disposition of safeguard bonds; the halt to every building activity; the arrangement of the needed Detailed Plans of Conservative Renovation. Moreover, the Chart «refuses the criteria of reconstruction and stylistic additions, of mimetic rebuilding, of the demolition of buildings, also the unpretentious ones. It does not accept rarefaction of the texture, the isolation of monuments, nor new insertions in ancient environments»^[5]. A year later, the same promoters of the conference will give life to the National Association for the historical and artistic centers (ANCSA)^[6].

If the recovering of historic centres and their integration within the General City Plans have represented one of the main issue in the national debate, a special credit goes to ceaseless battles carried out by cultural association: ANCSA, Italia Nostra, Fondo Nazionale per la Natura, Istituto Nazionale di Urbanistica.

In those years, the historical campaigns of Antonio Cederna and Umberto Zanotti-Bianchi with the Association "Italia Nostra" have been crucial to prevent devastating demolition of Rome historic centers. The action of Renatuccio Bianchi-Bandinelli and Luigi Piccinato have preserved the historic center of Siena with its natural slopes. Very important were the plans, respectively, of Edoardo Detti and Giuseppe Venuti for the defense of the hills of Florence and Bologna, and the plan of Assisi by Giovanni Astengo^[7].

All this Institutions and people had the asset of debating the problems of historic centres and landscapes in their multiple theoretic-methodological and technical-administrative aspects. They had busily acted, through actions of denunciation, awareness raising and promotion, for the identification of an intervention guideline that would be able to combine the socio-economic needs and the naturalistic-ecological ones^[8].

2. The Italian Touring Club: the role of Tourism in the years after Second World War

The ancients used to talk about *natura naturans* and *natura naturata* with an impressive exactness of perception and expression. In 1985, Carlo Giulio Argan stated: «the so told beauty of nature» should also be read as «the product of intelligence, thinking and human work in the course of various millennia; a huge book, a sum in which are written millennia of history»^[9]. Such awareness had widely been revealed within the fundamental principles of the biggest and prestigious Italian tourism association, the Italian Touring Club (TCI). Federico Johnson and Luigi Bertarelli founded it the 8th November 1894, together with some enterprising lovers of trips, knowledge, and progress^[10]. The Constitution asserted that the goal of the association is to pursue the «development of tourism, also meant as mean of knowledge of countries and cultures, of mutual comprehension, and respect among people». The main action are: «2). to exert oneself for preserve landscapes, distinctive natural environments, the geology, flora and fauna, the single monument and works of art in general, as well as urban complexes of remarkable historic, artistic, and ethnologic importance; to facilitate knowledge [...] about the environmental and historic heritage and its touristic fruition; 3). to exert oneself to solve every problem linked to tourism, by helping the spreading of a more qualified touristic culture and entrepreneurship also regarding the city planning issues»^[11].

The ability of tourism to represent an effective tool of mutual knowledge among people resurfaces during the debate about the recovery of tourism industry, which grew busy since the first few months after the end of the World War II. As a matter of fact, also in Italy, tourism seems to be the most suitable sector to catalyse the hope of those who foretold a return to a climate of international relationships dictated by peace and tolerance. The importance to share and promote the authentic national identity revival as world heritage was declared during the congress of Northern Italy Provincial Tourist Boards that took place in November 1945. It was the first confrontation point among the sector operators after the end of the war^[12].

These applications were kept for the following years too, taking the aspect linked to the natural-environmental heritage preservation and landscape safeguard, as well as the more and more emergent phenomena of uncontrolled urbanization and building, for the maintenance of “urban decorum” and the city aesthetics. In the following decades, the considerations about the effect of mass tourism on the collective identity had progressively imposed themselves. In the ‘60s, at global level, a tourist model emerged, and this, in a material point of view, turned into an overbuilding of touristic places, able to provide standardized services. In meanwhile, the town planning of tourism places has seen the speeding up of transformation processes into action in the previous decades, even at the risk of compromise the original environmental value^[13].

In the years after World War II, the TCI committed itself to rebuild the country morally and materially, faithful to its principles, it carried on its awakening campaign, involving Ministries, bodies and local governments. It got ahead a constant campaign for the reopening of Italian museums, and it especially engaged in the fight for the tourism development and against the tourism-invasion^[14].

During the ‘50s, also the divulging activity restarted with a new ardour: guides map-making, and official magazines: “Le vie d’Italia” (“Routes of Italy”). The first number of the magazine was released in 1917, supervised by Luigi Bertarelli. The publishing went on until 1967; it was stopped only during World War II. In 1919, the magazine became the ENIT (state-controlled body of tourism studies and promotion) official organ. For the first time, with the establishment of this body, the Italian State recognized the importance of tourism in the life of the country. For the promotion of this *Vie d’Italia* were created during the war.

3. Malfunctions and wounds of Syracuse: the fight of a fan “Architecture Historian”

The collaboration between Giuseppe Agnello (Canicattini Bagni 5 February 1899 – Syracuse 28 September 1976)¹⁵ and Italian Touring Club monthly magazine “Le vie d’Italia” begun in 1928 with an article dedicated to *Un monumento millenario che risorge. Il Duomo di Siracusa già tempio di Athena* (A reviving millenary monument. The Cathedral of Syracuse once temple of Athena)^[16]. In the occasion of the reopening of the Cathedral, after the end of restoration, the 14th January 1927, the scholar attended the official conference with a speech that he repurposed in the mentioned article.

In those years, Syracuse was living a climate of artistic and cultural interesting fervor, arouse around the famous figure of the archaeologist Paolo Orsi. He was sent to Syracuse in 1890 as Supervisor of Excavations and Museums; he was a scholar with a positivist education, whose activity, diverging from the antique tradition, put on a definitely innovative nature^[17]. Agnello shared the same education with Orsi. Both they went to the Istituto di Studi Superiori di Firenze, a well-known school to which trace back the structure of the historicist-philological studies. Agnello taken this approach as hinge of his scientific activity, it is clearly recognizable in the whole methodological structure^[18]. These general lines found the bases in the primary importance given to the historic document, to the discovery of the work, to its recognition, to the explanation, always accompanied by a detailed archive and source research that he considered unavoidable to the historic-philological investigation.

Fig. 1: Magazine cover. “Le vie d’Italia”, XIX 1963.

Fig. 2: Magazine cover. “Le vie d’Italia”, XX 1964.

Fig. 3: Giuseppe Agnello.

The filiation of Agnello's studies was shown up more than once, coming from those themes, which had gained the interest of his master Paolo Orsi. The first and fundamental studies on Middle Ages and its architecture took shape under Orsi's protection and pushing. In 1926 Agnello published *Siracusa Medievale. Monumenti inediti* (*Medieval Syracuse. monuments unknown*). It would obtain the appreciation of important personalities such as Benedetto Croce and Pietro Toesca. In 1935 it was published *L'architettura sveva in Sicilia* (*The Swebian architecture in Sicily*), within the "Collezione Meridionale" ("Southern Collection"), thanks to the good offices of the director himself Umberto Zanotti-Bianco. This volume was already prepared in 1931. It won the award from the Accademia d'Italia. Inside the series "Collezione Meridionale" in 1942 was published *P. Orsi Sicilia bizantina* (*P. Orsi. Byzantine Sicily*), in 1952 *L'architettura bizantina in Sicilia* (*The Byzantine architecture in Sicily*), and in 1961 *L'architettura civile e religiosa in Sicilia nell'età sveva* (*The civil and religious architecture in Sicily in Swabian age*). The interest of the scholar was not limited just to the investigation of Middle Ages. An important core of researches would involve the Renaissance and Baroque Syracuse: again, on "Collezione Meridionale" was published *L'architettura aragonese-catalana in Siracusa* (*The Catalan-Aragonese architecture in Syracuse*), in 1959 was released the essay dedicate to *I Vermexio architetti ispano-siculi del XVII* (*The Vermexio Spanish-Sicilian architects of the XVII*)^[19]. In collaboration with his son Santi Luigi, *Siracusa Barocca* (*Syracuse Baroque*)^[20] was edited in 1961 and, shortly after, in 1964, *Siracusa nel Medioevo e nel Rinascimento* (*Syracuse in the Middle Ages and the Renaissance*)^[21] would be released. Besides, Agnello – who held the chair of Christian archaeology at the University of Catania – gave a remarkable contribution to the study of the history of art within the very first Christianity, by bringing to light the early Christian age, until then little known and investigated. Syracuse's hypogeum area is second only to the Rome one, and its maximum expression is in the area of St. Lucia, St. Giuseppe in St. Marziano, and Vigna Cassia catacombs^[22]. During his career as scholar and teacher, Agnello had fully embodied that ideal, inhering in Toesca, for which to train to understand the work of art means to teach how to "see". Ability considered both intellectual and physiological, of the eye and of the mind. This deep sense of "seeing" was already theorised by Adolfo Venturi and become fixed in the famous formula "to see and to see again", it had been introjected in Croce's way also by Agnello^[23]. Beyond the different periodization, the relation between the scholar and the monument, always accurate and thorough, firstly took place through recourse to a direct investigation on the field, based strategically on *Feldforschung* (investigation on the field, analysis live of monuments throughout photos and surveys). In these terms, he showed to already have a scientific maturity such that included both theory and the science of building, how Gustavo Giannoni, a Camillo Boito follower, would reassert it^[24]. Therefore, the primary document identified with the work of art itself, strictly studied and well known. From this belief, it took shape the other fundamental aspect that characterised most of Agnello's activity; it was focused on the preservation and the safeguard of the goods and of their environment. Since 1948, the scholar committed in a stubborn fight in favour of the defence and the safeguard of monumental and landscape goods, of which he powerless was witnessing the growing decay. This new campaign, carried on through the pages of National and regional newspapers and supported by researches and scientific studies, gave him the appointment as president of Commission for the Safeguard of Natural Beauty in Syracuse Province, which he held from 1950 until 1974. The 18th July 1969 the Syracuse section of "Italia Nostra" was set up, in accordance with the model of what Zanotti-Bianco was doing in Rome.

Fig. 4: View of Syracuse town from Ortigia Island.

Fig. 5: Map of Syracuse ancient and roman (*Pentapolis*). By Charles Rollin (XVII-XVIII).

It was created thanks to the will of Giuseppe Agnello and the marquis Gioacchino Gargallo from Castel Lentini. This was created with the exact intention to actively work for the control of territory and for the safeguard Environmental and Cultural Heritage ^[25].

Also in Archimedes' city, the town planning events, started from the '50s, were characterised by the devastation of cultural and historic resources, by the neglect of the historic centre, by the uncontrolled and often illegal growth of suburbs and peri-urban areas. If the years just after the World War II mainly saw a city still concentrated within the boundaries of the old *Naos* of Ortigia, in the '60s, in the name of a demographic rise that would soon reduce, the city changed completely ^[26]. That process of expansion, started in the first half of XVIII century, sped up with a frantic rhythm. It was characterised by the massive occupation of all those areas that made "*Urbem Syracusas maximam esse Graecorum, pulcherrimamque omnium saepe audisti*" ^[27] already in classical age. The districts of the old *Pentapolis* of classical age: *Acradina*, *Tica*, *Neapolis* and *Epipoli*, all characterised by hill grounds, witnesses and keepers of monumental remains, were assaulted by agglomerate of concrete, incorporating the area of necropolis and the Monumental Archaeological Park of the *Neapolis* with the Greek Theatre, the Roman Amphitheatre, Ierone's Altar and the *Latomias*. Everything was surrounded, almost submerged and concealed by building.

Already in 1958, Cesare Brandi threw himself against this attack to the monumental heritage from the pages of the "*Corriere della Sera*": «with how much the foolish destructions in 1885, the buildings of the Fascist period, and the very recent ones had done to Syracuse, it is not really possible to hope in a miracle [...] the situation is so compromised, for some crucial areas, that worse would not be possible. However, it is essential to check this, and that the barricade of buildings on the edge of the archaeological area would not move forward anymore» ^[28].

If the focus on the preservation of archaeological sites was somehow primary, a similar idea could not widen also to the areas of early Christian catacombs that, in those years, Agnello reported in the light and explained. Syracuse, in fact, has perhaps the most important complex of late antique tombs after Rome. Among these it is particularly important the group of the Catacombs which are arranged from north-west to southeast, according to an internal arc taking up again the one formed by *Latomies*. The localization of these cemeterial areas is very interesting with regard to the planning history of the city in late imperial period: in fact, they are inserted inside of *Neapolis*, along the edges of *Acradina*. It is a clear indication of the narrowing of the inhabited area. The catacombs, use by the early III century AD, are preceded by a necropolis dating back to the first and middle imperial age. This confirms, with great emphasis, the news reported by Strabo (*Amasea*, Pontus, before 60 BC -20 AD approx) in the VI book of his monumental *Geography* (2, 4). In this passage the Greek historian and geographer explain like the city, almost abandoned and partially destroyed during the war between Octavian and Sextus Pompey, was largely rebuilt under the reign of Augustus, but just limited to the *Acradina* ^[29].

From the second half of twentieth century, after more than eighteen centuries, the city returns to expand on the mainland towards uptown of ancient *Pentapolis*. The building occupancy came to compromise irreparably the green zone that stretched from the Forum of Syracuse to the *Temenite Hill*, reaching *Dionysian Walls* that culminate in the *Euryalus Castle*, an imposing military area built by the tyrant *Dionysius* between 402 and 397 BC. It faded the confident hope to protect the area, between the complex of *Neapolis* and the *Capuchin catacombs*, expressed by the Superintendent of Antiquities and distinguished archaeologist, Luigi Bernabò Brea.

Fig. 6: Necropolis. *Neapolis* Archeological Park. Syracuse

Fig. 7: Lower area of the *Neapolis* Archeological Park. Syracuse

Fig. 8: Roman Amphitheatre. *Neapolis* Archeological Park. Syracuse

In an article published in the newspaper "Corriere di Sicilia" in 1947, he stated: «tourism was until a few years ago, and we hope it will return to be in a near future, one of the major resources, perhaps the major economic resource of Syracuse. The care of its beauty, the respect and the enhancement of its monuments are thus not just a luxury for Syracuse or the fulfillment of a duty to the culture, but an intimate breath of life and well-being [...]. It is now an area above all to protect and enhance from the expansion of the modern city [...]. This is what we would like to define the major tourist artery of Ancient Syracuse» ^[30].

With respect to this expansion of the city on the mainland, uncontrolled and unaware of the values of archaeological, historical and environmental heritage, we were witnessing the depopulation of the historic center, Ortigia: an island within an island. The tradition handed down to us by Strabo tells that the first Corinthian settlers led by the oecist Archie came here around 734 BC. The Temple of Athena with its Doric columns still stands on the highest and better visible point of the island, now part of the Byzantine basilica that is framed by the exquisite Baroque façade.

The proposal made in '52s by Agnello himself, as Chairman of the Commission for Natural Beauties, to put the landscape restrictions on Ortigia was worth nothing ^[31]. The regulation, amid obstacles and bureaucratic delays came, in fact, only in 1969, when by then the most serious damages were done: «Now more than ever speculative needs were a burden, with such clear threat, to the remaining heritage, in defense of which rather than the sanction of the laws of the state should stand the open condemnation and rebellion of the citizens themselves» ^[32]. This is the intimate reason with which Agnello returned, after more than thirty years, to write on "Le vie d'Italia". In 1963, with a careful report he denounced *The malfunctions of Syracuse*; malfunctions that just a year later became symbolically *The wounds of Syracuse* ^[33].

Both the articles complained the stages of urban transformation, the state of destruction and of caging in which the most outstanding city monuments were forced. Agnello explained the failures of the institutions often unable, more often willfully obstinate to postpone the approval of the General City Plan (GCP), for which in 1954 was announced a public competition. A young architect won it, Vincenzo Cabianca. The plan was approved twenty years later because of several vicissitudes and different relationships. The GCP classified all Ortigia "special conservative Area, "approving the bond of "inalterability for everything that is already existing" ^[34].

In the period between 1952 and 1969, the worst damages to Ortigia urban heritage took place. Dates back to 1947, the first official act of "the beginning of the invasion". It was the alienation of two of the major squares of Ortigia: «the old town had very few squares: so few that, for counting them the fingers of one hand were too many. Two – Luigi Greco Cassia square and the castle square – had disappeared. In place of the first, which was also bordered by the sea, there is now a pretentious modern building, which, with difficulty, it was possible to obtain a reduction of the height. The other, very large, on the tip of Ortigia, which housed the superb Federico II castle, was spoiled by inserting a senseless building agglomeration that has eclipsed the view of the sea».

It is clear from reading the two articles the scholar's belief that the alleged work of restoration of the historic center was too often interpreted by local authorities as an opportunity to alter and destroy, using for their aim the pretext of forced demolitions in order to allow freedom of action to speculators.

Fig. 9: Square Luigi Greco Cassia before 1950. Ortigia

Fig. 10: Square Luigi Greco Cassia with INAIL building. Ortigia

In the two reportage for the TCI newspaper Agnello writes about the case of the "splendid concrete box" cleverly inserted between the Baroque Church of St. Giuseppe and the theater Damiani, the bank building built close to the "splendid ruins of *Apollonion*" the oldest Doric temple in Sicily. He mentions

the project for “a six and more floors barrak” that would occlude the fourteenth-century Palazzo Mergolesi and the fifteenth-century Palazzo Gargallo. He also explains the incomprehensible events that led to pull down a baroque palace in Archimedes Square, to destruction of the district between Giudecca and Logoteta Street and to break down the last remains of the monumental city wall built by the Spanish Emperor Charles V.

However: «where the frenzied speculation has reached paroxysmal forms is out of Ortigia [...]. To the relentless aggression, which spreads in all directions, not even one's palm of green does escape. The intervention of the Superintendent had managed to delay here and there the advance of new construction; but the resumption of the offensive, by speculators was violent and relentless».

The Civil Hospital was built in the place where Landolini discovered the famous *Venus “anadiomede”*, in the early nineteenth century. The statue is today one of the top attraction of the Museo Archeologico Regionale “Paolo Orsi”. The Archaeological area of *Neapolis* was surrounded and the beautiful view that from the Greek theater opened on Ortigia was obscured. The building arrived to cover the “Grotticelle” necropolis, where legend placed the tomb of Archimedes; the same treatment was reserved to the beautiful Byzantine church of St. Giovanni and St. Marziano with its catacomb complex.

Among the most pervading interventions against Syracuse perpetrated in the years after World War II it is not possible neglect the events that led to the creation of one of the largest petrochemical settlements in Europe.

In a speech that took place in Syracuse in the March of 2012, Vincenzo Cabianna, recalled the long years of work at GCP: «In the early postwar period the easier and more common resources for local economies was formed by the parasitic income urban housing. It happened in the absence of town planning schemes and for the higher-level economy formed by big pollutant industrial settlements of semi-finished products of the petroleum industry. It was an expansion based on the illusion of the possible development of their induced form petroleum industries, by the mythology of iron and steel industry and by factories, very concrete, in cement» ^[35].

Within the perspective of conquering international markets, it was decided to set in coast between Augusta and Syracuse the industries for the oil refining and basic chemical and petrochemical industries.

The beginning of this industrialization that can be dated back to 1948, when a young Milan industrialist, Angelo Moratti, bought the facilities of a disused American refinery in Longview, Texas, thus the RA.SI.OM (Refinery Sicilian Mineral Oils) was born and subsequently sold to Esso. Taking advantage of the many benefits and economic incentives provided by the Cassa per il Mezzogiorno, in order to attract to the South both private and public groups, it began what was commonly called the “Economic Miracle”. After RA.SI.OM, other industries such as Liquichimica, Cogema, Eternit, Sicilfusti, Edison, Celene settled. In 1953 was built the thermal power plant, Enel Tifeo, while in the early '70s was built ICAM (Joint Undertaking Anic Montedison) that still produces more than 700,000 tons/year of ethylene. And were assembled also the Enel thermal power plant Melilli, the Consortium of IAS Purifier (Syracuse Water Industry), the ISAB refinery, built by demolishing more than 200 houses in Marina di Melilli and literally erasing it from the map ^[36].

The ancient vestiges of the civilizations of Thapsos and Megara Ibla are “Cathedrals in the desert” incorporated between 30 km of iron. In this places, during «one of the many earthworks carried out at the foot of the hill where there are the RASION plants, the bulldozer invested time ago, and reduced to a heap of minute fragments a Greek statue of exceptional importance. In the little peninsula of Magnisi - the Virgil *Tapsus iacens* - a group of Sicilian tombs was destroyed to obtain blocks for the construction of the great dam of the port of Augusta».

On 12th May 1976, the Sicilian Region issued the regional law for “The protection of historic centers and special rules for the district of Ortigia in Syracuse and for the historic center of Agrigento”, on 28th September of the same year Agnello died.

«The Tourists who, after long routes through the Peninsula, ended their trip to Syracuse, remained fascinated by the sight of this beautiful coastal area, cut by the railroad, lapped on the one hand, by the tides, on the other hand, closed by an intense green frame extending up to the massive ramparts of the Ibleo plateau. Today everything has changed [...]. At the very least you left a good documentary, which fixes forever the face of the city that disappears: documentary that is jealously preserved in one of our museums, it would be able to leave in the tomorrow visitors that same moved and quiet admiration that the relics of past civilizations arouse in us».

Abstract

The aim of this Paper it is to present a research project which derives from Italian National Research Framework PRIN2009: "Regeneration and renewal of rural landscape. Building strategies in the surroundings of new urban centres". This issue aims to the regeneration of the rural landscape, with particular focus on architectural design, which can become the instrument for promoting the value, the memory, the identity and the environmental quality of the rural landscape as cultural heritage.

The awareness of the fact that the categories "rural" and "urban" appear meaningless, where it is a question of marking out the boundary that do not have a well-defined specific function and that are increasingly characterised by mixed complexity – economic, functional, social and cultural – leads to reviewing the strategic guidelines of managing the landscape and draws increased attention to the qualitative aspects of the landscape development and the human-environment relationship.

A second very important aspect to point out is the resilience of the architecture in this concept of rural intensification: in landscape construction, every measure involves the subject of shape and space. From the building of a small footbridge to the renovation of the banks of a large stretch of river, from a project for a fountain to one for a roof garden or a park, it is difficult to tell the difference between a region's natural and man-made structures, since they should be always connected and interrelated.

Keywords: Rural-urban boundary, Humanlandscape design, Eco-social design, Architecture design

1. Section Introduction to the Rural Architectural Intensification

The paper describes methodology and results of a branch of research project that derive from Italian National Research PRIN2009 "Architecture as Heritage: innovative instruments for the tutelage and the improvement of the local border systems"; within this National framework authors from University of Pavia (coordinate by Prof. Tiziano Cattaneo) participate, deepening the theme "Regeneration and renewal of rural landscape". This issue aims to the regeneration of the rural landscape, with particular focus on architectural design, which can become the instrument for promoting the value, the memory and the environmental quality of the rural landscape as cultural heritage. Authors expose a operative action for the regeneration of rural heritage with a specific application to Rural Architectural Intensification (RAI). Rural Architectural Intensification is an innovative design action for architecture and landscape design. This operative action is applicable for regenerate and transform the contemporary city-landscape into use that are suitable for contemporary ways of living through the construction of a new paradigm that will shape an architectural project committed to sustainability.

The concept of Rural Architectural Intensification include three words:

Rural as high quality environment with richness of history, values, memory and identity;

Architecture as a process and construction product, which can create social, cultural, economic and technological innovation;

Intensification as a strategy for creates sustainable density of activities and spaces for citizens in which the natural environment and the rural-urban environment coexist harmoniously.

Moreover, the term rural has to face the modification of the economy system and needs also to be rethought it in terms of definitions. In different disciplines we assist to a controversy related to the distinction and definition of the terms *agrarian*, *agricultural* and *rural*.

In Geography, for example, the three terms are defined as follow: the agrarian geography is concentrated on the line of intervention for the agricultural development; the agricultural geography is related to the morphological form of the earth and, finally, the rural geography is the most recent discipline that investigate the whole rural space as the extra-urban territory. The term *rural* seems to take in account the technological and social evolution of the countryside. The countryside has to deal with different issues: the city, the multi-activities, and the climate changes. Furthermore, the term *rural* considers all the different elements of this non-urban territory affected by a continuous transformation.

2. The role of Architecture in the process of intensification of the rural context

The developments of European cities and their speedy urbanization have created a perception of contemporary space like a homogenous continuum in which city and landscape have lost their origin boundaries. So, the concept of boundary in the European cities includes some enlightenment – social, cultural, economic, geography, architectonic - and the rural landscape itself becomes a boundary, and it represents the real contemporary city-landscape.

The crisis in rural areas is essentially a European problem: depopulation and ageing of the population, abandonment and decay of small town centres, difficulty in keeping existing businesses, intensive agricultural practices to the detriment of biodiversity, pollution, a lack of infrastructures and services for tourism, as well as a shortage of job opportunities for the population, etc.

The research project addresses the specific cultural and productive features in the Italian and European areas in which this phenomenon it is processed and has reached significant levels of deprived neighbourhoods; like a big boundary whose either urban and rural shape cannot be surrendered to simplifications imposed by tourism's occupation, but towards hypothesis of regeneration the rural landscape of old villages and farm buildings.

The research aims is to identify the Best Practices which can be assessed in a qualitative way trough the description and interpretation of operative tools for architecture and landscape design that allow to regenerate and transform the contemporary city-landscape into functions that are suitable for contemporary ways of living. The rural landscape has seen a tendency to overcome the urban growth culture and quantitative development that had left a strong mark, represented by the negative concept of the countryside – only diversified by the varying quantities of building and non-agriculture related activities, and thus a decline of the concept of nature.

The awareness of the fact that the categories “rural” and “urban” appear meaningless, where it is a question of marking out the boundary that do not have a well-defined specific function and that are increasingly characterised by mixed complexity – economic, functional, social and cultural – leads to reviewing the strategic guidelines of managing the landscape and draws increased attention to the qualitative aspects of the lands development and the human-environment relationship.

The research project underlines the importance of the role of the Architecture in the process of intensification of the rural context for the landscape construction that involves the shape of the space. Rural Architectural Intensification means that every architectural intervention in the territory - from a small pedestrian bridge to the regeneration of the river banks, from the public space design to the project of a roof garden or park - have to restore the relationship between landscape and architecture as the history has taught. Through the Rural-Architectonical Intensification, is possible to create sustainable density of activities and spaces in which the natural environment and the rural-urban landscape coexist harmoniously.

Then think of the existing richness: in Italy's rural areas, not just its cities, the artistic and architectural heritage is often of a very high cultural level and this just brings the subject of architecture into the centre of this debate. In a region's various implementation strategies there must be an aspect of independence, of a close relationship and a necessary connection, not just at the level of regional marketing but above all in the construction quality of these measures and of their economic and environmental sustainability.

Enhancing rural architecture, small towns, farmsteads and ancient relics is one of the main components for the regeneration of the countryside. It is a strategy with a positive outcome, even only if it has been supported simultaneously by the possibility of creating more business (also working from this architectural heritage), but which nevertheless is planned taking into account the improvement of the perceived aesthetic structure of the countryside. Therefore, in this development process for business in the region, there also has to be an increase in environmental quality and in the infrastructures, which allow people to use the environment, etc.

The development of small and medium-sized enterprises also forms a possible opening strategy, but in this case as well, only if it allows the possibility at the same time of reusing the existing building

heritage or at least respects its presence as a unique value for a region. In the meantime, small and medium-sized enterprises should be supported by specific services, such as access to information and communication technologies, and they must also have new types of sustainable infrastructures for the environment which allow businesses to establish themselves in a region and to promote new initiatives. The protection of biodiversity, as well as new models of organic and bio-dynamic farming, can translate into opportunities to diversify the range of services towards other economic sectors as well, such as tourism.

3. Process and research's Parameters

The process starts with the identification of a “main aim”, that is the final goal of the whole design procedure; in this case it is the RAI. Authors consider it is fundamental to specify the sequence of the phases that characterize the whole process because it combines various approaches that can be referred to the different scales and disciplines involved.

What we are interested here is the role which architecture has to play in this framework of rural intensification. In order to this reason was built the RAI Best Practices Report and it is a basic reference in which many experiences from all over the world have been classified and assessed in order to find general criteria. So, considering that RAI application depends on the characteristics of the territory in which it should work, once the main aim is defined, planners or designers analyze the territory starting from available net information. Based on the characteristics of the analyzed territory, decision makers and stakeholders define specific aims such as for example: concentration of new commercial activities in existing small centers, creation of a system of mixed use small centers, creation of a decentralized hotel, definition of territorial facilities, distribution of residential settlements in existing underused buildings, renewal of existing rural settlements, etc. Obviously, territorial interpretation depends on certain specific aims: in fact different spatial or economic factors may have particular relevance for each specific goals. At the same time the entire Best Practice database can be consulted and appropriate examples may be selected. Lastly a compatibility assessment among the territorial interpretation and the selected case studies carries to possible scenarios that decision makers and stakeholders should consider.

At this point the question is: What parameters can be used to assess the improvement of a rural region?

In the Best Practice Report built for the main aim RAI, each project is catalogued by four parameters:

- a. development of local business capability;
- b. development of cultural and tourist activities;
- c. environment preserving;
- d. facilities for population.

With more details:

- a. development of local business capability: business and tourism, diversification into non-agricultural activities, diversification and innovation in agriculture, cultivate the landscape, cooperation and short chain, growth of the bio-economy, business and infrastructure;
- b. development of cultural and tourist activities: tourism and architectural heritage, tourism and environment, small-scale tourism services, countryside vs sea and mountain, tourism and water, tourism and infrastructure, tourism in less-favorable areas;
- c. environment preserving: environment and biodiversity protection , environment as heritage, environment and water, soil and environment, environment and animals, environmentally sustainable operations, limit consumption of the environment, bioenergy, environmental reservoirs, environment and urban space, environment and infrastructure, environment and waste, environmental risk, environment in disadvantaged areas, diversified environmental redevelopment;
- d. facilities for population: population and employment: tourism, population and employment: diversification of agricultural activities, essential services to the population, country-city, population: energy saving, young population, population: infrastructure, cooperation in development, safe population, population and environment.

Thanks to the above parameters of intensification identified, we analyzed numerous architectural case studies through a double movement: for each parameter we identified a series of goals and strategies, that generate positive strategies in the territory through which we have evaluated the production of Rural Architectural Intensification. The overall framework has been interested in terms of quality and design's behavior.

4. Architectural Design Strategies for rural heritage

This article not intends to make a detailed and analytical description of the RAI Best Practices Report (which is composed by 140 case studies and more then 500 pages) but authors believe it is important to outline the concepts and the goals developed for the research project. Therefore, are listed here

below brief descriptions of the parameters that can be used to assess the intensification as design strategy for rural heritage.

4.1 Architecture for Development of SMEs

Agriculture stopped being the driving force of economic development for the countryside a long time ago now. For this reason, in recent years rural development policies have focused, and will focus more in the future, on strengthening jobs in non-agricultural areas, while taking into account the necessary involvement of farmers and existing farms in multi-sectorial rural development strategies. The creation of start-up companies linked to agriculture, which make the most out of a rural region's potential could improve the population's quality of life, bucking the current trend towards the socio-economic decline of these regions.

This study shows that the entrepreneurial projects which manage to take off are usually of a moderate size. We're talking about small and medium-sized enterprises, which are often family-run micro-enterprises in the processing and marketing sectors for agricultural products, livestock, local handicrafts, tourism, essential services, but also energy generation facilities from renewable resources (biomass and biogas heating plants, photovoltaic and solar panel).

Many people are involved with these businesses, which transform the region, not just from a socio-economic point of view but also in terms of the countryside, and, the architecture and their architectural heritage. For example, small food companies that have developed a wide range of products often choose to convert unused or under-used spaces within their companies or farms: old granaries, unused animal stables, silos which have now been empty for a while and converted into areas for new production plants, educational workshops or exhibition halls, stores, restaurants, ateliers, show-rooms, etc.

Often a small amount of precise, localised work is enough to stimulate more widespread development dynamics throughout an entire geographical context. When this happens, whatever the intervention, it is Architecture that makes it possible.

In 1997, Achleitner wrote about the Vals thermal baths designed by Peter Zumthor: "The tourism industry should be criticised for endorsing a town's cultural and environmental resources, without creating any new ones. This creates the architecture of tourism without the tourism of architecture. But at Vals a resource has been created that not only enriches the tourism of architecture with an essential attraction, but also represents a considerable boost for conventional tourism"[1]. The example of Vals is a paradigm: the thermal baths attract visitors due to their architecture.

4.2 Architecture for the development of tourism and cultural activities

Among its peculiar features, Italy has a very high number of abandoned towns: there are 5,308 ghost towns, 72% of all Italian municipalities. This phenomenon began after World War II and has not yet stopped: in most cases, the city seems to have a powerful magnetic attraction and the countryside as a place without a future.

These small abandoned town centres are often the only evidence of the many stories and layers behind a place's history, its identity and unique features; they are a memory of events, characters, the traditional agricultural economy and the evolution which the countryside went through. They must be kept alive.

During the architectural restoration of a building or of an entire inhabited centre, several more interesting solutions arise from the diversification of the planned activities compared with the original activities: an old sawmill can become an architectural studio; an unused granary can house a factory for producing traditional food products; a farmstead's neglected stables can become artists' studios, etc.

In Italy, where tourism is one of the main driving forces of economic development, there is a focus on inventing new tourism hospitality models working from this restoration of abandoned architectural heritage.

The research report shows that the measures which have an impact on the existing architectural heritage try to move away from the idea of second homes and therefore seasonal regeneration, which is purely based on tourism. The region needs to be permanently inhabited, only then can it avoid falling into decline. Rural architecture has a communal nature, either when it comes from reusing existing buildings or when it is about new buildings. Under this communal sense of responsibility and respect for the protection of the environment, the projects opt for essential qualities, the simplicity of form, easy solutions, low land take or even subterranean solutions, underground solutions that look to be discreet, making the most out of the context for its requirements, with minimum impact.

The nature of these places, their history, the shapes which describe and outline their landscape, their colours, but also all of their man-made structures with their materials and construction techniques, provide the tools which many designers work with and use to understand the region.

When you opt for new, industrial, pre-made materials, the relationship with the context is shown in these compositional choices, in the relationship between full and empty in the façades, in the form of

the roofing, the chimneys which take you back to the local architecture, or the local population's uses and traditions.

This research highlights how you can also enhance the architectural heritage through forms of "simple" census and surveys of cultural goods. As Aldo Rossi wrote: "A town is a monument of culture: housing, technology, law, economy, it is a settlement of endeavour, expertise and imagination. By observing its monuments, urban structures and rural settlements, by promoting a morphological and typological study, and by examining the distributional, architectural and iconographic analysis, the field of architecture lays down the foundations for a rational and systematic understanding of form"[2].

4.3 Landscape architecture for protecting and enhancing the natural environment

The general state of the environment is in the midst of a serious collective crisis. Biodiversity is disappearing and with it the "form of the countryside". Land is scarce even for farming; uncontrolled building developments continue in line with the constant population growth, taking much needed land away from plants, animals and ecosystems. Woodlands are being destroyed to make space for industrial expansions around the outskirts or for intensive farming of one-crop systems; species of animals are disappearing, which are deprived of their habitats.

The expansion or shrinkage of a city and its ability to attract tourism through hospitality, rather than a strong immigration phenomenon, may also transform rural areas. The emerging projects shine a light on a diverse series of possible measures. The afforestation of agricultural land with permanent forests for environmental and tourism purposes is a good example of how to cultivate the countryside by converting wild or over-grown land, rather than the arboriculture of wood for the manufacture of stakes, biomass or paper.

Also, the modelling which the landscape has to go through is undoubtedly needed in order to reduce environmental risks and hydrogeological disasters. However, this is just the practical objective: the spatial response which it generates in the landscape also needs to be considered, as well as its impact and sustainability. This is where landscape design comes into play, where the awareness of the architect in the skilful use of form and space is essential during a place's regeneration process.

Therefore it is a kind of "restoration" through protection, rebuilding characteristic elements of the countryside, such as built heritage, river dykes, woodland areas, ditches, hedges and swampland; and also protection to plan for the future of the land, to carry out work which represents an effective redevelopment of the region while keeping people in mind, providing activities for people that are in line with the principle of sustainable development.

This research shows interesting cases of protection, in particular, focusing on cases in which the re-naturalisation of a region has become an opportunity for its more general regeneration.

4.4 Architecture for Services for the local population

Rural areas are showing a gradual ageing of the population. The gradual reduction of the critical mass needed to financially support the services system has triggered a gradual but continuous loss and destabilisation of the essential services and functions required for families and companies to live in the region (housing, healthcare, communications, transports, education, modern information technologies, job, infrastructure, etc).

Through case study samples, this research has analysed the work carried out to develop services and initiatives for the implementation of integrated local strategies, which aim to improve the quality of life in rural areas and to develop the attractiveness of these areas for future generations.

The revitalisation of villages and rural areas through integrated initiatives including diversification, the creation of new productive activities and investment in the enhancing of cultural heritage can form a development strategy for the directly involved local population.

The projects implemented in the area of education are: farm nursery schools, primary schools, services for children and families, educational courses in food and the environment run by educational farms and gardens, etc, and also the development of cultural activities for the dissemination and passing between generations of the cultural heritage and identity, as well as the traditions of rural populations.

In the area of sport, well-being and relaxation: sport centers, swimming pools, cycle paths, hippotherapy centres and games rooms, recording rooms, discos and clubs, dance halls, pubs, general areas which help young people to invest in the rural region.

In the area of healthcare: herbalist shops, clinics, first aid, hospices, analysis laboratories, veterinary clinics for farm animals, home help, and mobility assistance for elderly and disabled people.

Lastly, one of the main essential services for the rural population is infrastructure. The railway, the road system and, in general, the main highways have often interrupted the existing road networks, blocking their accessibility and leading to the isolation and abandonment of small town centres. Any infrastructure should be seen as a vehicle for regional intensification, even a tiny structure, such as a

small footbridge which connects two parts of a region, can be crucial for the accessibility and the social and economic recovery of a given location.

5. Conclusion

For over a decade, various projects for the intensification of rural areas have been launched over Italy and Europe. These are multifunctional measures that aim to develop businesses, especially those linked to tourism and cultural activities, or linked to the improvement of areas of society which have often deteriorated. At the same time, these measures aim to protect and enhance the natural environment.

In fact, the idea was to stimulate a whole series of various intervention models in rural areas. As a whole, these models would add to the development of rural regions. They would build a management system for goods and services based on innovative forms of multifunctional businesses. This would ensure adequate flows of income for those involved in these initiatives and would therefore help to guarantee the success of the work carried out on the goods which the region has to offer.

In Italy, for example, the same Rural Development Plans which every region has prepared, as well as the National Rural Development Plan, confirm the need to intensify multi-sectorial, multi-axis projects with regard to the protection of the environment, the development of local business skills, tourism and cultural activities, as well as services for the local population.

This need for multi-model and multi-sectorial intensification would seem a given fact for anyone who, in theory and practice, plans, designs and carries out concrete actions in a rural region. The idea of area micro-projects organised by macro-projects, which theoretically should help the single management, is often found in local implementation plans and programmes.

The reality is very different and often when something does occur, it happens with such erratic and fragmented reasoning that it only creates partial success which is too limited to represent real, concrete development for the region. In most cases, there is not even any intent during the planning phase to prepare any multi-model and multi-sectorial intensification measures. It just works through impermeable districts, while in the region as a whole even a route from one municipality to another will interrupt the building of a cycle path.

In fact, even the aforementioned Rural Plans, developed through a series of objectives and strategies belonging to different models and axes, do not specify that these connections are necessary, these intertwining objectives and strategies which need to be put into effect. There still seems to be little awareness of this issue and with it the possibility that the implemented measures have a resilient effect on the region.

Conversely, in our opinion, it is a decisive issue when:

- The measures do not reach sufficient concomitant, multi-sectorial development and they are not able to simultaneously be strategies for the protection of architectural heritage, the natural environment, the population and for tourists;
- There is no real recovery and they do not create the conditions in the region that could stimulate economic, social and cultural growth.

Only the combination of architecture and measures seems able to provide results in terms of quality: this intertwining of measures and also therefore of the regional policies which are studied and put into effect at every level and on every regional scale.

The relationship which links and connects all the components involved in development processes cannot be separated, just as a small town or a small architecture is inseparable from its own history, from its surrounding natural and man-made elements, its forests, fields, industries, and infrastructures which outline its surrounding landscape.

6. Appendix

In this section are introduced 4 project description that are included in the Best Practice Report as examples of the virtuous architecture of Rural Intensification.

6.1 Upper Twyford Studio. Farmhouse regeneration as office of architecture. Hereford, West Midlands, UK, 2009. Architect: Architype

Upper Twyford demonstrates the possibilities for transforming derelict structures into modern sustainable buildings. It was also an opportunity for Architype to develop our approach to sustainable design, which we describe as 'eco-minimalism'. This approach is based on assessing from first principles what is actually the most efficient and effective way of achieving long term sustainability. At Upper Twyford this meant avoiding tech-no fixes and add-ons, and focusing on making the basic architecture work in an efficient sustainable way.

Learning by doing:

The design, construction and occupation of Upper Twyford was also envisaged as a learning process for Architype, and so the building is being monitored in use. This monitoring is enabling us to:

- compare performance with theoretical predictive models, so that we can understand the relationship between prediction and performance;
- assess our subjective experience of comfort against the building's actual performance;
- experience at first hand natural ventilation and daylighting, thermal mass and night cooling, high levels of insulation and airtightness;
- achieve further energy reductions over time.

Fig. 1: Upper Twyford Studio. Farmhouse regeneration as office of architecture. Hereford, West Midlands, UK, 2009. Architect: Architype.

Upper Twyford has become a focus for how we as individuals and as a practice can develop more sustainable ways of living and working.

Economic sustainability

It is also having a positive impact on the local economy and is influencing debate about the sustainable economic development of the Herefordshire economy. For example we:

- buy fuel (woodchips) from local supplier and woodlands
- have daily staff lunch supplied by a local café that sources local organic ingredients
- have vegetable box scheme delivery to the office, for staff then to take home
- have sublet space to establish a new business selling ecological paints and green building products
- encourage cycling to work by staff
- recycle our waste and buy office supplies from sustainable and fairtrade sources
- host regular visits and lectures from local organisations

Upper Twyford demonstrates the potential for high quality employment in rural locations dispersed around the county, rather than locating in existing towns and industrial parks.

Design Approach

With a sensitive respect for Upper Twyford's history, and an appreciation of it's context in the landscape, our aim was to create a modern workplace from the ruins of the old barn, which was an exemplar of sustainable contemporary design, and an inspirational place to work.

We set out to create a design studio amply lit by daylight, providing exceptional views across fields and woodlands, unpolluted by chemical treatments, naturally ventilated and heated, with ample space for working, meeting and socialising.

Externally at ground floor level the barn is rough stone but the partly rebuilt first floor is constructed from and clad in untreated Douglas fir. This is departure from the original building, which was all stone because substantial parts of the original stone building had fallen down or were very weak. At first floor level we replaced the stone with timber framed construction. The pitched roof is reclaimed Welsh slate. A studio space has been inserted at first floor level and is set back from the glass screens creating double height spaces at both the front and rear entrances to the building.

Eco-design principles

A summary of the principles of eco-design applied to the project, are:

Orientation and the use of daylight and sunlight for light and solar gain; Use of 'breathing' timber construction; Use of thermal mass; Using high levels of insulation; Minimise cold bridging; High performance windows and doors; A range of options for natural ventilation; Biomass boiler for heating and hot water; Re-use of materials from original building; Use of UK sourced timber; Adoption of state of the art water efficiency measures; Natural paints and stains; Innovative low energy purpose made light fittings; Landscaping to extend local biodiversity.

6.2 Nørre Vosborg - New Hotel. Vemb, Jutland, Denmark, 2008. Architect: Arkitema

Fig. 2: Nørre Vosborg - New Hotel. Vemb, Jutland, Denmark, 2008. Architect: Arkitema

In Denmark, we have many beautiful manor houses. Some still function as agricultural producers, but many now offer experiences instead. Nørre Vosborg is among the latter – a place where people can enjoy unique experiences. Surrounded by nature and architectural history, and with gastronomic experiences, cultural and conference activities close at hand.

A manor house with a long history

The history of Nørre Vosborg stretches back to the original stud and barn buildings constructed in 1532. Today, after surviving various fires, the manor farm is an interesting mixture of 18th-century history and architecture, together with more contemporary alterations from the post-war period 1946-50, and a great many functional alterations since then.

Now after restoration, conversion and extension, beautiful Nørre Vosborg manor is now an up-to-date hotel, cultural venue and conference centre, with a newly-built hotel wing and new design solutions for all of the manor's many different buildings.

New building for hotel accommodation

The new hotel wing matches the largest of the complex's buildings in terms of volume. Despite its size and location, however, it does not compete for attention with the historical courtyard area and the main axis of the complex. To lower the impact of the hotel wing and avoid an imbalance in the historical structure, we sought to use alternative materials in relation to the stud buildings' dominant red brick and thatched roofs. We used wood, which satisfied the relevant criteria, and which is an unpretentious material alongside the frugal red-brick buildings. Wood pervades the entire building, even the roof, which is clad with planks of radial-sawn Siberian larch, laid in a clapboard pattern.

The hotel is characterised by a roof without dormer windows. We have lifted and opened the clapboard pattern, and thereby enabled the creation of a belt in the roof surface which integrates the openings necessary for habitation in the roof storey.

6.3 Burgenland. Sprawl hotel in the vineyard. Deutsch Schützen-Eisenberg , Burgenland, Austria, 2011. Architect: Pichler & Traupmann

Fig. 3: Burgenland. Sprawl hotel in the vineyard. Deutsch Schützen-Eisenberg , Burgenland, Austria, 2011. Architect: Pichler & Traupmann

In the vineyards surrounding Wachter-Wiesler Ratschen, an award-winning restaurant in southern Burgenland, Pichler & Traupmann Architects have developed a project in which an association of prize-winning wine-growers from the renewed winegrowing area of Deutsch Schützen took part. It offers guest a pleasant way of ending a day spent wine-tasting in the various cellars.

The work of Pichler & Traupmann Architects is known for its dialogue with the landscape and sensitive handling of each project's particular context, but also for a high level of innovation and the contemporary interpretation of unusual building commission.

In this case the project development involved a number of special factors, as the aim was to combine the simple, authentic and meditative qualities of the space with a high quality ambience.

In the area of tourism distributing the bedrooms of a facility that offers overnight accommodation amongst the vineyards is an usual approach. From the restaurant, where the reception and breakfast room are also located, you can retire at the end of an enjoyable evening to one of the free-standing bedrooms amidst the vines. The units, each with two beds and an additional couch, are provided for guests.

The free-standing residential elements are oriented on the culture of the rows of vines and are derived from this landscape element. The long side walls of the rooms take up the lines of the rows of vines and the distance between them, making them into built elements between which the various functions are placed. One sleeps between the rows of vines, so to speak, and they are reflected in the large windows and appear to continue into the rooms.

The language of the materials also express the strength of this design concept. Inside and in the outdoor area wood is used throughout as a naturally renewable building material, in different surface finishers and with different characters. The building's energy concept incorporates renewable energy. Thanks to the excellent collaboration between all involved in the project, it proved possible to implement in a "record construction time" of around 100 days.

6.4 Regeneration and reuse of existing mill. Lochussie, Dingwall , Scotland, UK, 2011. Architect: Rural Design

Fig. 4: Regeneration and reuse of existing mill. Lochussie, Dingwall , Scotland, UK, 2011. Architect: Rural Design

Incorporating the few remaining freestanding walls of a former mill building, the project engages with the buildings past, without replication of its traditional forms.

The starting point for the Mill project was the few freestanding walls that remained on the site. The existing walls created a series of courtyards, some of which has begun to be re-inhabited by nature.

Our clients brief was for a large family house. We were keen to re-imagine the building in a progressive form, layering a series of forms over the ruins to create a clear juxtaposition of old and new.

Some elements are clearly defined as freestanding objects, the Garden Room, Gym and Garage building slide alongside the existing walls, the new raised upper story is overlaid, with a folded larch roof and wall floating over the castle-like structure of the existing walls.

All the forms create new and intriguing courtyard spaces, allowing the creation of a variety of sheltered spaces to allow our client to engage in his passion for gardening. Two south facing courtyards have been created, the eastern courtyard terraces down in insitu-concrete walls inhabited with plants to a

small burn. The western courtyard allows evening light to be drawn through the depth of the house, through an existing tree that has been preserved, and also became the axis for this series of spaces. The internal spaces are typically one room deep, with simple linear circulation, capturing light at ad hoc points where existing openings remained. Where possible stone walls have been preserved internally, allowing a look through the layers of the structure.

A three storey timber “tower” sits at the southernmost part of the house, rising from formal dining room, to sitting room, to master bedroom, which has a high level 270 degree view of the wider countryside. The master bedroom is accessed by a stair that floats alongside the old rough stone walls, and cantilevers out from a massive larch wall.

At all points the houses axis’ are terminated by events, light, and occasional symmetries.

The existing fabric has been treated with respect, however this has occasionally required major surgery, for example the new arched window to the formal dining room has been cut forcefully into the existing fabric, recalling not only the water wheel, but also the art deco furniture collection contained within.

Preserving “*Time*” in Space and “*Space*” in Time: Cultural Urban Landscape of Niš, Serbia

Jelena RAKOCIJA¹

⁽¹⁾ PhD candidate, Department of Architectural and Urban Design, School of Architecture,
Aristotle University of Thessaloniki, Thessaloniki, Greece.
jelena.rakocija@gmail.com

Abstract

The main objective of this paper is to study the process and patterns that influenced framing of spatial imaginary of the city of Niš. The focus will be on the understanding of modern and heritage urban landscapes, and their interactions as a products of creative activity between man, space and time. The questions were raised upon persevering historic landscapes in urban environments and understanding spirit of the place and time. In this context it is proposed landscape architecture approach to urban heritage conservation. The study of the spatial imagery is based on the evaluation of its historical and cultural values through analysis of landscape qualities. The proposed approach has been applied on the cultural urban landscape of the city of Niš, Serbia, using as a reference historic sites and contemporary comprehension in using them as primary expression of identity. In creation of cultural urban landscape, general inquiry has been conducted on the topological level through history, art and culture of Ancient, Byzantine and Ottoman city of Niš. As a result of the analysis, the potential of the historic site of the Fortress built in 18th century at the place of Roman castrum, has been reconsidered in correlation to the belonging urban and natural environment, what gave the guidelines for future sustainable development of the city. Historic *time* in space and *space* in time, is an urban texture, becoming the focal point for future enrichment of urban life.

Keywords: Niš - Serbia, landscape study, pattern-process, spatial imagery, spirit of place.

1. Introduction

“...their past, as much their spaces are crucially constitutive of their presents”
Christopher Tilly [17]

Unique distinctiveness of cities in south-east Europe, and the city of Niš in Serbia as one them, is related to their rich shared past which is embodied in peculiarities of open space. The fact that in this part of Europe public spaces in the historical city center are predominantly, above all, at locations of historic monuments and archeological excavations, engages their timeless spatial quality that originates from the long history, contemporary everyday experience and changeable and vivid character. The questions raised in proposed research are considered upon persevering historic sites in urban environments through landscape study and landscape architecture approach of reading the quality and meaning of historic sites as urban open spaces of the city.

Our starting hypothesis is that these open spaces of the city at the historic sites are not empty voids (J. Simon, 1984), but a place full of memories, activities and experiences (P. Dauvergne, 1977), made through socio-economic values of life and culture and ecological conditions (M. Ananidou, 1991) [1]. Finally, the paper focuses on the research of historic site of the Fortress and urban landscape of Niš in Serbia through methodology of reading the cultural landscapes used as a method of analysis in landscape architecture in order to support subsequent explanation and interpretation of the flows of materials, energy and information, which characterize the city. Main objective is to study the historic patterns and process, rhythms and values that were layered through time and space, on and within the land and gave “spirit” to a place, framing the spatial imaginary of the city of Niš. The evolution of

Niš cityscape and its impact on the contemporary landscape is outlined. As result of the analysis, the proposal for the future design measures was made.

2. Terms and Methods

2.1 Monument - Site - Cultural Urban Landscape

The first and essential step in reading the quality of historic urban sites is to come to terms with the phenomenon of space-time and monument-site- landscape evolution. In the process we are also hoping to clarify some of the semantic dilemmas which confront us in relation to the terms of urban open space and landscape concept.

Phenomenon of space, along with time, is one of the basic concepts of reality and existence of the matter [9], where human existence in the space (real - objective: *anthropomorphic(cultural, social and physical) /natural* or symbolic (*cosmic*) - subjective) is associated with his relation and understanding of the world and its image: "imago mundi" [16]. This understanding of space is materialized in place and its spatiality through duration of time and times (temporality). Factors of making the place are first, and sometimes continuous, acts of design that transform, or conserve, space for human inhabitation and use and inescapably embody a concept of space.

Such environments of sensual experience, past actions and memory, are referred to as having attributes of a site (Greek: τοποθεσία, contains two words: τόπος - place and θέση - position), the meaning that in contemporary understanding corresponds to the concept of the "site" as used in archeology: *the location of human activity in the past* [7].

Dichotomous discourse of historic sites comprises the relations of the architectural monument as an archive of authentic sources - containing universal order – static message of the past which is superimposed in the dynamic and vivid space setting of everyday life, its natural and social context, devoid of apparently manifested order [3]. But those values created in urban open spaces of the city are evolved from human-space-nature relationships subliming harmoniously in the process of reconciling within each other, and resulting in framing the urban land and *scape* of the city. Exactly those "topos" became the places of identity, places of reality and open spaces of everyday life and perceptions of the city and therefore the cultural urban landscape as a whole.

As used here, and according to the accepted understanding of landscapes as works of art and culture [6], a cultural urban landscape is a matter of an artistic production of urban open space, a creative activity between man and space, architecture of land (landscape as architecture) and in that sense whose artistic volition of meaning is possible. Hence, the cultural urban landscape is conceived as a mirror of the development of the city, its form and metamorphosis of the space and it is defined as the physiognomy of the city, its spatial image and imagination[1]. Within recent trends toward landscape understanding, according to Tom Ingold: *landscape is defined as a processual, material and perceptual engagement of body and world, enacted in terms of a distinctive temporality – a rich duration of inhabitation*. The significance of the development of social-cultural and physical (real-objective) environment in space and time led to the perception of landscape as a process or landscape as a long-term history. Also for Simon Bell the landscapes develop and evolve through an interacting series of processes – climatic, geological, ecological and cultural – over varying periods of time. These processes shape the structure and character of the landscapes which we experience and by understanding this complex pattern-process interaction we can obtain a deeper awareness of landscape [5].

In that context accepted attitude toward the urban open spaces is that they are not voids nor empty spaces according to J. Simon, and on the other hand, according to the Jackson [4] landscape cannot be seen as simply natural space, a feature of the natural environment or simply environment, the most frequent semantic dilemmas which confront us in relation to the terms of urban open space and landscape understanding.

According to the synthesis of recent thinking about the complex but vital phenomenon of landscape, conclusion is that cultural urban landscape cannot be seen separable from human activity in space over time, as a product of a complex and multiple pattern-process interactions, where historic sites serve as "coordinates" in a primary expression of identity that influence the framing of spatial imaginary of the city.

2.2 Landscape Study and Urban Preservation: Preserving "Time" in Space and "Space" in Time

Many academic disciplines have found the concept of landscape very important, used as a qualifier that delineates whole sub-disciplines: landscape ecology, landscape planning, landscape archaeology, and so forth. Another case is that landscape studies progress under a broader banner, such as heritage studies [8]. In this regard, within international charters for heritage conservations, last is given by the 2011. UNESCO recommendation on the Historic Urban Landscape. It is outlined a

need for understanding and preserving spirit of the place through application of new methodologies dealing with the concept of landscape which includes a broader interpretation of the historic site, integrating the evolution: monument - site - landscape.

Landscape architecture analysis methods of existing conditions and landscape character are proposed, as the most relevant for the topic of inquiry. During the landscape study specific ecological, social, historical and cultural information about the landscape are collected, revealing particularities and character of given landscape, its genius loci, what represent backdrop for guiding principles necessary for decision making in design proposal [15].

This reading of landscape qualities is possible through analysis based on a socio-ecological and perceptual approach in order to specify the potential, suitability, capacity and the capabilities for future development [2].

It is argued that application of this methodology and landscape architecture approach can make an important contribution to heritage practice.

3. Case Study: Cultural Urban Landscape and Historical Site of Niš Fortress

City of Niš, in 2009 became the member of *L'Alliance de Villes Européennes de Culture* as the first municipality from Serbia, regarding the fact of an almost 2000 years long cultural history as a well known imperial city and the birth place of Roman Emperor Constantine the Great. Today Niš is the second largest city in south Serbia and the capital of Nišavska region with approximately 300.000 inhabitants.

Diversity of natural landscape types in Niš territory has been shaped by two dominant rivers, South Morava going from the south and river Nišava – going from the east, that gave birth to the outstanding landscape developed in the Nišava valley, characterized with cultivation patterns in contrast to the mountain terrain in the north-east direction (Fig. 1) [13]. During the history the city was considered “the gateway to the East”, connecting East with the West and North to the South. All this influenced the turbulent and violent history of the city, followed with glorious cultural urban climax and forced disappearances. Today, material traces of life from antic, byzantine and medieval period are rare to be found in great number, but markers and scares of its long history are integrated in spirituality of modern city core.

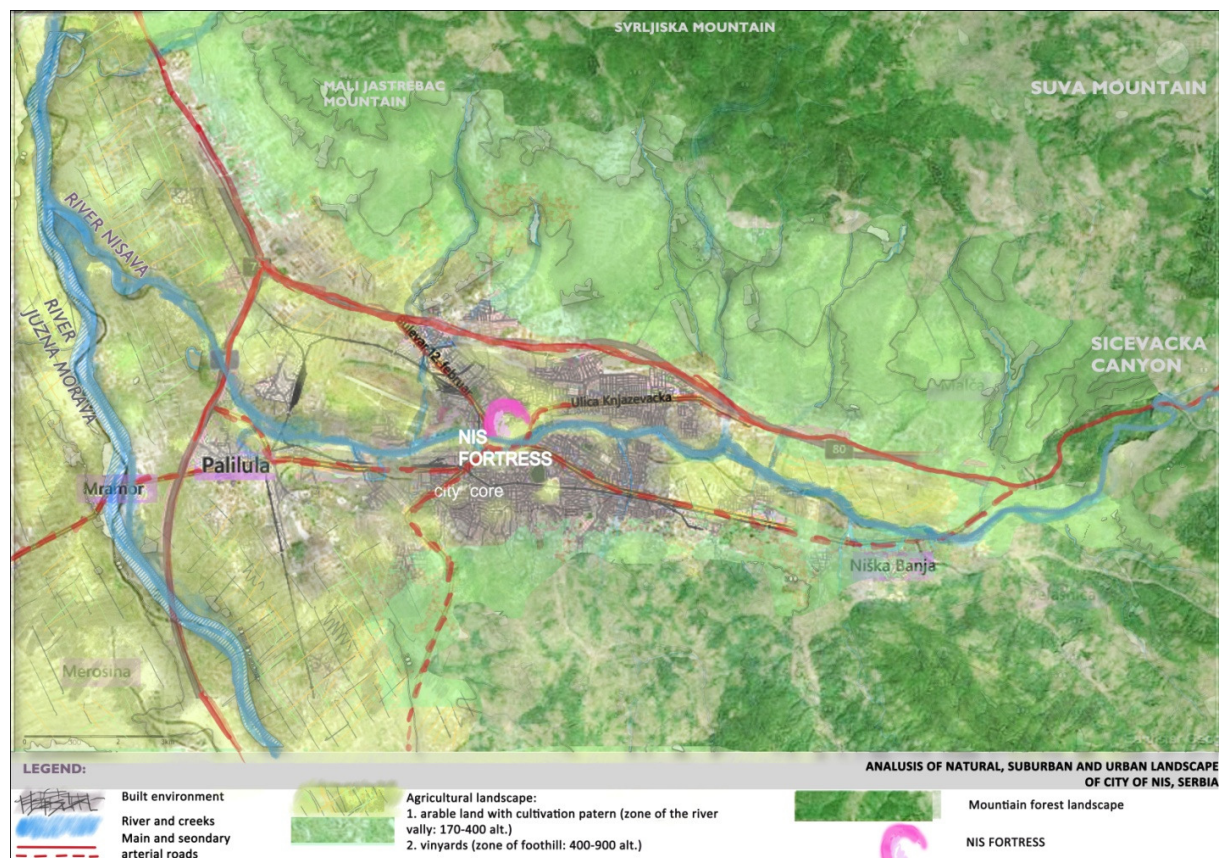

Fig. 1. Analysis of Natural, Suburban and Urban Landscape of the City of Nis (after: J.Rakocija) [13]

3.1. Heritage Landscape and Pattern-Process Evolution

The Ancient city of Niš (*Naissus*, *Ναῖσσος*) occupied the central position in the Roman province of *Moesia Superior*, formed in the first century AD in the center of the Balkan Peninsula (Fig. 3). It was situated at the crossroads of the main roadways connecting the southern cities (Thessaloniki, Scupi, Ulpiana) with the northern ones (Singidunum). This was definitely recognized suitable geographic location, right on the elevated plateau at the foot hill of the Vinik and strategic position: for the formation of a military camp castrum. The Romans conducted the process of urbanization with main streets (*cardo* and *decumanus*) and forum (The route of the street, a decumanus, is discovered in the center of the Fortress) [12]. The continuity of the space and ancient urban pattern with forum is archeologically confirmed also to be used in the Early Byzantine and Byzantine period, when the church replaced the roman municipal building, and even in ottoman Nis, when the Beli-Bey mosque was built in 1521 (today preserved) on the place of the church. Important landscape metamorphosis is featured in the first regulatory plan of Nis made by Austrian architect Vinter from 1878, which respected the the spatial orientation on the south river bank of Turkish oriental Niš, but introduced the western models of streigh lines (Fig. 3 right-iv) [14].

The evolution of urban space from ancient to medieval city was followed by great destructions: the city was eclipsed in the massive damage of the Huns and finally In the seventh century, by Avar-Slavic invasions. In X century Nis again was revived in the Byzantine commonwealth, now named Nisos (*Νισος*). As the other major Byzantine cities in this region (for example Novi Pazar) and city of Niš was formed on the three hills, the core of the walled city was its **acropolis** inside the fortress and particularly esteemed sacred part around the city wall is formed with church and monastery complex (the remains of the early Christian necropolis in today's urban settlement Jagodin Mala and preserved remains of the a **monastery complex with Church St. Nikola on one hill and Church Pantelejmon on the other**) (Fig. 2.). In this directions was happening the expansion of the urban space, what is predominantly seen in today's layout [12]. At the beginning of XVIII century Turks started construction of one of the biggest fortresses at the Balkans that covered surface of 22 hectares dominating still the existing urban layout (Fig. 3 right-iv) .

Without a doubt, the most prominent landscape transformation in Nis occurred with oriental-Ottoman invasion, but on the other hand it is confirmed that Turks have respected the heritage and sacred spaces, adjusting them to their own needs. Therefore, Byzantine influence during the Middle ages, is probably the most important, crucial period in framing the spatial imagery in the Balkans, because it is precisely the moment when the conception of space was influenced by new interpretation of the world shaped by the new religion, Christianity. Break down of the Roman empire, meant also the first break down between east and west, influencing the landscape imagery. Religious conception of the space, generated the type of urban open space - with symbolic and structural unity of the landscape in recognizable manner and relation of the city and the church[10].

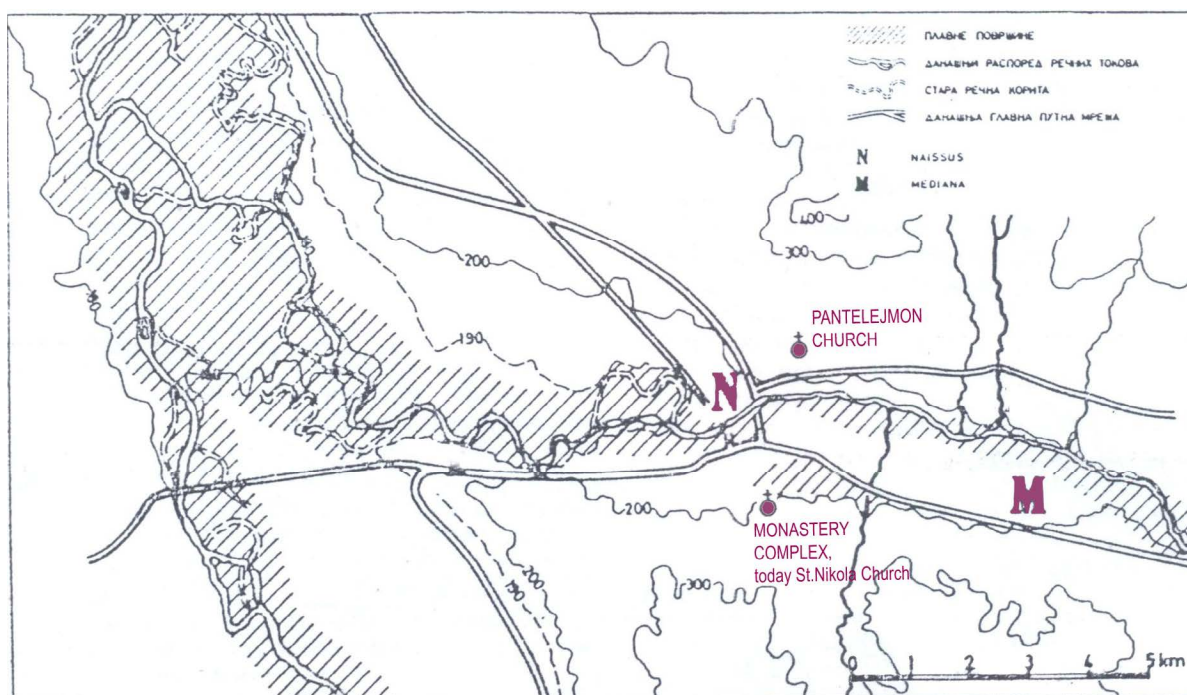

Fig. 2: The character of Natural environment with position of the walled city (N) with surrounding location of byzantine monastery complex-today Church St. Nikola and church St. Pantelejmon in Niš valley. Marked position of Roman Villa urbana – (M) Mediana.(source: J.Rakocija, according to J. Ćirić)

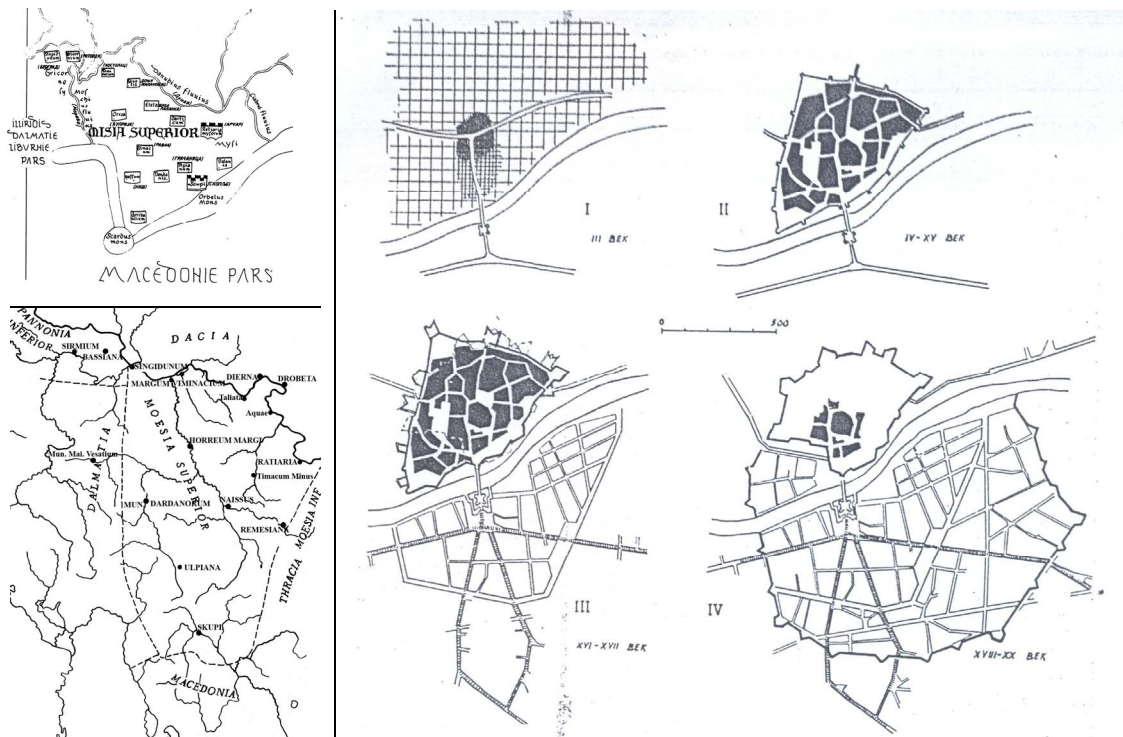

Fig. 3: Left top: Ptolomej map of Balkan peninsula, II c. (M. Мирковић, Istorija srpskog naroda 1, 1981). Left bottom: Central Balkan provinces of Early Empire. Right: Stages of urban landscape evolution: I – until 3rd c.; II – from 3rd until 15th c.; III – from 16th until 18th c.; IV – from 18th until 20th c. (after: D. Jovanovic, Neki topografski podaci o starom Nisu, in: Starinar, 1956)

3.2 Contemporary Urban, Cultural and Historical Landscape of Niš Fortress. Proposal

"In our vision of the modern Niš, was installed and that width which in its time radiated a thriving imperial city."
D. Medakovic [11]

Fig. 4: Panoramic view on Nis fortress from the city center (photo: <http://sr.wikipedia.org/sr>)

The landscape qualities of evolved urban landscape, as the long-term process, reflects the scenery that is framed within topography and revealed in the sense of spatial atmosphere:

1. Obvious centrality of the urban tissue emerged on the dominant curve of the river Nišava, as to be later centrifugally developed under the curve, seen today in radial lines of central urban tissue, together with linear extension of the city along the river front and parallel to it.

2. Built environment shaped around the river, folded and overlaid around it, in compositional unity which essentially follows the river flow, and seems to start from the confluence of two rivers, and disappears into the crack of Sićevačka mountain.

3. Scenery of the Fortress within natural composition as the live green north boundary of the city with reach natural feature of high trees dominating the inside the Fortress and giving that artistic simulation of emerging from the plain of the river that ascends into the mountain ranges within the background of the city (Fig. 4.).

In addition to the analysis of the cultural urban landscape, as the basis for planning and design proposal, it is concluded that a key element in giving Nis its worldwide identity is understanding of rich layered history and topological semiotics that occur inside the fortress in coexistence within natural and urban landscape. The unification plan of public open spaces with historic monuments and constituting main network of axis, named historical paths [13]: connecting Nis Fortress with the Byzantine monastery complex near St. Nikola church, and with the sacred space of the martyrdom in Jagodin Mala (the remnant of the necropolis and Early Christian Naissos), is proposed (Fig. 5.)

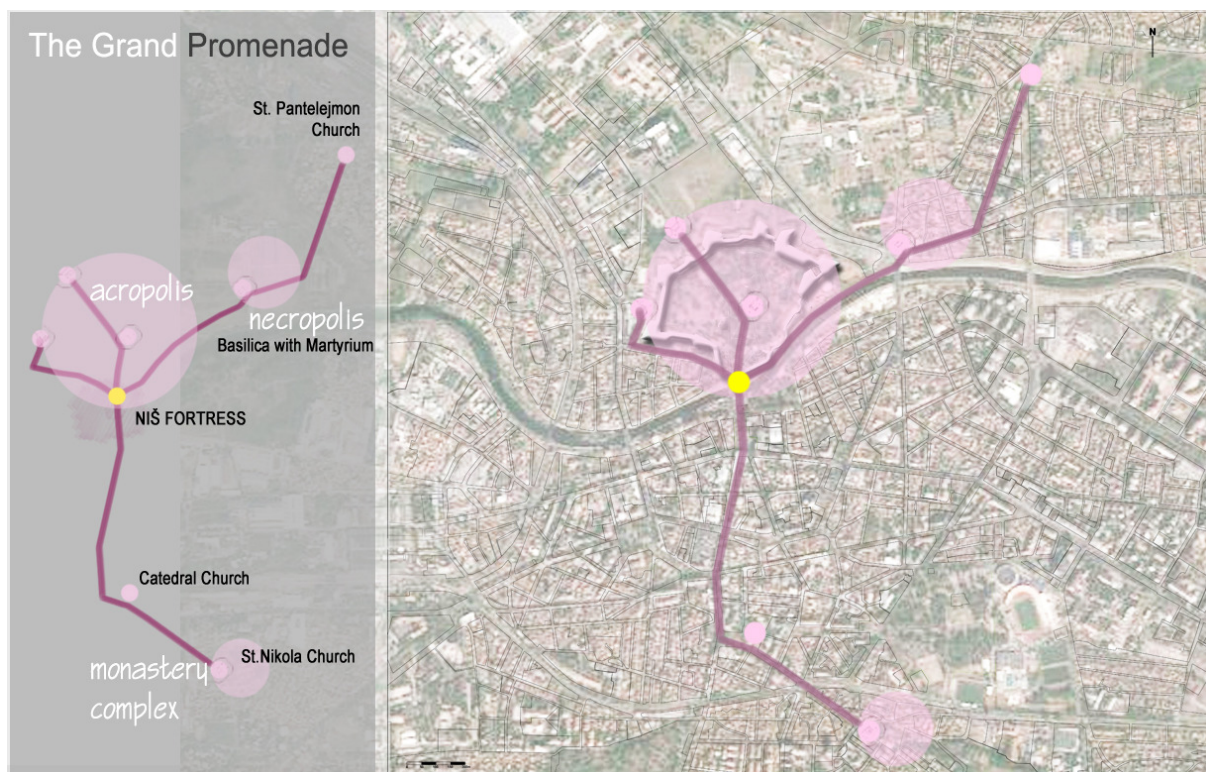

Fig. 5: Revival of the Christian historic landscape of Nis: position of Acropolis, Byzantine monastery complex and Necropolis, with possible connection of historic sites within Grand Promenade (after: J.Rakocija) [13]

According to the landscape analysis of Nis Fortress, four landscape character entities [13] are defined on the basis of broadly similar cultural, social, ecological and perceptual patterns, whose quality should be considered in future design proposals:

1. Entrance area is defined in predominance of urban character and planned vegetation associated as "TRANSITIONAL" site from the built environment of the city center into natural Fortress ambient (Fig. 6., Fig. 10.)
2. FOREST site is found in the central and east parts of the Fortress, characterized by high vegetation (Fig. 7.)
3. "ENCLOSED" site with archeological remains of roman street at the place of the forum, is found in the center, on the highest point of the Fortress - acropolis. The sense of enclosure is found in the tree mass that represents natural perceptual boundary (Fig. 8.)
4. "FILTER" site, occupying the west, central and peripheral parts, is characterized by scattered vegetation masses which disappear in the marginal spaces of the fortress and edges of the walls. This transition is characterized as filtration of the natural vegetation and accordingly the name is assigned (Fig. 9.)

Fig. 6: Perception of the Fortress from the city center, TRANSITIONAL site from the built environment of the city center into natural Fortress ambient. (photo. J.Rakocija, 2013) [13].

Fig. 7: ENCLOSED space of central are of Nis fortress with Beli Beg mosque that used to be Acropolis of the city, has a potential to represent an symbolic scene as a former place of city forum. (photo. J.Rakocija, 2013) [13].

Fig. 8: Central inner part of Fortress characterized with dominant natural character of FOREST landscape (photo. J.Rakocija, 2013) [13].

Fig. 9: Marginal east spaces inside the Fortress. Interruption of tree masses on the open views is characterized as FILTRATION of the natural vegetation what gives an possibility in perceiving of the Wall edge. Feature that should be incorporated in design proposal (photo. J.Rakocija, 2013) [13].

4. Conclusion: Continuity of Discontinuity

Fig. 10: Hand Sketch as a imagined proposal for entrance area (J.Rakocija, 2013) [13].

Niš is the spatially organized city, coherent urban and natural entity that has its genesis, development, climax and forced disappearance. All this in a period ranging from antiquity to the late Middle Ages, in a way recognizable for many important urban centers within the wider Balkan region.

Historic sites in the city, apart from being a palimpsest of architectural forms encased in a network of urban discontinuities, are also places with deeper sense of meaning where continuity of landscapes in temporal contexts reveals **patterns and process**, rhythms and values that were layered through **time and space**, on and within land and gave “spirit” to the place. The concept of dynamic change and urban discontinuities is associated with continuity of rhythm and ways which according to G. Jellico create urban spaces and demonstrate a sense of human purpose in place and time.

In addition to the pursuit of the landscape study as the basis for heritage preservation, planning and design proposal for historic sites as open spaces of the city, the proposed paper forefronts the landscape architecture as science and art dedicate to reading and understanding of landscapes as a creative products and records of human experiences, actions, beliefs and relationships in space over time, capable of expressing identity and society’s goals and ambitions, where historic *time* in space and *space* in time, is an urban texture, becomes the focal point for future enrichment of urban life.

Proposal was made in constituting of the network of historical paths to revive the past pattern and process as a symbolic framework for Christian Niš, with recognized four landscape characters in relation to the contemporary life and perceptions within the Niš fortress.

The Sarno river and its plain

Rejana LUCCI

Dipartimento di Architettura DiARC, Università degli Studi Federico II, Napoli, Italia
rejlucchi@fastwebnet.it

Abstract

The research deals with the theme of the reclamation of a territory rich in memories of the past and in important traces of its country and settlement's culture, today overall largely degraded.

The study area is the plain of the Sarno river, on south of Vesuvius Mount, between the slopes of the volcano, the Picentini mountains and the sea coast, with the river as central axis.

It's just an area full of historical memories: Pompei stood there with its harbour on the river, Stabiae and Nuceria, and there are the remains of several *centuriatio* that left the marks on which the territory was built. Since ancient times it has been crossed by major communication routes between north and south. The Sarno river, with its central axis and an extensive network of tributaries and canals, was the principal resource of the area, due to the abundance of water and to the rich volcanic soil, and it has always been a land of specialized crops and of manufacturing production. Even today it's an important agricultural area, and a landscape of interest.

But now the plain, especially towards the sea, is a territory invaded by an uncontrolled urbanization, with high density zones of poor-quality buildings, who have paid some cities between them. And the carelessness made the river the first cause of the ecological disaster of this area (with waste, industrial and food poisons): a typical urban territory sprawled and polluted.

So we think an important design issue is thinking of the Sarno River as the soul, the element that still can restore the lost area identity. So (after the rehabilitation already begun) it will be possible to redevelop the relationships between urban areas, rebuilding their hierarchies, and restore the character of agricultural areas and the existing typical nature, by protecting and enhancing them

Keywords: Urban design, geography, infrastructures, urban-rural settlements, collective centers.

1. Geographical structures and urban-rural settlements

The architectural issues addressed in this study mainly relate to the theme of the existing relationships between the territory's geographical structure and the urban settlements and human works arrangements. From this relationship we think today it's possible to start again for the reclaiming and the transformation of deteriorated areas.

The history of the human land occupation has always been linked, as it's well known, to the criteria of selection of the most suitable places for different activities, of practical choices for a good life, safety, health, productivity. These criteria then become rules, measures and settlement's forms with ritual, canonical, symbolic characters, all closely related to the different cultures and eras. Just think of the recurring foundation's elements of the Hippodamus city (Coppa 1968). Or the *sulcus primigenium* in Italic settlements. Or the *centuriatio* of territories in Roman times (Bussi, 1984), when the practical needs of the division and allocation of the fields is matched by a whole world of measures (the actus, the iugerum, the heredium, the centuria), of guidelines, of hierarchies that have become persistent signs of a settlement culture. But also they have become the particular characteristics of entire areas of the Italian territory, recognizable landscapes. Fields, roads, urban settlements, canalizations systems, are all signs around which the transformations of those territories has been carried out. And still today they could be the structure around which to rebuild a persistent character and a recognizable identity.

Already in Vitruvius the choice of the places where *condere urbem* or *coloniam deducere* was linked to health and fertility. Or in the pages of Alberti we find information on "the shape of the decent and charming place; never lower sunk, but rather high above the surrounding area, and that can be continually cheered up by a good air".

So even in the modern era, considering the problem to devise the new post-industrial city, Ludwig Hilberseimer (1949) designed a precise limited-size settlement units, to be distributed in a widespread and regular way on the territory. He divided them into different functions, arranged in a non-confrontational way and careful of the exposure and winds. And he tested the feasibility and adaptability of these schemes right through their inclusion in geographically and topographically different places: along a river, on a hill, in rural areas of varying nature. And the geographic features determine the adaptation and variation processes, related to that specific place. So he reached a definition of an *urban-rural planning system*, where to retune industry and agriculture with the human settlement, as a new model of modern urbanization with regional character.

Starting instead from a reading of architecture and design of a well-defined geographical territory (Abruzzo), Agostino Renna (1980) detects a character that he still calls "urban-rural", in which "the emerging feature ... - relating to the use and the occupation of the soil, to the precise demarcation of the place, to the very small buildings amount compared to the entire area - is that both the buildings and the not built land assume the same role and dignity in the overall composition ... the possibility of an urban shape, including the countryside as its permanent member, emerges from this research." The countryside, with the activities that take place there, it is understood as an element of the construction of the morphology of this particular form of non-compact city.

Not only the relationship with nature and the topography directs modifies and conditions the human intervention, the urban forms and the architecture, but the same structure of the territory, the elements that are present, their reciprocal arrangements define the character and the shape of the areas.

What I mean is the morphological structure of a persistent territory, arisen from the defined relationships between the present elements (that river with that plane, with those mountains ... linked to that specific location), is the matrix of identity and recognizability. And really those are the characters that scattered or cumulated current urban and territorial transformations tend to forget and cover with indifferent plots.

With this setting, this study is aimed at the reading of the Sarno plain, a territory between Naples, Vesuvius and Salerno, a clear geographic structure, rich in resources, full of memories and signs. But today it's affected by large deeds of scatter and land consumption, with linked settlements, and a high environmental pollution.

Even in the existing urbanized areas, difficult to read and to understand, as the Sarno plain, it continues to seem inevitable a reading methodology to highlight, to describe and to make a list of their basic elements. As always it's important for us to try to identify what is really part of the city building, or of the territory, whatever is the nature of the described area.

And so also in the case of contemporary problematic areas the aim is always to think that "the so-called chaos is quite a still not understood order" (Corboz 1998), to know and investigate its components, to "find places in the chaos" of the urban territories, "to give them a name, and to develop their peculiarities. It's therefore an art of urban discovery and not of invention" (Ungers 1997). Today we must understand which aspects of these complex urban territories (and compromises) are the real components of their structure and the potential development points for the transformation, and which ones are to overcome and abandon, avoiding to raise the "degradation" in an aesthetic category.

So it's necessary to describe, select and put back together the area's interesting data with a different logic, with the same attention to everyone: from the special characters, with the memories that each past filed and transformed into meaningful marks, up to the current emerging issues that these areas show us. We want to together re-put them, to give other possible readings of the elements, and to form, with the design interpretation, new and varied interesting relationships between things. This one, with appropriate and realistic (for feasibility and use) visions of the future (needs), will let us imagine a more beautiful and livable territory. (Gregotti 2008, De Solà Morales 1999).

The characters of the reading of urban areas, so as we have done it, have a designing and an interpretative valence. This complex and layered reading will allow us to identify inherent issues in the different areas, where the generality of the chosen theme joins itself to its precise delimitation and to the peculiar needs related to the place's individuality. (De Matteis 1996, Lucci 1998).

This reading then has taken to identify the overall Sarno plain as a city-countryside: a spread polycentric urban-rural city, consisting of small urban centers, from a tiny network of local roads that follow the trends and divisions of the fields, and finally, from an extended part of productive countryside.

The themes of the project, identified to conduct the plain to its regeneration as an unified and eco-sustainable settlement system, have addressed the issue of the relationship between natural

infrastructures of the territory and public places of the city and of the countryside, understood as a system oriented to the overall area's reconstruction.

2. The study area

The study area is the Sarno river plain extending to the south of Vesuvius Mount, between the slopes of the volcano, the slopes of the Picentini and Lattari mountains and the sea coast between Torre Annunziata-Pompei and Castellammare, with the river as central axis.

It's an area full of important historical traces: Pompei stood there with its harbour on the river, Stabia, Nuceria, and there are some remains of three different centuriatio (Choquer 1987).

The urban settlement types are of different nature and they have different roles and locations, also due to the particular nature of the alluvial soil: each one chose places that would give security against the river's floods: there are two towns on the coast, at the two limits of the area (Torre Annunziata and Castellammare). Then there are the piedmont settlements, standing in upper areas not subject to flooding, as Sarno and Nocera, and those built on small hills in the valley, with the typical circular pattern, such as San Marzano, San Valentino and Striano.

Almost in the center of the plain there is the town of Scafati, real crux of the area, born at the crossroads of two major existing infrastructures: the ancient Puteoli-Nuceriam road and the Sarno river.

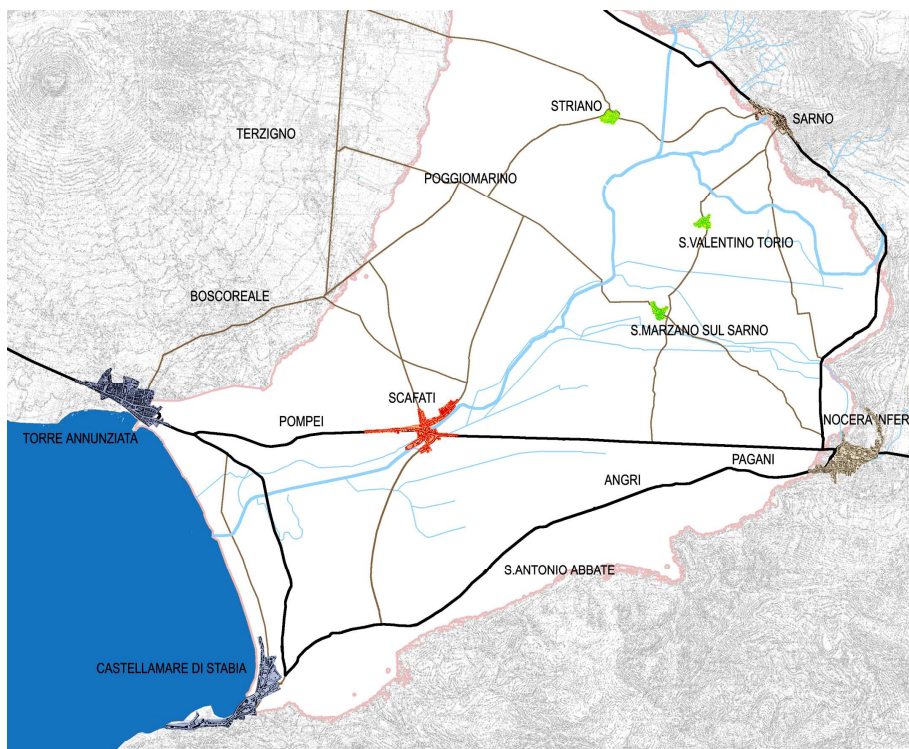

Fig. 1 The original structure of the Sarno plain

Still today the whole plain is a very rich volcanic soil with a dense network of waterways, and this is why it has always been a place of special crops and manufacturing production, a rich and beautiful countryside dotted with farms and isolated individual buildings, with the typical shape of a vaulted ceilings cube (Musi 2003).

Today, especially at the lower stripe towards the sea, the plain is a invaded territory by an uncontrolled urbanization, with high density areas of poor quality housing that have welded together some urban centers (Torre Annunziata-Pompei-Scafati-Angri-Pagani-Nocera) and have lost any distinction between urban and agricultural territory. There are areas of tiny building, often abusive, widely scattered, and a significant presence of plastic greenhouses covering the agricultural soil.

Since ancient times, the area was crossed by two main routes between north and south: the Puteoli-Nuceriam road - then road of Calabria, now 18 SS on the coast side - and the Popilia, at the foot of the Picentini mountains, from Nola, on the other side of Vesuvius Mount. At the present time, these well-established roads have been placed side by side, with a similar direction, by the A3 Napoli-Salerno-Reggio Calabria motorway, and the upper section of the A30.

However the plot of the minor roads until today has remained a minute and irregular network, not organizing for the scattered settlements: the roads do not join two defined points of the plane, but they follow, surround and accompany the shape of the fields. This one enhances the feeling of

disorientation perceiving through the entire area. The Vesuvius remains the only strong element of orientation.

Lately the fully elevated SS 268 Vesuvius road, running in north-south direction, was added to the two highways transversely crossing the flat, in order to improve the possible evacuation of the area for eruptive and seismic reasons. There is also an extensive network of state, regional and local railways, starting with the first and most famous coastal railway line Naples-Castellammare (1840), with the bridge over the Sarno river. The last addition, on the other side, is the current extension of the high-speed line to Salerno. All these lines are uncritically superimposed on the territory with their own technical layout, and still today they are not organically connected to each other.

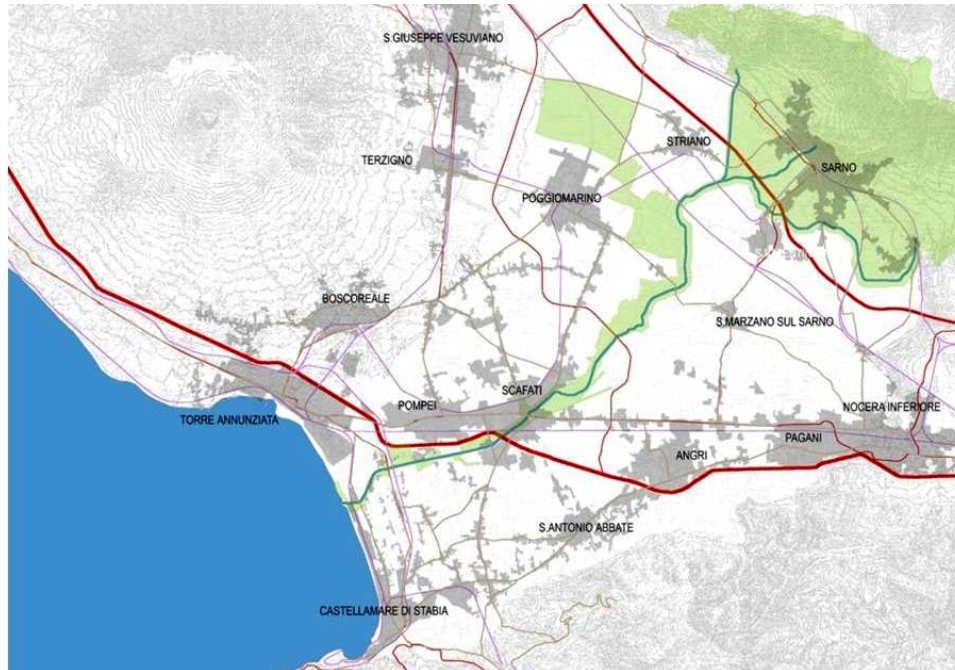

Fig. 2 The plain today

3. The design

The Sarno plain is currently an area where carelessness turned the river, once so important in the local identity to be identified with the deity of the place (Pesce, Milone 2006), into the responsible of the ecological disaster of the area, with the discharge of waste, industrial and food poisons, and with the lack of maintenance and upgrading of plumbing necessary for the proper flow of the water.

Therefore now it's a typical urban contemporary territory, dominated by housing densification and sprawl, by an extensive network of various infrastructures and by a significant pollution. But, though much impaired, the area still shows a possible unitary structure.

It's a clearly bounded area, with a polycentric network of urban settlements, that we can name city-country because of the structure and the relationships among its components (the close relationship between morphological structure of urban settlements and the agricultural land, and the widespread presence of type of houses linked to production), and finally because of the agricultural vocation, preserved in a large part of the area.

Altogether, it's evident the current lack of clear "urban" relationships between the various settlements, namely the lack of a balance and a mutual role of "necessity" between the elements of the set, and of a hierarchy between parts. Each town has expanded (with different dimensions) according to their own ways, still today in an individual manner through the existing planning instruments. The expected growth and the public facilities are designed with a limited overview of the relationship between the municipalities and the plain. Each administration autonomously develops, "in solitude", the plans for the own municipal territory, and the whole plain is further divided between the provinces of Naples and Salerno.

Whereas the current PTCP (Territorial Coordination Plan of the Naples Province, adopted in 2009 with programming 2009-2014) argues that "the analysis of the identity's components allows an allocation of the provincial system in meaningful areas related to the recurrence, the unity and homogeneity of the environmental and cultural roots". It suggests a vision for over-communal homogeneous areas to perform a strengthening of "environmental infrastructures", a conservation of biodiversity and of landscape identity.

With a similar perspective, the reading design led to believe that the river Sarno can be the soul, the fundamental element that still can restore the lost identity of the entire area. This one will make possible to reconstruct the relationships between the existing different urban areas, giving them a clear hierarchy and returning the typical character to the agricultural areas and the nature, by protecting and enhancing it, even with a reconstruction of the historical plots of rural landscapes. The axis of the river thus becomes the place along which locate a unique crossing way and the major public places for the overall settlement's structure of the valley, the city-country, where to place over-communal facilities enhancing the identifying characteristics of the territory. The design mainly identifies the way to "slowly" cross the plain with a new road (all running on the ground, with bike path, pedestrian walkways and parking areas, the red line in the figure) substantially parallel to the course of the river, recovering as much as possible existing paths and local roads. The new road starts from the current Ripuaria road at the mouth of the river and continues until it reaches the town of Sarno at the foot of the Picentini mountains. So it reconnects the coast and the mountains - the two limits of the plain - with a clear sign of orientation and crossing that allows a continuous relationship with the river, now lost, and systematizes the plot of the minor roads.

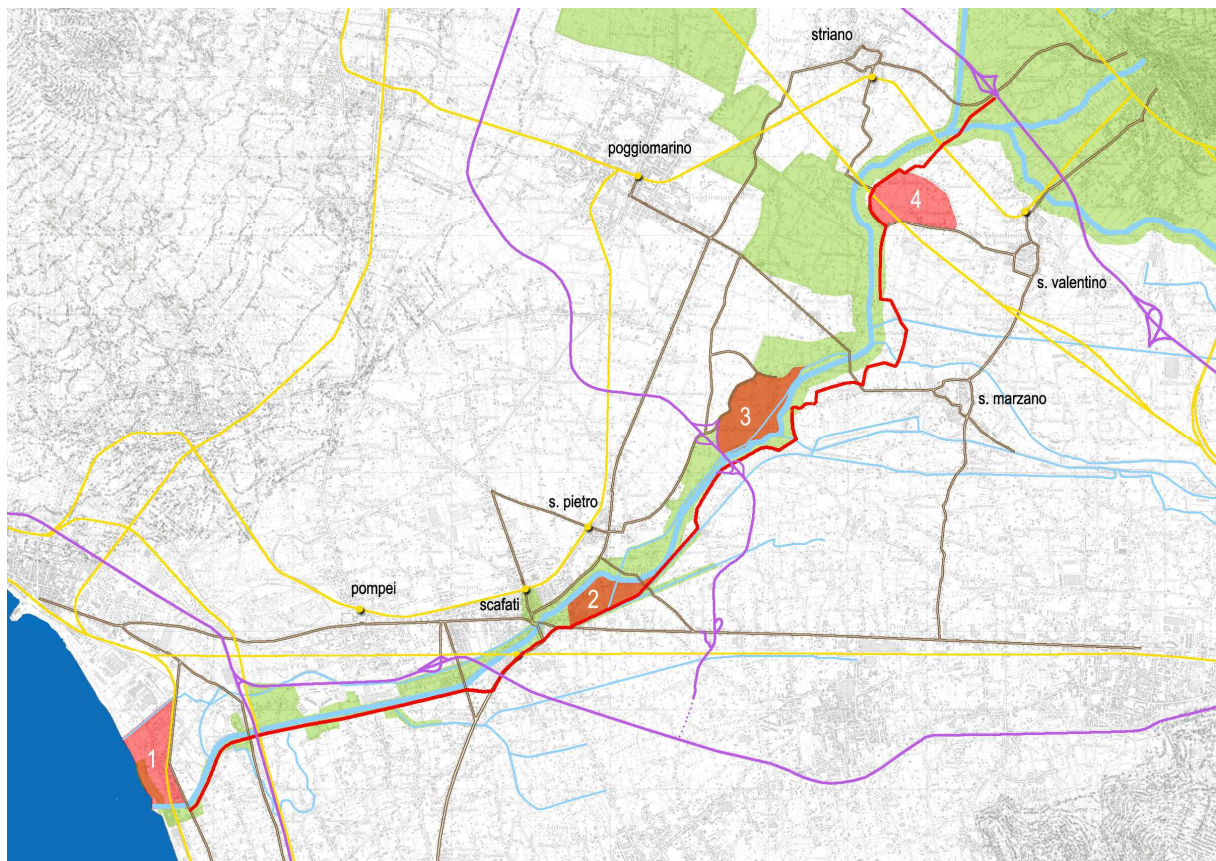

Fig. 3 The design of the plain

The new road is thought as the backbone, as a long central spine along which are arranged the new collective places: along its going there are so localized a series of collective territorial centers, linked to the particularities of crossed zones. Different activities are here condensed, related to present value elements (archeology, nature, agriculture, tourism), to become the main attractive characters for the whole area. These places are connected in an organic way with all existing infrastructures (roads and rails), and are located in different areas of special nature, according to the strategic role of the various zones in relation to the morphology of the valley: the mouth of the river and the coast; the central area of Scafati; the agricultural areas and the landscape on the point of confluence of several river branches and canals; and those areas related to small towns originating in the upper part of the valley, close to the new archaeological discoveries.

The prescribing's principle of the settlements, characterizing all areas, is to consider them as centers of the urban/rural city. Collective activities are here realized in low-density buildings with appropriate characters to the existing urban and rural types. The predominance is given to green areas, some with facilities, part of reforestation, but largely the agriculture is still left. Always everything is in close relationship with the river, and with the new road.

4. The collective territorial centers

In the area of the **Mouth** the theme is the reconquest of the relationship between river and sea, lost for the localization in this coastal area of industrial and manufacturing sectors. Between the current mouth and the new canal that will be the second mouth it will be created a tourist accommodation and spa, with a building structure that refers to the courtyard type. There is also a landing on the new canal and a restored beach. It's provides for a new regional railway station (now there is no intermediate stops between Torre Annunziata and Castellammare), a railway bridge-station reconnecting parts of the territory now cut off from the sea by the tracks. And finally, between the two mouths, it's located a park with facilities, linked with the city of Torre Annunziata in an only urban waterfront, along the beach for bathing use.

In the area **The center**, in Scafati, we want to consolidate the morphologically central structure of the city for all the plain. Like the Sarno city, at north, Scafati is the only urban center where the structure of the river had a strong presence and had entered in the definition of its character. In fact the city was founded around the pons Sarni on Ubulana road from Pompei, and its name originates from "scafa", an old ferry-boat's type. The oldest central district, the Mulini, is born just from the milling activity developed in the sixteenth century. And here it was made a dam and was opened the Bottaro canal to improve the flow of the river. Just beyond this central area, in a bend of the river even in urban areas, it is located the second collective center of the plain, a point to start for the knowledge of the area, and also an improvement of equipment for the city. Here it will be a great info-points (either on news on the riverside park or on the whole area of the Sarno plain and on its vicinity). It consists of a wall's enclosure fabric, with fences and courts, related to the texture of the ancient urban fabric, and directly accessible from the new crossing road. Towards the river shore lies a urban park with facilities for rest and sports (tennis, gymnastic routes, little athletics), and with recreational facilities (outdoor theater and cinema ...), and a naturalist trail on the river, with an wooden elevated walkway with resting places, from which to resume the view of the river, whose banks are often covered by tall reeds.

At the height of San Marzano sul Sarno, in an agricultural area located at the confluence of the Sarno with the Cavaiole canal and other small waterways, there is a **Knot of water**. The elevated road S.S. 268 is the main access, and pedestrian bridges are connected to the new crossing road. Here the prevailing theme is nature, green, and enhancement of agricultural production, with large preserved farmland, and extensive areas of gardens and reforestation (especially towards the river). Here is localized a "SouthEataly" (market and restaurants km. 0) such as a large greenhouse into a garden. Then there is a scattered hotel with small residence buildings in the countryside, some cubes placed in a little regular pattern of new canals; and finally, there is the same elevated wooden walkway, as a mark of constant relationship with the river.

At last, there is the center **Nature and Archaeology**, close San Valentino Torio, in a wide bend of the river with crops and greenhouses, close to recent findings of ancient pile-dwellings . So it was decided to locate in this area a system of public places with a small archaeological museum that collects the finds, with guest quarters and workshops, and a center for training (for River Park employees and other local needs). There are also educational farms, still reforestation areas along the river and the wooden walkway along the shore, connected to the archaeological site with small pedestrian bridges.

FROM THE WORLD TO POMPEII

Aversa / Capri, 12,13,14 June 2014

ADA. A *Bilderatlas* of images, bodies and cities

Malvina BORGHERINI¹

⁽¹⁾ Department of Architecture and Arts, University Iuav of Venice, Italy

E-mail: borgheri@iuav.it

Maps are to the world as the anatomy of a dead corpse is to a beating heart.

Karl Ritter, *Einleitung zur allgemeinen vergleichenden Geographie*, 1852

We should always remember that the work of art is invariably the creation of a new world, so that the first thing we should do is to study that new world as closely as possible, approaching it as something brand new, having no obvious connection with the worlds we already know.

Vladimir Nabokov, *Lectures on Literature*, 1981

Thinking of a figure signifies looking at them. Figures are seemingly elementary things but strange powers emerge from them; just show some things, people or situations, yet they never tell you what to think directly. On the contrary, it'll be up to you to represent them when you begin looking at them, but to do so you have to be willing to become like those figures, a mystery that never ceases to pose the thorniest of questions for the beholder. Once you have thought of them, you will be fully-fledged authors of those images, this play of emotions and what emerges from them. Are you ready?

Fanny & Alexander, *Ada, romanzo teatrale per enigmi in sette dimore liberamente tratto da Vladimir Nabokov*, 2006

Abstract

Collecting pictures in order to remember lives from the past, examining the built spaces that have housed these bodies more closely, observing them together with their accoutrements which have since dispersed, yet to emerge on the surface as forgotten traces, and thus shedding light on a present which is interwoven with the past in a multiplicity of ways... these are some of the reasons why more than thirty years ago a group of scholars at Iuav – meeting in what was previously the Institute of History and later the Department of the History of Architecture, including Bruno Zevi, Manfredo Tafuri, Francesco Dal Co – assembled a collection of slides and old glass plate negatives which now amounts to nearly 100,000 images.

This atlas of images, organised through archipelagos of meaning – in practice transparent envelopes containing up to twenty slides each – conveniently viewable on a large light-box. From time to time new routes might be plotted or those previously drawn up by early explorers may be followed.

The digitalization of these images, carried out in the late nineties, has paradoxically impoverished the atlas-like form of this remarkable collection: the archipelagos of architecture, painting, sculpture, coinage, artefacts, drawings, plans, documents, maps, portraits, film stills – once organised by various scholars as a rotating display for the walls of Palazzo Badoer – were no longer appreciable in a single glance, whether or not its limits and boundaries were redrawn.

This led to ADA, a searchable web database in the form of a *Bilderatlas* (picture atlas). It quantifies at first sight the abundance and outstanding nature of its iconographic material, distributing them in the

Fig. 1: ADA, Housing the game #03.

form of bright points on a map of the entire globe, thus giving back the ability to visually explore, via 'light boards' to both old and new archipelagos of meaning.

Keywords: Architecture, art and technology platforms; Heritage, art and memory

1. The name ADA: a way to describe oneself, reading the other

ADA is a palindrome that gives freedom to movement, which allows entry (*ad*, going to somewhere) and exit (*da*, coming from somewhere) to stand above or below, to look right and left.

ADA or *Ardor* is a literary work that oscillates constantly between fiction and reality, passion and perversion, body and writing, its summation; it is a world in which the geographical and linguistic nomadism of its author — Vladimir Nabokov — is an anticipation of postmodern globalisation.

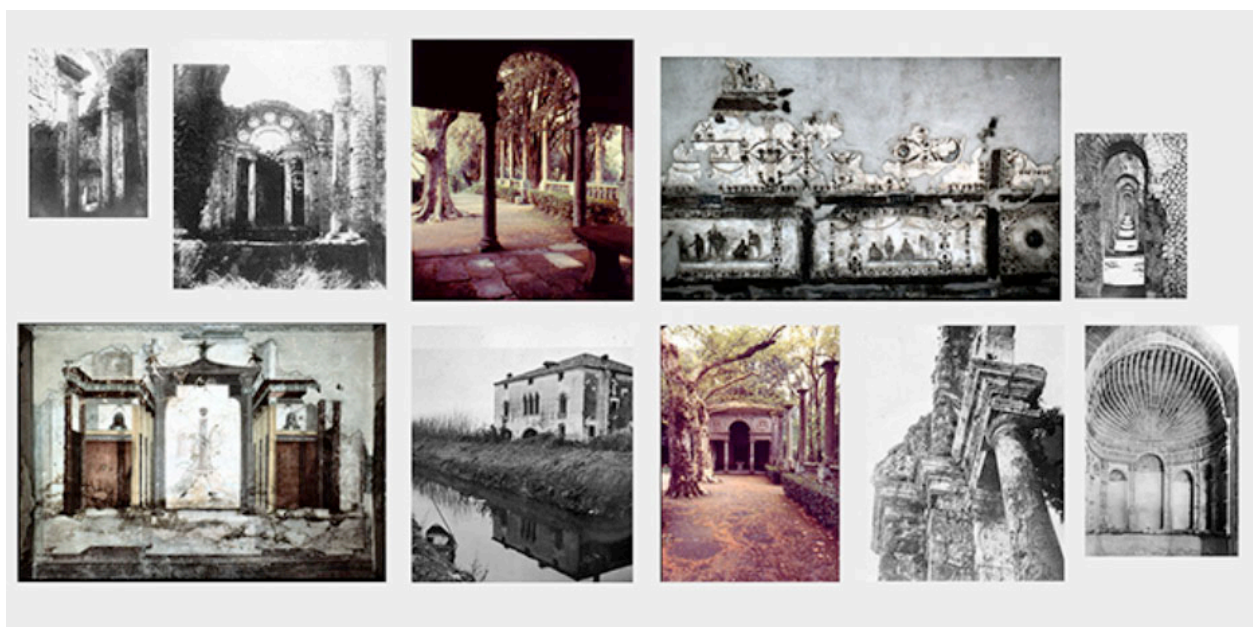

Fig. 2: ADA, Nature and artefact #07.

ADA is a theatrical play; a novel for enigmas in seven dwellings, a game in book form and a free interpretation of Nabokov's work — created by Fanny & Alexander (theatre company) — in which every show/room in turn leads to other rooms, variously linked together.

ADA is one of a number of possible acronyms (Atlas of Digital Architecture, Art Database for Architects or *Archivio di Diapositive Analogico*).

ADA is a searchable web database parting from a map — an intangible and mutable point-cloud created from images of artefacts and bodies that make up the collection — tracing and overlaying those images onto today's world.

ADA is a *Bilderatlas* consisting of a series of islands, partly formed during the last decades of the twentieth century, partly in an adjustment phase, partly undiscovered.

ADA is a project coordinated by Malvina Borgherini (Department of Architecture and Arts, scientific director of MeLa media lab) and Vitale Zanchettin (Department of Architecture, Construction and Conservation), also bringing together Flavio Rizzardi (design and construction informatics), Anna Casagrande Zennaro (archival supervision), Gianluca Asmundo, Alessandro Forlin and Eleonora Porcellato (editing and digital graphics).

Fig. 3: ADA, Joints #12.

2. The atlas form: a visual form of knowledge, a knowledgeable form of seeing

Hailing from Greek mythology, the figure of Atlas — the Titan condemned to carry the world on his shoulders for all for eternity — is the image of necessary toil so that knowledge can be grasped. And as a

Fig. 4: K. Blossfeldt, *Unformen der Kunst* (1905-25). From G. Didi-Huberman, *Atlas. How to Carry the World on One's Back?*

demonstration of his importance the vertebra that supports the most consequential part of the body – the head – takes its name from the powerful giant.

The form that the endeavour will model itself upon will be precisely that which has established the spread of knowledge of both the starry heavens and the entire globe: that of the atlas. No longer mythological (where things are found inside one another, like the earth contained within the celestial sphere), but in the form of a modern map collection, in which for the first time in space (deriving from the Greek *stadion*, the unit for measuring of distance) all parts are mutually equivalent (Farinelli, 2003). Indeed, from the sixteenth century onwards, atlas maps displayed geographic scales, the graphic indicator for the linear scale of the drawing in ratio with the measure of reality.

But if we reflect on the ways in which an atlas is traditionally used – and in this regard we follow the path around the margins of the exhibition (and in the book) *Atlas. How to Carry the World on One's Back?* (Didi-Huberman, 2010) – we find that it does not ‘read’ as a novel or a historical essay from first to last page. We note that this strange book is not made of ‘pages’ in the usual sense of the term (written or illustrated), but rather *tables* within which a number of *images* are arranged. When we consult it, seeking highly specific information, sooner or later our attention will start to veer off down streets and take unforeseen turnings where we are inclined to lose ourselves, forgetting the passage of time.

The atlas, in short, with its seemingly innocent and utilitarian aspect is a unique ‘visual form of knowledge, knowledgeable in the form of seeing.’ [...] «Yet, combining, overlapping or *implicating* the two paradigms that this last expression assumes – an *aesthetic* paradigm of the visual form, an *epistemic* paradigm of knowledge – the atlas in fact subverts the canonical forms in which each of these paradigms tried to find its own excellence and even its fundamental condition of existence» (Didi-Huberman, 2010).

Platonism has handed down an epistemic model founded on the primacy of the Idea: true knowledge assumes that an intelligible sphere is extracted or purified from the sensible space – the world of images – where the phenomena appears to us. And in the modern versions of this tradition things (*Sachen* in German) find their reasons, their explanations only in causes (*Ursachen*) correctly formulated and deduced through the language of mathematics.

The atlas form, in spite of every epistemic purity, introduces the sensible dimension into knowledge, and the diverse, and the lacunary character of each image. Its principle, its drive, is nothing more than

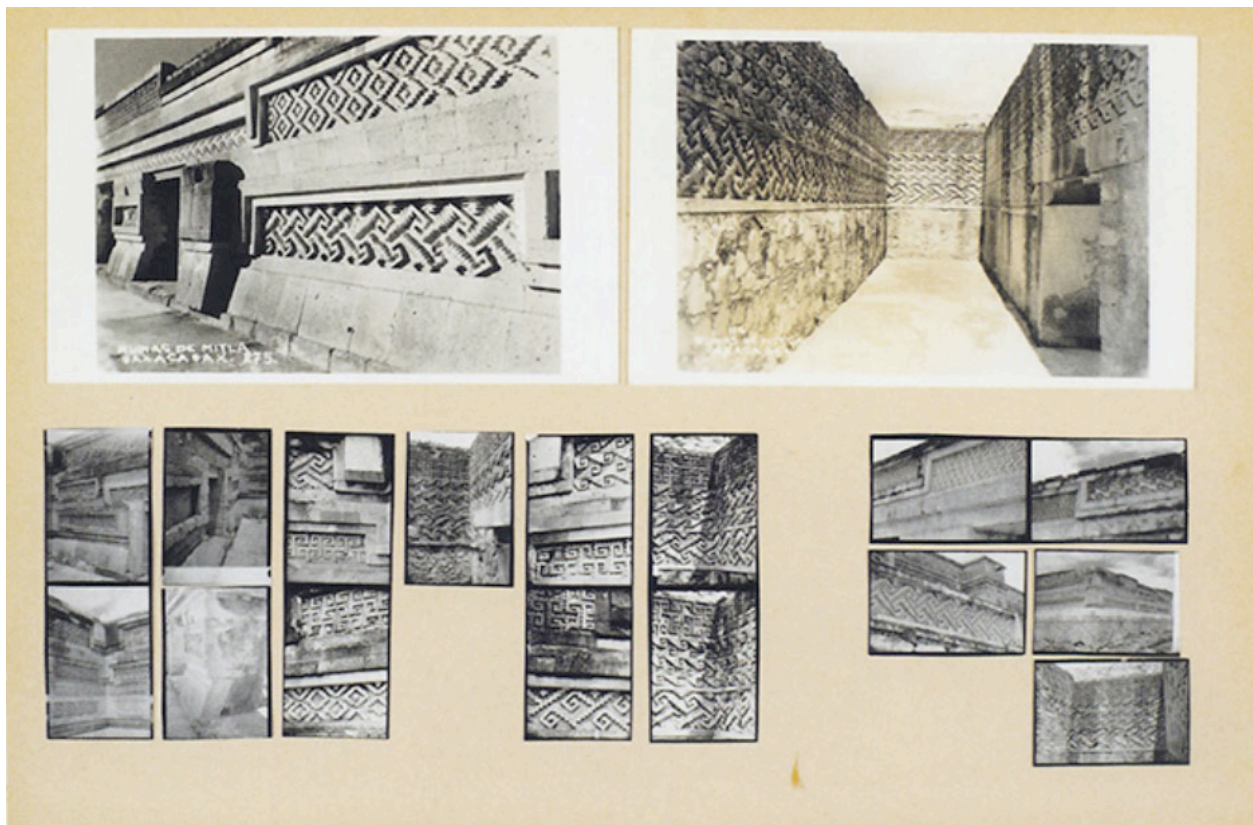

Fig. 5: J. Albers, *Mitla, Mexico* (ca. 1937). From G. Didi-Huberman, *Atlas. How to Carry the World on One's Back?*

imagination, that extraordinary aptitude by which a casual glance may suddenly reveal connections which might otherwise have escaped a more meticulous observation.

«The Imagination is not fantasy; nor is it sensibility, even though it is difficult to conceive of an imaginative man who would not be sensitive. The imagination is a quasi divine faculty which perceives first of all, outside of philosophical methods, the intimate and secret relations of things, the correspondences and the analogies.

Fig. 6: G. Richter, *Baader-Meinhof gang* (1977). From G. Didi-Huberman, *Atlas*.

The honours and functions that he [Poe] confers on this faculty give it a value such... that a wise man without imagination non longer appears like a false wise man, or at least like an incomplete wise man» (Baudelaire, 1857).

There are two ways of understanding the passage: one, the most direct, chasing the message, and another, more imaginative reading which stretches into the montage. An atlas of images can thus be a reading machine in the very broad sense that Benjamin wished to confer on the concept of readability: you get into a constellation of devices ranging from the *camera obscura* to the photographic camera and camcorder, as well as from the cabinet of curiosities, or more mundane versions; shoe-boxes stocked full of postcards that can still be found amongst the stalls along old Parisian thoroughfares .

At the end of the nineteenth century, and especially during the first three decades of the twentieth, there erupted an earthquake among scholars working in what we now call the humanities, triggering a collective consciousness: not only in the works of George Simmel's sociology, but also in Marcel Mauss's anthropology, as well as Sigmund Freud's ventures in psychoanalysis and Aby Warburg's studies on iconography; the mediating role of the imagination and its imagery as a basis for knowledge was recognised for the first time.

The Warburg's *Bilderatlas* (picture atlas) *Mnemosyne* in particular not only radically changes the way to organise and reproduce studies of ancient and modern artworks – from the first decades of the twentieth century onwards – but also acts structurally as a way of conceptualising and laying out the works of many contemporary artists.

Fig. 7: T. Dean, c/o Jolyon (2012-13).

3. Memory and imagination: thinking about memory as an act of creation

In the exhibition *Atlas. How to Carry the World on One's Back?* by George Didi-Huberman (in Madrid at the Museo Nacional Centro de Arte Reina Sofia, Karlsruhe's ZKM Center for Art and Media and Hamburg's Sammlung Falckenberg in 2010–11) the intent seems to be the creation of a montage of figures, a constellation of graphic, photographic and video-graphic memories accrued by invited artists in order to shape this magnificent atlas inspired by the Warburg's *Mnemosyne*. It ushers in a comparison between the idea of an imaginary museum and the more recent hypothesis of a virtual museum or universal access to images, yet it's also a reflection on the close relationship that we forge between memory and the act of creation.

The theme of memory and its reinterpretation in the form of work/atlas is not an unusual one, it's even found in major international exhibitions such as dOCUMENTA (13) in Kassel in 2012, curated by Carolyn Christov-Bakargiev. In the main venue, the Fridericianum's Rotunda, I saw the most touching 'atlas' that I have ever had the chance to explore. To name but a few pieces: a small glass showcase containing Man Ray's *Indestructible Objects* (1923–1965) and *Perpetual Motif* (1971), accompanied by a letter from Lee Miller to Man Ray (1929) and a photograph by the artist of the young student Miller (1932) who then reappears, shoulder to camera, in Hitler's bathtub a few years later (1945). Along the perimeter of the Rotunda are other objects placed between two seemingly identical stones: actually it's a single work by Giuseppe Penone, *Essere fiume 6 (Being River 6, 1998)*, consisting of a sizeable river

Fig. 8: dOCUMENTA (13), the Fridericianum's Rotunda, or *the Brain* (Kassel 2012).

boulder and its exact Carrara marble replica. Penone places them (as a collector more than an artist) amongst display cases containing other, much smaller, older, hand-fashioned stones: these are the so-called Bactrian Princesses, mostly female figurines, carved from small pieces of soapstone, calcite and river pebbles between the late third and early second millennium BC, by an ancient civilisation from the Turkmenistan, Uzbekistan and northern Afghanistan region. Here also are two old postcards sent from Afghanistan, images of pre-war Kassel by Tacita Dean, after having water-coloured them, superimposing small fragments of modernity, and sent via Jolyon Leslie, CEO of the Aga Khan Trust for Culture from Kabul. On the opposite side of the wall to Lee Miller's photos I found a curious piece of Giorgio Morandi's world: in addition to six of his oil paintings were five objects that the Bolognese painter had obsessively depicted throughout his life (both on canvas, portraying them as beloved bodies, and on their own surface, as if transforming them into objects that he wanted to see). I reviewed the world of Giorgio Morandi in an exhibition at MAMbo (2013-14), in his home town of Bologna, where Tacita Dean had previously shot and shown her Morandi related films: *Still Life* (2009) and *Day for Night* (2009). These two films – the first follows the intricate lines that Morandi used in determining the precise positioning of the objects of his compositions, the second shows portraits of every single component that makes up this unusual 'family' – makes use of slow-motion, close-ups and light as a tool of interpretation.

Memory to cultivate, memory to recall, memory to create. Memory that can even be activated by looking at the back of an image. This is the case with Elisabetta Benassi's artbook *All I Remember* which takes its title from a supposedly unpublished novel by Gertrude Stein, exposes her personal atlas of images, consisting mostly in written form. All parts of the work, shown at the Venice 54th Biennale Art Exhibition 'ILLUMInazioni' in 2011, were photographed by the artist over the years that she spent browsing through Italian and international press archives. Her images don't merely reproduce news photographs from the newspaper archives but rather illustrate the underside, the B-side, or the location in which they are shown – meticulously in some cases, in others hastily and inaccurately, occasionally with incorrect data – with indispensable caption information for publication (date, archive reference, handwritten notes). These 'images', brought to light via nine microfilm readers that automatically – with syncopated

movements, horizontal or vertical – projected onto nine screens the hundreds of amassed facsimiles, revealing an innovative assortment that mixes memorable events with everyday life and gives us a portrait of the twentieth century to envisage and explore. Benassi, in subtracting the materiality of images from the spectator, adds potential by way of projection that invites the viewer to traverse a new iconography of the twentieth century.

Subtracting the ornament from the fairytale Gino Coppedè architecture. The case of the villa of the Fairies in Rome

Laura CARNEVALI,¹ Mariella LA MANTIA²

⁽¹⁾ Department of History, Drawing and Restoration of Architecture "Sapienza" University of Rome

laura.carnevali@uniroma1.it

⁽²⁾ mariella.lamantia@uniroma1.it

Abstract

The contribution mentions the well-known fairytale neighborhood in Rome, which was designed by architect Gino Coppedè and the works began in 1918. The district consists of palaces and villas, which are characterized by a decorative baroque with monstrous and unreal figures, unmistakable emblem of "Coppedè" style. This style has no precursors nor followers and it denotes a linguistic formula personal and easily recognizable. The buildings are carriers of forms and expressions without boundaries, so as to be called "fantastic and fabulous architecture".

The goal is to check if the fabulous and fantastic character of the architecture is due to the form as an extension of the content or, conversely, this appearance is due to the overpowering decorative apparatus which wraps facades and goes up to their immediate surroundings. The target of this study is to carry out, with the help of new technologies and in particular through three-dimensional simulations, a methodological process of "stripping" or "subtraction" of typological categories of decorative elements which are present in these buildings (stone ornaments, masks, wall frescoes, niches, columns, wind vane, gates, torch holders, etc.).

The three-dimensional elaborations produced were also drawn with the photo modelling technique with which we are able to realize pseudo three-dimensional models directly from the measured data, which are accompanied by real textures acquired directly from the photographs.

Keywords: Coppedè, Villa of the Fairies, survey, modelling.

1. Premise *

The "Modern Construction Company" began to work in 1919, on behalf of the Financiers Cerruti, on the construction of a new neighborhood in Rome in an area between Parioli and the neighborhoods, still under construction, of Trieste and Salario. The task was given to Gino Coppedè, a renowned Florentine architect who, for the scope of the work to be performed, moved to Rome, the Eternal City where, in the last three decades of the nineteenth century, two master plans were made at only ten years of distance, the first in 1873 and the second in 1883, without avoiding what revealed to be a real "building fever". Only at the end of the first decade of the new century, in 1909, a new Master Plan, conceived by Edmondo Sanjust di Teulada, established the rules for expanding areas. It was with these new rules that Gino Coppedè began working for the new Roman neighborhood that now holds his name. A district that occupies an area of 31.000 square meters in which palaces and villas coexist harmoniously, and that is permeated by a fabulous atmosphere that is the more palpable in the central hub of the neighborhood.

The formation of Gino Coppedè is definitely unusual; along with his younger brothers Charles and Adolph, he trained at the Casa Artistica, the Florentine workshop of his father in which carved and sumptuous furniture typical of the décor of the Umbertine age was created. Only in a later time he began to devote himself to architecture. At the end of the 19th century, he completed his training by attending the vocational school of Decorative and Industrial Arts and was awarded by special merit with the title of Engineer in addition to being lecturer in Architecture at the University of Pisa. Gino quickly became the star of an architecture in which elements, materials and shapes of different

derivation coexist, defining a neo-eclectic language that became almost synonymous with the expression of " fantastic architecture ".

His architecture re-proposed elements of Renaissance, Gothic, Mannerist, Baroque and Babylonians styles, whose peculiarities were mixed by the designer with great skill , receiving a substantial number of professional duties by a particularly demanding bourgeois clientele interested in architecture.

The great skill of Coppedè resided mainly in the ornamentation, that ornament so varied in design and use of materials that represents the unique character of its architecture, able to complete and connote it [1]. The works in the district began on 09/13/1919, as shown in the application that was submitted by the building company to the 5th Office, the Building Inspectorate of Rome, and that is now preserved in the Historical Capitoline Archive.

2. The villa of the Fairies *

The centerpiece of the Coppedè neighborhood is constituted by Piazza Mincio, the square that, if observed by the monumental big arch which is the entrance to the neighborhood, along the diagonal street, now Via Dora (Fig.1), is a real scenic backdrop, with at its center the small but articulate fountain of the Frogs in the baroque style (Fig.2) . The entire composition recalls, and seems to want to pay homage to the Turtle Fountain in Piazza Mattei and most of all, through the shells and the presence of large bees [2] placed in the hinge of the valves of the shells, to the small Fountain of the Bees, which was planned by Bernini to give honor to his client (Pope Urban VIII Barberini) by inserting the three Bees of the heraldic symbol of the Barberini family and which is now located between Via Veneto and Piazza Barberini.

The great monumental arch, the fountain, the fronts of the buildings (Spider and Ambassadors) and the Fairy Cottage create forms and spaces of refined sophistication and are bearers of a decorative architectural appearance without boundaries, place and contents so as to be defined , " Fantastic and Fabulous Architecture".

But of all those architectures that face the square there is one in particular, the so-called " Fairy Cottage ", that contributes strongly to confer such a look at this site. (Fig.3)

Fig. 1: The Coppedè. The monumental arch of the entrance to the neighborhood (via Dora, already Diagonal Avenue).

Fig. 2: The Coppedè. Piazza Mincio with the Fountain of the Frogs.

Fig. 3: The Coppedè. Piazza Mincio. The Fairy Cottage.

Located between Via Brenta, via Tanaro and via Olona [3], it has a covered area of about 500 square meters and is surrounded by a garden that, in order to give even more the fairy tale aspect, Coppedè had enriched with lush exotic vegetation; the garden is surrounded by a sinuous design wrought iron railing that rests on a low brick wall and access is secured through both the wrought-iron gates and the ones finely crafted in wood and wrought iron.

The project drawings of the cottage [4], consisting of plans at various levels, one section and two elevations (the shorter one on Via Tanaro, and the longer one on Via Brenta) do not at all stand apart from the realization (Fig.4).

The particularly articulated facades are punctuated by a varied series of elements. Canopies, turrets, arcades, balconies, windows of various types, round and pointed arches, stairways, etc., follow one another at a brisk pace (Figs.5,6) .

Dense decorations return and emphasize an architectural unity also through the use of different materials, their cut, their processing and their different design obtained through different modes of installing the material. Brick, travertine, marble, terracotta, iron and glass are associated with colonnades, mullioned windows, capitals, moldings, etc., and give, together with ample wall frescoes, a chromatic and perceptual appearance which brings us back immediately to mental images of our childhood: fairy castles and houses that made us dream!

Fig. 4: Gino Coppedè. Project design. The elevations of Fairy Cottage.

3. The dispossession of the elevations of the Fairy Cottage *

This contribution does not aim to investigate the cottage according to Vitruvian criteria like *ordinatio*, *dispositivo*, *distributio*, *eurytmia*, *symmetria*, *decor* [5]; it simply aims to verify a methodological path of "subtraction" of typological categories of decorations, fundamental architecture components that are able to enhance and accentuate certain parts of the overall aesthetic value and exist along the facades of the eccentric architecture. In this way the architecture is deprived of any ornament, bringing to the light the tectonic-functional aspect of the building, its pure form as an extension of content and verifying how the fantastic and fairy-tale character can be attributed to the architectural unity of form, function and decoration, or to the sole decoration, or again, to the formal and proportional qualities of the building.

In order to achieve the goal and to be able to provide a possible answer to the above question, we will use the new information technologies that, even in this case, assist to our problems. In order for the new information technologies to be bent to our specific purposes in an intelligent way, knowledge is required together with a preliminary analysis of the building that allows us to identify and systematize the main membering, to catalog them and then start some sort of decorative subtraction. The preliminary direct type approach to the work, together with a proper photographic documentation made it possible to highlight, beyond the most obvious decorative elements, all the finer and less redundant, but no less significant, details which determine by their presence the perceptual, chromatic and chiaroscuro aspect of the cottage (Figs.7,8,9,10).

The study, still in progress, provides that "spoliation" is done first for the entire building and, subsequently, to extend the process to all buildings fronting on the square in order to understand the perceptual effect that you would get.

The categories identified were as follows:

- *Stone ornaments*: columns with only aesthetic value, sculptures, moldings, architraves, entablatures, shelves, etc. ...
- *Brick Ornaments*. cornices, arches, windows, thresholds, etc. ...
- *Treatment of the plaster*: rustic or smooth.
- *Frescoes*: large, borders, frames, cornices, quoins, soffits of arches, Latin writings, painted edges to mark material changes
- *Windows*: stained or leaded glass.
- *Iron ornaments*: fences, gates, balustrades, grates, lamps, lanterns, wind vane, torch holders, etc. ...

The architecture, as usual defined through the Vitruvian triad: *Firmitas*, *Utilitas*, *Venustas*, is then subjected to a spoliation of all elements belonging to the above categories, verifying, at the same time,

also the components which mainly influence to confer the surreal and fairy atmosphere to the entire composition.

In this regard, we firstly operated executing the survey of the building and then developing a three-dimensional modeling of the architecture in order to be able to separately analyze the above mentioned categories. After the spoliation operations will the architecture, reduced to nuts, still be able to be defined as "Fairytale"?

4. The digital survey of the Fairy Cottage: the use of digital photogrammetry and laser scanning for three-dimensional modeling **

Today it is recognized that both the surveyed architecture and the designed one are represented through segmented virtual models, broken down into various elements, editable, visible from infinite points of view, which simulate a real or imaginary context. The three-dimensional view is the most complete means of display of the formal, morphological and textural aspects of the surveyed or designed object. In this research, the objective of which is the documentation and analysis of the decorative exterior facades of the architecture of the Coppedè neighborhood, 3D modeling is therefore the method of representation more meaningful and functional to the purpose, as an effective tool documentation, interpretation, communication, and analysis of architectural elements.

The graphic and communicative completeness of three-dimensional models that makes them easy to understand, clearly demonstrates their fundamental and irreplaceable value. The increasing use of this kind of processing has also influenced in part the subject area of the survey that, as that of the representation, has undergone significant changes with the introduction and use of advanced technologies that have revolutionized both the operational processes dedicated to the withdrawal of the measures and those of graphical display of data in terms of restitution and representation. In particular through the new digital technologies, represented symbolically by the laser scanner and the photo modeling, it is possible, in an almost fully automated way, to realize the pseudo-three-dimensional models directly from the measured data, with different processes of transformation, union and representation, ruled by algorithms that are diversified for each program.

The laser scanner system, as well as that of photographing, provides, as a direct result of the measurement session, a set of three-dimensional coordinates, in a reference system correlated with the instrument, for a very high number of points that are hit by the laser beam or acquired through photography; the cloud of points so generated apparently describes the outer surface of the scanned object. Regarding the use of photo shoots for the photo modeling technique, this also responds to the need to achieve a pseudo-three-dimensional models directly from the measured data [6].

The two technologies, now widely diffused, are a valid support to modeling and three-dimensional (3D) rendering of the observed physical surfaces.

Fig. 11: The Coppedè. The Fairy Cottage. Views of the scanworld in RGB color, in black and white and in reflectance mode.

Fig. 12: The Coppedè. The Fairy Cottage. Examples of photo-modeling elaborations obtained with 123 Catch software.

Fig. 13: The Coppedè. The Fairy Cottage. 2D and 3D elaborations of the scanworld with and without meshing.

The Fairy Cottage lends itself favorably to the integrated use of these techniques especially for technical and practical requirements dictated by the need to act quickly and in areas not physically accessible. The survey project was therefore set up in order to integrate the data acquired with a laser scanner with those derived from photographic detail, taking into account first and foremost the objective of the survey itself, that is the development of a three-dimensional model to be explored. For the acquisitions of data the following devices were used: a Total Station TCR 703, a Focus 3D laser scanner CAM2 (Faro) and a digital SLR camera Nikon D90. In the overall survey activity, a total of 25 records have been carried out with range-based technique together with approximately thirty shooting stations with image-based technique (Figs.11,12).

The polygonal topographic framework network that was realized allowed to fix the plano-altimetric configuration outside of the complex, producing the coordinates of the support points for the direction and control of the produced point clouds.

This ensured, subsequently, the correct assembly of both restitution and the other processing resulting from the use of these measuring techniques. The programming of the campaign of acquisition with a laser scanner also took into account what was to be the next phase, relative to the union of the pairs of clouds and their processing; the planning of the measuring stations was conducted trying to keep distances which may prove optimal for the processing of union of pairs of clouds maintaining a large gap overlapping homologous areas in order to reduce the error margin. The post-processing activities led to the recording of all the acquired data in a single scanworld which provided a three-dimensional view of the complex.

5. The analysis of the decorative elements of the Fairy Cottage: from the real to the imaginary perception **

The aspects to be analyzed in the context of this research are basically two: the facade (and ornament) and the environment or best the context in which the architecture is inserted. In this phase, the focus will be only to the analysis of the decorative and ornamental elements of the facades of one of the most significant buildings of the Coppedè district: the Fairy Cottage. The implementation of the model was obtained from the processing of point clouds acquired with a laser scanner: these were recorded in a single scan world with the Reconstructor software and subsequently exported to the Geomagic platform for meshing (Fig.13). The model produced was further synthesized and translated into geometric volumes that are easily manageable for the operations of "spoliation" of the decorative elements. Specifically, we report in this paper the elaboration carried out on two sides of the cottage, namely the north-east (of which only a portion is shown) and the south-east ones. On the basis of photographic documentation and of models made with digital photogrammetric image-based method, the mapping of the model was carried out in all its formal and decorative aspects, namely the brick thresholds, the sculptures, the lintels, the shelves, the frescoes and all the other elements that are typical of the architectural language of the Coppedè district and that makes instantly recognizable its buildings.

Fig. 14: The Coppedè. The Fairy Cottage. 3D modeling of the façade prospecting on Via Olona after “spoliation”.

Starting from this three-dimensional complete model, the operation of "spoliation" was conducted in successive stages that involved, from time to time, decorative elements attributable to a well determined type of membership (Fig.14). Following this methodology, have been removed first the painted decorative pieces, then the stone sculptures and finally the colors of the stained glass windows (Fig.15). The architecture thus virtually represented, albeit depleted of these decorative elements, and then in a certain sense deprived of its formal identity, still maintains those characteristics of sobriety, simplicity and quality of the composition that refer to an essential ideal of beauty. A dual valence of the ornamental element is then showed: on the one hand, it contributes greatly to define the character of the architecture, making it unique and unmistakable; on the other, in his most blatant and elaborate realizations, it is likely to be a superfluous something that indeed hides the substantial and essential character of the architectural structure itself.

Fig. 15: The Coppède. The Fairy Cottage. Illustration of the "spoliation" process as conducted on the 3D model of façade prospecting on Via Brenta.

Although the architecture has rarely considered the applied ornamentation as extraneous, perceiving them as an integral part of his language, often displaying and emphasizing the essential structures, to describe the construction and define it in its organic structure, there have been, over the centuries, authoritative opinions that instead refused decoration and ornament as unnecessary and even "tacky". If so Vitruvius attributed to the embellishment a place of honor, as long as you do not come to the excessive decoration and the useless pomp, as he recognized that the order, arrangement, number, décor, and the distribution itself of architectural elements had an intrinsic ornamental purpose, on the other part Adolf Loos argued that to embellish corresponds to "defile the walls with obscene drawings" [7].

This contribution comes from organic collaboration of both authors agree that attributed respectively to paragraphs marked by asterisks (*Laura Carnevali, **Mariella La Mantia).

Abstract ID 095

The expansion of the culture of the Roman Empire beyond the Alps has left significant traces of his passage on the territory of Southern France. Evidences of considerable interest that embrace not only archeology, but also the religious sphere. They give rise, especially in the Middle Ages, the proliferation of congregations and, consequently, churches, monasteries, cathedrals, around which they have developed the current concentric.

The attention has been focused on Vaison-la-Romaine for its peculiarity to possess within itself the distinctive characters, perfectly preserved in the various historical phases. It is observed that in Vaison, in the alternation of periods, each of these hasn't devastated the previous one, so in the eyes of the visitor today, the city is clearly divided into three parts: the matrix of Roman , medieval era and the modern . The richness of the cultural heritage has favored the tourist aspect triggering processes of conservation, promotion and communication, involving in this process the settled community and indirectly the entire territory.

With a view to sustainability based on local resources, we can say that Vaison-la-Romaine is a clear example of how the cultural and historical heritage lives in symbiosis with the city today. The survival of each of the periods is linked to the existence of the other, in a dynamic that generates large-scale benefits.

Keywords: Paysage, Archaeology, development strategies

1. The archaeological site

The attempt to reconstruct, through an examination of the evidence received from the past, the evolution and the relationship between the individual and the environment, leads me, inevitably, to the period of Roman colonization and the birth of Christianity in Southern France. The research is carried out on Vaison-la-Romaine, whose organization of the plan differs from the planning rules dictated by the *castrum* which was based on the *cardo* thistle and *decumano*. Being this small town located in the Province inner, away from the commercial and military routes, the Roman influence was manifested differently, making it a particularly interesting case.

Vaison does not appear as a colony, but the capital of a vast territory south of Narbonne inhabited by Voconces (fig. 1), mountain tribes strongly attached to their land and their freedom, close relatives of the Ligurian peoples. The alliance of this population to the Roman army against the Cimbri and the Teutons, gives them the title of the civic federation and, therefore, become citizens of the Empire. It is in this period (75 BC), who as a result of peace occurred, Vaison manifests its peak with great development of the arts and sciences, and an administrative organization composed of seven districts, called pagi. It possesses all the attributes of a thriving city where the architecture marries the culture by adapting the Roman style to the climatic needs of the region, in particular at the periodic occurrence of the Mistral.

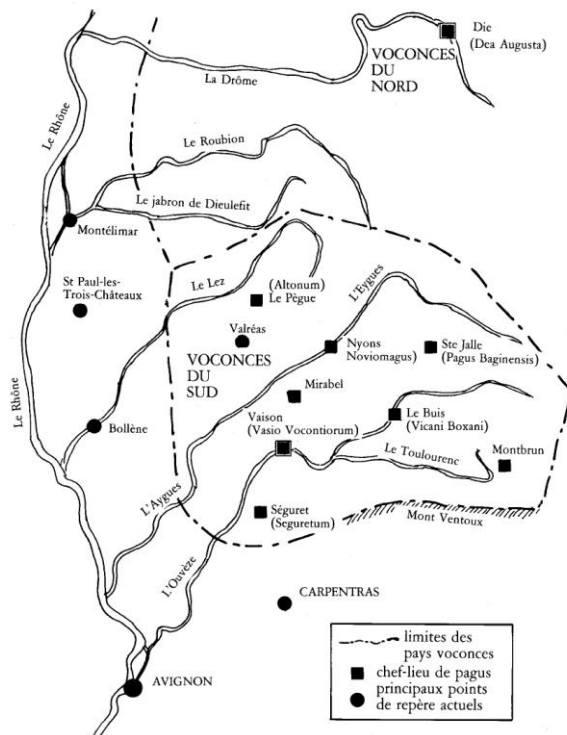

Fig. 1 - Territory of South Voconces (XI sec.)

It has not yet been able to trace an exact plan of the ancient Vaison because only two districts have been affected by archaeological digs that of Villasse and Puymin hill, located to the west at the edge of the watercourse called Ouvèze (fig. 2). A dense network of canals across the two areas by feeding the civilian houses and fountains. Our itinerary starts from the known Villasse. What most impresses is the sheer size of the buildings fronting on the main streets. The road of the shops has a straight line with a moderate slope and is surrounded by columns on the left and on the right you can find small

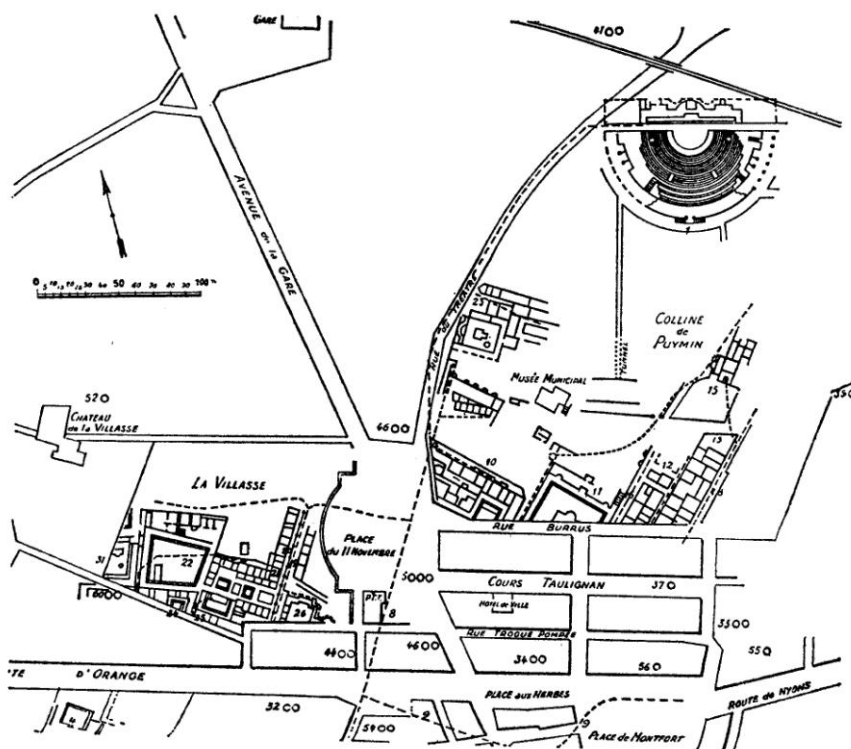

Fig. 2 - Plan of archaeological site

Fig. 3 - Excavations in the area of Villasse

buildings used to store. It is a large shopping street, on which, at the time, was facing a covered gallery that it appears inside a headless statue of Mercury (recognizable by the winged sandals) dominates the environment (fig. 3). At the edge of the area is located just across a large arch, the only survivor of the building used to Thermal Baths and so identified by the finding of a dense network of canals which are concentrated in its vicinity.

This whole area is headed by a large villa known as the home of the Silver Bust, in which, during the excavations, they found a metal bust dating from the time of Traiano. It is a large and luxurious complex that, slowly, has incorporated the nearby houses to take up a considerable size. Here we find the classic ground plan of Roman settlements, *atrium*, *oecus*, *peristyle* with basin and *tablinium*. At the extreme west of the villa there is the home of Daphne, much smaller than the previous one, but of considerable architectural interest.

The excavations in the hill Puymin have revealed a set of buildings patricians and the Theatre, it was built in the time of Tiberius, and, from what has been found, it seems, was adorned with countless statues and rich wallpaper that shows that the life that led to Vaison was extremely wealthy. Dated around the year 20 BC in the classic style, could accommodate 7,000 people. The steps to access and stairways are entirely carved into the rock, and thanks to the restoration and reconstruction of 1932, is still used to the present day, especially in summer season (fig. 4).

Fig. 4 - The roman theatre (20 B.C.)

Fig. 5 - Particular of mosaic

Below the theater, at the foot of the hill Puymin, whose name refers to the cult dedicated to Minerva (Podium Minervae) extends the noble district with splendid buildings. Among these I remember the home of the Roman family of the *Messii*, directly connected to the theater by a staircase. You enter a large room which gives access to the bathrooms and the kitchen, which envisage two internal courtyards. In addition you will discover the atrium, the heart of all Roman houses, squarely, around which there are the apartments. It takes the light from the top and at the center *impluvium* collects rainwater that fed into a large basin helps to refresh the environment. In this place was found a beautiful head of Venus, mascot of the house. Adjacent to the Atrium, the *lararium* hosts the depictions of the protectors of the hearth. Not far away there are the apartments that overlook a large peristyle that surrounds the large basin open pit. In the words of Abbot Sautel , passionate archaeologist who, for half a century, has participated in excavations in Vaison-la-Romaine, contributing to the discovery of important findings: *“La partie centrale du péristyle, qui n’était pas couverte, comportait un bassin de 15,70 m de longueur sur 2 mètres de largeur, qui occupait tout le côté exposé au soleil, le long de la colonnade. Le reste de l’espace libre paraît avoir reçu des plantations de fleurs et d’arbustes, mais tout autour de ce jardin avait été établi un ruisseau d’écoulement, enduit de béton à tuileaux, d’une telle solidité qu’il a pu être utilisé à nouveau pour assurer le trop-plein du bassin. Quand on connaît le goût des Romains pour l’eau et pour ses mille jeux dans les cascades, on peut imaginer le caractère pittoresque de ce péristyle, entouré d’eaux courantes et orné de fleurs, ainsi que le plaisir qu’apportaient aux yeux ces ondes claires animées par les nombreux animaux dont la fantaisie du propriétaire les peuplait souvent...”*

Finally, through a long path you will reach within the *oecus*, where they held meetings, parties and banquets. The floor was marble, slate and decorated with mosaics (fig. 5).

Definitely for fans of Roman history, visiting these places will discover the charm through the abundance of artifacts, with the paths in the various districts of the city, you will fall into a timeless dimension enriching their culture.

1.2 The historical center

You could talk endlessly and in more detail about the monuments exposed to the curiosity of the visitors, but Vaison-la-Romaine offers other features that deserve attention. I am referring to the period that spans the Middle Ages and that propels us on a scale of values and conception of space different from the previous era the Upper Town is the current center (fig. 6). The first inhabitants of Vaison-la-Romaine, in pre-Roman times, settled on the rocks that looked out over the river Ouvèze in a sort of *oppida*. In Roman times, most of them descended to the functional and magnificent city built by new allies. After the destruction of the barbarians and the incursions of the Saracens, drawing much of the building material from the Roman city, they settled on the hill and gave rise to a new fortified town, which occupied an extent greater than that existing today. Finally, when the peace and tranquility is re-established, many residents of the Upper Town, for reasons of convenience, returned to live in the lower part of building up in the vicinity of the current excavations. It is for this reason that the historical center, although nicely renovated is considerably limited compared to the size reported to the seventeenth century, at the time of its greatest splendor when, locked inside a double wall, the houses came up to castle dominating the entire region. The robustness of the ramparts (late fourteenth century) and strategic location on the steep rocks, was such that during the Wars of Religion, Vaison-la-Romaine had never conquered. Bad luck also had the bloody Baron of Adrets, skillful Dupuy-Montbrun, the fearsome Gaspard Pape St. Auban, which, to their credit, they had conquered, almost all of the cities of Provence and the southern Dauphiné.

Crossing the Roman bridge (fig. 7) over the river and past the first door of defense, you are immediately in a medieval atmosphere: high walls with loopholes, protruding towers, heavy doors in

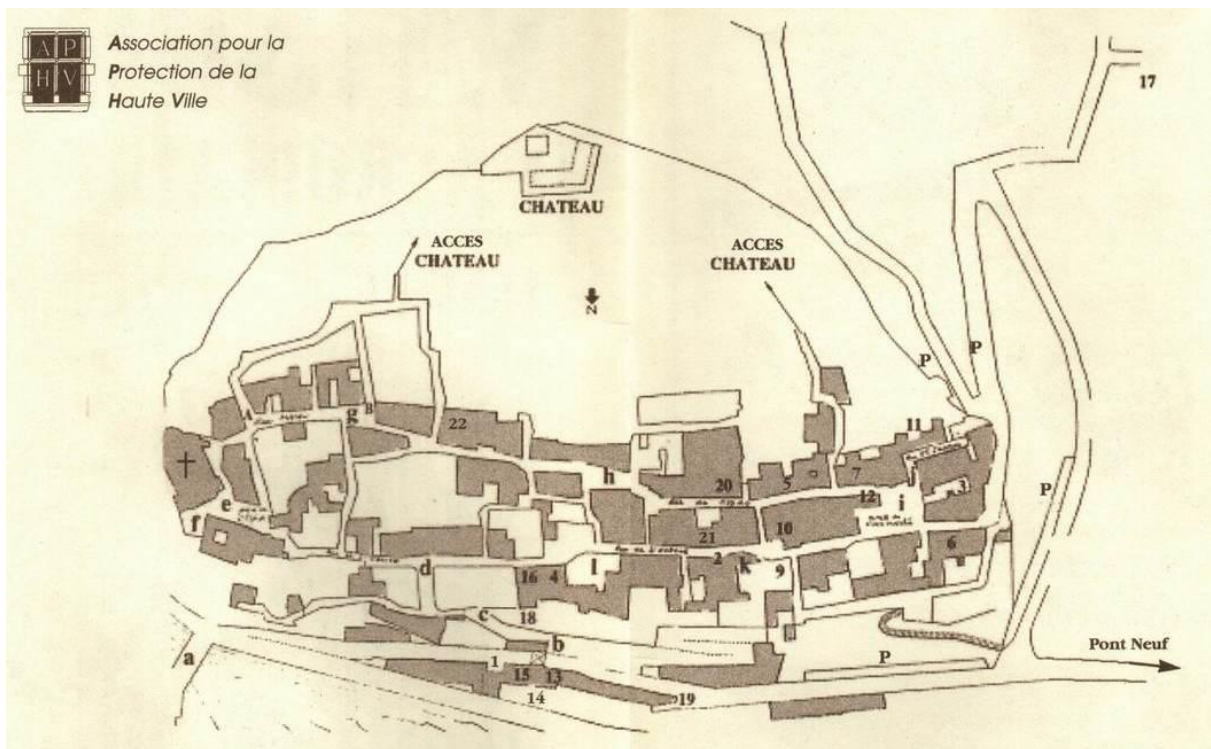

Fig. 6 - Map of historical center

wood and iron windows with thick iron bars. Only when you get to the second boundary wall, the door of the Belfry, which in ancient times was equipped with by a drawbridge, and go into the real village. The constant remakes and adaptations through the ages gives the place a tone of Renaissance. There are many monuments that you can visit but definitely the protagonist of the visit is the atmosphere that you breathe so far from our time and yet alive and throbbing. I dwell on the description of two squares, in my opinion, tell us much about the history of Vaison-la-Romaine. The first is the Elm Square, a place full of charm, with a fountain, the old presbytery which supports a large stone doorway surmounted by an oculus and a spire, belonging to the facade of the chapel of Santa Costanza, now destroyed . To complete the set, you can see two buildings on the square, one of the sixteenth century, belonging to nobles (fig. 8) and the other, in front of the fountain, in the Provencal style of the late eighteenth century with pergola and attached an old shop.

Fig. 7 - The Roman bridge (watercolor)

Figura 8 – Palace of nobles (XVI sec.)

The second is the Market Square shaded by huge plane trees and adorned with a fountain that throws water from Mascheroni, this is the oldest fountain in Vaison-la-Romaine dating back to 1460. The square is surrounded by ancient and well-preserved palaces and its functions were various: from market to a place of entertainment and justice. Studies and research shows that here was located the pillory for citizens to expose the condemned to public ridicule. Southwest corner stands a large stone portal that allowed the isolation from the rest of the Jewish quarter of the city.

Visual landmark is the Castle, belonging to the Counts of Toulouse, that dominated from the top of the hill the whole Vaison-la-Romaine. Its history is linked to the bloody struggles arising from supremacy between political and religious power. Currently it is not possible to visit it, the bad condition in which it is deserves a careful restoration and requalification aimed to rescue this building, on the one hand as a missing link of union between the Roman period and the Middle Ages, on the other hand, from the point of view landscaped, as panoramic observatory on the complex of Mont Ventoux, on the countries of Dentelles and the mountains of Baronnies (fig. 9).

Fig. 9 - The Castle

1.3 The religious heritage

The most interesting monuments, from the religious viewpoint present in the territory of Vaison-la-Romaine, are the Chapel of Saint-Quenin and the Cathedral of Notre Dame de Nazareth. The first is located near the Theater in a dominant position, and offers a wonderful view over the whole city. The most extraordinary part of the building is the triangular in shape apse on the outside, whose workmanship greek-latin style did think that it was originally a temple dedicated to the cult of Diana. The experts agree that the reconstruction and adaptation of the building to the needs of Christianity occurred in the second half of the twelfth century. The period coincides with the religious fervor of the medieval period, which has given rise, not only in Provence but throughout Europe, to the great monasteries and the immense wealth dedicated to Christian worship. The chapel is built of blocks of white limestone enriched with cornices, columns and capitals, finely sculpted that emphasize the perfect architectural proportions (fig. 10).

Fig. 10 – Saint Quenin

The Cathedral of Notre Dame de Nazareth is a large complex built on the places of worship of the past. Excavations show that the building has a basement composed of fragments of Roman monuments, portions of columns, huge Corinthian capitals, chiselled cornices, geometric bands which make us think that the church was built on a large Roman temple. The bell tower, square plan, overlooking the church and cloister, which is also the same historical period (fig. 11).

Fig. 11 - Cathedral of Notre Dame de Nazareth

2 The development strategies

The brief description of the huge archaeological-architectural-historic heritage of Vaison-la-Romaine, where each sector would deserve to be investigated in detail in its various aspects aims to contribute to the knowledge of the site and help us understand the development strategies based on complex and articulated system of tourism.

The modern part of Vaison-la-Romaine stretches from the archaeological digs and the medieval area further south. Like all towns of Provence is very lively and animated. Its economy is based exclusively on tourism and, consequently, has developed all forms of openness and incentives as a function of it. In fact, they were made choices related to cultural and social identity of the place. In this case, the residents have been working on a project for a tourist offer based on their own history, heritage and archaeological territory.

In this way it is also acted on agricultural production and craft, discovering knowledge, oral traditions at risk of permanent loss. Here we see an opening as prudent and sustainable tourism can serve as the catalyst for the revitalization of the community and the whole area. The roots in the values together with the need for new concrete relations between settled communities and territory, have stimulated the recovery of historical memory in the form of museums, infrastructure at the service of tourism, the recovery and restoration of monuments, commercial activities.

3 Conclusions

We can therefore say that local development, namely the development project of the local society, through the recognition and valorisation of the territory, fuels innovation reinterpreting this knowledge, characterizing them with the peculiar quality of the development, its individuality and differentiation. Along with these types of sediments are all the appearances of memories in the form of permanence invariants that constitute a repertoire of useful elements to understand the character of the place and the rules of its evolution by allowing you to recognize the singular traits and identity of the place (fig. 12).

Abstract

The Abbey of Santa Maria *extra moenia* is a historical complex located in the Marche region (Italy). It has undergone substantial transformations over the centuries. For this reason, the historical and critical interpretation requires a key capable of simplifying the understanding of all the modifications. Starting from both an archival study and an architectural survey, we created different 3D models to help analyze and understand all the historical and architectural phases of the complex. The 3D-model reconstructions are based on metric and land surveys. The survey permitted us to identify seven main historical phases. In this way knowledge of the abbey becomes an elaborate history that needs an appropriate dissemination tool. The abbey is now abandoned due to its poor state and no action has been taken for its improvement or preservation. A first step in raising awareness of this forgotten cultural object is to foster better knowledge of its history through a new visual interface that is able to clarify all the events that have occurred over time. In order to explain the complex history of the abbey, we tested a new approach based on the use of a mock-up as a physical interface allowing access to different digital content. For this purpose we used open-source hardware: an Arduino-based microcontroller, named Makey Makey, connected to different parts of the mock-up through wired buttons. In this way, the computer processes the signal coming from the buttons using the mock-up like a keyboard to manage all the information related to the abbey.
