The perspective of the present contribution is linked to the world of cultural communication, which aims to transfer historical, architectural, artistic, and cultural knowledge to a public that may then enjoy the cultural heritage in an immediate and interactive way. Dealing with methodologies, contents, and themes that are related to history, restoration, information technology, and theories of communication, this research used a multi-disciplinary perspective capable of finding convergent solutions for a series of problems that at first glance seem very unrelated. The strategy used was to define common ground where the historical knowledge and techniques for representation come together in an interrogable model.

This area of study, which is relatively new, unites knowledge of the humanities with information-technology skills in order to study, conserve, improve, and communicate the cultural heritage through new digital technologies. From an epistemological point of view, the research centers on the definition of models and language appropriate for communicating historical content. Attention to historical/cultural data that can be transmitted is of fundamental importance in order to avoid superficial, inexact, or even incorrect information. It is therefore necessary that 3D models be based

on precise information deriving from the careful analysis of historical sources or direct (geometrical and material) readings of the ancient architecture.

In such a research field, it is necessary to adopt a rigorous methodology that produces detailed documentation, even if it is simple, in order to be able to communicate the data in an understandable way. It is therefore necessary to clarify such a methodology, fixing recognized standards, rules, and principles that render the reconstruction a rigorous practice based on the authenticity and accuracy of the cultural content. In 2005, the combined efforts of many sector entities such as research institutes, museums, associations, and foundations dedicated to protecting the cultural heritage produced the so-called *London Charter* [1]. The principles established are aimed at simple communication that is understandable to and assessable by different types of users. It is therefore essential to indicate the techniques used in collecting the representative data, the methodologies used in interpreting the data, and, obviously, the level of truthfulness of the historical/cultural simulation based upon them.

In light of the preceding considerations, we illustrate a case study used to experiment with new means of interacting with the cultural heritage, a new model to allow the knowledge and spread of information regarding an architectural object that has been “forgotten”, but is of great historical/artistic relevance. Technology is the vehicle through which it is possible to explore the complex levels of transformation, to optimize enjoyment and render the architectural object readable on many levels.

2. Case Study

The religious complex of Santa Maria, in the Macchie zone of the village of San Ginesio in the province of Macerata, Italy, presents itself as a palimpsest of various strata that over time have defined its form and function, despite having always been situated in a state of geographical marginality. It constitutes a work that is particularly significant for understanding the dialectics between abbey life and civil involvement over time. The first tests brought to light a series of events that have decidedly impacted the general image of the complex. Ample documentation was investigated from different angles to reach a wide level of knowledge of the architectural object.

Fig. 1: The religious complex of Santa Maria delle Macchie *extra moenia*.

Different levels of knowledge were expanded upon by interrelating bibliographic, archival, iconographic, and cartographic sources as well as by directly surveying the building, extending this to the various material and structural components, in order to decipher the complex evolution of its form. The information gathered was envisioned through an interrogable model, an instrument of technical/cultural divulgation for the research activity undertaken.

The dominant appearance of the abbey dates from its foundation, with subsequent modifications and expansions. To clarify the historical evolution of the complex, seven phases of development have been identified [2]:

2.1 The Phase Preceding the Structure, from the Romans to Religious Settlements

From the time of the Romans, a fundamental role was undertaken by the network of connections internal to the territory of Macerata. A series of archeological and epigraphic acquisitions attest to the existence of an important branch of the Via Salaria: the Salaria Gallica, which ran north/south through the entire region. The tract of interest to the Macchie zone was in use at least by the Triumvirate age and experienced prolonged use over time, undoubtedly for the better part of Late Antiquity. Such access therefore favored Roman settlements, with the foundation of the city of Urbs Salvia.

2.2 The First Building Phase

The initial core of the complex was built around the 11th century using *spolio* material, capitals, and column segments taken from the nearby Roman city. In the first building phase, the church with its Latin cross layout consisted of a crypt overlaid with a raised transept. Scholars have characterized the abbey as being typical of Benedictine architecture in the Marche region after the year 1000.

2.3 The Reign of the Counts in the 12th Century

At the beginning of the 12th century, the Prontaguerra Counts inherited a part of the goods from the Benedictine complex. It was still a totally embryonic period for the Macchie area; in fact, the church still had not taken on its role as an abbey, but thanks to the Counts, it began to enjoy a small economic stimulus, given its favorable geographic position. As a consequence, the original layout of the complex was expanded, with the addition of new buildings.

2.4 Transformation Phase – the 13th Century

The main building of the abbey dates from this period. After various events, the complex fell under the jurisdiction of the village of San Ginesio, which introduced the Cistercian monks. This order developed from the Benedictine order and emphasized greater rigor and rationality motivated by the search for a poorer, more genuine spirituality. In this century, the situation is of an abbey undergoing growth, with possessions and churches under its patronage. Such important growth produced a notable increase in monastic environments to satisfy the new needs of the religious community.

Fig. 2: The religious complex, illustrating the functions present in the various architectural buildings.

2.5 Expansions and Modifications in the 16th Century

The 16th century brought a raising of the church, with the creation of an upper environment where the monks could celebrate Eucharist. The abbey probably experienced a period of hardship after work was begun, and the work was left uncompleted. The main nave of the church was covered with a system of sexpartite vaults in stone. The presence of such vaults probably represents one of the most interesting aspects of the abbey. For centuries, it was believed that their construction occurred in a later period, and only through careful study of the construction and architectural characteristics of the church was it possible to determine the correct timeline of events that affected the complex, the signs of which remain in the form of fragments within the stone and brick walls.

2.6 Restorations and Embellishments in the 17th Century

Substantial transformations from the architectural point of view were undertaken in the 17th century under Cardinal Giovanni Battista Maria Pallotta and the Curia of Camerino. The cornerstone in the wall bears the year 1658 in commemoration of the work that Cardinal Pallotta, as commendatory

abbot, ordered to improve the complex. One of these changes affected the principal façade of the church, which was modified to be more agreeable to the tastes of the period.

2.7 Monastic Decline and Civil Ascent: The Last Historical and Restoration Events

The last phases of the complex are characterized by interventions that contributed to the degradation of the original character of the building, so much so that deciphering fragments dispersed in the walls has become almost impossible. Only by carefully reading the material traces through analytical work to record the different components can the evolution of the construction be reconstructed up to the current state. It is not possible to understand from the documentation what work was undertaken after the end of the 19th century, and the most recent projects reiterate the complexity of restoration interventions.

Fig.3: Analytical models for the different evolutionary phases. The principal architectural modifications are highlighted in blue.

3. The Survey

To complete the body of knowledge and move on to constructing the interactive model, surveying operations were made with the awareness that it is not a single perspective, plan, or cross-section that we wish to achieve, but rather the representation of the physical space, the architectural quality, and the transformations that the complex has undergone.

The surveying procedures were organized into three phases:

- in-field (architectural sketches, photographic survey, and measurements);
- site layout of the spaces;
- floor plan, elevation, and 3D drawings of the individual architectural object.

Creation of the initial sketches provided a way to identify the general layout of the complex and the main geometries. Due to the shape of the terrain, which is particularly steep, it was not possible to identify a single basic elevation, and we therefore proceeded using the method of breaking tape.

Traditional direct methods, triangulation in particular, were used for the planimetric survey. To identify the external perimeter of the complex, a series of support lines were constructed, which, when appropriately integrated, constituted the layout network. This network, when compared with the survey of the internal areas, gave the site layout, with an indication of the different wall thicknesses.

Fig. 4: Floor plans of the ground, first, and second floors.

In relation to the historical information, the survey presents aspects for further investigation, especially regarding the underground environments.

The crypt is arranged in seven small, slightly raised segmental arches supported by brick columns. Heterogeneous elements, reused without any apparent design or symmetry, alternate in the seven aisles. In reality, this is a true collection of *spolio* fragments arranged according to functional and aesthetic criteria.

The study proceeded with the creation of various geometric measurements, plans, sections, and perspectives which were then developed into a photo-rectifier study with *Archis* and *Tridmetrix* software. The next step dealt with developing the architectural survey by using the photo-straightened images in order to extrapolate and highlight the building materials and different construction details. This procedure was reiterated for all perspectives and for internal sections, treating the walls of each environment in a similar manner in order to create an overall reconstruction of the interior. Such steps expanded on the knowledge of the building, allowing acceptance of the past to be transmitted to the future.

Fig. 5-6: Characteristic elements of the underground crypt taken from the nearby Roman site of Urbs Salvia. (Layout elevation -0.40 m. The omphalos, 1st Century AD, is a rough stone venerated as representing the “navel” of the world. Capital mounted upside-down on one of the four columns of the sacramental area.)

Fig. 7-8: Principal perspective and cross-section; the texture was processed in Autocad after photo-straightening was complete. Such a section of the transept highlights the three-level system: crypt, church, and upper environment.

4. Communicating the Data

To be able to illustrate the various evolutionary phases of the building and make them understandable, it was necessary to identify an expository method that allowed the data to be organized and presented in a way that expressed the available information simply [3].

The choice was aimed at constructing a tangible mock-up, that is, an interface to access informational content that can augment the model. In this manner, the observer can direct their own tactile and visual exploration. The purpose of a model constructed this way depends on the moment in which it is experienced. If it is explored before a visit to the site, it provides preliminary knowledge, anticipating some historical information. On the other hand, if it is explored after the visit, it can be useful in clarifying and expanding upon observations made during the visit.

4.1 The Architectural Mock-Up

Representing architecture with models constitutes an important step in understanding a building, both in its design phase and for the knowledge and analysis of its *de facto* state. As well, the ability to create digital 3D models together with the possibility of dressing them in astonishing photorealistic

material attributes certainly has not weakened their didactic and representative roles. In this vein, the need to create traditional architectural models has not diminished.

In fact, physical mock-ups do not insist upon a preferred viewpoint, and they are far from the hyperrealism of digital representations. Physical models are representational tools on par with digital models, and together they can and should be integrated to improve the cognitive process regarding the building.

The importance of physical mock-ups in communicating aspects of the architectural project is manifest in the model's capacity to facilitate understanding of the material/spatial elements of the project. The mock-up is thus delineated as a clarifying element in the building's morphology and as a tool for investigating the spaces.

In addition to simply portraying the building, representation via models therefore allows the relationship between the building and its construction history to be analyzed, reconstructing situations and layouts that have been lost, or anticipating possible new design configurations.

Fig. 9-10: Diagram of the tangible mock-up and construction of the architectural model. Note the metallic sensors/buttons on the faces of the model.

4.2 The Tangible Mock-Up

In the study of tangible environments in contemporary museography, a particular type of exhibition is implied that makes possible the interaction between physical elements and non-material dimensions, emphasizing the central, active role of the spectator/user in manipulating interactive technologies to "elicit" video and images.

A complete cognitive experience is thus realized. This occurs through the use of videos, animations, diagrams, and the most basic perceptual and sensory processes of the individual.

Along these lines, by tangible mock-up we mean a particular type of model that makes it possible to integrate and interact with the physicality of the architectural model and the non-material digital content.

For an architectural show, for example, 3D digital content can be used as valid illustrative support, even more so if this is combined with the traditional exploratory means of a spectator who is not used to reading traditional elaborate 2D graphics of architectural representations.

An architectural model becomes tangible through the introduction of interactive interfaces that transform the model itself into an exhibit in which spectators can start along free, evocative narrative paths, stimulating their sensory capacities beyond the visual dimension. In this way, the spectators themselves activate visual content that augments the model with information connected to it.

An augmented mock-up thus enables a learning process in which the use of the body and gestures becomes the principal means of exploring the space. The model becomes sensitive to the behavior of the user through the use of sensors that respond to human behavior and audiovisual output such as monitors or video projectors.

Those profiting from such smart architectural models can therefore be: experts that habitually use architectural models as tools for knowledge and investigation; and those lacking disciplinary knowledge, who can use the model as a tangible object, a natural interface without awkward technological aids, that responds to primary means of understanding such as tactile exploration.

Fig. 11: The electronic apparatus hidden within the model. Each button/sensor is connected to the Makey Makey board with metal cables. The board is connected via USB to a PC that controls the activation of digital contents.

4.3 Technological and Audiovisual Contents

The technology that allows an architectural model to be intelligent is available at a low price and makes use of the resources available in Physical Computing, i.e., the science of the development of interactive physical systems through the use of integrated software, hardware, input systems (via sensors), and output systems.

Combining the use of sensors and microcontrollers, one can translate external requests into digital information that defines output in both the physical space and the digital environment.

There are different types of sensors. They may react to direct contact or proximity or they may “listen” and react to sounds or voices.

A large impetus in the development of this discipline comes from open-source, electronic prototype platforms, which provide enormous advantages in terms of simplicity and accessibility.

It is precisely the area of open-source physical computing that provides the hardware device used to technologically equip and make tangible the model of the Santa Maria delle Macchie complex.

In order to do this, we used the Makey Makey kit [4], which is capable of transforming any object that can conduct electricity into an input device, making such objects potential buttons.

The installation consists of a 1:50-scale model of the entire complex. The model reacts via metallic nails distributed throughout, which are connected to the board housing the microcontroller. Each nail senses contact with the user's hand and, acting as if it were a "play" button, sends an activation signal to a series of audiovisual contents that integrate and complete the knowledge process. The nails/sensors are located near areas that were the object of particular events in the building's history and which led to substantial changes in the formal or distributional layout of the building. The visualization sequence of the different phases is therefore not predetermined, but rather is chosen by the user, who, by exploring the model via the means mentioned above, transforms the model into a true hypertext narrative.

Each button gives access to an informational page visualized on an external monitor. At the top of the page, a timeline indicates the historical moment related to the phase "touched" by the user. The rest of the screen is dedicated to a non-photorealistic animation of the 3D model in which the architectural partitions subject to transformation are shaded within the overall spatial encumbrance of the architectural installation, presented as a wire-frame model. The right-hand part of the screen presents a series of images, diagrams, and renderings that expand upon the historical/cultural aspects.

Fig. 12: Two informational screens activated by buttons/sensors on the model.

Fig. 13: Animation frames from one of the models corresponding to the *de facto* state of the complex of Santa Maria delle Macchie.

5. Conclusions

In the case study described in this article, we have aimed to analyze point-by-point the phases of development, which, through subsequent additions, have determined the current layout of the complex. An ideal ontological mock-up was thus developed, which is useful in verifying different semantic features in the management of cultural information. It has the double goal of allowing cultural enrichment through easy learning and full comprehension of the historical, artistic, and cultural themes of the place, as well as offering support for interventions since the information is organized on the basis of architectural restoration.

The development of an architectural mock-up not only constitutes a technical or visual procedure to complete the set of graphics or to understand the spaces in the building, but also allows an interface to be created to access other informative levels of knowledge. Together with 3D digital models aimed not at hyper-realistic representations but at simplifying the understanding of the different historical phases characteristic of the complex, the use of technology and sensors related to physical computing has led to the construction of a prototype for an interactive exhibit in which the spectator/user can experience the architectural object by touching a scale model to access additional levels of information.

Users are invited to explore the effects of their actions, interacting with the model and producing events that integrate and complete the cognitive experience, thus becoming both a spectator and an additional player in the exhibit.

Reflections on history and current operational safeguarding device in the Casbah of Algiers.

Kamel RIGHI,

National Superior School of Architecture of Marseille. France.

kamel_righi@hotmail.com

Abstract

Since the enactment of Algerian law on the protection of cultural heritage (in 1998), including its implementing legislation, new regulatory and instrumental, are emerging to protect and enhance the historic urban groups considered as heritage.

At the same time, the further development of communication and mobility, provide actors and managers of planning a variety of approaches to be implemented to achieve goals. These objectives are to identify and to mature continually. Dealing with the issue of the role of government and services in support of urban heritage, this article analyzes the contribution of managerial approaches in this area.

The case study, namely Florence in Italy, is selected according to the size we wanted to emphasize throughout this paper. This is less the historic city center in itself, as actors, strategies and backup devices that are processed. Thus, the goal is not to seek to transplant models systematically, but rather to identify components of specific and relevant, meaningful and logical in relation to our urban heritage, including the Casbah of Algiers.

The aim of this work is to open a site for reflection on the role and organization of public urban action and on the importance of project management. The optimization of this link may be the trigger a virtuous process, benefiting the entire chain of actors involved in the preservation of the Casbah, which is listed on the World Heritage List of U.N.E.S.C.O.

Keywords: Urban Project Management, Casbah of Algiers, Safeguarded Area, Florence, Urban Strategy.

Nowadays, and all around the world, it is no use to prove that the historical urban centers have a value of identity and become, above all, an instrument of cultural valorization in a context of an inevitable globalization. This contribution deals with the case of Algeria through the Casbah of Algiers which is the first implementation of a new regulatory and instrumental device of safeguarding and enhancement of urban heritage in Algeria.

While the law n ° 98-04 relating to the protection of the Algerian cultural heritage [1] is starting up, altering the tools of intervention on urban areas with recognized and protected heritage values. it seems that Algeria has since been at a significant stage in acting on its historical urban centers. Indeed, following the country's independence, support of cultural property obeyed to the Ordinance No. 67-281, relating to excavation and protection of historical and natural sites and monuments [2], which was no other than the continuation of the law in effect during colonization. [3] After reading the article by Y. Ouagueni, we retain that no strategy could be taken under the order since it covered in its category definitions, only the concepts of archaeological and natural monuments and sites. As for the historical urban centers (considered in this text as monuments) was planned interventions specific to monuments, that is to say the restoration. [4]

Today, it is clear that the mode of intervention on a living historic center and characterized by its scale and its evolving nature, goes far beyond the single restoration action. [5] For more than thirty (30) years, the conventional planning instruments (PDAU and POS) [6] governed Algerian historical centers. These instruments showed deficiencies in their management of historic urban sets.

Among the novelties of the 1998 law, the recognition of the specificity of historical centers by introducing a new protection scheme, which is safeguarded sectors [7], with an assimilable instrument to the POS but with provisions and content appearing specific the particularities of historic centers.

Regarding the issue of project management, it should be noted that prior to the 1998 Act, and in the absence of urban instrument specific to historic urban centers, project management during development studies of the POS, including those harboring an urban heritage, was entrusted to the Directorates of Planning and Construction of the concerned Wilaya (province), local authorities lacked budgetary resources and staffing to ensure it. Since the promulgation of regulations implementing the Act, including that relating to the Arrangements for the PPSMVSS (the algerian safeguarding plan), the concerned Directorates of Culture of Wilayas are responsible for project management during the development of the safeguarding plan. It remains unclear if these deconcentrated state services are able to perform this task.

The term "plan" referring to the "planning". However, the current trend in countries that have developed policy and procedures inherent to urban intervention is directed towards a so-called "Urban Project" approach and consequently a critical review after the relative failure of spatial planning [8]. It is clear that the approach of the Urban Project is not yet implemented in Algeria. [9]

This article seeks to examine the process of patrimonialization in the Casbah of Algiers and describes the current implementation of the safeguarding device and its management. Thereafter, it will browse the current florentine experience to detect relevant principles to adopt for the Algiers case.

1.The patrimonialization process of the Casbah of Algiers.

1.1. Historical overview.

What is called Casbah today constituted the entire city of Algiers intra muros in the early nineteenth century. The word Casbah referred then to only the Citadel [10] which crowned the top of the medina (city) at the Ziride era . [11]

This term was later extended to the whole of the medina which was a highly urbanized and delimited by a system of ramparts dotted with batteries, bastions and doors . Located on the Mediterranean coast, the site of the Casbah of Algiers was populated at least from the sixth century BC when a Punic counter was installed. [12] Since then, a combination of historical, political, and administrative conjugated to a particular geography have led to the development of Algiers. [13]

During the period of Ottoman Regency, development of Algiers was marked by a particular development. Its port and the fleet attached to them, became a major naval base in the Mediterranean. The cosmopolitan character of its social component, the various exchanges with various countries, and a system of governance introduced by the government in power, favored a certain prestige of the city and a level of management of different aspects of city life. At the end of the Ottoman period, Algiers consisted of a highly compact body tissue, located in a highly undulating area, according to a system that is complex, original and flexible. [14]

The capture of Algiers by the French in 1830, marks the beginning of major disruptions particularly in its urban dimensions. In fact, since the first years of colonization, significant demolition, construction, urban development sites and expansion ones were started under the control of the army. The construction of the city according to the design of the conquerors from the other shore of the Mediterranean, had been materialized first in the lower part of the medina, according to military imperatives, financial considerations and topographical criteria. However, an event can be noted at the beginning of the colonial era, which will save the upper part of the medina from destruction of the French Military Engineers. N. Oulebsir in a book devoted to the history of heritage in Algeria, cites the intervention of Napoleon III in 1865 during his second visit to Algiers, opposed the demolitions carried out in the Upper Casbah so as to realize the *Boulevard de la Victoire*. [15] From the earliest years of

the French occupation, architects went documenting and inventorying the wealth of conquered territory. [16] In addition to Oulebsir's work previously cited ., and harnessing two important archives funds relating to these campaigns [17] two Algerian architects and academics in book published in 2003, resituated another dimension of colonialism and stressed the birth of a heritage consciousness. [18] A number of sites, palaces and mansions were classified as historical sites and monuments from the late nineteenth century by the colonial administration. Besides the heritage of the Roman era, a number of the production of the Ottoman period were also classified as such.

1.2. National classification of the Casbah of Algiers.

At the time of independence of Algeria, Algiers Casbah was not yet officially recognized as urban heritage. This could be partly explained by the fact that in France, the birth of an official recognition of heritage in its urban dimension was performed immediately after the independence of Algeria. It was not until 1973 that an order initiating proceedings of listing among the historical sites was issued in favor of the Casbah of Algiers. Nearly twenty years later, it was finally classified as a historical site in 1991. The period between these two dates saw the creation of a number of structures for the management of the Casbah in particular or the city of Algiers in general. For the Casbah, the literature reveals that although many studies have been conducted since the first interest was expressed by policy makers in the 1970s.

At first, the permanent committee of studies, development, organization and management of the Algiers region (C.O.M.E.D.O.R.) produces a schematic structure of Algiers on the horizon in 1985 and a General Plan of Orientation Plan (POG) for the year 2000 which was approved in 1975. Besides the development of the urbanization of the town, the POG includes a Plan of Renovation and Restructuring of the Casbah of Algiers. This instrument was developed by a structure created in 1974 by the C.O.M.E.D.O.R., Atelier Casbah (workshop of Casbah) which was composed of a multidisciplinary and international team. But in 1979, the P.O.G. was questioned, and thus the plan for the Casbah was not implemented.

The workshop of Casbah, after being dependent on the C.O.M.E.D.O.R. which was under the auspices of the Presidency of the Republic, was attached to the Central Bureau of studies, public works, architecture and urbanism (ETAU), which was at his turn under the Ministry of Urban Planning, Construction and Housing. With experts contributions from UNESCO, the workshop of Casbah developed the Project of Revalorization of the Casbah, which was completed in 1981. But once again, in 1983, the Workshop switched to depended on the office of studies of restoration and preservation of old neighborhoods (BEREP). Two years later, the workshop disappeared Casbah and was replaced by the Office of Intervention and Control of Operation of planning on the Casbah of Algiers (OFIRAC) which was placed under the Ministry of planning, Building and Housing as well. A year later, changed his guardianship, to be placed under the authority of the Wali of Algiers. Set to standby status and without workload, this office will eventually disappear after the paradoxical decision to entrust the project management support for the work specified in the Casbah of Algiers to other bodies created at the same time of the OFIRAC Such was the case for the O. F.A.R.E.S. Yet created for the development and restructuring of an other area of the capital (Hamma-Hussein Dey).

Although the classification of the Casbah of Algiers, at the national then the international level, to be done in the early 1990s, the country context at that time had stopped all kinds of working on the historic center of Algiers. The introduction of the Governorate of Greater Algiers (GGA) in 1997, the development of the Grand Urban Project (GPU) and the swift of the Casbah into an urban district in 1998, did not change anything in the situation thereof, it continued to undergo a process of continuous and multifaceted degradation [19]. Besides the status G.G.A. was abandoned in 2000.

This period seems particularly characterized by a series of institutional decisions that led to instability in the definition of the actors involved in the Casbah of Algiers, which deprived it of studies carried out and possible funding; incessant degradation of the Casbah into its components: social, environmental and heritage in addition to the proliferation of so-called informal activities The absence of a specific instrument to historic centers legally established. Regarding this last point, the system of protection that is safeguarded sectors with PPSMVS.S. Introduced by the 1998 Act, will see the promulgation of inherent application text in this instrument in 2003 . The first PPSMVSS launched is that of the Casbah of Algiers which started in 2007 and approved by Executive Order in 2012.

At international level, expert missions took place in the Casbah before its registration in 1992. As soon as 1966, the year of A. Lézine's report, until today, UNESCO experts' reports have been produced on the Casbah. [20]

1.3. International classification of the Casbah of Algiers

During the application of the Casbah of Algiers, the registration was conditioned to the State party by: on the one hand, the existence of a specific regulatory framework for historic preservation and on the other hand, the establishment of a safeguard plan. [21] The first condition only existed in 1998 (6 years after enrollment) and the second condition has become a reality since 2012. This tells us about the ambiguity surrounding the process of classification of this site (conditions not gathered to its registration).

This "amputated" departure of a very important part, which is the basic component for the management of a historic urban center, that the Algerian state has already accumulated a delay from the initiation of the registration process. Despite this, in 1992, the Casbah of Algiers officially listed on the World Heritage List under criteria II and V. It seems clear that maintaining of the Casbah of Algiers on the World Heritage List requires maintaining values that have led to its inclusion on the one hand, and action on factors that threaten these values the other one. This should go through, first, the most accurate knowledge and most shared as possible from these values and, then, the most accurate and most shared knowledge as possible from the factors that threaten these values. I.e, the device management of the historic urban center should be designed and action organized according to these considerations.

1.4. The difficult implementation of the new device.

Practice has shown that, ultimately, only the Department of Culture of the Wilaya of Algiers was responsible for project management of the operation of preparing the PPSMVSS of the Casbah of Algiers on behalf of the Wilaya. Notwithstanding the relative seniority of the decentralized state services, staff of the directions of culture of wilaya is little expanded and more specifically on the task of project management in the development of a document such as the PPSMVSS. During the development of the P.P.S.M.V.S.S. the Department of Culture of the Wilaya of Algiers, included in its staff a majority of archaeologists and few architects. It should be emphasized here that no support contract to the contracting authority has been established as part of this operation. No supervision by experts, or targeted training was for the staff.

Before the selection of the engineering office (and his architect-project manager) who was the CNERU, a framing system of project management has been put in place to develop the PPSMVSS. It should be noted here that in the regulated content of the plan, there is a phase of study and implementation of an urban project (Phase I: diagnosis and draft emergency measures). This framing system materialized by a "Joint Committee" had been set up to coordinate the operation. This committee was chaired by the Minister of Culture and was composed of representatives of the Ministry of Culture, all decentralized departments of the State in the territory of the Wilaya of Algiers (Executive of the Wilaya) and Popular representatives assembled communal (APC) territorially concerned with the safeguarded area. A "Technical Committee" - chaired by an architect "qualified" in the monuments and historical sites, and composed of technical representatives of members of the Joint Committee - was established as the technical instrument of the Joint Committee. With this configuration, the engineering office (CNERU) had as interlocutor on one side the Joint Committee (policy and decision level), and on the other, the Technical Committee (technical level) including Directorate Culture (contract level). The Technical Committee is immediately proved to be a space for debate, exchange of information and knowledge, guidance and developed especially methodological during evaluation sessions of work. The frequency of meetings of the Joint Committee was less frequent than its agent of complementarity: the Technical Committee, and wanted to be the decision-making place (with their financial impact) and ensuring consistency of the implementation of sectoral policies and that, in order to safeguard the protected area of the Casbah of Algiers.

Working with this configuration finally lasted only little time, because the two Committees disappeared for reasons beyond our understanding. Therefore, the Department of Culture of the Wilaya of Algiers was left alone ensure the project management for the development of PPSMVSS and had the text as a unique reference for the accomplishment of this mission. In a context characterized by the absence

of statistical coordination where sectoral data differ according to their sources, and the coincidence of several projects and studies in the area of the conservation area (in addition to almost daily actions of the people on their living space), the CNERU began the study of P.P.S.M.V.S.S. in January 2007. Leaving the framing system, originally planned (Joint Committee and Technical Committee), data collection was done in an almost informal way between the engineering office and the various sectoral and local structures overstepping the project manager. The processing of data was done in camera by the engineering office and the role of other actors, was more to give an opinion on the engineering office accomplished work (thus downstream) than in logic joint development. In addition, we noted the absence of instances of college type for the definition of basic concepts inherent to the specific values of the Casbah of Algiers (national and world heritage) on the one hand, and uncertainty assessment that affect the validity of the data processed by the engineering office on the other hand. Comments and concerns expressed by some stakeholders during the presentation sessions of the various phases of the safeguarding plan were supported punctually in the context of inexistence of clear and codified procedures inherent to this point.

Under these conditions, and on the basis of an initial diagnosis developed by the engineering office, a major operation fully financed by the Ministry of Culture was launched in late 2007. A dozen consulting firms (each with an architect and project manager "qualified") were engaged to carry out a project of emergency measures on a number of buildings (all types combined) located out in safeguarded sector. These interventions consisted of: temporary shoring (interior and exterior) of buildings and elements deemed threatening of ruin; the realization of reinforcement walls and temporary coverings against the infiltration of rainwater with repair and installation of a provisional system of stormwater drainage, spot repairs of various networks including those of alimentation drinking water and wastewater, cleaning interventions (including "empty" fields, wells and water tanks) and the sorting of different rubble and building materials. Although the safeguarded sector is a living and inhabited site, this operation was not systematically accompanied by a comprehensive program of temporary or permanent relocation. This has spawned a number of difficulties for interventions in buildings for the most part inhabited by a relatively large number of people.

Far from making an assessment, this operation was marked according to us, by a certain number of points, namely: the absence of an instance of coordination and organization of all stakeholders and actions undertaken, which led to the non-mastery of all interventions in safeguarded sector undertaken either by the various local and sectoral services either by the owners or private sector, deepening or correction of initial diagnosis by other offices studies, which were not involved in its development from the outset, the provisional nature of all actions; The lack of specific certification to work on a protected real estate complex to select the company carrying out the works; the lack of a systematic and accurate inventory of patrimony covered by tangible heritage located within the boundaries the safeguarded area; unilateral and centralized financing of the operation and a heaviness in contractual procedures and compensation, visits by experts of the World Heritage Committee to assess work in progress.

In February 2010, while the operation of emergency action was still ongoing, a decision moved the project management of this operation to the Office of Management and Exploitation of Protected Cultural Property (OGEBC) renewing, thus, with the unstable character in the definition of responsibilities relating to the management of the Casbah of Algiers. Officially completed in 2010, the P.P.S.M.V.S.S. was approved in March 2012 and that, following a public inquiry and the submission of the project to the assembly procedure wilaya. In January 2011 came a new executive decree creating a new player in the device. The National Agency of Safeguarded sectors which is not yet operational, is defined as a public administrative institution (EPA) under the Ministry of Culture. It has a primary mission the implementation of all the PPSMVSS in the national territory. What impact will it do? What mechanisms will be its roots in the context? And how will its integration into a device that is being implemented in Algeria?

This retrospective showed us the sequence of steps in the process of heritage in the Casbah of Algiers and the beginning of the institutionalization of the safeguarding device and management of urban Algerian heritage. Initially marked by instability configurations adopted for the management of the Casbah of Algiers, the device seems to benefit from a new regulatory framework established by the 1998 Act. What would be the perspective of organizational design able to save and to effectively manage this urban heritage? It is clear that the nature of the instrument is the logic of spatial planning. The only operational output of the P.P.S.M.V.S.S. as defined by the current regulations, an urbanistic project and not an urban project (emergency measures).

However, this exercise of implementation has allowed us to highlight failures including organizational level. The short experience of implementation of the safeguarding plan of Algiers (which is still

ongoing) has lead us to conclude that the PPSMVSS that are assimilable to land-use plans in their status and in terms of their establishment, are not carriers by their owns an urban project or strategic guidance. We noted also that no special measures (either regulatory or institutional or instrumental) govern the Casbah of Algiers as holding values that allowed international recognition.

Now observe how another city established its device of safeguarding and management.

2. Case example: The management plan for the historic center of the city of Florence.

The management plan of the historic urban center of Florence 2006-2008 appears as a successful experiment according to _ World Heritage Committee. [22] The historic center of the city of Florence has been included in World Heritage List in 1982 according to the whole criteria inherent in cultural property of outstanding universal value. The mission of coordinating the development and implementation of the management plan was entrusted to an office created for this purpose: the historic center office of UNESCO (*il ufficio*). [23]

2.1. The context of the implementation of management plans for Italian sites inscribed on UNESCO list :

The U. N.E.S.C.O. has recently decided to increase its efforts to safeguard cultural and natural heritage by adopting active policies to protect property and to try to identify a new direction for the instruments enabling them to combine the requirements of conservation with sociocultural dynamics in continuous transformation in cities and landscapes. To this end, the U. N.E.S.C.O. Established in 2002, the inscription of new sites on the World Heritage List should necessarily be subject to the predisposition of management plans and successively in 2004, recommended the establishment of these plans for the sites already inscribed on the list. Because the U. N.E.S.C.O. established such obligations without providing a single management plan template, the Italian Ministry of Culture has established the Advisory Committee on Management Plans UNESCO sites by decree in 2003.

2.2. The approach to the development of the management plan:

The management plan has not been considered as a simple analysis document, but rather as an operational tool of strategic approach and that, setting goals and defining the actions and strategies to achieve them. In addition, the plan is presented as a dynamic instrument, able to evaluate the effectiveness of selected operational strategies _ capable of replacing inefficient projects by new actions (or projects) suitable for individuals and temporal needs of the site. This approach is in the guidelines established by the Advisory Committee on Management Plans UNESCO sites.

The management plan of the city of Florence was designed in four major parts, the first highlights the general framework of the plan including the reasons for the inclusion of the site in _ World Heritage values and recognition of values that make this site a unique one. The second part on the analysis of the territory in question is a preliminary phase to identify operational strategies. and action plans to be adopted for the safeguarding and protection of the site. This section provides an overview of cultural resources and landscape that distinguish the historic center. It emphasizes the production of tangible and intangible culture and conduct a socio-economic analysis of the territory, with particular reference to the changes that took place in the city and the risk factors and pressures threatening the historic center. It performs analysis of resources and protection plans developed by the administrative authorities for the conservation and enhancement of the site. And finally, an analysis S.W.O.T. concluded this part and starts the next one. The third part sets out the objectives of the plan whose main is to identify, protect and improve the site and transmit it to future generations. It is in this part that the strategy and action plans are set. The fourth and final part consists of monitoring and supervision of the Management Plan, provided by the historic center Office of the UNESCO.

Using an iterative approach, and following the definition of the strategy, it was available in four action plans that correspond to four themes. This is the Action Plan for the protection, preservation and enhancement of the heritage, the Action Plan for Research and Knowledge, the Action Plan for the Environment and Mobility Plan Action for Tourism. Each action plan is divided, in its turn , into projects (operational output).

The desire to achieve coordination among government agencies in the management of the site has been empowered by the Ministerial Decree of January 2005, which established the creation of a working group with the participation of the Italian Ministry of Culture, the region of Tuscany and the Municipality of Florence. To define a shared operational strategy, inter-directorate group is comprised of representatives of the Ministry of Planning, those of the Municipal Police, Ministry of Transport, the Office of the Metropolitan Region and Decentralization, those of the Economic Development, the offices of the Strategic Plan and the Ministry of Economic Development, in addition to decentralized State services in charge of Culture.

The existence of a strategic plan for the metropolitan area of Florence called "Florence 2010 pushed the office to take advantage of consensus on the key issues and the common vision of the city already acquired. Relying on the existing organizational configurations, public partners are the provincial government of Florence, the regional government of Tuscany, the Ministry of Culture, the University of Florence and the Chamber of Commerce of Florence. Private organizations are: Association of Manufacturers of the province of Florence, the National Confederation of Crafts and Small and Medium Enterprises, the bank Cassa di Risparmio di Firenze and the Foundation for the artistic crafts. The office has expanded this list to voluntary associations who live and work in the city.

Monitoring is done on two different levels of control: assessing the progress of intervention projects selected in each action plan in relation to agreed objectives. This assessment is done with the managers of each project subject to a quarterly audit of indicators. These evaluations are useful to highlight the validity of a project and whether it should be replaced and / or upgraded, the second level is the evaluation of the effectiveness of the Plan and its impact on the area in the middle and long term. To ensure joint and coordinated management of the cultural and landscape heritage, it was decided to carry out a check of its effectiveness every two years especially in the first stage of its implementation.

In conclusion

The existence of an outstanding universal value is the origin of the inscription of a site on the World Heritage List. Its alteration leads to the risk of its delisting. Therefore, the management of a World Heritage Site should be focused on the management of safeguarding and enhancement of this outstanding universal value. As we have seen in the case of the management plan of Florence, beyond the purely regulatory aspects, this management through operational outputs in the form of concrete projects under various action plans resulting from an approach that ought to be reflexive, global and strategic. The strategic approach, stability and sustainability of devices put in place seem to be a guarantee of success of the processes expected.

Le livre des exemples*, (trad. Abdesselam Cheddadi), Paris : Gallimard, coll. « Bibliothèque de la Pléiade », 2002, 1560 p.

[12] The hypothesis of an earlier _ Phoenician presence to that of Punic has been issued as a result of investigations and archaeological excavations _ conducted _ by Gsell. S. quoted in: Le Glay. M., *A la recherche d'Icosium*. In: *Antiquités africaines*, t 2, Paris : 1968. p 7-54. Anyway, a chance discovery made in November 1940 at the headquarters of the Navy (Lower Casbah), confirmed the Punic presence in the site. There were 158 pieces of Punic coins discovered at a construction site of the Housing Management, with the inscription: Icosim. See : Leschi, L. *Chronique. L'archéologie algérienne en 1940*, In *Revue Africaine* n°85, Algiers : Société Historique Algérienne, 1941, reissued by : l'Office de Publications Universitaires : Algiers, 1982. p 137.

[13] Initially part of the Punic system scales , like countertops that gravitated into the orbit of the Carthaginian empire in the Western Mediterranean, the site was later annexed to the Berber kingdom of Mauretania under the reign of Juba II, then to the Roman Empire around the year 40 AD and became Icosium. After being under Vandals domination then the Byzantine until the seventh century AD, the tribe of Beni Mezghenna settled on the site at the dawn of Islam. Around the year 950 _ Zirid prince Bologhine founded the city of El Djazaïr Beni Mezghenna. The city came under the control of the Almoravids then the Almohades prior to the emergence of the three rival dynasties (Hafsides, the Marinids and Ziyenids), which disputed sovereignty. Towards the middle of the fourteenth the Arab tribe of Thaaliba which governed the city. After the fall of Granada in 1492, El Djazaïr received a large influx of population from Andalusia and was immediately besieged by the Spaniards. The three centuries of the Regency of Algiers began following the coming of Barbarossa brothers who helped El Djazaïr to defeat Spanish and annexed it to the Ottoman Empire.

ARCHITECTURAL ANALYSIS OF ARCHAEOLOGICAL CONTEXT - HYPOTHESIS OF RESTORATION OF THE DOMUS del Torello di Bronzo (reg.V, ins. 1, civ. 7) - ARCHEOLOGICAL SITE OF POMPEII

RAFFAELE MARTINELLI

ARCHITETTO, DOTTORE DI RICERCA, DOCENTE A CONTRATTO

Abstract

The archaeological site of Pompeii is unique for several reasons.

One of these is the need for a multidisciplinary approach to the analysis of the monuments present them.

The specific and unique mode of burial has meant that here more than anywhere else, you will not only preserve intact archaeological information, but also the perception of architectural spaces related to the lifestyle of the inhabitants.

In this sense, an architectural, spatial and cultural analysis, allows you to decode the monument with a new interpretation, highlighting aspects that are outside the ordinary course of archaeological investigation without replacing it but supplementing thereby providing a complete overview useful for design practice, maintenance, use and preservation.

Specifically, the monument under study, the Domus del Torello di Bronzo (House of the Bronze Bull) reg V ins.1 civ 7, in the archaeological site of Pompei, it's organized along a prospective axis aligned with the entrance marked by fountains and water features.

This axis affects the surrounding spaces limiting concepts such as symmetry or module to a secondary role preferring a privileged perceptual axis closely related to life and the representativeness of the inhabitants of the house.

In this sense, the architectural analysis of the archaeological resource can be a guide for a correct restoration work also based on the creation of 3d models useful in the design.

Keywords: Survey, Archeology, Perspective.

1. Introduction

"We had done just in time to sit down when night fell, but not like when there is no moon or the sky is covered with clouds, but as a light off indoors. You could feel the dark desperate cries of women, the cries of children, the shouts of men, some with screams and tried to recall the cries were trying to trace the parents of the other children, others their spouses, each complaining about their woes, other than those of their loved ones for fear of certain death, he wished death, many raised their hands to the gods, in the majority, however, it formed the belief that the gods now no longer existed and that that night would be the last and eternal the world."

"Second Letter of Pliny the Younger to Tacitus"

The archaeological site of Pompeii is unique in the world.

Frozen by the eruption of 79 AD, it became a time machine able to travel information directly from the past to the present preserving not only typical archaeological information but also the traces of everyday life that took place there.

The amount of information that can be accessed by analyzing a shop, or a domus thermopolium are outside the purely archaeological practice and can reach any field of study of modern sciences, architecture, sociology, religion.

The multidisciplinary approach is, here more than elsewhere, fundamental because the understanding of complex dynamics can only occur through the decoding of various specific languages from different fields of inquiry.

Here the key proposed it's architecture, by which it will be possible to perform an analysis of the spaces useful to understand the relationship between form and function is always present in the ancient ars aedificandi. This analysis also brings additional considerations related to the lifestyle of the inhabitants, their habits their customs and traditions that have left traces in architectural structures remained.

2. The Domus of Bull Bronze.

The domus in question is located in the north east of the city, following the current classification, is located in the region V, insula 1, number 7, directly opposite the building of the Central Termae.

This location it's significant because it poses the house in an area not far from the Forum and the castellum aquae, which allowed the construction of a water system particularly spectacular.

It is one of the houses belonging to the earliest phase of the city, which probably belonged to the aristocracy Samnite, and so adopt in its conformation some architectural elements useful to enhance the prestige of the inhabitants.

The layout follows the classic Roman domus scheme articulated in the three canonical moments of the Atrium, Tablinum and Peristyle, using a particularly well studied perceptual axis alignment.

2.1 The Fauces

Starting from the outside can be seen as the main entrance, the Fauces, have a particular configuration. The main door has a size of more than four meters in height added to a wall in opus quadratum in blocks of gray tufa well worked that highlight the importance of the home. In the same space entry, has been made a secondary entrance to a much smaller size.

This solution, used in other domus, means that for everyday you can use a port (secondary) of conventional size, while opening the main door could be reserved for special events.

2.2 The Atrium

Pass the Fauces, you get into a tuscanic Atrium, characterized by the classic impluvium on which was erected a marble pillar which supported a bronze statuette in the shape of a torus (hence the name of the domus) which served as a fountain.

Here, too, the style is rigorous, the clean lines of the environment added to the size of doors of cubacula who enter here, two on each side all big greater than three meters, configure a strict space and inspiring respect. On the bottom there are two Ale, left and right, inside of which were made of wood cabinets, while the configuration is closed on the final prospectus consists of two doors of the same size as the other accompanying symmetrically space dedicated to tablinum, the appointed place to welcome the guests.

All the space of the atrium is configured in size and proportion, to center their the eye on tablinum who becomes the main space but not limited because it is completely open to the peristyle behind and separated from it by a step up from which served more likely by sitting than transition element.

2.3 The Peristyle

The peristyle was accessed through the door on the right (east) behind which is a gently sloping ramp can overcome the height difference with decking. Around this place a number of other environments, some minor but very representative qualitatively different from those of the atrium and certainly much more private, a triclinium, a large living area and access to the hot baths and the kitchen.

The peristyle is organized into three branches, while the fourth, to the north, was made a nymph that closes the perspective axis perceived from the entrance.

The realization of the Nymphaeum is to relate to the installation of a complex water system that has fostered a substantial change in the habits improving water quality and reducing the use of tanks as yet. The proximity to the castellum aquae has allowed us to take advantage of the pressure to produce

a series of water features which on the one hand absolved in functional tasks such as feeding the hot bath or kitchen, on the other hand allowed an increase in the space of representation 'atrium already appointed to this task.

2.4 The water system and the Nymphaeum

In most parts of the domus are traces of fistulae, lead pipes for water supply, but in this domus system appears to be more organic and organized that lets imagine one-step installation of the same.

Starting from the left side of the fountain, are visible three taps for the adjustment of the water or better for the closing or opening of the spouting fountains which is an interesting indicator for water management which could be interrupted for maintenance operations and cleaning.

The Nymphaeum is composed of three niches containing statues from the foot of which flowed a small waterfall.

This ended in a rectangular tank which incorporates all three niches. From inside starts two jets placed in two brickwork columns lower than edge of the tank. Closed the composition of a group of twelve fountains that poured from the edge of the still water inside the tank.

The water games then extended to a fountain located at the center of the peristyle and two jets coming out from two columns of the peristyle.

In fact, in correspondence of the tablinium window, a column is deleted, in the space generated have been positioned against the remaining columns two pillars useful to hold the lintel but also to hide the vertical ducts of two jets coming out from the columns and ended in two containers of lava rock.

Rests of fistulae are also present at the side of the ramp connecting the atrium, passing by the door jambs to feed the statue of the bronze bull nell'impluvio atrium.

From the traces on the columns, it is then deduced that there were fences around the perimeter of the peristyle.

2.5 Perspective and water games

The axis prospective often spoken is now evident as well as the quality and the shape of the spaces. From the outside, we would have been before a two imposing door, if they were to remain closed, we would have gone through the back door, in a narrow corridor that exceeded the fauces and would have entered the atrium where the visual effect would certainly be undoubted, even more so just come out of that small space.

Lighting conditions in an atrium were limited, the light coming from the top and from the bottom of compluvium tablinium would dilated space, making it even more impressive, while the high gates of the side rooms and the jet of the fountain in the center would accompany the 'host up to tablinium suggesting respect for the hosts.

The vanishing point of light and water of the peristyle would complete the whole turning back the scene once in tablinium.

It thus appears that the space that you configure here is purely public and representation, even more so if you compare it with the second part of the house.

In the rooms around the peristyle, the perception of water games and the nymph becomes more intimate spaces are shrinking and the atmosphere becomes more domestic and especially, if you will, can be completely isolated from the atrium.

3. Analysis and conclusions

3.1 Analysis of Materials

he domus is in generally good condition, especially from the architectural point of view, while the same can not be said of the apparatus of painting and coatings. Therefore, the more detailed analysis which is given here aims to better identify the problems which the dwelling is subject for groped to propose an appropriate plan of action.

Therefore retrace the domus, starting from the entrance trying to focus on the most interesting elements.

The front of the domus presents with a characteristic monumental entrance into blocks of gray tufa, apparently does not appear to be any significant damage, but there are two interesting elements in the first place the color. In fact, in spite of gray tuff, the color of the material appears reddish.

From a fracture present on the front of the right side of the entrance, it is noted that this chromatic alteration affects one layer not just pushing inside surface of the material for at least 5 mm, beyond which the tuff resumes to its greyish coloring. It was not possible to understand the causes of this coloring, has suggested an alteration due to weathering combined with the natural aging of the stone, but on the one hand it is observed that the alteration affects the entire hanging in a compact wall

without a difference to both sides of the entrance and part of the interior, on the other hand are "reddish" other entrances (if not all) present in the archaeological area which suggests that it may or characteristics of the stone, or an alteration that has affected at the same time as the material in question could have caused the exposure of the stone to the heat of pyroclastic materials or their simple burial.

Another interesting point it's the backdoor on the right side.

Being the main gate of considerable size, over 4 m, is likely to prove more convenient in ancient use more frequently according to its input. The lintel of the door has been created by carving a block of tuff large, and because of the damage is split and topped with a large lesion which also affects the upper row.

This injury has caused the detachment of a section of the lintel which is currently held on the spot by a shore-shaped gate that closes such access. The inner part of said wall, presents a series of holes, probably housings of old beams.

Static survey carried out showed that the causes of this injury is not to be sought in the rotation and consequent collapse of the facade of the house, but rather a failure in the bottom of the intermediate zone of the entrance. In fact, if it were a rotation of the front one would expect to find at least the external face off lead, so it does not happen while having occurred by means of a spirit level on the perpendicularity of the tuff blocks. Therefore, the slope of the lesion, the stagger the joints of the blocks and clear the modern reconstruction of the compartment wall lintel of the right side of the fauces provide enough evidence of a failure in the foundation of the middle section of the entrance. It is also noted that the plaster of the last part of the fauces and in the space behind the secondary entrance, there are other injuries that are consistent with the hypothesis assumed.

The floor of the entrance is in excellent condition, given the presence of basalt, while that of the fauces and the atrium has several damages.

This floor is , in fact disrupted in several places , probably due to the infestation of vegetation that currently seems to be effectively kept under control in general is clearly visible warping the original fragments of marble and limestone drowned in the mortar , but the lack of adequate protection from the weather has meant that the mortar was washed away so that in general the fragments of stone emerge from the floor . In general the right side of the floor is the best preserved , and on the left some gaps and detect the presence of biological attacks , especially mosses and lichens, which also invade the floor of three rooms on the left side of the atrium and part of ' watershed in marble , the latter in particular being attacked by lichens. The greater presence of mosses in this part of the atrium can be explained by the absence of sun that does not beat almost never on this side .

The walls facing the atrium , as well as almost any environment here, keep a record of plaster , it is reported as being decorated by multiple sources, but at the moment looks completely white and apparently in good condition . In fact, by hitting , all the plasters are detached from the holder and it was possible to observe a particular phenomenon. Indeed , in several points of plaster bubbles are present , such as on the central sector of the left side of the atrium , in the environment at the right, indicated as lararium, and in the *ale* of the atrium on the right side than on the left where are the remains of a wall cabinet , some of these are broken and the underlying layers are visible which are completely pulverized and tend to collapse to the ground. The superficial part of the plaster , however, is compact for a thickness of a few millimeters and particularly flexible , which suggests the presence of a surface layer of material laid in order to compact the plaster , which if it has actually performed this function in a superficial way , however, is not able to avoid or detachment of the hanging from the media , nor the pulverization of the deeper layers .

The two environments are best preserved on the right side of the atrium on which was built a reinforced concrete pavement and whistled act for the protection of the walls with frescoes. The plasters are still well preserved, and they indicate damage to the roof structure. In the ceiling of the second room, there is a lesion from which in case of rain water enters, the damage does not look very old, but has already caused the detachment of fragments of the ceiling highlighting the reinforcing bars that have rusted and the 'percolating water has given rise to the phenomena of decay on the back wall of the cubicle as well as damage caused by dripping to the floor.

Same situation regard large fragments of plaster in tablinum , *ale* atrium and service areas to the right of tablinum , while in the latter and in the right *ale* of the atrium (the one with the remains of the cabinet) indicates the presence of vegetation on the floor , for the most part mosses .

With regard to the impluvium, it is noted that the bronze copy of the bull was stolen in the seventies leaving behind only small fragments of the stand on the podium near the impluvium .

The unique environment of the atrium to submit sectors walls a bit ' shabby is the tablinum .

Indeed on the two opposite walls which delimit it the mortar joints are most emaciated perhaps for a different technique used for their construction , which present two different textures walls, the upper most damaged , with a polygonal opus of variously square brick , the other lower, composed of volcanic rocks purple more irregular in shape but uniform in size and appearance more compact .

Are also in excellent condition also the necks of the walls, on which there is an area of sacrifice very compact, slim and seemingly very tenacious that is lying below the limit of some elements of the wall protruding from the inside.

More interesting is the second part of the domus which includes the peristyle and the neighborhood of small baths. Throughout the area, with the exception of the Nymphaeum, there are no large areas of plaster, those present, however, always have the same characteristics of compact surface, leaching of color and sound dull to percussion, while the plasters in the Nymphaeum are best preserved. To protect this, was made a coverage sloping inwards that has ensured the preservation of most part of the plaster that simulated marble on the sides of the three niches, and three decorative elements in "Fried Egyptian" present below the three fountains and trained by stucco and sea shells.

In general, the state of the plaster in this area is particularly good and compact, not excluding some sections in which the percussion was found a hollow sound characteristic of detachment. Most damaged are plaster decorated on the edge of the tub, perhaps because it is less protected by the cover, which are broken down into several parts, such as broken down into at least two points at the ends of the tank is the layer of earthenware which defines the surface.

The floor of the porch is at the perimeter formed by cocciopesto and fragments of limestone, compact but extremely disrupted, while the central area of the portico particularly compact but the coloration varies from summer to winter because of revival of mosses present over the entire surface.

On the right side of the porch, in the central columns, had to be present the walls reported by Mau to hold the barrier to close the porch, but only one of these are still in place losing the upper part of which was reported the recess for the barrier, the second is completely demolished and remains the only visible trace left in the right column, you have to say, however, that at the time of the survey there was a shapeless block of masonry near the column in question, perhaps what remains of the original wall.

The columns that make up the porch are plastered and there are no significant damages if we exclude the usual dull sound on percussion of the plaster.

Particularly interesting is the environment to the left of tablinum which is referred as a triclinium.

It is here a beautiful mosaic floor with black and white tiles depicting a highly complex draw on doorway while the interior space is covered by cards rotated 45 degrees.

In this environment there is only plaster on the front wall, too washed out and detached.

It remains to consider the last part of the Domus, the service areas that take place on the left side of the porch.

The latter are of particular interest not being completely devoid of decorations lost already at the time of the Mau, and the floor of every room is covered with moss, but the last three are interesting environments that make up this area.

Walking through the corridor which is connected with the porch, you will reach a small hallway which owns the three environments. The first, the one in front, gives entrance to the kitchen of the domus, perfectly preserved, the floor is slightly lower than the floor level, we highlight inside the workbench on which to light the fire and the fire that has left a massive trail of his chimney in the north wall. The work plan, however, is a bit too low which suggests that the original floor is under the layer of moss to the exclusion this, all environments that are located here do not have a trace of further damage being even the walls undamaged.

The hearth, in particular also serves as praefurnium for the two environments one of them adjacent to the kitchen which is accessed along the narrow corridor turned to the right of the hallway mentioned.

In these two environments was built a small spa facility fully functional, in fact the room adjacent to the kitchen is equipped with a bathtub on the wall directly opposite the fireplace in the kitchen, and on the outer walls are visible tegulae mammate characteristics of the most famous bath, the floor of both environments is also built on the characteristics suspensurae. These environments are the only ones in the latter part of the domus to have preserved part of the plaster, in particular the first accessible environment, the tepidarium of the system, presents the decorations intact for the full height of the walls except for some small gap, most damaged the upper part of the plaster on the north wall, where the fracture line is very clear and does not seem very old since then also present fragments of the plaster on the floor. In general, the plaster of this environment is well preserved, but here seems to have a dull sound on percussion, the north face has a particular phenomenon, the whole layer of plaster is detached from the support of less than 12 cm, so that it could raise us an ivy plant of medium size, and this separation is visible next to the front door from the hallway to the environment, however the thick layer of plaster is very solid and compact, perhaps because it is made in a different way in order to support the humidity of the heated rooms.

In the following, however, the lining of the walls is only up to half height, but the stratigraphy, perfectly readable on the west wall, is different due to the presence beneath the plaster survivor of the above tegulae mammate. The hot here present, has lost the original plaster coating, while on the floor there is a soil mixed with fragments of plaster fell from the walls and moss, also the floors of both

environments are boarded because of subsidence induced by suspensurae that have lost their original alignment, apparently the floor shows no immediate signs of abating.

The last room left is accessed from the left side of the hallway corridor. The hallway gives access to an environment where there should have been a ladder and which today remains a sort of ramp being invaded by all the debris and mosses probably cover the original scale. From this ramp also leads to another room adjacent to the kitchen, but whose function is unknown not present anything remarkable or significant damage. The ramp then leads to a room that was originally to be below a triclinium which was accessed from the porch, this environment is divided into two sections by small wall that probably had to bear the beams that formed the floor of the environment above and the holes of these are perfectly visible in the walls.

The floor of such an environment, however, is not too high compared to the alignment of the beams resulting therefore impractical, then it is conceivable that the current one is not the original decking. Besides that this environment is also covered with moss and does not show any particular damage in the masonry or plaster which was not present in, except for the lintel of the small door.

This, in fact, as well as others in the domus, was made with a layer of cement and irons as armor, probably excess moisture led to the oxidation of the iron and then the consequent disintegration of the cement that here more than elsewhere is missing.

Even in the two areas covered atrium, above the two entrances that face the street and on the two openings on the sides of tablinium new lintels were made, and these are beginning to suffer the ravages of time, but not for damage except for a few small horizontal serious injury, which suggests that it is likely to be more patient in the iron content but in any case do not present serious problems.

3.2 Assumptions about the operation of the original shell

The analysis carried out so far, focused primarily on examining the quality of architectural spaces, from this and from the analysis of archaeological data still in situ it is possible to make some assumptions about the operation of the old shell that could confirm the spatial perception so far analyzed.

From here we proceeded to the construction of a three-dimensional model in order to have a confirmed space than assumed.

The main problem was that there are no traces of the housing in the atrium of the beams that were to support the ceiling.

Having to cover a light of almost nine meters, the beams had to have a section of some relevance, but in the East wall of the atrium, which is the one that retains a greater height, there is no trace.

It should be noted, however, that in the upper part of this wall has been realized coverage of cubacula left, it is therefore presumable that the top of the walls is not the original one, and that the upper part of the wall has been integrated with ancient material as it is not easy to locate the restoration.

It is observed that in the peristyle is perfectly visible the eaves line of the old shell, starting from these data it was possible to advance so the following hypothesis:

there is no doubt that we do not know the height of the beams sets the peristyle, but you can rebuild it starting from the eaves. The tiled roofs, in fact, to function properly must have a minimum gradient of 30-35%, assuming a gradient of 35% on the side of the porch with greater light, can be seen a line of sets of beams that supported the entire roof whose slope increased in the other two sides in order to have a consistent junction in the corner of the roof. was assumed the same height for even coverage, almost certainly flat, of the tablinium, thus achieving a new level for the beams of the atrium.

Obviously, such a plan is completely random, but returning the same slope to the beams from which the beams at the sides tablinium reached of impluvium, determines a level for the beams at a height immediately above the east wall of the atrium, which could match with the information reported by the texts of the conservation of the total height of the walls.

In addition, as the medello 3d signals, the spatial effect built, appears to be consistent, as they seem to be consistent heights of the entrance rooms and the gate of the tablinium that create, with the two gates adjacent, an image already seen in other domus reconstructed inside the archaeological site. for which we can assume a greater conservation of archaeological evidence.

4 Conclusions

The observations conducted so far show that the field of investigation can take root in different ways and that the multidisciplinary contribution is crucial to Pompeii more than in any other archaeological site in the world.

The study may result in a list of the traditional measures of restoration and consolidation of the existing walls, with a proposal for construction of roofs to preserve what still remains a fundamental and basic observation.

The main problem focused is that it is impossible in Pompeii to stop the action of time and weather and at the same time leave the site with a picture of romantic ruin, what is to preserve and pass on to future generations? A consolidated picture of the archaeological site or the informations on the lives of its inhabitants that weathering systematically erased?

In this sense, the domus in question is an emblematic example, excavated in 1836 has completely lost the decorations described at the time of the excavation and the question is what should have been done to prevent 178 years of rain, wind and sun to destroy everything ?

The restoration conventional are meant to salvage what they can, not for freeze what its found intact but exposed to the elements and if this application is expanded to the entire archaeological site we realize that are the doubts rather than the certainties to be successful.

I conclude with a challenge: Pompeii is not an archaeological site! (certainly not conventional)

It is a city without inhabitants or more where the inhabitants are just gone that contain a massive set of information about its inhabitants and that we have to preserve.

As long as we do not think in that size, in Pompeii any action strategy may not be able to solve the problems that from time to time will be reposed.

Interpreting structure through critical regionalism

Iosif DAKORONIAS-MARINA

Architect, School of Architecture, National Technical University of Athens, Greece
MArch, Architectural Association School of Architecture, London, United Kingdom
idm.arch.design@gmail.com

Abstract

Throughout history building has been guided mainly by structural and material simplicity in accordance to locality. However, in the last two centuries, through the process of industrialisation and modernity, along with the split of the architect and the engineer, architecture seems to have lost this sense of local simplicity. Local knowledge is lost and the builder is no more a craftsman.

This sense of locality seems prominent in the theory of critical regionalism. However, this theory seems to be mainly polarized on the functional and formal aspects of the building. Regionalist architects have mainly produced buildings that respect their surroundings using, however, structural systems incompatible to the previously existing regional schemes.

In search for the appropriate structure in a regional context, local empirical schemes and the anecdotal relationship between the architects and the engineers is used to prove the point that local approaches, long-lasting schemes and experimentation can be more beneficial for the output of small-scale regional projects.

The following paper concludes to a six point methodology towards a structural critical regionalism, advocating that in our world that faces today a crisis of the architect there needs to be a reconciliation of the discipline with local, long lasting schemes in order to produce a more influential and integrated architecture and advance forgotten techniques that can be used locally and generate more competitive buildings.

Keywords: Critical, Regionalism, Structure, Hooke Park

1. Introduction

Rem Koolhaas, the curator of the forthcoming Venice Architectural Biennale - titled "Fundamentals" - states in one of the paragraphs of this year's theme description: "In 1914, it made sense to talk about a "Chinese" architecture, a "Swiss" architecture, an "Indian" architecture. One hundred years later, under the influence of wars, diverse political regimes, different states of development, national and international architectural movements, individual talents, friendships, random personal trajectories and technological developments, architectures that were once specific and local have become interchangeable and global. National identity has seemingly been sacrificed to modernity." [1] In a similar way, Kengo Kuma states in one of his interviews: "Currently local character is being destroyed by mass standardization." [2] The construction world, mainly controlled by contractor practices, focuses today on the international application of building systems that were introduced after the industrial revolution. The advent of structural engineering as an autonomous discipline in the 19th century has led to an institutionalization of the production of structure and a globalized so called "common practice" in building. In the short paragraph above, Koolhaas touches on one of the most challenging questions of today's architecture: Where has the identity of Architecture gone?

Fig. 1: The regional identity: 1. Shinto Shrine, Ise, Japan 2. Windmills, Mykonos, Greece 3. Thatched cottage in Wool, Dorset, United Kingdom

Fig. 2: Ise Shrine, Japan. The two building sites of the Jingū shrine where every 20 years the buildings are reconstructed on the adjacent plot. The surrounding managed forest and factory produce and process the 12,000 trees needed per rebuilt.

The following paper revolves around a question focused on a specific aspect of Architecture: the structure. I will investigate how we can interpret locality in the local today, expressed through a consideration of structural needs in localized building practices, as opposed to the long-lasting fight between the architect and the engineer, generated at the split of the two disciplines. Looking into the history of the rivalry, through the theories of critical regionalism and using the Architectural Association's Campus in Dorset, I will propose a new way of looking into structural systems. In contrast to an architectural world where more architects care on how buildings look -a mentality prominent in the majority of the interpretations of critical regionalism- I will appose an approach to building that cares about what buildings are and should be made of in a local context.

One of the main terms in the following paper is the "local" or "regional". The idea of a region, as described by Liane Lefaivre and Alexander Tzonis "has gone through several shifts [...]. While for ancient geographers it meant an 'objective', 'natural' division of the earth's surface, an area defined by boundaries, landforms, paths, zones of vegetation and climate, with administrative borders placed on top, by the end of the eighteenth century it had become associated with human rather than natural attributes, such as continuities and discontinuities of language, religion, ethnicity, and economy, or mental aspects significant for local people, aspects defining place, belonging, community." [3] In this framework, the regional is used in the next pages to define a place where people have a continuous application of one or more building systems through history, the access to specific building materials unique for a specific place and the existence of labour that practices specific crafts. For example, Ise Shrine in Japan - the most sacred Shinto shrine - that gets rebuilt every 20 years, is a unique local example due to a surviving technique and a managed forest that are only there to serve that purpose. Ise Shrine is only feasible and sustainable in Ise.

The localized approach is linked to a sense of scale. In order to perceive locality we need to isolate ourselves from the vast urban areas that have lost their regional identity and focus on areas where buildings do not need to shout, that are there to serve a purpose and cover needs. In small scale, localized projects, the need for a methodological approach to building is more evident since the economies work in a different way. In large urban projects where all technologies and expertise is available, the choice of a specific system linked to previous schemes could be beneficial, but the economies of scale in this context would not be really affected. On the contrary, in small projects that are essential to people and communities, as is for example housing, and even more specifically self-built structures, the output of a project depends on efficiency, materials, cost and simplicity.

A significant number of projects around the world have been designed through an architectural approach to locality, adopting features of the local mainly in a visual and functional way. These buildings have an excellent relation with their surroundings and landscape, incorporating, though, international modes and techniques of construction mostly foreign to the place where they were built. This approach has been widely known as critical regionalism and has mainly been interpreted in the last forty years through the work of Liane Lefaivre, Alexander Tzonis and Kenneth Frampton. A different interpretation, as seen in the work of Hassan Fathy in Egypt, relies primarily on the efficiency of the structure in accordance to the locally available structural materials.

In a period less than two centuries long the majority of architectural practice has managed to isolate itself from locality focusing on international styles and globalized methods, applied mainly on large-scale projects. Residential and smaller-scale ones are mainly driven from contractor practices and, sometimes, self-built approaches that rely on mass production of predefined and prefabricated systems. In this context, architects have managed to control less than 5% of the building development, [4] having less and less influence on the qualities of the built environment. The following paper will conclude to an interpretation of the structural system from a regionalist approach, proposing that in our mid-recession world the contemporary designer-maker needs to critically choose structural systems that are suitable for a specific place, based on the assessment of the available structural materials, the inherited local building knowledge and the available labour. This proposition will be based on an investigation on the theory of critical regionalism as expressed through the work of various architects and theorists around the world and the analysis of localized practice as experienced through the project in the AA's campus.

2. Building and structure

Structure is usually perceived by architects and engineers as a system of bearing elements that support a building. Fights between engineers and architects have been anecdotally documented, the one struggling for efficiency and the latter for the preservation of the features of his design. This "sibling rivalry" as described in the work of Andrew Saint [5] is a product of the evolution of building practices and of the advent of the structural engineer as an autonomous discipline in the last two centuries. In this time we, as architects, have come to believe in "The idea that architecture (which by dictionary definition includes design and construction, "has an autonomous aesthetic dimension" [6] The relation of the architect and the engineer is so unclear that it has led to controversial interpretations of their interaction and boundaries:

"The fight between architects and engineers derives from the urge of the first to build something infinitely rigid and of the latter to build something infinitely moving." Alain Billiard

"The architectural desire to build something that is in 'infinite movement' is one of the central desires of modern architects" Sigfried Giedion

Through history, we can identify an evolution on the relation of the building and its structural system. From the start of building history, the moment when the prehistoric man decides to leave the caves and grottos and move to his self-built house of local materials, to the classic buildings of the ancient civilizations, the medieval large scale buildings and the late 1800s, the structure is not thought as a different system than the building itself.

Across the world, there are examples of structures –from the primitive Neolithic hut to the Gothic cathedral- that have one thing in common: structural appropriateness and material simplicity in accordance to locality. The building is not supported by a structure but it is the structure itself. From the conception of the building to its final outcome, every detail is defined by structural and functional needs. Builders of that time generate buildings and, subsequently, structures according to what is the simplest way to use materials available in the vicinity of the construction site in order to produce a building that will respond to human and structural needs.

Fig. 3: Simplicity in accordance to locality: 1. The primitive hut, Western Pacific, built with local straw. 2. The Parthenon, Athens, Greece, built from local white marble. 3. Salisbury Cathedral, United Kingdom, built from local limestone. 4. Cottage in Dorset, United Kingdom, built from local stone. The building follows the natural slope, minimizing complexity in construction..

The architect of the time is the leading builder. He is the one that has a deep knowledge of construction that emerges from an oral tradition and a process of locality, temporality, trial and error and, sometimes, success. The building and structural practices of that time were also defined by the deep local knowledge of the natural phenomena that could compromise the longevity of the edifice. Data on geological movement such as earthquakes and landslides, and meteorological events were passed on from generation to generation informing designs and structural systems. This thousand year long lasting practice of building according to local availability and local knowledge produced numerous buildings that have survived up to these days.

In the mid-1800s the industrial revolution generates a need for speed, efficiency, maximum production, and optimisation: values that can be achieved only through thorough calculations and scientific studies. A new discipline is formed: the engineer. Engineers seem to discover the beauty of new materials, are given the opportunity to test them and produce bold structures that mainly serve the purpose of the industry: infrastructure, industrial buildings etc. In that era, where engineers talk about efficiency and optimum performance, architects represent plurality, ornament, richness and grandeur, borrowing and copying components and stylistic features from older buildings, generating styles such as, for example, the neo-classic and the neo-gothic.

The first world, especially in urban context, manages to discard any tradition in front of the new exciting process of mechanization and mathematical calculation, and the grandiosity of the neo-styles. The process of locality that was inherent to builders seems to vanish or is set aside by the fast growing industrial world. The vernacular becomes picturesque, a museum piece that has no other value than the aesthetic one, although produced in mass amounts in the non-urban areas.

In the mid-war period, architects discover the qualities of the engine and the factory, introducing to the world the modern movement. Machinery is at that time glorified as the ultimate expression of finesse and style:

"A locomotive...has its peculiar physiognomy, not the result of caprice, but of necessity. It expresses controlled power; its movements are gentle or terrible, it advances with awful impetuosity or, when at rest, seems to tremble with impatience...its exterior form is but the expression of its power. A locomotive, then, has style... A thing has style when it has the expression appropriate to its use... We who in the fabrication of our machinery, give to every part the strength and the form which it requires, with nothing superfluous, nothing which does not have a necessary function, in our architecture

Fig. 4: The industrial revolution: 1. Philip James de Loutherbourg (1801), *Coalbrookdale at Night*. 2. The imposing structure of the Forth railway bridge over the houses of North Queensferry, Scotland.

foolishly accumulate forms and features taken from all sides, the result of contradictory principles and call this art.” [7]

The modern movement, based on “photographic evidence rather than on the ancient and previously unavoidable techniques of personal inspection and measured drawing” [8] produces buildings that were “purely formalistic imitations of structures that had never been studied at first hand” [9]

The ideology of the modern movement followed and adopted by a large proportion of the architect force of the time and its influence to architectural education lead to an absolute disconnection from the local and long-lasting building rituals and materials. Local vernacular practices were rejected as outdated and international new materials, mass produced by industry were considered the future of efficient and quality building, especially in the large scale.

According to Hassan Fathy, one of the most influential architects in Egypt of the last century: “Until the collapse of cultural frontiers in the last century, there were all over the world distinctive local shapes and details in architecture, and the buildings of any locality were the beautiful children of a happy marriage between the imagination of the people and the demands of their countryside”. [10] Unfortunately, the collapse that Fathy describes has led to interpretations of architecture as K. Frampton presents: “Today the practice of architecture seems to be increasingly polarized between, on the one hand a so-called “high-tech” approach predicated exclusively upon production and, on the other, a provision of a “pensatory façade” to cover up the harsh realities of the universal system” [11]

Today, we witness a strange relationship between the architect and the engineer, the building and its structure. And this relationship can mainly be perceived in large-scale projects. As described by Alan Colquhoun: “The purpose of the building is not primarily to satisfy the practical and economic needs of the client, but to celebrate the idea of technological progress and to suggest a technological utopia”. [12]

In this large scale, architects and clients are trying to push form as far as possible aiming for extreme complexity that derives from a desire to create iconic buildings. In many cases the structure is ignored or totally misjudged. Trying to respond to this need, architects and engineers come up with extremely costly solutions that rarely take into account the local factor in form of materials and technical knowledge of the builders.

On the other hand, small scale projects are mainly based on contractor practices that just adapt international systems based on mass production economies and material efficiency. Architects seem to have minimal impact on these projects that lead to the degradation of the architectural value of the built environment.

All around the United Kingdom - but also in many northern European countries and the United States- we can see massive areas covered with housing projects of poor or no architectural value, mainly favoured by their cheap materials and the speed of construction. These developments, guided by a maximum profit policy, incorporate materials that could have been produced anywhere, all delivered as a kit of parts and assembled on site, as fast as possible. These contractor practices have tried to minimize errors through the ideals of the industrialized production.

Work that once would depend on the exclusive and deep knowledge of a specific craft has now been replaced by the mechanized process introduced through modernity. Builders in the past used to be artisans with deep knowledge of their craft. These craftsmen used to move in groups from place to place and carrying their trade’s secrets, producing buildings of great quality and durability. Although these builders did not necessarily belong to a specific place, they used techniques and especially materials according to the building’s surroundings. Buildings produced by these travelling and secretive construction crews can be found all around Europe. This practice of localized building, mainly known to us through the study of the Gothic Cathedrals survived up to the early 1900s.

Fig. 5: “the harsh realities of the universal system”: 1. Part of the Guggenheim Bilbao as seen from the exterior. 2. The structure of the above part. Architectural Design by F. Gehry and structural design by Skidmore, Owings & Merrill, 1997

Fig. 6: 1. Low-cost housing in the United Kingdom. 2. Low-cost housing in Belgium.

Since the modernization and industrialization of the building production, the builder has become a part of a huge mechanism where everything is synchronized to produce the same product again and again. Same international structural system, same walls, same floors, same cladding, same doors, same windows, same roof. Due to the above process, local quality craftsmen have become really rare and extremely costly. For example, in Dorset, thatched roofs made of local straw get replaced by cheap ceramic tiles, local stone masonry gets replaced by mass production timber framing and brickwork, since these trades cannot fight the competition of the massively produced components. The builder of our days, taking part in those mass production practices, does not require any special knowledge or craft, given the vast amount of standard systems that just need someone to assemble a puzzle. In this framework of the “standard” practice, the structural system has become a feature that is sometimes not even thought of. Since the uncoupling of the building from its local references - through the advent of the structural engineer in the industrial revolution and the development of the contractor practices described above- the structural system today seems to be a feature of the building with no local roots, no regional identity.

Why is it important, then, to evaluate the local factor today? If we can use the “Think globally, act locally” theory - first introduced by Patrick Geddes- on town planning, environmental and business approaches, then why not on a building and more so on its structural aspect? An evaluation of the local knowledge and the previously used structural systems can help us understand structural needs in specific areas. Finding the most appropriate structural system is vital for the outcome and the longevity of a building project.

3. Critical regionalism

Critical Regionalism seems to be the theory that best suits the “Think globally, act locally” approach. As described by Liane Lefaivre and Alexander Tzonis in their book “Architecture of Regionalism in the age of Globalization”: “Regionalism always opposes centralization and universalization, and instead supports decentralization and autonomy”. [13] The theory of critical regionalism was introduced in the 1970s by Lefaivre and Tzonis has been commented and expanded by Kenneth Frampton [14] and Alan Colquhoun [15]. The theory was developed in order to “draw attention to the work of a number of young architects in Europe who challenged post-modernism, the fashionable tendency of the period, proposing an alternative approach to design”. [16]

The whole theory is based on schemes of architecture in an *arrière-garde* position “to cultivate a resistant, identity giving culture while at the same time having discreet resource to universal technique.” [17] The common ground of the architecture collected by Lefaivre and Tzonis lies on various aspects of a built project: the interaction and connection of the building to the topography, the material expression of the buildings, the relation of the form to the existing structure, the quality of light and the ventilation of the edifice and other long tested aspects of the vernacular. The buildings studied were “‘embedded’ in the landscape ‘through discovering, adjusting and restoring’ the ‘relationship and texture’ of ‘the past and the future’”. [18] “By way of general definition we can say that it (regionalism) upholds the individual and local architectonic features against more universal and abstract ones. In addition, however, regionalism bears the hallmark of ambiguity. [...] critical regionalism is a bridge over which any humanistic architecture of the future must pass” [19].

In this context Lefaivre, Tzonis, Frampton and Colquhoun draw examples of “the architecture of resistance” [20] from all around the world and throughout history, identifying the qualities of the critical regionalism in works among others of Jørn Utzon [21], Josep-Antoni Coderch, Mario Botta, Tadao Ando, Dimitris and Souzana Antonakakis, Dimitris Pikionis,[22] Alvar Aalto, Oscar Niemeyer, Renzo Piano [23] etc. The work presented is centred on the principle that “Architecture should grow as a tree and become one with the landscape”. [24] This approach “goes beyond the objective of just minimizing the disruption of the landscape or hiding or blending the new structure, methods known since the picturesque, but engaging in a critical ‘dialogue’ with the site, foregrounding its particularity.” [25]

The paradox in the critical regionalism theory as presented up to today is that it focuses mainly on the visual and the functional aspects of a built project: topography, materials, form, light, ventilation totally disregarding matters of structural systems and cost. Even in the latest book by Lefaivre and Tzonis their interest seem to navigate towards an ecological architecture, avoiding the issues of the bearing structure and the financial aspect of the buildings. In his 1983 essay: *Towards a critical regionalism-Six points for an Architecture of resistance* K. Frampton seems to “forgive” Jørn Utzon for the use of a “relatively uneconomic mode of construction” in his 1976 Bagsvaerd Church in Copenhagen for its “direct associative capacity [...] and second for its multiple cross-cultural references”. [26] Later on, in the same text, Frampton seems to be contradicting himself by saying that “the primary principle of architectural autonomy resides in the tectonic rather than the scenographic”. [27] Scott Paterson wrote in his critical analysis of the above text: “the effect of this is to direct ones attention away from the critically regional [...]”. The kind of situation where one asks themselves what is he really saying.” [28]

Fig. 7: Two of the works prominent in the work of Lefaivre-Tzonis and Frampton: 1. Pathways around the Acropolis of Athens, Greece by D. Pikionis. 2. Apartment building in Athens, Greece by D. and S. Antonakakis.

Fig. 8: Bagsvaerd Church in Copenhagen, Denmark by Jørn Utzon.

Fig. 9: Exterior view and structural detail of the Tjibaou Cultural Centre in Noumea, New Caledonia by Renzo Piano

In the latest work of Lefaivre and Tzonis the example of Renzo Piano's Jean Marie Tjibaou Cultural Centre in Noumea, New Caledonia is used as an example of architecture focused on a "critical and not regressive" [29] regionalism where Piano pays "homage to New Caledonia's culture, traditions, and history, while putting European technology and expertise at the service of this goal, a synthesis between local and global. He used the shape of traditional Caledonian huts, regional materials and building methods, and local beliefs about wind, light and vegetation". [30] Again, most technological and structural systems are imported from Europe, getting stylized in order to manage the desired blending with the local culture. Glue-laminated timber sections and steel connections are morphologically treated in order to come closer to the way that the New Caledonians build.

Given that critical regionalism is an architectural approach that emerged as an opposition to post modernism and practiced initially by architects trained as modernists, we can identify a common ground in the use of typically modernist structural systems such as reinforced concrete and metal structures, as well as composite materials and prefabrication techniques, inventively combined with cladding materials that lead to the desired 'blending' of the building in its natural and built environment. However, the use of structural systems incompatible to the previously existing regional schemes has led to built examples that seem to be in contrast to the core of the critical regionalism. As Frampton points out about the work of Aris Konstantinidis, whose work has been used to support critical regionalism: "In all of Konstantinidis's public work, a tension appears between the universal rationality of the trabeated reinforced concrete frame and the autochthonous tactility of the native stone and blockwork which is used as infill." [31]

Critical regionalism seems to be trapped to the mentality of the superficial. As John Cotman once stated: "Three quarters of mankind, you know, mind more what is represented than how it is done". The way that Lefaivre, Tzonis, Frampton and Colquhoun have interpreted critical regionalism has always revolved around the functional, formal and morphological and lately to the ecological. However, the term 'critical' on its own gives us a flexibility of interpretation, meaning that critical regionalism as a movement can continue evolving, adapting to new data, accepting new perceptions and incorporating other aspects of the built project, depending each time on the architect and or the builder and his consideration towards the architecture he/she wants to produce.

In this framework, we could identify in the work of Hassan Fathy, a regionalism centred on the structural system and its applications in the most suitable way taking advantage the local knowledge and workforce. "Here (in Egypt), for years, for centuries, the peasant had been wisely and quietly exploiting the obvious building material, while we, with our modern school-learned ideas, never dreamed of using such a ludicrous substance as mud for so serious a creation as a house. But why not? [...] Why not use this heaven-sent material for our country houses? And why not, indeed, make the peasants' own houses better? Why should there be any difference between a peasant's house and a landowner's? Build both of mud brick, design both well, and both could afford their owners beauty and comfort." [32]

Fathy realizes that modernity has set aside a traditional system, that was then considered as cheap dirty and lower class. However, the financial reality of the times leads to the application of the system given the scarcity of the engineered materials of industrialization: "Soon afterwards the war started, and all building stopped. Steel and timber supplies were completely cut off, and the army requisitioned such materials as were already in the country. Yet, still obsessed by my desire to build in the country, I looked about for ways of getting round the shortage. At least I still had mud bricks! And then it occurred to me that, if I had mud bricks and nothing else, I was no worse off than my forefathers. Egypt had not always imported steel from Belgium and timber from Romania, yet Egypt had always built houses." [33]

Fig. 10: The architecture of H. Fathy is mainly driven by locally available materials and long practiced structural schemes.

Apart from the systems and the materials, Fathy recognises the value of the local knowledge and values the abilities of the labour he has available: "They worked rapidly and unconcernedly, with never a thought that what they were doing was quite a remarkable work of engineering, for these masons were working according to the laws of statics and the science of the resistance of materials with extraordinary intuitive understanding." [34] The designs of Fathy do not impose a system; instead they are adapted to the local existing structural systems and take maximum advantage of the local knowledge, labour and materials, creating an architecture that is feasible and cost-effective, even being considered nowadays sustainable.

4. Interpreting structure through critical regionalism

As seen on the previous section, a vast amount of works of architecture around the world can be considered an expression of the theory of critical regionalism. This expression has been mainly focused on the way that these buildings link with their surroundings in means of forms and cladding materials. However, one cannot overlook and disconnect a building from its structure. A technocratic and/or capitalistic approach would easily discard structural locality as irrelevant to a globally developing construction sector that should be based - as introduced by the modern movement - on a mass production. This mass production is based on fast and simplified techniques that make use of industrially processed materials.

On the contrary though, especially in small scale projects, finding the appropriate structure can be a major factor on the output of the project and its feasibility. In the last forty years there has been a movement for the developing world called appropriate technology. Based on the book by E.F. Schumacher: "Small is beautiful: a study of economics as if people mattered" [35] "The goal of Appropriate Technology (AT) is to increase the standard of living for the developing world without condescension, complication, or environmental damage. Typical AT inventions are more labor intensive, require fewer resources, and use low cost or readily available materials wherever possible. Special attention is paid to the social, cultural, and ethical aspects of the communities the technology is intended for" [36] The immediate question is: why is appropriate technology only applicable in the developing world? In our so-called developed world we have come to consider that since our problems are supposedly solved, we are allowed the luxury to spend massive amounts of money in complicated building techniques and structures, no matter the place, no matter the people.

Appropriate technology should not and cannot be only an investment for the developing world. We saw in the work of Fathy, how the scarcity of materials led him to the use of previous schemes. In the same way, in areas where materials are abundant, and the local knowledge is of some sort, the critical perception of the architect and the engineer needs to produce systems that would ensure the continuity of building practices in a specific place. Local schemes are considered boring, simple, non-experimental, non-revolutionary, not worth looking into. The first world is bombarded with images and costly ambitions for revolutionary buildings, a product of architects dreaming of a high-tech future. As Denise Scott Brown once said, "Basically, the idea is that with everyone striving to be revolutionary, you will be most revolutionary if you try to be ordinary". [37] This practice of a revolutionary, globalized high-tech system that is being glorified by the international prizes has led to interesting articles with amusing titles like "I'm in a Stirling prize winner ... get me out of here!" [38] or "Dear architects, I am sick of your shit". [39]

In a total contrast to the globalized and complex architectural practice, the buildings in Hooke Park stand as an example of appropriate technology and a down-to-earth approach to the buildings' structural systems. The buildings seem to follow an interest in the maximum use of the locally produced timber in various structural configurations, based on local experience and labour, and a self-built approach equivalent to the practices of the pre-industrialized world's master builders. As seen above in the example of the newly built Student Lodge 3, we can identify a methodology towards a structural critical regionalism. In this methodology the structural system derives from the input of six parameters.

First of all, there is an identification of a need and the development of a building intent. The building intent is the one that will define the level of structural complexity, depending on the formal ambition and the desired architectural, in means of functionality, output. Secondly, there needs to be a thorough research on locally practiced structural systems. This research should include systems even if these are not traditional in the long term, but can be considered embedded to the local culture through the longevity of their application in a specific place. A third point is the materiality of the system. An evaluation of the locally produced and available materials is important for the financial feasibility of the project and the contribution to the local economy. Another very important point is the available local labour, from the most skilled to the least. A careful assessment of the workforce available can generate systems that can be adaptable to the capabilities of each member of the team. The next point lies in the systems that need to be developed, calculated, assessed and tested in order to meet the skills of the available workforce. The last and more important point lies in the time-scale available for the above process and the construction of the project, as this parameter can define many of the

decisions. The designer-maker can spend unlimited time in defining the strategies that he/she will use and unlimited amounts of time refining the systems to be used to suit his/hers own powers. However, in a tight schedule, compromises need to be made in order to move the project forward.

A locally influenced structural practice as described above can have a significant positive effect to the local, small scale application of architecture in any part of the world. In a short-term scale, the cost of the building can be significantly reduced by use of locally available techniques that have been practiced for a significant amount of time combined with materials and labour that have a specific experience in these systems and schemes. In the long-term, the building can be repaired and undergo maintenance more easily without need for expensive specialists and analysis processes. The structural system, which is the core for the survival of the building being based on already known techniques and materials can be extended and modified according to the user's needs through the user's own means or other locally available workforce.

Bearing in mind all the above, we can summarize the structural interpretation of critical regionalism in six questions that can be used as a methodological guideline:

1. What do I want/have to build?
2. What is the available local common structural practice?
3. What are the available structural materials and resources?
4. What is the available local knowledge?
5. What systems do I need to develop?
6. What are the timescale/other restrictions?

5. An example: Hooke Park

Hooke Park is a 350-acre working forest in Dorset, owned since 2002 by the Architectural Association. The Hooke Park campus is in constant development since its early beginnings as a woodworking school in the 1980s. As described on the Architectural Association's website: "The existing buildings at Hooke Park, designed by collaborations between ABK, Frei Otto, Buro Happold and Edward Cullinan, are remarkable demonstrations of an intelligent approach to maximising the resource provided by the forest – by using green round-wood poles provided by forest thinning, a silvicultural waste product. The future projects at Hooke will aim to resurrect the ambition of that approach to building." [40] Although small in scale, for the standards of Robert Mark's theory described in the previous section, the first buildings of Hooke Park are an excellent example of the appropriate structure.

Having a young forest, the developers of Hooke Park had to find an inventive way of using the thinnings produced by the forestry operation - timber of minimal value and low structural quality. The two initial buildings in the campus, the refectory and the workshop were built using small section round-wood in tension and in compression, taking advantage of the flexibility of the whole tree. In the refectory building built in 1987 the small section roof members (around 70mm in diameter) support in tension the secondary structure of the roof. In the workshop, built a few years later, the 150mm in diameter members form arches, supporting in compression the light buildup of the roof.

The urge for the maximum use of the resources of the forest in the above buildings led to an interpretation of the structure through locally available schemes and materials. In their urge for experimentation and maximum efficiency, the architects and the engineers of these first buildings instinctively acted as the primitive builder, taking advantage of the locally available timber and its poor quality. Armed with the privilege of the knowledge of the industrial revolution and the rationalisation of the structure, they managed to produce two buildings that stand as a perfect example of structures and structural systems that are embedded to their surrounding resources.

Fig. 11: Building with forestry waste: 1. The workshop building during the bending process 2. The workshop's arches nearing completion 3. The building of the refectory under construction.

Fig. 12: Continuing the tradition: 1. The Big Shed 2. Student Lodge 1&2 3. Student Lodge 3 4. The Timber Seasoning Shelter.

In 2002, the Architectural Association acquired Hooke Park and since then the campus has turned into an exciting playground for architecture students and their tutors, experimenting with forms and structures, creating a collection of prototypical buildings in various scales, sizes, materials and technologies. Design and Make students, visiting units, workshops, summer schools etc. all have produced through these ten years a vast collection of permanent and temporary structures, sculptures, and installations scattered in the forest.

The Design and Make Masters Programme undertook in 2010 the design and construction of the buildings needed for the development of Hooke Park as a fully operational campus, trying to continue the “Hooke Park building tradition”. Since then four buildings have emerged through the Design and Make process: The Big Shed, Student Lodge 1&2 (SL1&2), the Timber Seasoning Shelter (TSS) and Student Lodge 3 (SL3). All four buildings are totally different in means of structural system, form, conception and output. However, one can identify common ground in their materiality (Hooke Park timber) and an approach to design, structural system and construction that is linked to local practices.

As a cohort of five architects of totally different architectural backgrounds (Curacao, Greece, Panama, US) we were given the task to deliver a student lodge of 60 m² of enclosed area that would house two full time students and that would cover all the building code requirements of safety, energy and performance (CDM, Code for Sustainable Homes etc.). SL3 was designed as a two-part building, the bedrooms/bathroom and a so called social area divided by an exterior deck. The building would be a demonstration for the creative use of recycled and salvaged materials, combined with the maximum use of the resources of Hooke Park and its surroundings.

The structural system was one of the first parts of the building to be designed. When designing a house through a tight budget, architects sometimes fall into the trap of the “common practice”, especially when it comes to structure. Looking into common practice in the UK, we can see a vast use of brick and block cavity walls, prefabricated insulated panels of natural timber studs and structural plywood sheathing, combined with beams and trussed rafters of defined dimensions. The immediate question was how to transform this system so that it could be used in Hooke Park. Given our time and, mainly, money constraints we had to come up with a structural system that would work in three ways: first, make maximum use of the available resources of the forest, second, provide the necessary load bearing capacity as defined by our structural engineers and third be easily constructible with the available people, tools, infrastructure and materials. One of the main drivers of the decisions on the system was budget and time. As per the first parameter, given that all natural timber that came through the forest would have a minimal cost to the Architectural Association we decided that we should minimize or even eliminate the use of any imported and moreover processed timber (e.g. OSB,

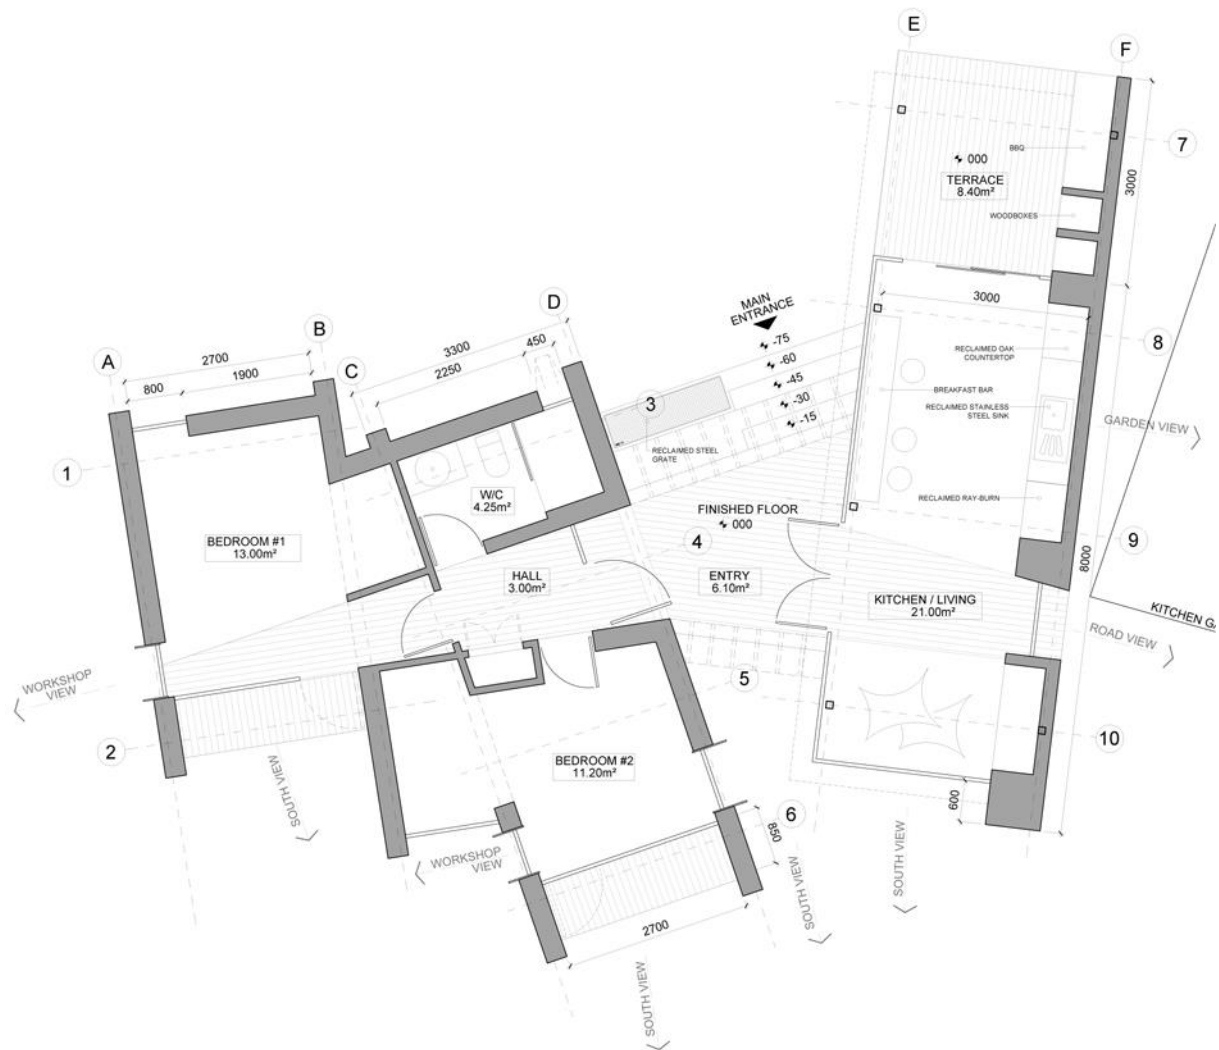

Fig. 13: The floor plan of Student Lodge 3. The layout of the building is defined by views and levels of privacy.

plywood etc.). The goal of the elimination of the sheathing materials became one of the main goals of our group. However, all timber produced up to this day in Hooke Park is used green and is unofficially graded at a structural quality of C16 - whereas the ideal would be C24 - meaning a significant increase to the bearing sections. As per the second parameter, we generated a mock-up of our proposed structure and load tested it in order to reach the necessary loading, by simple means available in Hooke Park. In order to cover our third requirement, all members of the system developed would have to be cut and processed by the available machinery and tools, assembled in the Big Shed and be easily movable by hand or the telescopic forklift. Also important in the whole process was the fact that the building would have to be constructed by the available labour which consisted of five unskilled students of various backgrounds with a six month experience in small projects in Hooke Park, one skilled timber framer with long experience on traditional timber framing and a group of unskilled summer volunteers. This meant that the systems developed would have to rely on simple connections and a simple assembly scheme.

The first system we came up with was a lattice wall of 100mm in thickness that would work in the same way as a Belfast truss, comprising of a spruce frame and diagonal lattices at 40 x 40mm. We constructed a mock-up wall of 2.00 x 3.00m and it was tested to a load of 1500kg (500kg/m of wall). The wall proved that it could work although its whole design (sections of timber, distance of the lattices etc.) came out from pure instinct. The reluctance, however, of the engineers and their fear for the unknown and uncertified quality of the timber combined with the need for the accommodation of a large amount of insulation (245mm) lead to a redesign of the bearing walls. This time the design – which was used in the final build-up of the lodge- comprised of 245 x 50mm vertical studs braced by diagonal battens on the interior and the exterior that would also serve as the supportive structure for the cladding. Although the new design used a significantly larger amount of timber, this had a minimal effect on the cost of the building, given that it all came from the forest around the construction site; it

Fig. 14: The structural system developed for the Student Lodge 3 building.

Fig. 15: Student Lodge 3 nearing completion

was blessed by the engineers and was consistent with our goal regarding the minimal use of processed timber like plywood. Any part needing diagonal bracing usually provided by sheathing materials, was replaced by natural timber members: diagonal battens on the walls and diagonal boards on the floors and the roofs.

Another part of the building that serves as a great example of the paradox between the experimentation in making, the local practice and the mathematized way of the engineers was the debate for the trusses of the roof of the social area of the building. The social area was planned to be covered by a single-pitched roof supported by four trussed rafters that had to be made of green spruce, the only species already available in Hooke Park at the time of the design. The engineers, uncomfortable with the use of non-graded, green timber came up with calculations that seemed exaggerated to our minds, as our tactile experience up to this point had shown that we could achieve the same things with smaller sections. This feeling of exaggeration was corroborated by the long experience of the timber framer that worked on site with us and the puzzled looks of an engineer

visiting the construction site of the Timber Seasoning Shelter. The time needed, however, for redesign and negotiations with the firm in London seemed at that time not feasible, so we continued as calculated. The trusses came out bulky, disproportional and heavy, adding an extra risk when handling them on site.

Later on, during the design of a different part of the roof, seeing that the given dimensions were ridiculously big, we decided to negotiate with the engineers the size of the beams. The short exchange of e-mails is interesting:

“- Engineer:

Same section sizes for the entrance area. Will resend the calcs next week

Regards,[...]

- SL3 team:

Could you check the calcs to see if we can use 200x50 roof rafters for the social area building rather than 250x75?

Also, for the entrance roof. We sent a proposal showing 250x150 beams for the main beams and 150x50 for the transversal rafters. If we follow your suggestion and place the rafters on top of the main beams, could we look into the smallest size we can use? We are currently running low on big timbers and are struggling to get anything bigger than 150x150

Best, [...]

- Engineer:

I have reviewed the calcs for the roof rafters and the engineer seems to have left some ‘fat’ in the rafter design due to uncertainty of loading. You have clarified the roof loads so yes happy for you to reduce the section size to 200x50.

If you want me to see what I can do with the entrance roof then can you send a revised drawing showing the final arrangement and the final cladding details on this roof. I’ll then see what options we have.”

Although all the above seem anecdotal they are perfect examples to prove the point that local approaches, long-lasting schemes and experimentation can be more beneficial for the output of projects. The disconnection of the engineer from the primary application of his work which is the construction site and the depreciation of the deep experience of the local labour and the knowledge that is produced through experimentation have led to an institutionalization of the production of the structure. Common practice, worldwide standardized materials and systems are used with no questioning for their efficiency and adaptation to local needs. “At the moment, global or multinational corporations, global networks and alliances, as well as global institutions, dominate the making of buildings, cities and landscapes. They promote universal, centralized design models, manifesting their creative but also destructive force on the environment, on cultural heritage and on human community.” [41]

6. Conclusion

Interpreting architecture - and furthermore structural systems - through critical regionalism can be sometimes risky and controversial. Given that the term on its own - critical - has a level of subjectivity embedded in it, one could argue that structure is not the core of architecture, going back to the fundamental question: What is then architecture? A question that could not be answered on such a short text.

In the above presented paper, structure is considered as the part of the building that defines the most crucial decisions of the architect. Architectural practice and moreover structural needs have been affected throughout the latest history by the advent of the structural engineer as an independent discipline and from the sprawl of modernism and industrialization. After the 1900s, industrialization and modernity represent the ideal for a globalized world of maximum efficiency and maximum profit, setting aside an evolution of construction of some thousands of years, where structural schemes and building techniques developed smoothly, proving through time their successes and failures. The industrial revolution brings an abrupt change to the perception not only of construction, but also of the world. Through this process of mechanization and mathematization we have witnessed a disconnection of the architect and the engineer from traditional and locally applied schemes of construction, losing the touch for the most appropriate structure.

In Hooke Park, since its beginnings, appropriate structural systems have been the core of the park’s building research. Thirty years ago, the waste of the forest - thinnings - generated a revolutionary set of buildings, launching a discussion on covering structural needs in conjunction to the surrounding resources. Through the process of the Student Lodge 3 project and the anecdotal relation of the team

and the engineers, we saw how the cohort developed a structure based initially on intuition and then adapted it gradually in order to satisfy the structural requirements.

Using the examples of Hooke park as a paradigm, we can see a strong relation of the structure with locality, expressed in the low grade timber of the forest. In the last forty years, locality has been the core of an approach to architecture called critical regionalism. Some architects around the world, characterized as regionalists, have tried to find a way of adapting their design methodology in order for their buildings to be consistent with the area in which they built. The majority of them, though, focused on the visual and programmatic aspect of the building, relying on international structural systems to support their edifices.

On the contrary, we saw how the building process of Hassan Fathy, a product of necessity due to lack of materials, and the approach of Hooke Park based on a tight budget and locally available materials can generate a different approach to regionalism that focuses primarily on how the building is supported and secondly on how it looks. Structural systems that rely on locally available materials and technical knowledge are embedded in the culture and collective identity of a specific place. The majority of an architect's clientele doesn't need complex structures. People need buildings that they will understand, that will provide the necessary feeling of safety that will be affordable and easy to maintain with the locally available labour.

The connection of structural system and locality generates a methodology that is based on six basic points: needs, common practice, local materials, local knowledge, development of systems, and, restraints.

The above presented approach to regionalism does not see locality in a romantic or authentic way. The locally long-tested schemes, individual to each place, cannot be considered a picturesque but a set of systems that can improve the senses of economy, longevity and versatility.

In our world that faces today a crisis of the architect there needs to be a reconciliation of the architect with local, long lasting schemes and techniques in order, firstly, to produce a more influential and integrated architecture and, secondly, advance forgotten techniques that can be used locally and generate more competitive buildings.

A comprehensive approach to the protection of Dougga Tunisia

Archaeological heritage is part of the national identity of Tunisia. Since 1994 Tunisia had voted a national Law related to Heritage.

To allow for the development of its heritage the Tunisia government had organize to reinforce its legal and institutional framework for the management of its heritage.

In this context, Dougga, one of the major heritage site in the Mediterranean basin was made a national archaeological park in 1994 and listed in 1997 on the UNESCO world heritage sites

"The archaeological site of Thugga/Dougga is located in the North-west region of Tunisia, perched on the summit of a hill at an altitude of 571 m, dominating the fertile valley of Oued Khalled. Before the Roman annexation of Numidia, Thugga had existed for more than six centuries and was, probably, the first capital of the Numidian kingdom. It flourished under Roman rule but declined during the Byzantine and Islamic periods. The impressive ruins which are visible today give an idea of the resources of a Romanised Numidian town.

The archaeological site covers an area of approximately 75 ha. These ruins of a complete city with all its components are a testimony to more than 17 centuries of history. They are an outstanding example illustrating the synthesis between different cultures: Numidian, Punic, Hellenistic, and Roman."¹

After a competition run in conjunction between Tunisia and France, our team² was selected to conduct the study for the development of the Protection and Enhancement Plan (PPMV) for the site, as defined by the Heritage Code of UNESCO.

Following a detailed study including all the parameters, which constitute the historical, geographical, landscape and legal environment³ of the site in its context, we proposed a Protection and Enhancement Plan and an Action Plan.

I propose to present the following aspect of our work:

1. The archeological park, the general rules for its protection and enhancement with their legal implications.

This part will describe the various services that can be used within the adjacent areas. It will also note the areas where new "craft and tourist area" could be developed with proper relationship with the archaeological park. The pedestrian path around the park and the equestrian possible promenade leading to the park surroundings were also investigated.

The archaeological park itself was subdivided in areas corresponding to various level of heritage status:

¹ From the UNESCO description of the site

² Our team was made of Amira Noura, Pascal Prunet, Marc Baraness, Ruth Cawker, Sophie Besson, Sana Ben Achour, Co-Managing, Christiane Garnero Morena, Jean Luc massy, et Simone Ricca. The client was the Tunisia National Heritage Institute

The study was made between 2007 and 2009

³ Only a few of the topics are noted in this abstract

Heritage area for archaeological investigation and research (these were principally areas, which had not yet been investigated).

Heritage area for archaeological delicate investigation; these were areas where significant fragments of the city had been found, which had also been described epigraphically

The rest of the park was subdivided in relationship to: the state of the ruins; their importance in the hierarchy of the city and the Roman society; their position within the possible promenades within the site; their potential use for contemporary events. An area for visitor centre was defined with a potential bus parking and tourist amenities.

2. The proposal for the management of the archaeological park

An overall organisational chart was developed with its staffing. All staff positions were described to allow for a direct staff search. All the existing staff on site had been interviewed and most of them were repositioned within the chart. Of course additional management positions were to be created and staffed.

A second layer of staff management was even proposed in case of high development of the park activity.

3. The proposed visitors paths and signage

Sets of promenade within the archaeological park and its context were proposed. The started with the approach arrived at the interpretation centre, crossed the formal gate, linger on the promontory edge, enabling the visitor to comprehend the importance of the context of the site, move into the heart of the city and to the theatre itself open on the overall landscape and closed on the "souvenir" gift shop.

This was the "minimal" promenade, which could be enhanced with three other thematic paths crossing heritage areas further from the centre of the archaeological park.

A detailed signage system was developed respecting the ruins. Each sign position was carefully studied to ensure appropriate relationship to the heritage and the context.

A specific promenade was developed for physically challenged visitors.

4. The proposed security principles for the buildings and the site

Area and system of temporary shelter from the sun were designed.

Each part of the physical quality of the site were inventoried and classified in respect to their security for visitors. Principles for securing each part of the site were investigated, drawn and illustrated in detail. They range from displacement of blocks to three types of handrails, protecting fences and enclosed areas.

Methods of constructions were proposed to ensure total respect of the heritage nature of the site.

5. The proposed landscape plantation and management plan

Three levels of landscape refurbishment and development were proposed.

6. The proposed functioning program

Two phases of creation and development of the archaeological park were proposed.

The first one secured the park itself and legally preserved the surroundings. It also offered minor transformations within the park allowing the visitors to have more appropriate amenities.

It put in place the various promenades and dealt with the security measures that were the most significant.

The second proposed to bring the archaeological park to an appropriate UNESCO standard with all the services and amenities for such a heritage site.

Although this program was cultural under the umbrella of the UNESCO co funded by the Tunisian and French governments, it got lost in the "Arabian spring".

After the last presentation at the director level in the presence of the highest French client representative, some team members have tried to get the project implemented unfortunately without success.

A comprehensive approach to the protection of Dougga Tunisia

Archaeological heritage is part of the national identity of Tunisia. Since 1994 Tunisia had voted a national Law related to Heritage.

To allow for the development of its heritage the Tunisia government had organized to reinforce its legal and institutional framework for the management of its heritage.

A first attempt to ensure protection of its heritage was made around the site of Carthage. In light of various interest and political pressure this attempt did not succeed.

In this context, Dougga, one of the major heritage site in the Mediterranean basin was made a national archaeological park in 1994 and listed in 1997 on the UNESCO world heritage sites.

“The archaeological site of Thugga/Dougga is located in the North-west region of Tunisia, perched on the summit of a hill at an altitude of 571 m, dominating the fertile valley of Oued Khalled. Before the Roman annexation of Numidia, Thugga had existed for more than six centuries and was, probably, the first capital of the Numidian kingdom. It flourished under Roman rule but declined during the Byzantine and Islamic periods. The impressive ruins which are visible today give an idea of the resources of a Romanised Numidian town. See Figure 1

The archaeological site covers an area of approximately 75 ha. These ruins of a complete city with all its components are a testimony to more than 17 centuries of history. They are an outstanding example illustrating the synthesis between different cultures: Numidian, Punic, Hellenistic, and Roman.”¹

After a competition run in conjunction between Tunisia and France, our team² was selected to conduct the study for the development of the Protection and Enhancement Plan (PPMV) for the site, as defined by the Heritage Code of UNESCO.

The team necessary to respond to all the parameters are very large, complex and made of extremely qualified people. However the coordination is a very difficult and subtle task, which in the case of this project was even more delicate. We had two governments who did not really have the same objectives, and the temporary head of the project, although a very learned scholar on her specific subject (epigraphy) was not a very astute manager.

The study of the area with all its historical, geographical, landscape and environmental parameters in its context could be considered as rather straightforward. The understanding of the political dimension of the legal framework was a more delicate parameter, we wanted to put in place a framework that would protect Dougga, that would include potential plan of action respectful of its heritage, but we wanted to ensure that it would not be dismissed for political reason.

After too many presentations to various committees we proposed a Protection and Enhancement Plan and an Action Plan.

In this paper I will outline some of the most significant aspect of our work, detail two of them and conclude on the impact of the “Arab spring” on its implementation.

1 The archaeological park, the general rules for its protection and enhancement with their legal implications.

See Figure 2

The part of Dougga that was originally included in the proposed UNESCO park was of 62 hectares. The areas where we knew other significant archaeological ruins were at least 30 times larger. They included land used for local agricultural farming. But these lands were also the potential sites for tourist-centre, bus parking and other difficult facilities.³ And by the end of our studies parts of the context was also the site for some petroleum digging (luckily for Dougga this was not successful)

¹ From the UNESCO description of the site

² Our team was made of Amira Nour, Pascal Prunet, Marc Baraness, Ruth Cawker, Sophie Besson, Sana Ben Achour, Co-Managing, Christiane Garnero Morena, Jean Luc massy, et Simone Ricca. The client was the Tunisia National Heritage Institute
The study was made between 2007 and 2009

³ If tourism had originally a good impact on heritage sites, the large number of visitors has often now become a threat to heritage on this see CHOAY F. *L'allégorie du patrimoine*. Paris: Seuil, 1992.

We divided the 62 hectares archaeological park in 4 areas corresponding to various level of heritage status:

- 1.1. Heritage areas for archaeological investigation and research (these were principally areas, which had not yet been investigated).
- 1.2. Heritage areas for archaeological delicate investigation; these were areas where significant fragment of the city had been found, which had also been described epigraphically
- 1.3. The rest of the park was subdivided in relationship to: the state of the ruins; their importance in the hierarchy of the city and the roman society; their position within the possible promenades within the site; their potential use for contemporary events.
- 1.4. An area was dedicated for a visitor centre with a potential bus parking and tourist amenities.

But we also provided protection for the immediate context

Indeed a very large context of almost 2 000 hectares was placed under “agricultural” bylaw. This designation placed all future developments under the approval of a regional committee (This committee was large and varied to protect it from political interferences). Within this large land we designated

- 1.5. Areas for local arts and craft display and sale;
- 1.6. Areas for small tourist housing with strict design rules;
- 1.7. And 4 pedestrian or equestrian paths.

We hoped that the effect of creating “promenades” by foot or by donkeys or horses in the larger surrounding of the park, will establish the site at large as a heritage site.

2. The proposal for the management of the archaeological park

One part of our team conducted a rigorous questionnaire with all staff present on site. From our experience on such archaeological park of this nature, we proposed a chart for the structure of the park in this final stage (with its expected full potential). We also propose a transitional structure that would allocate all the existing staff within the overall organisation.

The acceptance of the proposed administrative structure of the park was one of the most difficult part of our work. Researchers specialised in restoration of heritage items such as mosaics, are often not the best in management structure. We had many sessions to explain where we started from, what were the parameters we included and why, in light of their demands and our knowledge, we proposed such a management structure.

We also gave a job description for all the position existing or created so that it would be very simple to put in place. Our expert in this domain Jean Luc Massy who has had a senior position in the French archaeological administration and who knew very well the Tunisian context had extreme difficulties in getting this part of the work understood. Two of us had to literally do detailed presentation of every step of our thinking process to enable the guiding committee to accept and appropriate the proposed management organisational structure.

3. The proposed visitors paths and signage

From the beginning of our encounter with the site of Dougga we were moved by its magical beauty. Imagine an almost complete roman ruined town, where the limits are fields moving in the wind, where the horizon are clear but distant low mountains on the other side of the plain, where the light is clear as there are almost no pollution, where the wind is the only music that whispers at the rhythm of your steps on the roman large paving.

At night the stars and the moon gave Dougga another atmosphere which had to be respected and revealed.

But the keepers of the site were interested in music, in artificial lights, they had seen too many sound and light in places like Versailles. They might have even liked a “Dougga Disneyland”

So our first task was to reveal to them the intrinsic significance and beauty of Dougga. Walks through the site where we stopped and listen to the wind, promenades around the site to feel its presence in

the landscape were some of the exercises we had to go through to raise the consciousness of what they were the keeper of.

It seems that starting from the world as it is with a fine understanding of its qualities is often difficult as we all arrive with our baggage.

Following this raising of consciousness phase, we proposed sets of promenade within the archaeological park and its context.

3.1. The arrival from the adjacent town of Tébour Souk with a road that would need minor modification allowed an understanding of the large landscape and after a curve offered a view of the cliff reason for the site of Dougga in the first instance as a high point dominating the plain. At that point, on the right, the silhouette of the cliff surmounted by columns of the temple of Saturn, is cut on the lipid blue sky. On the right a first fountain tells how on the side on the nourishing plain, the cliff and the promontory offer view and protection while the numerous sources have allowed human establishment.

See figure 3

3.2. At the interpretation centre models, didactic documents give the keys to a better understanding of some of the elements that the visitors will encounter during their promenade.

3.3. Crossing the formal gate the view is directed towards the mausoleum with fields in the background.

3.4. The path on roman roads linger on promontory edges, enabling the visitor to comprehend the importance of the context of the site. The first houses and their gardens can be visited.

See figure 4

3.5. The roads lead the visitor into the monumental heart of the antique city. Majestic ruins that face the landscape surround him. Traces of the various cultures that have occupied the site are present: a forum, a bath, a roman temple, a mosque.

3.6. A curve to the North-West part of the centre get the visitor closer to the cliff and lead him to the top of the theatre. There he discovers the perspective that opens from the theatre to the landscape. Nature and culture, which are so present here, can again be seen in a new light.

See Figure 5

3.7. The visitor is back at the "souvenir" gift shop.

This described the basic promenade through the centre of the Archæological Park. This promenade could be enhanced with three other thematic paths meandering through further heritage areas, each could be related to a more specific theme.

To guide the visitor, with respect of the ruins we developed a detailed signage system. It included directional signs See figure 6. It proposed interpretation panels, and referential panels. On figure 7 one can see an illustration of one of the proposed entrance sign, which use stone found on site as well as a large copper plate that could be worked in the adjacent town, while the panel itself would have to be done away from the site. It was not possible to find anyone able to engrave illustration on metal or stone.

Each sign position was carefully studied to ensure appropriate relationship to the heritage and the context.

A specific promenade was developed for physically challenged visitors.

4. The proposed security principles for the buildings and the site

As a first level of amenity we designed a system of temporary shelter from the sun. They were inspired by local tents that are used by the sheep keeper as shelter from the sun.

Each part of the physical quality of the site were inventoried and classified in respect to their security for visitors. Principles for securing each part of the site were investigated, drawn and illustrated in detail with relationship to their hierarchy on site.

See figure 8, 9 and 10

They range from displacement of blocks to three types of handrails, protecting fences and enclosed areas.

Methods of constructions were proposed to ensure total respect of the heritage nature of the site. All of these were illustrated with details and photomontages
See figure 11

5. The proposed landscape plantation and management plan

Three levels of landscape refurbishment and development were proposed.

The surrounding landscape of Dougga is also its *raison d'être*. It was molded at the numidian period around the agriculture of cereals. Today the plain is still a very viable economical area with good healthy farming the preservation of these lands as agriculture was paramount and was suggested in the immediate surrounding of the archaeological park.

The other significant landscape elements are the olive trees, which are numerous directly around the site. They constitute a splendid frame to the park and we have requested their preservation.

See figure 12

Beyond these are of preservation we suggested the rehabilitation of roman garden as part of the restoration of the major houses.

6. The proposed functioning program

To ensure an appropriate transition from the “raw” state to its final archaeological park in line with UNESCO guidelines we propose two phases of creation and development.

6.1 The first one secured the park itself and legally preserved the surroundings. It also offered minor transformations within the park allowing the visitors to have more appropriate amenities. Those mentioned earlier for sun shelter.

It put in place the basic elements of the signage system and secured the major parts of the ruins. This would allow for the main promenade to be safely open to the large public with appropriate amenities and explanations. We also recommended a subtle promotion of the archaeological park, to ensure that it would be appropriately included in the interested visitors trip to centre Tunisia.

6.2 The second one proposed to bring the archaeological park to an appropriate UNESCO standard with all the services and amenities for such a heritage site.

This project was based on cultural understanding of the site under the umbrella of the UNESCO co funded by the Tunisian and French governments. The French government had allotted funds to put in place some of the security elements and some of the signage. Many “final” presentations were made to the Tunisian authorities in presence of the highest French representatives. However although they had follow step by step the whole process and had approved and often complimented us on the work the Tunisian members of the guiding committee could never decide to move to the implementation phase. After many months of frustration, the French government did not want to have funds marked for a project that did not seem to progress. In 2010 the “Arabian spring” gave a definite brake to the implementation of the project

After the last presentation at the director level in the presence of the highest French client representative, some team members have tried to get the project implemented unfortunately without success.

The importance of anthropological analysis in the comprehension of the cultural heritage. The study case of Rocca di Cambio (AQ).

Valeria Amoretti,¹

⁽¹⁾ Dipartimento di Architettura e Disegno Industriale Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Aversa, Italy
valeamoretti@gmail.com

Abstract

This intervention wants to highlight the importance of the anthropological analysis in the field of archeological work, through the specific case of the study of a medieval cemetery, excavated in the years 2008-2011 in Rocca di Cambio (Abruzzo, AQ) by L'Aquila University-Chair of Medieval Archeology, director Prof. Fabio Redi.

The cemetery, that is opposite the Santa Lucia Church, was placed exactly above the leveled walls of a previous building, probably a Monastery related to the control of transhumance in the Appennini mountainous land.

The archeological excavations discovered 33 burials that date to the middle of the XIII century to the middle of the XIV century; the grave goods, consisting of metallic object and jewels of good quality, are the statement of a good social position of the people buried. Also the anthropological analysis on human remains were concordant on this point. But anthropology was also able to recognize and identify some important pathologies – not so commonly found in archaeology – such as echinococcus, rheumatoid arthritis and brucellosis. It is possible that brucellosis, typical in human groups that fed on infected dairy products, was the triggering event for rheumatoid arthritis. The bacteria of the same morb was found in Herculaneum, not just in osteological reports, but also in contaminated remains of cheese.

Keywords: Archeology, Palaeopathology, Abruzzo, Brucellosis, Life Reconstruction

1. Introduction

Talking about archeological excavations, is really impressive to note that a great part of them is concerning ancient necropolis or cemeteries: approximately the half part of archeological excavations dig up human bones.

At this point, it is natural to point up that human remains are one of the commonest archeological material in the world. But, for the reason of their particular *status* of testimony of human body, bones were for a long time interred a second time, without the option to be studied like all the others archeological materials.

Actually, a good part of burials are dug up and studied by professional figures that have the specific task to understand ancient life from human remains from archeological contexts.

It is really important to introduce the fact that the osteological and taphonomic study of burials could really light up some important cultural and material facts.

One of the most important information we can have about ancient times could be extrapolated by bones: in fact physical anthropologists do not have just the assignment to determinate the individual data for every individual studied and his biological profile, but they could have a picture of the way of life and works in ancient times.

This is possible because bones are an extraordinary biological archive: in fact, a great parts of the facts that happens to human body are reflected on bones. In particular, a great part of the important stresses that happens in life have a direct consequence on skeletal and muscular system.

Muscles and ligaments have a really close connection with all the skeletal apparatus and their development is strictly mirrored in the signs that they might leave on bones.

So, one of the work of physical anthropologist is to record the development of all the MOS or Markers of Osteological Stress [1] and to construe ancient life from them.

Another way to reconstruct ancient behaviors and way of life is to conduct an accurate paleopathological analysis: in fact, a great number of pathologies are direct consequence of environment, climate, occupations and habits. There is a branch of medicine, called paleopathology, that is delegate to study development of illness through the ages.

Unfortunately, not all the diseases leave traces on bones, but just some of those: the ones that could damage the osseous substance. In the number of those disease there are some called zoonosis, from the fact that are produced by an interaction between man and animals, in particular some kind of cattle.

As things stand, we have to state as anthropological and paleopathological analysis are included in the best practices in archeology. The use of the knowledge descending from biology, medicine and history, crossed together, could be a great way to understand the results of a great number of excavations and to increase the research potentiality.

2. The study case of Santa Lucia in Rocca di Cambio (AQ)

In this writing we want to demonstrate the importance of good anthropological and palaeopathological analysis through the specific case of Santa Lucia in Rocca di Cambio (AQ).

Archeological excavation were directed by Prof. Fabio Redi, holding the chair of Medieval Archeology in L'Aquila University, in the mountainous area of Abruzzo, in the years 2008-2011 (with a stop in 2009 after the terrible earthquake who seriously damaged both L'Aquila and the small city of Rocca di Cambio).

The choice to start an excavation in the area just in the opposite of Santa Lucia Church – that is one of the most beautiful churches in L'Aquila landscape, by virtue of the beautiful frescos inside, dated XII-XIII century a.C. [2]– was taken after the unexpected discovery of some ancient walls in front of the façade of the church.

2.1 Introduction to archeological excavation results.

The burial periods were found directly on the dejected walls, no longer in use. The exact moment of the shutting down of the first monastery is still not certain, because of the fact that the work on stratigraphy and on the materials are still in progress.

But actually there were recognized three periods of burials, with a little time within them: all together, they seems to cover the time between the half of the thirteenth century and the half of the fourteenth.

Finally, in the site were found 33 burials, not so much to reflect the real mortality of the town: all were single graves, with the exception of burial number 31 and 32, double (male and female), and burial 27 and 28, where burial 28 removed part of burial 27 [3].

All the graves are canonically oriented West-East, and are characterized by a long ellipsoid pit with a remarkable depth; the considerable depth of the grave was interpreted by the archeological and anthropological team as a solution to protect the corpses from wild animals.

One of most characteristic data regarding this cemetery is the unusual wealth of grave goods, that were present in a great part of burials and were composed by jewels and clothes accessory, both functional and ornamental, signs of the good economic conditions of the people buried. [4]

2.2 Anthropological analysis

All the human remains were studied in the laboratory of LAMIA (Laboratorio di Archeologia Medievale, Informatica ed Antropologia pertaining to L'Aquila University – Chair of Medieval Archaeology), in range of a Research Fellowship titled "*For a paleobiological approach to knowledge of Medieval human groups from archeological excavations in Abruzzo area*"

All the bones were cleaned, restored and measured, instead to recognize the most important physical characteristics of the human group interred in front of Santa Lucia Abbey.

In this way it was possible establish that the buried human groups was composed by males and females individuals but - except burial number 30 - there was no presence of child. There was a good number of adolescents, in the quote of 15% of the total, but just from 10 to 17 years old. The interpretation of this fact was that maybe there was a specific cemetery for children in a not excavated area, probably near the adults one.

To confirm the good economic *status* of this population, the calculated mean age at death is 42,3 years for males (37,8 including *juvenes*) and 34,25 years for females (26,5 including *juvenes*), that is a good value in Medieval Abruzzo. The sex variability is explained by the fact that women are more vulnerable in front of some moments in life, like pregnancy and childbirth.

The most important results are extrapolated by the analysis of the muscle stress observed on bones: all the factors induced to consider this group as a group of rich farmers, because of a series of

stresses that were registered. In particular, the greater part of the female individuals of the group presented the evidence of ischiatic bursitis (75%), that is commonly considered as the results of long sitting on hard seat or stools [5]; there is also a good use of shoulder girdle, in an asymmetrical way that suggest the use of horizontal loom, in which one arm is used to guide the spool and the other – the left one – to move part of the instrument. The dental situation confirms this suggestion, because of the fact that on teeth were detected grooves dues to the passage of filaments, during the act of weaving [6].

Other interesting trace of working activities were found in the male individuals skeletons: were recognized a really important load of muscle and ligament work on shoulder girdle, heavier than in females and with a different distribution: in a great part of them there was also a form of inflammation in carpals and in correspondence to flexors muscles in association with a form of thumb arthrosis (45,4 %). It is credible that this kind of inflammation is to be related to the use of the shear scissors. Furthermore, some of them showed the evidence of trauma lesions probably dues to interpersonal violence (63,6% of the male adult skeletons).

2.3 Paleopathological analysis

The analysis of human skeletal remains were able to highlight some common diseases in population . Those illness seems to be not specific, but they could be important to create a differential diagnosis. A lot of little factors were talking about little diseases, especially inflammation, localized in some body regions more than others: in particular, the vertebrae and the joints of pelvic girdle, hands, legs and feet.

Moreover, there was an unusual trend in this population to an extraordinary lengthen of some blood vessel reflected in endocranial surfaces, and a strong persistence of endocranial anomalies as an abnormal presence of Pacchioni depressions and granulations (16,12%)

There were also a case of a so visible disease that the diagnosis is really credible – but the medical corfirmation with x-ray, DNA extractions and thin sections are actually still in progress -: in burial number 5 was visible, still during excavations, a great cist in the place of right lung. This ossified cyst was inside another bigger half-ossificated one, with the dimension of about 10 cm.

Fig. 1: Burial number 5: it is evident the double ossified cyst at the place of right lung.

The morphology and expecially the presence of a cyst inside another bigger one (daughter cyst) led to the diagnosis of hydatid cysts, that are due to echinococcosis, that is really a uncommon disease to find in paleopathology – the greater part of cysts do not ossify - , but there is another proven case from the same territory [7] [8].

Even now this pathology is considered sign of sheep farming and evaluated as a professional disease. The reason is the fact that in the life circle of the *Echinococcus Granulosus* needs a intermediate host (sheeps), and a definitive host (dogs); man is just an occasional host, and the infection is deriving by handling infected dogs. For this reasons this is a typical zoonosis, considered as sheep farmers disease.

Fig. 2: Burial number 5: particular of the double ossified hydatid cyst

Fig. 3: Burial number 29: Pedro Pon's sign, marker of Brucellosis, on 4rth lumbar vertebra.

As things stand, It was not so surprising to find another zoonosis, quite rare to find because the just one sign to detect it is a little lytic lesion on vertebrae (generally last thoracic or lumbar ones), called Pedro y Pons sign [9].

In Rocca di Cambio population there were 4 trusted cases (12,9 %) of this typical sign of brucellosis or Malta fever, that is an illness deriving from the consumption of milk and cheeses made from the milk of infected animals, primarily goats and sheep, infected with *Brucella melitensis*. It is rare but possible also transmission from human to human, through sexual contact from mother to child.

This percentage is really high, but it is intended to increase because of the fact that there are some cases of probable brucellosis, identified by a considerable loss of osseous substance in the abdominal part of vertebral bodies: this happens in particular in young individuals, in which the skeletal grow was not concluded, in one of them there was the coexistence of both the signs (Pedro y Pons and bone thinning): this was visible in other 4 cases. In Albania [10] it was identified a similar case in

morphology as certain brucellosis using DNA tests to search the pathogen. In some of those young adolescent individuals there were significative signs of infections in correspondence to the main articular joint of hips and legs, but also in hand and feet. It could be an unspecific independent illness. But in two cases it was associated to a typical in-cup deformity in proximal epiphysis of hands and feet, deriving specifically from juvenile reumathoid artrithys. This disease could derive from brucellosis, and may be a symptom for identification of a disease so difficult to discover.

Fig. 1: Burial number 6: typical in-cup deformity in proximal metatarsal epiphysis.

At the same time the Malta fever could case also acute or chronic meningitis, that could be the reason of the detected lengthen of blood endocranial vessels, in particular the ones referred to the middle meningeal artery. In this case, the brucellosis case could increase up to the 48,3% of the population buried in our area. The consequence of this fact is that brucellosis was an endemic disease, and maybe the most common one and the main cause of death in individuals aged 10-17 years. This would confirm both the implication in transhumance of those individuals and the possibility of supply of food resources in a rich high-proteic diet , that was accidentally the cause of those endemic infections.

3. Herculaneum site

The best palaeopathological results regarding zoonosis and brucellosis in particular were led regarding the site of Herculaneum, by virtue of the extraordinary degree of conservation of both the sites. In particular, in the last years of XX century, there was an extraordinary anthropological study led on the "Herculaneum fugitives".

For a long time the absence of human skeletal remains inside the Herculaneum city suggested the idea that the citizens were more lucky than the ones from Pompeii, and they could leave the city before the ruin arrived. But excavation conducted in 1984 discovered on Herculaneum beach the skeletons of more than 250 persons, victims of eruption that could not move out.

The anthropological analysis were conducted in 10 years and bone lesions throws light in life conditions in Roman period. There were reconstructed also the alimentary habits and the main diseases affecting the population.

One of the most common pathologies that were found was precisely brucellosis or Malta fever - in 17,4 % - of adults [11], as testimony of the consumption of contaminated food and the strict contact with animals that was so common in ancient life [12].

The test case of the presence of the *Brucella* was founded in a single carbonized cheese that was in a great state of preservation. The analysis led to the discovery of a variety of bacteria, included cocco-like forms. Those really seems to be morphologically compatible with *Brucella* [13] [14]. Unfortunately, it was not possible to proceed to a molecular analysis because the cheese was exposed to a too high temperatures to allow this kind of investigation.

Also the historical sources confirms the fact that in the roman diet of Herculaneum and Pompeii there was a prevalence of cheeses from sheep milk, confirming the fact that in the roman world it was really rare to use cow milk for dietary purpose.

All the truly roman cheese were made with sheep milk, and the cow milk ones were imported from Alpine area. It is really unconvincing the idea of a *brucella* contamination from sheep flesh, because of

the fact that romans used to slaughter old animals (more than three years old), and they cooked or boiled flesh before consuming [15].

The evidence of this kind of bacteria bring life to a great part of little known details of life in ancient world, and in particular in the area of Herculaneum and Pompeii.

4. Results

So we can understand why is so important to consider anthropological and paleopathological analysis as essential for the study and comprehension of ancient site.

The comparison between the roman sites from Campania and the medieval site of Rocca di Cambio highlight how much different were the condition of life compared to present time: pathologies that now are really rare were diffused in all the population. In the specific case of Santa Lucia, the illness was the direct consequence of a relative prosperity, and helps to understand that also the high social classes suffered of now forgotten pathologies.

On the other hand the extraordinary case of Herculaneum, the first one in which the presence of *Brucella* bacteria were detected in food, was the start point to investigate on this epidemic so hard to detect, that could be unnoticed.

An accurate analysis of skeletons from archeological origin could be one of them in heritage practice to carry out in archeological excavations: there is no management or conservation without knowledge.

Traditional building technique of military architecture in Veracruz, Mexico and Cartagena de Indias, Colombia for conservation

Dr. Dolores Pineda Campos

Instituto de Antropología, Universidad Veracruzana, Xalapa, Veracruz, México

E-mail: dpineda@uv.mx : tlasolteolt1@hotmail.com

Abstract

Military architecture is a cultural heritage that emerged and developed between the sixteenth and nineteenth centuries, with economic - commercial purpose, in a place that was known as the New World. The fortifications had the role of ensuring the stability of colonial trade and protect malls port smuggling, privateering and piracy, which is exercised through the sea.

During this period many fortifications, military representative of classical modern architecture were built. Permanent bastioned fortresses were the most relevant. Their building codes reflect the principles of the Italian Renaissance, dominating the ideal of perfection, the perfect and shapely traces, geometric, harmonic, balanced, monumental and functional.

These forts functioned as main bastions of cities , which are communicated interact with other complementary works as military strongholds , coastal batteries and campaign platforms , towers , ramparts , trenches and magazines , establishing a maritime defense system and campaign .

This culminated in military device walls of earth and sea, which became commercial cities in solid strongholds.

In this paper the original technique for processing old for the conservation and restoration of the fortifications of San Juan de Ulúa in Veracruz, Mexico and San Fernando de Bocachica in Cartagena de Indias, Colombia supplies were investigated. The analysis of the materials used in its construction, has the purpose to determine its composition. Considering the problems presented landmarks , just point out the results of the analyzes carried out by the analytical techniques of X-ray diffraction and scanning electron microscopy , experienced the stone material used in construction , give us important information propose specific treatments for preservation.

Keywords: Restoration, Conservation, Architecture, Fortifications, materials.

1. Introduction

Scientific studies currently occupy an important role in the field of conservation and restoration of cultural heritage historic role. The monuments of military architecture of defense, built with coral stone, so far not been studied scientifically in order to achieve good conservation and restoration. This research tries to solve the problems presented building materials from the Fortress of San Juan de Ulúa in Veracruz, México and Fort San Fernando de Bocachica, in Cartagena de Indias, Colombia, considered as one of the most important fortifications of México, Colombia and the Caribbean, as well as the most renowned throughout the history of the Americas.

The analytical study of the materials used in construction, has the purpose to determine its processing technique and state of disrepair.

Referencing the problems presented landmarks and the results of the analyzes carried out by the analytical techniques of X-ray diffraction and scanning electron microscopy performed on stone materials used in construction , a treatment for preservation and restoration is proposed.

2. Historical Background

2.1 Fortress of San Juan de Ulúa, Veracruz, México

The fortress of San Juan de Ulúa is one of the most important and renowned throughout the history of the Americas. It is a colonial fortification that still exists in the Caribbean route, where many important events took place. It was built on an island off the port of Veracruz, is the only official port of the Viceroyalty of New Spain, and has been linked to the lives of our people very significantly, not only in the historical aspect but also in the economic and cultural. The place where the fortress was built was the initial starting point for the conquest of the American Continent, from the start of construction of the tower and the wall of the Rings where the loading and unloading of the Spanish fleet was made from XVI century, became the key link in the system of ports and defenses of trade and navigation.

San Juan de Ulúa, Veracruz is a commercial port on the Gulf of México with transcendent and certain historical and cultural characteristics. Here he made his entrance Hernán Cortés and his men in 1519, when the founding of Veracruz is commemorated. This place, then inhospitable and surrounded by a blanket of reefs, was not a suitable site for the conqueror of the Aztec empire, which, after a few days, he moved a few miles further north and settled in the coast in the Quiahuixtlan area, in a place called the Villa Rica de la Veracruz. In 1525, they move a little further south, along the river Huitzilapan, place known as La Antigua, until finally returning to the Sales Buitrón near its original settlement in 1600.

Meanwhile, during the sixteenth century, the island of San Juan de Ulúa, did not lose any time function and port must scale commercial fleet, because the surrounding coasts of Veracruz, riddled with reefs precluded parking ships. For these reasons, the historical significance of the fort that was built on the islet of San Juan de Ulúa is founded to have the dual function of defense and commercial port. Furthermore, because San Juan de Ulúa was the door European immigration in México, the only official port to enter the country, instead of crossing the inter-oceanic navigation between Europe, Asia and Africa, the key trade the Viceroyalty of New Spain and the first bastion of defense of Mexico.

Here the mineral wealth which was looted in Mexico, such as gold and silver, precious stones, richly decorated sumptuous objects deposited. In the port of Acapulco came as species other rich goods, silks and other sophisticated shipments from the Philippines and the Far East.

If there is a fortified work of the Mexican nation that symbolizes the Spanish colonial history and respond to the principles governing the American military architecture, is the castle of San Juan de Ulúa, name adopted by the island where he was raised. How much historical and cartographic wealth bequeathed to the country that dynamic relationship Veracruz -San Juan de Ulúa site intercontinental transit trade.

The castle of San Juan de Ulúa has all the attributes that identify the classic modern fortifications that arise from the sixteenth century. Its trace bastioned is one of its great aesthetic, where the elegance of its lines, shapes and structure predominates. Represent the permanent fortification bastion that was expression in stage reached the apogee of Italian Renaissance scientific level, which dominated the balanced composition, provided modern and functional defensive elements. Its geometric design consists of an irregular rectangle, each element, like curtains, are in proportion with its bastions and all are organically prepared to defend against pirates, pirates and smugglers who came to the city of Veracruz and the islet of San Juan de Ulúa.

This castle represents the complex constructive evolution of Spanish military architecture whose development responded to the scientific and technical artillery and military strategy developments. The Old Tower, with the Wall of Hoops, where moored boats coming into port and ground with the gentleman at the other end, are an image of the XVI century. These first defensive structures are promoted by the Viceroy Antonio de Mendoza, by General Cristobal de Eraso and finally Bautista Antonelli, an Italian military engineer, creator of the first defense system in the region. Later these works are replaced by a curtain and the defenses of San Pedro and San Crispino, with two towers crowning each of these defenses, buildings that are conducted between the XVII and XVIII century. There are still vestiges of the old tower and wall of the Rings embedded within the bastion of San Pedro.

In the seventeenth century the building Ulúa curtains and bastions mean is closed, rectangular adopting it still retains. In this long period the figures of military engineers and Jaime Adrian Boot Franck, together with the works of Ulúa, performed works and projects in the city of Veracruz. In the following century was expanded in stages, undergoing a process of modernization. The bastions means located at the four corners are replaced by the above defenses of San Pedro, San Crispin, Santiago and Soledad. In the second half of the eighteenth century the gap widens and double revellin of San Jose and the two lateral lunettes called Santa Caterina and Our Lady of Pilar and glacis standing. These works are due to other prestigious military engineers in America as Augustine Crame, Felix Prosperi, Manuel de Santiesteban and Miguel del Corral.

Even batteries are being built in the area barbeta glacis appearing as a witness in a plane National Corps dated 1850.

Ulúa works required a high level of expertise : military engineer, was gradually modernized the fort along with its drainage system, so important to supply a good complement of officers and soldiers of a

long siege and to protect the building moisture, the master mason, styled Mucara and coral stone, " taken from the reefs of the Veracruz coast, island of Sacrifices and other nearby locations," to lift the solid walls of the fortress and the works of advanced through the ashlar construction system, the carpenter, who ran with his manual dexterity huge Spanish bill gates , the drawbridges and fixed bridges, important from the practical and tactical point of view to defend the approaches to the fort, the blacksmith, who worked heavy wrought iron balustrades openings in the vaults, where they used to be placed bunkers, cells, stores of food, supplies and ammunition , troop dormitories, officers, and rakes, which protected the over the side entrances, the mason, whose expertise in the preparation of materials of construction, solidly up the walls, which are the fundamental obstacles to defend a fortress besieged and attacked by the enemy.

Along with this variety of master craftsmen, a heterogeneous workforce consisted of slaves, wage laborers, prisoners of war and civilians of different nationalities and social strata and free blacks or slaves adds.

The castle of San Juan de Ulúa was the backbone of a defensive big project. What's coastline north had placed strong house built by Cortés in Villa Rica, a battery in La Antigua, south, other batteries Island Sacrifices, Mocambo, Anton Lizardo and Alvarado. Another system was projected to the campaign, called Caminos Reales: from Ulúa and Veracruz, journeyed all goods coming and going to the City of México. These originally prehispanic roads were designed with sales, inns and fortifications for the protection of this lane.

In the nineteenth century the castle and barrack adopts a repressive character with independence struggles and foreign invasions. In 1810 Mexico achieved its independence. In 1838, during "the Pastry War", there are clashes with French troops, in 1846 against U.S. intervention and between 1861 and 1862, faced again with the Spanish, French and English troops.

During the nineteenth century , precisely in 1858, President Benito Juarez , takes refuge in Ulúa and established his government for three years and in 1864 landed at Ulúa Maximilian of Habsburg and his wife to act as Emperor of México on behalf of Napoleon III of France.

The twentieth century it became is symbol of national identity. In 1915, Venustiano Carranza, president, presidio function eliminates the Ulúa fortress there and set the presidential residence and the following year was delivered to the Ministry of War and Navy and becomes the National Arsenal.

In 1961 he recognized their historical and cultural character and declares Colonial Historic Monument by Presidential Decree and is given to the National Institute of Anthropology and History for safekeeping. In 1994 the Special Support Fund for San Juan de Ulúa comprehensive rescue of this monumental work is created.

Port activities developed from the early twentieth century have distorted the essence of the property because they have absorbed the castle. That historic image of Veracruz -San Juan de Ulúa (See photo 1 and 2) has been replaced in the last century by a movement of huge cargo ships, the city has gained ground towards the sea and the island joins the city by a stone tab. Huge areas are occupied by cranes and countless containers. Degradation and pollution are threatening to place a monument to which the first conquerors arrived and where the end of the rule of Spain in the Mexican territory was defined. This is a heritage that brings the story of a colonial system and constructive language conveys a representative of an era, of a nation and of a vast region.

2.2 Fort San Fernando de Bocachica, Cartagena de Indias, Colombia

The complex Cartagena Bay allows a peculiar defense system input channels Bocagrande the anchorage and the small inner bay, from 1642, to close the first channel, came into operation on Bocachica. Bocagrande input is protected with strong Matthias (1587), a square, and the platform Santángel (1617), the anchorage with the strengths of Santa Cruz (1610), also a square plan, and of Manzanillo and Manga (1631), the channel Bocachica fights with St. Louis (1647) and the campaign is protected with the Castle of San Felipe de Barajas (1656).

In Cartagena de Indias stands the castle of San Felipe de Barajas (XVII) of triangular plan , the restoration project is developed by Augustine Crame , engineer takes hard work during this period in the Caribbean: the castle is reinforced by multiple batteries side , pockets a hornabeque and a large underground mine and countermine system . The batteries in Cartagena are substantial: in Tierra Bomba the rise of Santiago, San Felipe and Chamba, on the side Bocachica Bay, the San Fernando (1753), San Jose and Santa Barbara and the Cerro del Horno, the San Rafael Angel. The Half Moon Battery (1730), the San Antonio revellín (1754) and San Sebastián del Pastelillo (1778) are the key works that complement the great defensive system; including highlights Arevalo hits late XVIII.

The role of the Fort as a cornerstone in the defense strategy of the Bay of Cartagena is the second half of the eighteenth century; its constructive evolution and other technical aspects are within the historical context of Cartagena.

The Viceroy Don José Pizarro director's custom engineers Juan Bautista and Evan Mac Don Ignacio Chamber, made the defense plan for Bocachica, inspected the canal banks and the two engineers in the company of Viceroy.

In its draft Mac Evan proposes to build battery Bocachica San Jose in a neighboring Baru Island and Fort of San Fernando on the beach Tierrabomba Strait island, about three hundred meters southeast of the old San Luis . Gov. Chamber accepts the idea of San José but as a combination of strong - bay, using the fort itself the remains of the fortification built by Juan de Herrera and Sotomayor thirty-five years ago and devastated by Vernon. There proposes artillery vaults and the gunpowder store for booking the adjoining island platform at the water for twenty guns.

The radical differences in the two engineers are presented in terms of the function and location of San Fernando. Mac Evan proposes a strong pass over the channel cross ring with San Jose from the vaults of a semicircular shade and protection for the front of the land of two mighty bastions, a moat and countermine gallery . This land expected reinforcement prevent San Fernando was rendered by troops landed in Tierrabomba, as had happened twice its predecessor the San Luis.

The governor is opposed to this project and its proposed San Fernando (name paying homage to both engineers reigning monarch Fernando VI) on top of the hills behind the village Bocachica. According to him, Evan Mac site was unhealthy and weak and exposed to strong ground attack and to be disarmed by an intense naval bombardment. The channel is able to defend with San Jose and Santa Barbara. You're San Fernando on the hills and out of reach of enemy ships was the complement to prevent the landing and occupation of the West Tierrabomba beaches, where British and French had set up camps of the importance of defense.

The Board of Fortifications and Defense of India dismissed the objections of the governor and Board in July 1752 ordered the construction of San Fernando along line of Mac Evan who could not enjoy this victory. He had died in April 1751 according to some anger and spite by humiliations.

As for the governor, the Viceroy not forgive delays that for almost two years (1749 -51) resists definitive to submit his defense plan Bocachca orders. It's up to begin construction of the Project was criticized, but has at the same time his resignation. A few months later he was appointed successor to time to inform you that "his Majesty very pleased with the zeal and love which your Excellency has served".

The fort of San Fernando in 1759 finish what Don Antonio de Arevalo, but with significant changes proposed by the new chief engineer Don Lorenzo Solis , partly to correct their weakness from the ground by the domination of the neighboring hills , the height was increased curtains and bastions. Arévalo complete works later adding two side booster batteries: Santiago to erase the northern glacis and San Juan Francisco de Regis, recently reconstructed from witnesses found.

The time came to do justice to confirm the correctness of the concepts of Don Ignacio Sala.

Strong Bocachica remain intact and survive as sentinels of the past and monuments to the military engineers who dedicated their lives to the defense of the empire (See photo 3 and 4).

3. Materials

3.1 Coral Stone San Juan de Ulua

Once the representative samples of coral stones as part of the construction of the fortress of San Juan de Ulua (foundation and architectural structure) and which will be used for restoration, coral species are *Colpophyllia natans* (photo 5), *Porites asteoides* (photo 6), *Montastrea annularis* (photo 7), *Siderastrea radians* (photo 8), *Montastrea cavernosa* (photo 9), and *Diploria* sp. (photo 10).

Photo 5: *Colpophyllia natans*

Photo 6: *Porites asteoides*

Photo 7: *Montastrea Annularis*

Photo 8: *Siderastrea radians*

Photo 9: *Montastrea cavernosa*

Photo 10: *Diploria* sp

3.2 Coral Stone San Fernando

The samples were taken in the walls of the fort where we observe similarity with some species of San Juan de Ulua as: *Porites asteroides* (photo 11), *Diploria* sp (photo 12) *Montastrea annularis* (photo 13)

Photo 11: *Porites asteroides*

Photo 12: *Diploria* sp

Photo 13: *Montastrea annularis*

4. Methods

The methodology for the analytical study of building materials (limestone, mortar and flattened) Memorial, was the analysis by X-ray diffraction, scanning electron microscopy. The study of scanning electron microscopy (SEM), also allowed us to ratify the results of the mineralogical characterization, observe the three-dimensional microtexture of corals, as well as the morphology of the constituent mineral phases, the structure of the porous system, precise chemical composition in different parts of the samples, and their transformations in the process of alteration. The corals were observed at different magnifications from 5,000 x, 2.000x, 1000x, 500x, 200x, 50x and 20x.

In the photo 14, image taken at 2,000 magnification, where we can observe the calcite crystals and skeletons of marine organisms within the coral.

Photo 14: Coral *Colpophyllia natans*, observed in scanning electron microscope (San Juan de Ulua, Mexico)

Fig 1: DRX coral species *Colpophyllia natans* (San Juan de Ulua, Mexico)

Photo 14: Coral *Colpophyllia natans*, observed in scanning electron microscope (San Fernando de Bocachica, Colombia)

Fig. 2: DRX coral species *Colpophyllia natans* (San Fernando de Bocachica, Colombia)

In the test carried out by the technique of X-ray diffraction, it was observed that corals are mainly formed of crystals of Aragonite and Calcite and mixture thereof.

In Figure 1 and 2. We note one practiced by XRD spectra of the sample of coral *Colpophyllia natans* analysis consists of Aragonite.

5. Results and discussion

In mortars with which Muca stones stuck it can be observed that are composed of lime, sand and conchiferous materials (pieces of soft coral shells, etc.) Or is calcite, aragonite and quartz. The percentage of calcite and aragonite is smaller than that of quartz. As for their planed or coatings are composed of lime, sand and shelly material (pieces of soft coral shells, etc., which were ground to achieve a fine texture to apply), or aragonite calcite and quartz. The percentage of calcite and aragonite is greater than that of quartz.

Regarding the study of Scanning Electron Microscopy (SEM) , also allowed us to ratify the results of the mineralogical characterization, observe the three-dimensional microtexture coral stone mortars and coatings, as well as the morphology of the mineral phases constituents, the structure of the porous system, timely chemical composition in different parts of the samples, and their transformations in the process of alteration.

In the spectra of X-ray microanalysis, we saw his spot composition, in this case the presence of calcium carbonate coral and mortar or coating flattened and noting also the presence of silica in the sand of the sea

6. Conclusions

Regarding conditions observe corals, which are part of the foundation of the buildings even though degradations suffered by water pollution are less impaired, and those who are part of the walls have greater impairment San Juan de Ulua, in San Fernando are in better condition because the species is more prevalent coral *Porites Corpophyllia natan asteoides* that according to the analyzes performed and the results obtained are able to investigate the manufacturing technique and based on the above the results we were able to prepare a mortar coatings to recover lost time and avoid the coral suffer further degradation.

Abstract

The re-use of a historical building is a challenge that an architect has to deal with a respectful and non-invasive way. Leave a monument unused means let him die; on the contrary, ensure it a new functionality means ensure it a new life. The flow through the ancient walls a modern lifeblood.

Today we try to achieve with minimal intervention, the best results for the historical buildings.

This is done to preserve the identity of the building: the deed must ensure some degree of reversibility and variations to the theme.

Writer Calvino proposes as solutions to "the hell where we live every day, that we form by being together" two ways to not suffer from this: "The first is easy to most of the people: accept the hell and become part of it to the point no longer see it. The second is unsafe and requires attention and continuous learning: endeavor to recognize who and what in to the hell, is not hell, and making it last and giving it space".

Today's solutions to "preserve" actualizing the historical and architectural heritage are minimal intervention, sustainability, modern reinterpretation of the old technology, enjoyment that is the lifeblood of any space, and finally maintenance.

The trend is therefore, as Calvino wrote, to "groped to give an order to the chaos of reality."

Projects that would like to introduce at this Conference are the new UNICEF Headquarters in Italy which will be hosted by the "Hospital of the Innocents" in Florence and another one in Bari, Apulia, a proposal for the reconversion of a building of 1844 into an Art and Crafts Museum.

Keywords: Restoration, Conservation, Protection, Technology, Sustainability

1. Introduction to the subjects of the conference

The idea of this group of research and planning for the conservation and enhancement of a historic building aims to guarantee him a life every day. We often tend to transform the historical buildings in cultural containers, but just as often it means giving life only for the first year or only in case of special events. We should instead try to bring together a constant function and usable every day with different cultural events, temporary or not.

The re-use of a historic building is an issue that an architect has to deal with in a respectful and non-invasive way. Leave a monument unused means let him die, and grant him a new feature means grant him a new life.

Today we try to obtain, with minimal intervention, the best result in the historical built environment. This is in order to safeguard the identity of the building itself: the intervention must ensure some degree of reversibility and variations to the theme over time to adapt to changing needs.

Heritage management is today a very complex operation because Italy is a place full of historic buildings and archaeological sites. The historical buildings and archaeological sites today are suffering from poor maintenance and are in a particular state of decay, which sometimes turns into a real abandonment, because for many decades the management policy was not working for a well common but for the exploitation, intended as a simple filling of functions of these sites.

We are today the conservatives of a glorious past and for this reason it is essential to grasp the intrinsic potential, as well as the vocation of heritage "suggests". On the contrary exploit the wealth has meant in terms of historical, aesthetic, distribution, and use of plant materials, a task not fair to pass on the benefit to future generations.

The programming of the restoration work today follows tools that are not always suitable to the actual operations necessary for the preservation. The restoration project must take into account all the possible variables of accomplishment - architectural, structural, plant - identifying objective solutions, especially suggested by a careful historical research, in order to fit a success of the work.

In Italy often happens that the different phases, from feasibility study, the various phases of the project, well as the project management, are followed by different figures. Like an actor in a theatre, that has to empathize with the character to be able to climb on stage and be that character himself, he needs a deep study and analysis of the one who is going to represent, also the restoration project should not be separated from the phase of historical study to the realization. Only in this way the design team, having identified with the historical building on which it operates, will be able to deal in an objective and respectful of the restoration project .

The importance of a project will be followed by the same design team for the entire procedure is for the benefit of sustainability, which should not be understood only as energy savings, but also sustainability of the timing of planning and execution, and therefore costs. Instead, the procedures often have a very long time to the detriment of historical building that instead requires urgent action in real time, but with full knowledge of the story.

Moreover, the choice of eco-friendly materials, or how the site needs to be organized, are elements that contribute to the development of the project idea. Locate the nearest quarry, the workers and the local techniques can be a major asset in the success of the work, as well as facilitating the local economy , sustainability also means putting a limit on the range of procurement of materials.

Finally, you may not think that the restoration of a historical building will finishes on the day of closing of the yard: this intervention continues to exist through a "sustainable" and planned maintenance to be carried out in the years to come.

Only then can the restoration project can be considered a " work performed in a workmanlike manner".

1.2 Areas of development

The restoration and refurbishment project experiences that are presented in this article want to explicate the methods of this group of research and design to approach the issues mentioned above.

The different professional experiences, even in academia, including Italy, Spain and America, have expanded the knowledge to work in particular on two very important projects.

The first is the restoration and refunctionalization as the Arts and Crafts Territory Museum of the Pontrelli's mansion in Triggiano, in the province of Bari. The work has been developed within the School of Specialization in Architectural Heritage and Landscape for the study and restoration of Monuments of the University of Rome "SAPIENZA". Today the building is used as a town hall and the municipality itself has proposed the idea of creating a reality addressed to the delicate area of the arts, crafts and traditions. The current offices are partially relocated to the same building following modern standards of contemporary work and in compliance with the current legislation in the sector of Cultural Heritage. The others are located in the municipal area especially to improve the service to the citizen, who will also be the recipient and user of the new "historical center". This appears to be a pilot project since the different aspects of design and plant engineering solutions aimed at preserving as much as possible the historic building , as well as technological solutions have been identified in an objective manner in order to pass on the benefit to future generations. The different themes are to be mentioned here that in a handbook are potentially to be developed on a project by project basis, such as the project has been presented below .

The second project is the result of an international competition for the new functions of the historic east wing, the maternity wing, at the Hospital of the Innocents in Florence , which will be used as the new headquarters of UNICEF in Italy. In accordance with the Technical office of the Institute and the Administrative Board of UNICEF is presented in this conference the work in progress of the project which is under preliminary study. The design team is composed of the authors of this article for the intervention of the restoration of the building, the architectural and interior design and of the inner court. Also by the Technical Office Peroni, renowned studio in Rome that deals since decades with consolidation and structural improvement in the sector of Cultural Heritage and structural design, even complex of new buildings. And finally by the Company OpEngineering S.r.l. that is a very important design company that operates in Italy and abroad in the area of mechanical and electrical design.

2. Pontrelli Building in Triggiano (Bari)

The building is in the expansion area of Triggiano built during the nineteenth century, in Vittorio Veneto square, a village in the south-east of Bari. It's consists by two floors, the first of which with

barrel vaulted ceilings and the second with vaulted pavilion. Each area is approximately 900 square meters, and in the basement floor there are two cisterns for rainwater harvesting, now linked and expanded to host the archive. The lining of the basement of the main façade is made from *dolomia stone*, as well as cantonal rusticated ground floor and the window frames, that are decorated with the hammer at 16 teeth. The masonry is in so called *carparo tuff*. These two materials are very easy to find locally, in fact there are quarries, now disused, in the immediate neighborhood of the town. The front and both side elevations have lowered arch openings on the ground floor and on the same axis of windows and balconies on the first floor. The central part of the main façade is protruding from the side: the portal of white stone has a *prothyrum* with two Doric columns on *cymatium*, set against in two pilasters that deviate laterally. Due to the tight modulation of the surface of the facade, are created three spaces characterized by an impressive alternation of full and empty so that the surface appears to be excavated. Mapping some points on both corner facades has been detected a feature of the construction of the wall structure not otherwise perceptible: the masonry walls taper from the bottom upwards, as buttresses, in favor of the balance of the building. On the rear elevation are noticed some modification that have occurred over time: the demolition of a small building sitting there until the '70s and the subsequent completion of the front elevation, the opening of a series of square windows and the presence of plants on sight, have transformed the *facies originaria*, however, not preventing the reading. Crossing the molded arched door leads into the hall beyond which, when the palace was built, proceeding on the same axis, it came in a citrus grove now only partially visible. In the rooms to the right of the hallway, where originally there were stables and the *trappeto* with four mills, today there are rooms used for municipal offices. A monumental staircase, built with climbing vaults, is illuminated by a lantern that sits on the pavilion vault ceiling, leads to the first floor of the palace.

2.1 Historical background on the construction and cultural contex

The construction of Pontrelli's mansion is closely related to events that occurred from 1861 to 1867, the period of its construction, on land adjacent to the town walls. To the umpteenth epidemic that broke out in 1867, the City Council commissioned at the architect Nicola Capriati to draw up the construction project of the New Village Road and extramural planning similar to that of the architect Gimma for the new district of Bari called "*Murattiano*". This new area designed by Capriati was developed around the Central square: the lots planned were further divisible into for commercial reasons, but one had to be the designer who had to take care of the design of each lot on the front elevations. Annibale Pontrelli bought the seventh block in full and had a mansion built on two levels and a citrus grove behind. The Palace, for its monumentality, for the attention in the design and proportions, became the symbol, the image of the country which from that moment was not only based on agriculture but also open to commerce and industry. This is the birth of the new local bourgeoisie. These environments were considered the "saloon" of the city, were held here dances, concerts, and cultural and political meetings, in which take part the new bourgeoisie of Triggiano. Today these rooms host the town hall. In the '70s, when the restoration of the palace took place, the original tiled floors, now visible only through photographic sources were replaced with tiles grit. Another element that emphasizes the importance and the monumentality that the building wanted to express are the works of the iron railings, gate and "roste", a sign of the increased attention that lent itself to these arts, and therefore the presence of master experts in working iron. Although these elements bring to the architecture of Architect Castellucci near Bari and his circle of master: as the railings of the balconies on the first floor, are the railings of the mezzanine floor of the Palace of the Baron Ferrara, while the shapes of the fan they resemble those of the main door the fan they prelate of the Palace of Acquaviva near Bari, all buildings that belonged to the same architect. Since the beginning of the '900 the Pontrelli family is having to lease the ground floor and the first floor due to financial problems: the wing to the left atrium and the rooms upstairs are divided into housing, while the right wing atrium, since the fascist period, hosted the Imbriani Cinema, the first in Triggiano. Later the fascist youth movement and then the Bank of Naples have been using the building. In the 70s, following the acquisition of the Palace by the municipality, the historical Cinema stops working.

2.2 Guidelines for the restoration

The restoration of the Palace aims to continue the memory, of what this building has meant and means for the population. The project aims to preserve, research and respect, in the recovery project, the character and identity of the original architecture. Weed control, disinfection, cleaning, consolidation, filling and final glaze of the wall surfaces is the preventive intervention. The Palace is in a good state of preservation and degradation burden on surfaces is caused, for the most part, by the poor maintenance. On the basis of documentary sources and cameras, as well as the historical memory of the citizens, it was decided to remove the plaster from the rear elevation to restore the continuity of the technique of construction of the building: in fact the other three elevations appear to be without plaster, but in blocks of *carparo faccia-vista*. This choice is also supported by the state of conservation of the stone, on the facades where it is not plastered, there are no serious damage due

to exposition to winds and to weathering. Other interventions are those that provide for the closure of the openings improper dating back to the '70s, no longer functional for the architectural design presented below, the dismantling of the installation as machines for the air conditioning, water supply pipes and the replacement of descendants. The most affected part of the elevation after the intervention is the angle at the time of construction of the palace, which was leaning against a pre-existing building, demolished around '67 (date of purchase of the building by the municipality).

The idea of restoration of the rear elevation starts from wanting to create a continuity with the rules of symmetry and axial drawing of the building and which today are not relevant features anymore for this elevation. After the demolition of the pre-existence, there was a feeling of "unfinished" and disorder if compared with the study of the proportions of the other elevations: the opening of windows functional for the services and the impost of the vault of the old building do not let us perceive the elevation as completed, with a sharp contrast with the perfection given by the study of the geometry of the other elevations. From the compositional point of view, are reproduced the two bays missing, specular with respect to the center axis of the gate, so the facade passes from five bays to seven, as the main facade; also the new side scene will consist of a perforated metal sheet etched and copper mounted on a light metal structure (Fig.1): this choice reinterprets the feeling of richness of color and spatial surface of the stone reinterpreted in a modern key. The holes in the metal sheet are reminiscent of the vacuoles of the original stone, as well as the choice of copper as the coating material which refers to the color yellow/reddish of the *carparo* stone. From a functional/technical point of view - on the ground floor there are two service entrances to the interior: this is consistent with the project of renovation of the building in the Arts and Crafts Territory Museum. This building has a floor area of coverage lower than about 3.5 m where all the plants will be hosted and will be shielded from the new side scene. In addition, through the new functions and the renovation of all the systems that are external (for example radiant floor float) and therefore easier for maintenance, we tried not to interpose with the original structure of the building, making any intervention potentially reversible.

Fig. 1: Pontrelli Building, rear elevation, perforated metal sheet

2.3 Proposal for enhancement and refurbishment

The project includes a partial change of use of the building which in part will become the office of the Arts and Crafts Territorial Museum of Triggiano and in part will continue to host some municipal offices. This choice aims to make Pontrelli mansion a receptive center for the development of the country and it will catalyze the rediscovery of the past and the territory of Triggiano, it will reorganize the multiple sources of the story and highlight the findings, today not usable, that belong there. The project will be developed in various phases: the concept aims to expand over time switching from the Town Hall Museum: jobs are divided to solve the logistical problems of construction due to the transfer over time of some offices elsewhere. The first phase is the adjustment and improvement of the engineering part: to not interfere with the historic structure of the building, it will be installed on both levels a floating - radiant floor that allows the passage of new electrical installations, security and data connection. By the same principle of reversibility of the process, the possible detection of vertical shafts, was considered most suitable because of its dimensions contained in the plant, the location of a single shaft that uses the central well of the scale of the service, which also host the elevator, with the aim of optimizing the accessibility for the disabled people. This shaft is also made of perforated sheet metal etched and mounted on light metal structure, and will be possible to be inspected when needed. The choice of radiant floor heating is also aimed at improving the thermo hygrometric wellness, well as to save energy: the radiant floor operates at a temperature of about 35°C, a radiator is common to about 80 ° / 85 °. In addition, by heating a diffusing surface of the heat, given the breadth and the height of the rooms, there will be no cold spots, as is the case with existing radiators, which are a point source. The second phase involves the reorganization of the ground floor : the rooms to the left of the hallway with access from Vittorio Veneto square will be reallocated to the municipal

offices open to the public. The rooms to the right will instead be used as a bookshop, literary cafe, restaurant and will also set up a small conference room, which can temporarily host art exhibitions and cultural events. In the entrance hall are provided, for the host service, the wardrobe and a permanent exhibition, which continues in the basement, about local products. On the first floor will be set up the Arts and Crafts Territory Museum that is part of the third phase of renovation of the Palace. The rooms are characterized by structures made of iron and wood, prefabricated cubes, with interactive desk. This choice is motivated by the desire to create a layout that is completely detached from the structure of the building and for its vocation of reversibility. At first, these volumes will be the archives of the various offices and desk workstations. The next step is to prepare the real set: with minor modifications of these cubes, prepared from the outset, the volumes will host the showcases and interactive areas of the museum. Through screens and video will be narrated the evolution and history of the area. There will be exposed some archaeological remains, now deposited in the Church of Santa Maria Veteran but not accessible now. There will be interactive areas where will can learn better about the working tools of a tradition that must not be forgotten. Finally there will be rooms devoted to educational workshops for schools and youth clubs. The last step to complete the installation includes the installation of a suspended structure, secured with tie for points, on which will be mounted on the projectors and the basic lighting of the rooms. This element, which develops the idea of the reticular bean for theater (Fig.2), characterize the intervention of refunctionalization of the Palace, will bring visitors along the outside of the museum (Fig.3), and will also be a recognizable element and appeal because, in different points, will be part of the main façade too.

Fig. 2: Pontrelli Building, interiors, reticular bean for theater

3. The new office of UNICEF in the Hospital of the Innocents

The construction of the monumental complex of the Hospital of the Innocents, which was the first orphanage in Europe, is launched in 1419. The initial project was by Filippo Brunelleschi and it represents one of the first works of Renaissance architecture.

From the sources the construction of the east wing that hosted the Maternity and which will become the new headquarters of UNICEF, between Fibbiai street and Alfani street, starts in the first half of the '500. In 1546 several houses were bought along Fibbiai street and belonging to the Monastery of the

Angels to "make places for nurses and other hospital stuff," while proceeding to the completion of the wing on Alfani street. In 1552 the Praetor Vincenzo Borghini builds a large lodge in the Garden of Women, which today is the courtyard towards Alfani street, and that was demolished in the late '800. At the same time the building on Alfani street was completed.

In the first half of '800 century, the building was expanded, incorporating the report to Fibbiai street that becomes a concrete foundation wall spine between the two perimeter load-bearing walls, one that already exists on the courtyard and the new one on Fibbiai street. In fact, the openings on the perimeter of the bearing wall from the courtyard are aligned with those of the central spine wall but not with those on the perimeter wall to Fibbiai street. In addition, the portals on the wall of the central spine are padded like those of the bearing wall on the court, but mirrored. Another intervention of the nineteenth-century is the realization of the monumental staircase with a square base with an internal courtyard lit by a skylight made on a wattle pavilion vault.

Between the '60s and '70s Guido Morozzi heads important restoration and renovation work in the entire complex, providing the former Maternity wing but not realizing the reopening of the drying rack on the top floor that had been hit by masonry walls towards the courtyard.

Until 2011 this wing hosted on the top floor some offices of the Province. For nearly two decades, the Foundling Hospital hosts a design institute and a school of fashion. In large dormitories that once housed the Maternity, offices, classrooms and hallways have taken place to meet the needs of these activities. The functional program and the use of unsuitable materials, such as gypsum board, mineral fiber tiles and linoleum, now hide to the user that walks inside the real importance of this building and its history.

A careful historical research in the archives of the Hospital of the Innocents, in the Headquarters of the Superintendence for Architectural Heritage, Landscape, Historical, Artistic and Ethno-anthropological Heritage at Pitti Palace and at the International Center of Studies of Architecture by Andrea Palladio, has reconstructed through documents and drawings the various transformations that the Maternity wing has undergone over time. This research has allowed us to know the life that was done in this wing of the complex, interpreting the spaces and listening to the inner vocation. These actions were necessary to define the concept of design for new activities that will be hosted.

The project team strongly believes that this refunctionalization project should be a significant sign of modernization and at the same time an example of a possible harmony between secular history and architecture of Florence and the needs of UNICEF, and a work environment completely contemporary..

2.1 Concept design for the new headquarters of UNICEF

We strongly believe that this work should be representative of the important work that UNICEF plays and of representation in the complex of the Innocents in the Florentine environment, national and international.

From an understanding of the work of UNICEF and its guidelines comes the concept of the project within the complex of the Innocents.

Fig. 4: UN General Assembly, 8 Millennium Development Goals.

Fig. 5: the 8 Millennium Development Goals and the speech of Director General Anthony Lake represented as architectural elements.

UNICEF is a complex organism of connection and equalization of multiple realities. In September 2000, during the UN General Assembly, were enshrined the 8 Millennium Development Goals, which are ever more ambitious goals set by the International Community (Fig.4). On this occasion, the Director General of UNICEF's Anthony Lake, who is a supporter of the 8 Millennium Development Goals, gave a speech in support of the Millennium Declaration: "At Their heart, the Millennium Development Goals are about giving the world's most vulnerable children Their a better chance to reach full potential - Whether it's improving on maternal and child health Increasing gender parity in education, or Eradicating hunger. We've got a lot of urgent work ahead, leading up to, and beyond, the 2015 MDG targets we've set for ourselves. And I believe we can do it with political commitment, sound strategies, adequate investment and the engagement of a global community".

Transforming into architectural elements the eight Millennium Goals and the speech of the General Director Anthony Lake and inserting them in the building, the outcome is the planimetric layout (Fig.5) from which we started to organize various functions required by the client.

The functional planning *ante operam* has a type distribution as a comb shape with a central corridor and work environments that open on this. The individual cells do not facilitate the social and cultural exchange, as they constitute an individual space. The central path is bidirectional and it isn't illuminated by natural light, which makes them less attractive as a space of socialization (Fig.6, left).

Fig. 6: individual cells, bidirectional distribution; open spaces, omni-directional path.

The new distribution of the project is in favor of socialization through an omni-directional path. The functional planning provides for the removal of internal partitions to form the open spaces that facilitate the life and work of the group. The open space evoke the spatiality of the past Hospital of the Innocents, the Maternity wing, who wants to return to live in a contemporary way. The service areas are organized within the 8 functional volumes, which represent the 8 Millennium Development Goals, and grow along the wall of the central spine. The alternation of full and empty spaces of the functional volumes along the central spine facilitates the distribution of natural light, open spaces and connective not have physical boundaries and therefore are optimal for the lighting of the central areas of meeting and report (Fig.6, right). Natural lighting also comes from above: there are skylights on the flap toward the interior elevation of the court which open at the empty space between the volume and the other. In addition, the floor of the second level is made of glass in correspondence with skylights to let in natural light coming from above to penetrate even the first floor. Finally, the skylights will open with electronic control. Speaking of sustainability an improvement of the building envelope will be made through the replacement of fixtures with new ones in accordance with current regulations and equal geometry: but also the optimization of the lighting and natural ventilation are in favor of saving energy (Fig.7).

Fig. 7: section, lighting and natural ventilation; color of volumes functional.

The bearing walls A and B have the openings in axis as the wall B appears to be from the historical sources as the original front elevation. Only later was made the C wall with openings on Fibbiai street. These openings do not match those of the existing walls. The gaps of the volumes that represent the 8 Millennium Development Goals and speech of the General Director Anthony Lake of UNICEF seek alignment with the windows so that by accessing the central connective workspaces there is always an on-axis opening (Fig.8).

Fig. 8: structural walls; the gates of the volumes seek alignment with the windows.

Within the volumes are organized toilets (men, women and disabled), the scale and the lift of the connection between the first and second floors, the closets, equipment rooms and office machines, according to the Legislative Decree EIGHT1/200EIGHT seeks to limit and circumscribe the toxicity of emissions from laser printers and copiers (Fig.9).

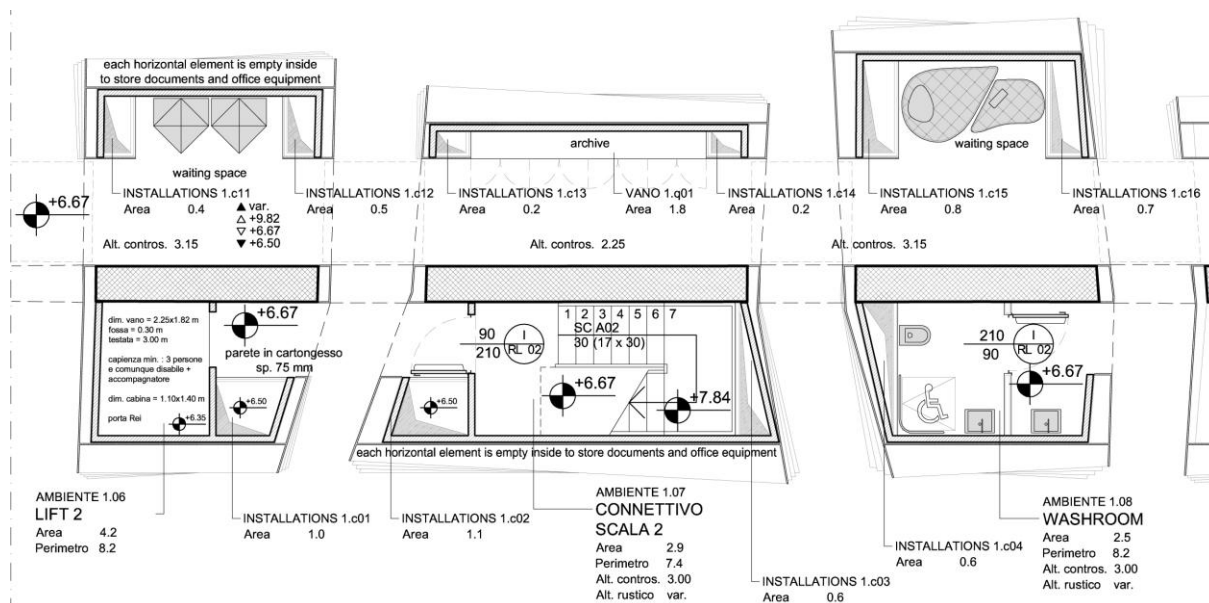

Fig. 9: functional volumes, toilets, the scale and the lift, the closets, equipment rooms and office machines, archives.

The volumes refined from the point of view of the relationship between form, function, structure and material, separated from each other and arranged in the large open space that recall the original spatial complex of Hospital of the Innocents, create a sort of unusual urban landscape, in which paths connecting the various functional areas "indoor and outdoor" space become users' communication. The overall effect is that of an organic randomness, which refers metaphorically to the image of a distant village where UNICEF operates, albeit in a completely modern way. The identity of each volume is given by the fact that they all have common variables and constants: constants are the use of various color tones and the rotation around its vertical axis; random variables are the use of shades of color, the angle of rotation and the function inserted internally.

The twist of the volumes, the splitting and the overlap of elements rotated between them along a vertical axis, generates an organic element which together with the other volumes appears to be a complex organism. That is also functional cause each horizontal element is empty inside to store

documents and office equipment: sliding ladders on rails anchored to the volumes allow a vertical archiving, thus create an archive widespread and not concentrated (Fig.10).

Fig. 10: open spaces and relational spaces and passage.

Concerning the internal distribution, the central spine appears to be a complex spinal column from which all the vital activities of UNICEF will radiate (Fig.11).

Fig. 11: particular skylight and passage.

In addition, the complex geometry of the volumes creates corrugated surfaces which improve the sound quality of teamwork in the large open space. Finally, along the space and connective report at each volume, will take place an artistic installations that recall, colors and slogan, The 8 Objectives and the speech of the Director General Mr. Lake.

In order to live with constant functions and usable every day with different cultural events, temporary or not, the open space can be divided with lightweight partitions and furniture. The open floor plan in this way can be used not only as offices, but also as a space for events, conferences and presentations, evenings charity. The functional volumes are transformed into the backdrop, due to the lighting project.

In the context of the regulatory choice of color for these functional volumes deserves particular attention in relation to the study of psychological reactions in relation to color. For this reason it appeals to a color code of safety applied and standardized by the International Commission of lighting and Organizations ISO and UNI: of particular importance to the standard ISO 6385 that requires the examination of the use of lighting and colors.

In holistic color therapy the green color is in the center between the cool and warm colors, thereby playing a balancing function. It 's the color of nature, the plant world and is a symbol of renewal, is associated with youth, adolescence, freshness, hope, optimism and new. It's neutral color, relaxing, encourages reflection and calm. It 's the color of the fourth chakra, Anahata: This Chakra is the wheel of energy of the heart and blood circulation. The key words of this Chakra are: friendship, love, companionship, public relations and interpersonal love and emotional links.

These are the fundamental concepts around which develops the design idea of this "special" work environment UNICEF which operates according to the principles of co-operation and humanitarian aid on a global scale in favor of the most vulnerable

2.2 Action of improvements on the building

The modern parameters by which this group intends to intervene, are the respect and appreciation of the historical memory of the context. In addition those of contemporary architecture in which there is sectorialisation of spaces, tasks, thus not facilitating the aggregation phenomenon, and finally the saving of energy and thermo-hygrometric wellness of the users, intervening where possible and in accordance with the current regulations and constraints, with integrated systems architecture and reversible. The flexibility of the space is the centerpiece of the proposal: at the various needs of users and for different functions, match the layout of the conformation space and the dynamism and versatility of UNICEF are concepts that are reflected in the Florence's headquarter. Maximum functionality of the space requires solutions designed taking advantage of the available surface, so that nothing is random, although having possible variables conformations.

The wall spine is the centerpiece of the project and not only from the architectural point of view to displace the different functions at the service of open space. In fact, along the central bearing wall will develop the primary distribution of electrical, data connection and ventilation, concealed by the same functional volumes .

The proposal of the various plant systems is aimed at a significant reduction in energy consumption. We have tried to combine the energy saving performance and environmental comfort.

In addition, the design team has proposed the installation of the machines service of heating radiant floor/floating and cooling via pipelines, integrated architecture and, therefore, in accordance with the historical memory of the Foundling Hospital in a compartment built from scratch under the floor of the court. This facilitates their installation and therefore the maintenance, thus reducing the costs. In addition, the proposal aims to stop affecting machines with bulky and heavy on the supporting structures of the historic building. Finally, this solution is optimal because the ventilation plant room is from vents integrated in the new garden design. In this way, within the offices takes place the only distribution utilities, thus reducing the risk of emergency situations caused by equipment problems and in favor of the safety of the end users.

To restore the condition of the premises of the large dormitories of the Maternity wing, and therefore the historical memory, this involves the removal of ceilings to enhance and make visible the wooden beams, obtaining in this way the very high ceilings: for this it has been decided for the laying a built-in floor radiant and float, so as to ensure the thermal comfort of the users.

The radiant flooring system installed on a floating floor, which also allows the installation of other equipment such as electrical and data connection, ensures accessibility to facilities and the flexibility of the space, without sacrificing the unparalleled comfort of the under floor heating. The low thickness of the package makes the heating system, low-inertia, the time for making the scheme appears to be reduced compared to conventional floor systems. The dry laying directly on the existing floor greatly reduces the material produced is intended to landfill also allows you to install the system in a short time and therefore is cost effective.

Finally, in addition to the installation of skylights was planned to lay solar tubes that allow natural light to illuminate a room without windows. The solar tunnel, which will be installed in compliance with the regulations and constraints on the building looks on the outside with a flat windshield wire cover in order to improve the integration with the architecture in the historic centers.

The light tunnel can be installed in any room and can be considered as a source of light and ventilation alternative/supplementary to the windows. By placing a solar tunnel it not only improves the quality of light, replacing the artificial with the natural one, but you also save on electricity consumption, as during the day there are points of light like spotlights. The tubes can be extended up to 15 m: this allows their installation not only in areas directly under the roof, but also those located on the first floor. These will be installed in shafts within the functional volumes to light and allow air exchange services and all areas enclosed volumes, both on the second floor to the first.

4. Conclusions

We resume to points of the themes that have allowed us to develop the projects submitted. Summarizing:

- both projects are started with a thorough historical analysis;
- research and interpretation of the intrinsic vocation of the building;
- revival and enhancement of spaciousness is in coherence with the new use;
- sustainability of the work from the design phase to the construction site and maintenance;
- coexistence of constant functions and usable every day with different cultural events, temporary or not. This is also allowed by the versatility of the space.

The close relationship with the customer, that is, with UNICEF, allows us to tackle the project in all its aspects.

Already in the preliminary phase, all parties concur, Client, planners and funders, working in harmony and cooperation to find the best solutions.

Crossing the river. Urban design in Pompei and Scafati

Carlo Alessandro MANZO

Department of Architecture and Industrial design "Luigi Vanvitelli" – Second University of Naples
carloalessandro.manzo@fastwebnet.it

Abstract

The enhancement of rural-urban landscapes of the Sarno river plain involves the bands along the river and the arrangement of the banks and the riverfront. The paper deals with the architectural redesign of the bands on the river edges, in order to highlight the important places of settlement and cultural heritage in the areas of Pompei and Scafati. We present studies and projects developed within the PRIN research and the Laboratories of the Department of Architectural Design Architecture "Luigi Vanvitelli", focused on the relationship between the public spaces and the types of the Mediterranean productive garden. The solutions are studying river band's accommodations compatible with the periods of "floods" and thus able to reduce the risk of flooding. The interventions strategy along the river, in the southern expansion of modern Pompei, provides for the localization of an agro-fluvial park with river crossings to enhance cross-connections of the plain. In order to redevelop the central Scafati area close to the locks on the river, the aim is a new design on the mills island and the renovation of public buildings, with the inclusion of accommodation in public-private joint management. The overall area's redesign is completed by the new square's solution for the Villa Comunale entrance, with the location of an "urban center" and other public utilities.

Keywords: Urban design, extended city, productive housing, riverfront

The theoretical basis of this work, starting from a national Prin research, are connected with the idea of the green extended city which could regenerate the periurban areas around the modern dense metropolis. The concept of the "city in extension", recalling a Samonà's theory, is aimed to create a *multi-polar* system, built up by small urban clusters made with residential-productive structures (integrated with public utilities) separated by rural areas and parks. The discontinuity of urban parts alternating with agricultural plots avoid that green and unbuilt areas among the detached cities will be saturated with more buildings. The main goal is to reduce sprawl and soil waste designing new urban roles, giving order and functional improvement to the urbanized territory for an efficient alternative to the chaotic overlapping of rural and urban structures. The outcome of the project research could be named as some *agro-urban* settlements thought as elements of a wide discontinuous fragmented city. The enhancement of urban and rural landscapes of the Sarno Plain needs new arrangements of ribbons and banks along the river and the redesign of the riverfront in the densely built areas. This paper deals on some issues of architectural renovation of the Sarno edges, considering them a necessary step to regenerate the important places of settlement and cultural heritage in the areas of Pompei and Scafati. In line with the *Prin* national research entitled "From urbanized countryside to the *extended city*", which assigns an organizer role to the river Sarno in the design of the urbanized countryside (1) (2), I show several urban projects developed within the *Prin* research team and within the workshop of the Department of Architecture and Design "Luigi Vanvitelli", aimed to improve the relations between the public spaces on the river, residential and productive developments and the types of the Mediterranean garden.

The thesis of this theoretical and design research is that the redevelopment of the river should play a leading role in the restructuring of urban centres and rural areas in the Vesuvian areas crossed by the Sarno river. The project themes are chosen to activate new relations between the two sides of the

river - to reunify both in visual and functional terms - improving their connections through the redesign of the infrastructure and of residential significant parts. In addition to the system of redevelopment along the banks of the river, we have studied urban and architectural projects able to give strength to several *cross ribbons* to Sarno, with the goal of improving the relationship between the river and its habitable contexts. In the most densely built-up lands, particularly in Pompeii and Scafati, you need to work through actions recovering old urban blocks, infilling in existing buildings and especially through redevelopment of the typological structures in close contact with the river and the secondary canals. In the areas where the river stream crosses the transversal infrastructures, the new earth modelling designs propose special "park arrangements" of the river banks to reduce the flooding risks.

In the area close Pompei centre, - the cross ribbon design is focused to a future agro-park running along the river, and creates a "pendulum" with two terminals: the north terminal is formed by the pole of the new green market and by urban house-gardens, and the south is formed by residences with greenhouses and utilities. The residential and productive core overlooks the agro-park on the river Sarno, which is solved by a system of house-gardens and small basins and canals, designed to contain any river flows. The narrow canals running through the southern end of the park are integrated in the design of green areas and homes with private gardens, which will also benefit from the practical and economic proximity to the new structure of the green market.

In the core of Scafati, which is the main study-area of this work, the strategy of interventions crossing the river is realized through the creation of two opposite polarities. The first one consists in a residential cluster, with both agricultural and urban characters, formed by productive houses and a new primary school that would create a public space aggregating the population of the whole area.

This cluster is located on the transversal axis that connects the towns of Scafati and St. Anthony Abate, according to the appropriate zoning here provide the urbanistic plan of the area, where new homes with greenhouses integrate with the old renovation work. The residential unit is crossed by a secondary channel that participates in a general design of the tanks overflow in the private and in the public gardens. Master-plan studies provide different arrangements of houses and greenhouses, which can be realized in open or fenced lots.

The second pole is located on the Sarno river near Scafati town centre, and includes the system formed by the town park named "Villa comunale", the old Town hall and a small island close the old "mills". The architectural interest for the entire nucleus of the Town hall building stems from its wonderful location overlooking the river, a solution which highlights the old courtyard building that had been, in the previous age, the Meyer's "palace", the residence of industrial man active in the textile field of Sarno area. The current municipal gardens, which coincides with the private garden of Meyer palace, includes two old brick greenhouses and a pergola for walking along the river. Therefore, we wanted to plan solutions closely related to the high quality of these places. Therefore our architectural solutions are aimed to enhance the public nature of these sites and to consolidate their role as "primary elements" of the system crossing the river.

Whereas the logic of the papers presented invests the relationship between the historic core of Scafati and the river, a relation today in crisis as evidenced by the abandonment state of the main goals of urban plans. The indications of the PUC (that is the town urban plan) and of the Piano di Recupero (a Recovery plan) provide for the central area, called the Mills, the recovery and development of landscaping in connection with the exploitation of the river park.

The Scafati PUC proposes a complex intervention for urban regeneration of the heart of the city, characterized by a compact urban fabric (the neighborhood Glaziers and Mills), some areas of poor urban quality (formerly the Gaizo area), some disused structures (former tobacco factory) and degraded peripheral area of the city. The Integrated Program for the Sarno River, elaborated by the public Park Company, highlights the economic resources available and identifies the regional territory to be involved: the project aims to build up, through the enhancement of the environment of the river route and of the historical, cultural, archaeological heritage of the territory, creating a park in order to combat the phenomena of severe environmental degradation. Other projects on the same area are aimed to environmental restoration and rehabilitation of the river. The goal is to increase the tourists flows around the cultural and eco-environment actions and at the same time increase the level of employment in the area.

The sphere is constituted by the historic settlements connected to the central core consisting in the Mills area, the settlements close the central road -Corso Trieste- and situated between Via Roma and the river. This area still have an original urban texture nevertheless it has been altered by insertions and substitutions of recent buildings, inconsistent with the preexisting tissue.

In this context, the administration proposes a measure of recovery and redevelopment of the area with enhancement of the river park. In particular, the mills island along the river has wide potentiality for significant redevelopment and enhancement Specifically, we can implement program interventions "More Europe" associated with the rehabilitation of Zara central street and with the reconnection with the neighborhoods Mills- Glaziers-Mariconda. The plan suggest:

- Pedestrian viability and adjustment related to central street via Zara ;

- Reutilization of the ground floor on the Canal;
- Recovering and redevelopment of the old mills; ...

In particular, the old Mills area is expected a feasibility study for the creation of a pedestrian bridge connecting the house with the City and / or a connecting passage between the former conference small structure wellknown as "Venice Hall" and the space on the south side of the Town hall , which is proposed for a global redevelopment. Also planned is the rehabilitation of facades along the river Sarno connected with the arrangement of green landscape interesting areas and with the redevelopment of discovered public spaces located in the undeveloped areas. In this sphere are permitted the following uses:

- Residence, hotels and bb. / business accommodation / retail shops / equipment and public or private social services / offices and public facilities as restaurants, bars, meeting-conference rooms, and entertainment hall with a capacity not exceeding 150 persons.

These planning indications were proposed as the basic data of the work assigned to ph.d., undergraduates, students, requiring them also a critical revision to propose new applications for architecture .

For the north area which concerns the so-called island of the mills, the project program is the construction of a small public-private partnership housing, intended as a small residence integrated with utilities and receptive nucleus, forming the counterpart to the existing Venice Hall. This problem requires you to keep clean and to improve the existing garden and to redesign the front of the river. The compositional themes relate to the embankment wall as a practicable structure, the chance to create a boat dock, and an efficient integration between the house and accommodation utilities. For the south shore area of the Sarno , located between the Town hall and the "villa comunale" park, the municipality requires the demolition of the large volume of the school, built up in the Sixties. Our choice was to propose the creation of a new Urban Centre, as a public facility providing space to develop, discuss and expose proposals and studies for the Sarno and vesuvian territory. A system of public spaces, thus allowing a strong presence and participation of the population .

As urban theme this project involves the construction of a public place well related to the structure of the historic Town hall , and suggests a general redesign of the new entrance gates to the public gardens, rethinking and rebuilding a new river front.

E-mail b.canonaco@unical.it

Abstract

The essay, seeks to provide a historic-architectural framework of the heritage of industrial archeology in Calabria, considering the socio-economic landscape in which the factories developed. The study examines significant examples in the province of Cosenza.

From the analysis of mills, spinning mills, sugar refineries, it can be deduced that Calabria, between the seventeenth and nineteenth centuries, showed the ability to exploit its agricultural resources in the evolution towards the industrialization process. By examining the industrial architecture present in the region, the focus on some specific characters and typological evolution demonstrates the permanence, symbolic-formal variations and functional distribution of the selected types. Some invariant characters derived from a cross comparison between the different factories, evident in a formal setting, in the functional distribution, defined as factory-farm. The artifacts are linked to the agro-industrial design. The productive module, in relation with the agricultural lot, is built around a courtyard, together with the residence, workers' building units, and spaces for activities, while the organization and composition of the factory is attached to the structure of the rural farm.

Finally, the essay aims to /or touristic improve knowledge of this heritage, of its architectural and constructive consistency, in order to provide both conservation actions as well as cultural and rehabilitation.

Keywords: Industrial archeology, Knowledge, Heritage, Conservation, Redevelopment.

1. Features of rural architecture and industrial archaeology in Calabria.

Although there is extensive literature on the subject of industrial archeology, little is known about the architecture of work in Calabria. It has always been considered to be a backward region in comparison to the productive actions of the entire nation. In fact, at one time, Calabria, and southern Italy, in general, in its heterogeneity of "*culture material*", possessed both resources and technological practices that bore witness to a good business capacity^[1]. This was based, essentially, on the transformation of agricultural resources, with the existence in the region of unique factories such as flour mills, oil mills, sugar mills, etc.. Today, they are not completely systematized, even if there is significant proto-industrial heritage in its identifying characteristics.

This essay, through different analysis and critical reading of a repertoire of archival data, seeks to paint a picture of the historical and architectural heritage of rural and industrial archeology present in Calabria, and intends to delineate the socio-economic landscape in which the artifacts developed, focusing attention on some representative examples within the province of Cosenza.

We wish to highlight this historical-productive legacy, which is often unknown, which exists in conditions of degradation and that in its meaning of "*monumento industriale*" requires census operations and subsequently reuse operations, with the aim of its cultural and/or touristic redevelopment.

In southern Italy in the 15th century, transformations of agricultural raw materials and the related business activities of the local feudal system, generated a production profile with the aim of developing the economy of the county. This, in turn, led to the start of the evolutionary process of the agro-industrial landscape, and in the southern architectural landscape, which resulted in the construction of several factories.

In Calabria, a primary sector in regional production was the cultivation and processing of sugarcane, which represented, the same as the silk and more recently the steel industry, one of the leading sectors of the economy, with the presence of several factories located on the Tyrrhenian coast between the fifteenth and sixteenth centuries.

It should be noted that sugarcane processing in southern Italy, was incisive on the economy in a remarkable way and its entrepreneurial story can be considered homogeneous and widespread throughout the south. Since the fifteenth century, there had been a technologically advanced activity whose origins lay in the Arabic tradition; it enjoyed an important position in European markets. For example, in the Sicilian economy, sugar production represented a significant chapter in pre-industrial activity, and occupied an emerging place^[2].

From an examination of the types present in the south, at the time referred to as *Imprese*, it is possible to note that large areas of land were required in order to grow sugarcane and the factory was always in the vicinity of the plantations.

The production unit comprised of a group of buildings: spaces for storing sugarcane, crushers for squeezing, rooms with boilers for refining, and storage space for equipment. Furthermore, there was also a farm or manor house, sometimes the lord's castle, and residences for hired staff.

The sugarcane factory was, in its spatial composition, designed as an articulated structure, responding to the system of dwelling - productive activities - agricultural activities. The same home was related to the agricultural lot and was inserted in the entirety designed for production^[3].

A significant example in Calabria, which provides an expression of rigorous architecture, was *Il Carcere dell'Impresa*, in the municipality of Santa Maria del Cedro (CS), south of the mouth of the river Lao. The structure dates back to the sixteenth century, with a defensive tower of Norman derivation, it refers to the type of fortified farms, now restored and dedicated to museum centers. The area that houses the architecture is of great archaeological interest due to the presence of numerous finds from the Hellenistic and Roman periods, which were found during recent restoration work.

Il Carcere dell'Impresa, defined as a castle in a document held at the Superintendence of Calabria^[4], was equipped with a spring that supplied water to a mill inside the complex. It is possible to infer that the factory can be considered as one of the references of the productive structures in Calabria related to the agro-industrial system. *Il Carcere dell'Impresa* is a complex typological system where the role of the farm castle-manor house is centrally located, with dimensions and architectural significance, with the presence of a tower, which represents the defensive element that, in turn, defines the entire complex. The tower generally existed prior to the agricultural structure, with workplaces for productivity, with mills, crushers, rooms used as stables and housing for workers, a chapel, all functions which were articulated around a courtyard and near the farm lot^[5].

Fig. 1: *Carcere dell'Impresa*, and plants of the ruins prior to restoration

In Calabria, there are many pre-industrial complexes thus organized, and from a summary discussion, it is possible to examine the cross-sectional and invariant characters exemplifying them in examples such as the feudal village of Cannavà, in the municipality of Rizziconi (RC), known for the cultivation and production of oil. Even in this case, the village appeared as a complex urban system, in close relation with the land cultivated with olive trees. It was designed around an attractive square, where the prince's residence and the church were located. The square was also the location for building units

used, in part, for farmers' accommodation and for local agricultural activities, such as stables, granaries, troughs, stores and two large mills with adjacent oil warehouses.

The structure of the rural farm type^[6] demonstrated an elemental architecture, except in the setting of the residence, which indicated the main type present in Calabria, with horizontal string courses to mark the two orders of the building and the arched entrance portal. The peasants' houses, overlooking the square, generally consisted of a single level to accentuate the horizontality of the building profile, with strict setting, resuming the essential characteristics of rural architecture in Calabria. Inside, the rooms were minimal, with brick floors, and *incannucciati* ceilings (made from cane and chalk) while the walls were lime washed.

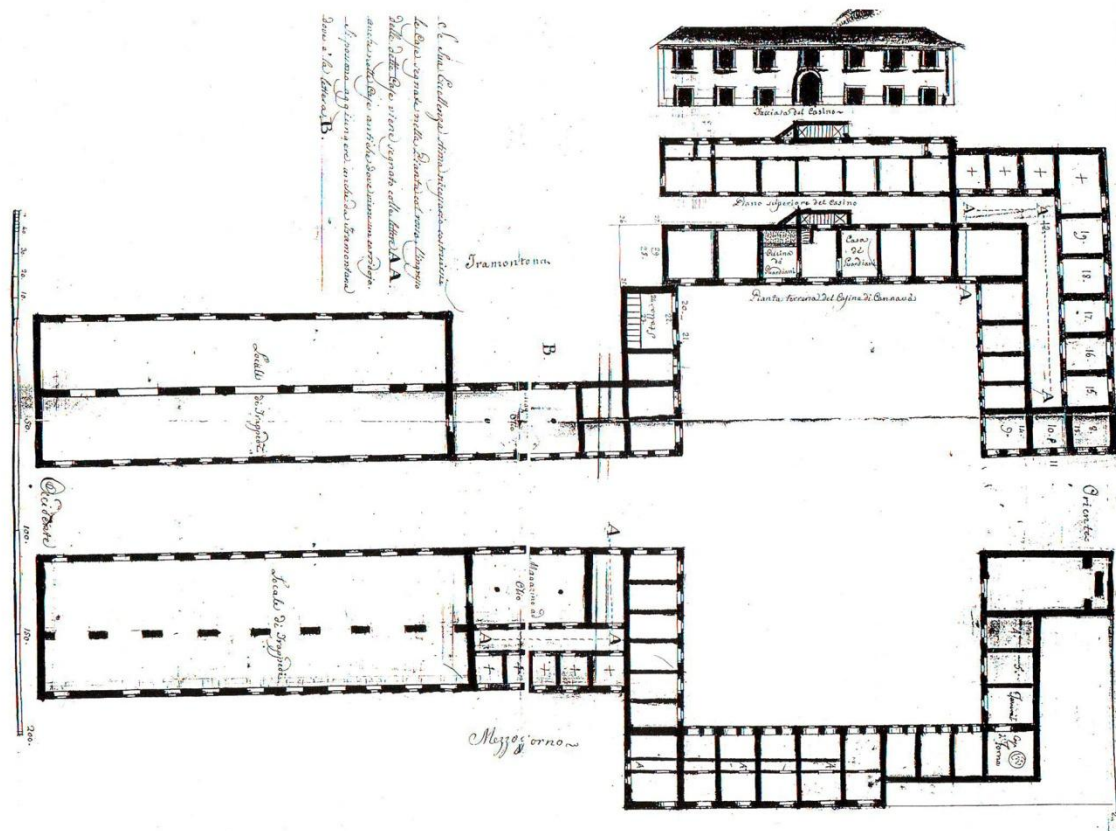

Fig. 2: Plant of the feudal village of Cannavà (from Ornella Milella)

Another example in which social life combined with agricultural production is the castle of Bivona (VV) called St. Nicholas due to the presence of a church dedicated to the saint^[7]. The sugarcane factory was located within the military and productive structure but no trace of it remains today. However, it is widely demonstrated in a detailed inventory of the environments and tools for production, while the existence of a mill with the presence of a *saetta*, also used for the grinding of sugar cane is still traceable^[8]. The factory was also equipped with a crusher^[9].

Fig. 3: Castle of Bivona and plant of the castle with sugarcane factory (from Antonio Montesanti)

It is understood, that in work architecture, there were some features that were repeatable, traceable in the conformation of installations, which could be ranked by homogeneous classes and were attributed to the same typological variety. The socio-economic landscape, between the fifteenth and sixteenth centuries, saw the local nobility manifest its entrepreneurial vocation related to agricultural production. The methods of land cultivation and the organization of production plants generated architectural systems that, although showing homogeneous character, also exhibited unique aspects and variations between them.

This can be found not only in the economic field, but also in the architectural results. It is sufficient to refer to the setting of the mansion that is related in some way to the needs of productive capabilities^[10].

This, in particular, is evident in the typological system and functional organization of the ground floor of the building in Cosenza, and of southern Italy, in general, with the presence of some constant features throughout the region.

The courtyard type ground floor was, in fact, used to service the residence, and consisted of areas for the storage and drying of foods, there were cellars, stables, warehouses, premises for the breeding of silkworms, contained environments for grinding grain with the help of hand-operated grinders, ovens, and nearby areas planted with vegetable gardens or gardens. While overlooking the street were shops to witness a strong commercial focus^[11].

The presence of vegetable gardens and gardens planted with a variety of plants and frequently mulberry groves, once again, emphasized the intention to meet food and productive needs in the same dwelling.

The internal organization of the house combined the need for representation, with the presence of a reception room, a library, a gallery, with the demands of farm life, especially in setting environments dedicated to servants. These reflected functions that satisfied peasant tradition: a fireplace with various boilers, coal cookers, a *cascia*, a piece of typical furniture found in rural houses, with the function of a sideboard, and tools: mortars, stone or wood hand mills, clay vases for meat in brine, and water jars. This was more evident in basic building as it represented a complex spatial culture linked to the needs of production. In fact, the distinction was significant and the names of the various neighborhoods and roads of the settlement, represented the activities that took place there (*vinella delle ricotte*, *via della neve*, *piazza dei pesci*, *piazza degli speciali*, *via dei cuculli* (silkworm), etc.)

The houses that constitute the basic construction were named in the *Catasto Onciario* of 1756, as *case locande*, *case torri* situated on parcels of agricultural land, *masserie*, *case matte* etc. The *case locande* were similar to the terraced plant, and were comprised of a *basso* and/or shop, one or two rooms and an attic called the *tavolato*, used for storage and the drying of foods. This is where the definition of *cannizzo* derives from due to the presence of horizontal planes formed by woven reeds used for the drying of vegetables. It produced a basic building with a legacy associated with agriculture, while noble architecture, despite the subtle relationship between the living space and the productive module^[12], gave rise to an erudite language, linked to the architectural vocabulary prevailing at the time. The described economic development, which can be attributed to the composition of the city and the formation and evolution of the urban fabric, as well as in the production system of the center, had a slight decline in activity at the time of the Spanish Viceroyalty. Nonetheless, cities such as Catanzaro, Cosenza and its surroundings, maintained a certain solidity due to the hard work in the field of traditional manufacturing activities.

In Cosenza, the rearing of silkworms and weaving were activities that drove the economy. In 1813 in what is now Corso Telesio, the main street in the old town with a strong commercial vocation, there were twenty-one active silk sellers, and a part of the population negotiated the sale of silk from their homes, not being owners of any commercial activity^[13]. This activity became the source of income of entire families. In the nineteenth century, several spinning mills operated in the city center. The spinning mill with garden belonging to the Campagna brothers, in San Giovanni Gerosolimitano Square, near the river Crati^[14] was active until the mid-nineteenth century, the Salfi spinning mill that of the female orphanage, and the Rendano mill located on Triglio hill, which was one of the most important factories in the city. The Mollo noble family initially owned the Rendano mill, which had had a significant functional and compositional evolution. It had a controversial history and came into possession of the Rendano brothers around the last two decades of the nineteenth century. In 1879, Stefano Mollo stated in a deed of sale that he owned a factory in the Triglio district “*per filanda di seta consistente in un grande locale per filarvi la seta ora ridotto a gallettiera.... una stufa per soffocare i bozzoli, un magazzino per pesarvi e ricevervi i bozzoli che si comprano, ed una piccola casetta baraccata di tre stanze e due bassi per uso di cernere i bozzoli e farvi altre operazioni concernenti il suddetto stabilimento industriale, più due grandi cisterne per conserva di acqua...il tutto circoscritto da mura a fabbrica*”^[15]. It is understood that, at that time, the mill was of limited size and with a spontaneous organization. Later the factory increased in size with the addition of other bodies and

with the transformation of the original. Thus, in 1887, in successive document refers to it as a “*caseggiato ad uso di filanda*”^[16] to indicate a series of adductions, which occurred over time and led to a different size. In fact, a precise description of the composition of the building is shown in a survey of 1886: “*Opificio Serico Dapprima a sinistra si presentano tre serbatoi in muratura comunicanti l'uno coll'altro per mezzo di brevi cascate... Di fronte 'havvi spazioso portone che immette in una corte scoperta, la quale di contro lascia vedere l'ingresso al trattolo medesimo. Entrando a pianterreno a dritta presentasi la macchina motrice con la rispettiva caldaia, e montando una scala in muratura si perviene a primo piano in un ampio camerone ... La fabbrica istessa comprende diversi ambienti occorrenti al compimento dell'Opificio, stufe, gallettiere, magazzini, deposito sete, locale di ricezione dei bozzoli e simili, nonché discreta abitazione pel dirigente l'industria; sicché la filanda in oggetto devesi ritenere per completa ed una fra le migliori delle Calabrie ...*”^[17]. At the beginning of the twentieth century, the factory was described as an integral part of a system consisting of three parts, two of which were used as a residence. The three buildings that made up the complex set around an open courtyard were indicated as *palazzo*, *palazzina* and *filanda* surrounded by a large green area. The mansion, built consequent to the spinnery, now restored, characterized by the architectural language of the nineteenth century was comprised of a ground floor connoted in height with ashlar base and entrance portal and two floors above ground. The spinnery was situated to the rear and consisted of two levels, driven by a steam boiler and comprising a variety of environments: stores, warehouses, premises for the cultivation of cocoons, for equipment, and an apartment of the company manager. A building with a formal composition, which was modest in comparison with that of the villa, was located nearby. At that time, the spinnery contained more than fifty basins for the manufacture of silk and employed about ninety workers, of whom a large number were women^[18].

Fig 4: Historical view of the villa and Rendano mill

There are currently few disused spinning mills remaining in Calabria to bear witness to the history of steam. The Caminiti spinnery, the Cogliandro spinnery and the Lamonica spinnery were important factories located in the area of Villa San Giovanni which were active in silk production between the 18th and 20th centuries. While, two factories were significant in the province of Cosenza: Gaudio in Mendicino, which is still active today, and the Zupi spinnery in Cerisano. There were also spinning mills in the area of Rogliano. The Quintieri spinnery in Carolei, was located in a park that also housed the main house, from the middle of the nineteenth century until 1940. Even in this case, it was in the presence of a composite system that adhered to the previously examined features; the residence is combined with the buildings for productivity. The main building and modest buildings for manufacturing activities, which are organized around it, form the complex. The spinning mill, designed as a cocoonery for the raising of silkworms, was built of local stone and spread over two levels, with a porch, which had a pitched roof with roof tiles. Adjacent to this building, another building was placed,

whose ground floor was used for spinning. There are traces of a textile mill located in Marano Marchesato (CS), quoted here both for the poverty and simplicity of its composition, adhering to a spontaneous rural system, both to highlight the spread of sericulture throughout the territory, even by means of family businesses. The rudimentary industrial system was articulated around a courtyard, with the presence of a rectangular building used as the spinnery. Other structures were present in the courtyard, namely a shack, a small lean-to room attached to the spinnery that housed the stove for the cocoons, a well, three clay case *matte*, an open space with roof, used to house trays for the production of silk and contiguous open space with boiler for the cocoons. The residence of the owner was situated on one side. Here, the drawing of the spinnery, which was attached to the 1918 Judicial Report is shown^[19].

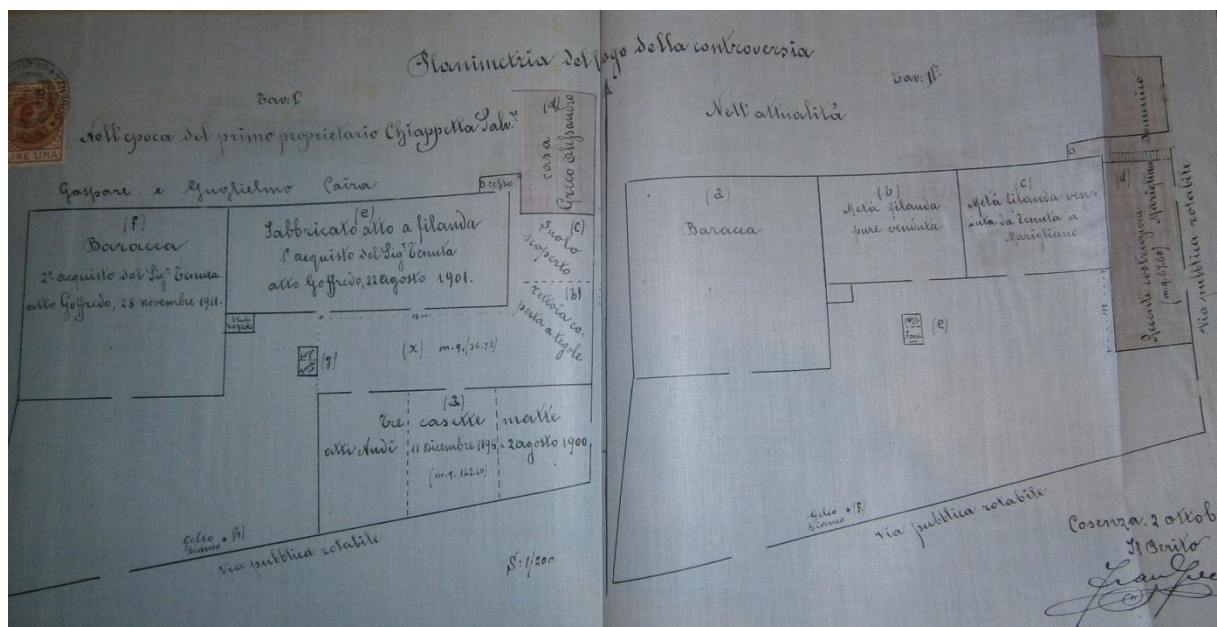

Fig. 5: Drawing of the spinnery attached to Judicial Report of 1918

The Filardi spinnery of Civit  results as being the most complex and significant in the Pollino area, powered by water, known for carding and spinning wool, today it is an eco-museum of industrial archaeology. The reading of this factory, once again shows a series of features to be found in the whole territory. The wool spinnery is part of a rural system comprising several buildings. Large pools for water collection are present, as well as premises for spinning, storage and mills, etc.

Fig. 6: Filardi spinnery in Civit 

Furthermore, the factory also had its own socio-economic value with an important effect on the entire community, and a relationship of integration with the production system of the entire rural area of the Pollino, enriched by crushers, mills, fulling mills. Even in this case there is an invariant feature present in the Calabrian centers. The economy and the population's source of income derived from the production of factories present. It was not a coincidence that the majority of the population was engaged in wool manufacturing, or other connected activities, that is to say that the entire social body moved around the work of the factory. At the end of the nineteenth century, there were several factories in Mormanno and the territory of Morano, witnessing, in the Coscile valley, an intense production activity with a significant impact on the economic and social system. The same natural environment, unique in its beauty, demonstrated integration of socio-economic activities in the agricultural landscape. The area of the fulling mills and mills located downstream from Morano, today still bears witness to the virtuous use of the area by a population which has always been engaged in agriculture and sheep-farming. The scenario of the work architecture in Calabria is complex and more detailed than previously shown and is accompanied by other different examples of architecture like the many water mills that dot the region. There are, in fact, many milling structures Calabria with horizontal wheels driven by water, which are in a state of neglect. The factories, which were present at that time, were located near rivers and streams, and were influenced by the amount of available water. Consequently, this influenced the type of plant constructed, which had to be capable of working even with a modest water flow. Storage tanks connected to feeding canals were necessary and some factories were inactive during summer months due to water shortages^[20]. The dimensions of the canals and the tank determined the self-management of the mill and the construction of the plant was adapted to environmental characteristics with an impact on the architectural features and construction of the basic type.

Based on inspections carried out, and from examined documents, it is clear that a single, rectangular shape in which the grinding wheels were housed formed the basic mill type. The interior space that housed the granite or limestone millstones, was essential. It had beaten earth or stone floors and unplastered walls. The roof structure was like that of a shed, and was in view. A prismatic volume and an elementary facade with arched stone underground structures, where the vane horizontal waterwheel was placed, characterized the mill, on the outside. The tower or *saetta*, which had particular variations across the region, was placed on the roof. The canal was set on arches. In the more advanced types, the factory was formed by two or more compartments, some mills were equipped with two *saette*, and in this case, even the plant was larger.

Fig. 7: Mill in Paola

There were, in fact, complex types, originally conceived for water that had been converted to electric turbine factories. The composition of these structures referred to the planimetric setting of the manor farm system but they were very close to the actual industrial design. There was a mill with several compartments, which housed the grinding machines, deposits, warehouses, stores and sales offices. The proto-industrial system included the miller's house, along with a modest church, in its composition. The house, similar in design to the mansion, was on the upper floors, whose entrance was accessed from an external staircase. It comprised of several comfortable rooms with the presence of a representation hall. Some significant milling realities were located in the municipalities of Aspromonte, Pollino, on the Ionian and the Tyrrhenian Coasts. For completeness, in shaping the industrial landscape in Calabria and its architecture, it is necessary to note, in this context, the presence of several distilleries, furnaces for bricks, and for ceramics^[21], which were located throughout the region, glassworks, *conci* for the production of licorice^[22], establishments for fish, etc.

Fish production was initially characterized as an entrepreneurial activity of the nobility, in which the *tonnare* had an important role in fishing and tuna processing, particularly in the Gulf of St. Eufemia, between the fifteenth and sixteenth centuries, with important examples in Bivona, Briatico, Pizzo, and Tropea. These centers were the main migration passage stages of migratory tuna along the coast of Calabria and Sicily. The *tonnara* of St. Irene and Rocchetta in Briatico and Santa Venere in Pizzo were significant during this period^[23]. At the end of the nineteenth century, a characteristic type of *tonnara* was the architectural complex of Bivona built in 1885 and renovated in 1911. It consisted of a main house, a large loggia, a sort of shed that housed the boats and was allocated for the initial stage of fish processing, of salt stores, of environments for equipment, and the home of the *Rais*^[24] and insiders.

This review highlights that Calabria, in the past, was not marginalized compared to national production, but appeared able to capitalize on its natural resources, fisheries, agriculture, and textile manufacturing, in an evolution towards the industrialization process. From industrial architecture in this context, it is possible to deduce some features specific to Calabrian factories, their formation and the socio-economic landscape in which they developed through the stages of cultivation of the raw material, production and sale. The focus on typological evolution of the examined artifacts has shown permanence and symbolic-formal and distributive-functional variations between the types studied where possible.

From an exegetical reading of sources and from different analyses and comparison of the types of factories, some of the recurring features were inferred transversely. The recurring features were evident in the formal setting, in the composition and functional distribution of the type that we can define as factory-manor-farm. These features have proven to be repeatable proto-industrial architecture in Calabria. Finally, the essay expresses the desire to improve knowledge of this heritage, through the evaluation of its architectural and constructive consistency, in order to provide proper care and conservation, but subsequently reusability and redevelopment of this significant heritage, capable of promoting the development of local economies.

Abstract

The use of architectures or inverse modeling, through physical or digital representations of buildings that are part of our cultural heritage, it is increasingly necessary and essential to know and put them in value in a way that is both rigorous and scientific; bringing it close to a large audience for its high visual and tactile content. On the other hand, this type of modeling, from a technical point of view, gives us a data bank where we can experiment and test possible solutions without having to act on the actual model, which is useful for analysis and study, all prior to any proposed architectural intervention. In this way, through the use of the technologies of advanced data collection, such as the 3D scanner and other lower-cost, such as stereoscopic photogrammetry, we obtain a reliable documentation appropriate to reproduce and make these models either through computer graphics or 3D printers. All this has been carried to term in a building of Renaissance character with Gothic influences in its construction, where is has studied with this method a stretch of the vaults of Church of Nuestra Señora de la Asunción in Vistabella del Maestrazgo, Castellón, Spain.

Keywords: Vistabella del Maestrazgo, Renaissance, reverse architecture, scanner 3D, advanced graphic representation.

1. Objective

The present communication aims to make known and to value the use of new advanced technologies of architectural survey and its later inverse modeling or building architectures in the documentation of architectural heritage from a graphical point of view. The drawing is the best language for the communication of technical information, increased by an increasingly incipient in the use of audiovisual media graphics that bring demand and approximate knowledge of architecture and heritage to everyone.

Therefore, from the emerging group of investigators studying the architectural heritage of the University Jaume I of Castellón is being made work and research in this sense in addition to introducing open and free software in order to optimize the cost.

2. History

The example shown is the parish church of "Nuestra Señora de la Asunción y San Miguel" located in the Village of Vistabella del Maestrazgo de Montesa in the former Kingdom of Valencia, Spain. This building is definitely the best Renaissance building of the Province of Castellón.

Outwardly, it appears as an exempt building, with a rectangular ground plan, with another smaller rectangular body attached at the apse of the church. Highlights in its main façade, faces to the south, the two portals and the bell tower. Special mention deserves the major facade placed in an impressive front altarpiece, sheltered by a pointed arch. It is built from ashlar stone and masonry, the main body is covered with a gabled roof tile, the apse it is cover with a five sides roof, and cover with a single pending the header, that is lower than the previous constructions.

Fig. 1: General view of the south facade of the church.

In his interior it is form by a single nave with four aisles, and chapels between buttresses, presbytery which is octagonal and ambulatory, with chapel and sacristy in the head-board. Both, the nave and the presbytery, are cover with ribbed stellar vaults and the lateral chapels with groin vault simply.

Fig. 2: Plano church vaults

The building was constructed between 1604 and 1624, ex novo, all at once and outside the medieval city walls, the temple was plotted and executed by the French architect Joan Tell, following metrology based in Valencia span and the prevailing Renaissance at the time. The use of Renaissance theories of symmetry, proportion, modulation, the correct distribution, the correspondence of the parties and party size in comparison with the whole and with your module, make the building is and should be considered fully Renaissance, despite its ribbed vaults of Gothic tradition, with straight terceletes northern French roots, but modernized to fit the stylistic point.

Fig. 3: Orthogonal cloud image scanning general points of the vaults of the main body of the Church

3. Methodology

The developed methodology is developed in the following stages of work: work planning the first and the second making consistent topographic data using 3D scanning equipment, total station reflector less imaging and GPS centimeter, or simply taking pictures , the third, and after obtaining field data , data recording and processing cabinet with specific software , and the last building a virtual or physical model.

The methodology faces uprising traditional architectural drawing , made with data collection methods , such as conducting drawings , measurement using measuring tapes , levels, plumb or comb archaeologist, leading to the award from floor plans, elevations and sections to details elements such as sockets, ribs or moldings.

The use of new technologies based on photogrammetry and laser scanner, has advantages and disadvantages compared to traditions measurement systems. One advantage certainly is getting more graphic and visual quality of the projects. Furthermore the documentation system through the laser scanner and photogrammetry is possible to perform a survey in its entirety without other traditional media. Besides the possibility of adopting hybrid solutions , combining different methods of data collection : traditional and modern , allows maximum use of each , provides some advantages since the main virtues of each method are adopted, and in this way turnaround times are reduced , the data quality (accuracy) is increased and decreases the final cost .

Although the work is done by combining different systems exposed measurement, due to the differences between the teams that make up each of them , each of the stages of work are carried out separately , comparing and combining the results after data processing to develop unique and relevant graphic documentation .

Fig. 4: Elevations of the vectorized by church and textured architectural photogrammetry.

The laser scanner provides information of a huge number of points in a short time, the exact location of these thousands of points, and information on the brightness and color of each. With this process as many points clouds obtained number of scans have been executed by the scanner, from which one can generate a realistic virtual representation of the object. The degree of definition of this model depends on the density of point clouds and gaps or shadows that occur when taking data.

Fig. 5: Views of the assembly point cloud from scans with different densities of the principal facades and their covers.

Using photogrammetry is possible to determine geometric properties of an object, however, in this case the data are obtained from only photographic images, eliminating restrictions positioning involved in moving heavy equipment laser scanner, as the data obtained with a simple camera, which also saves on economic investment.

However, the work of data processing is more elaborate, since unlike the laser scanner data are not obtained directly but it is necessary to obtain them using specific software, so it has to invest a greater number of hours of work to achieve similar accuracies to the system offered by the laser scanner.

4. Results

Once all the data collected in the field and after processing them can proceed with the development of virtual models, the principal is given by the sum of the different point clouds each sorting them either by using recognizable physical targets for the scanner or cabinet by using natural targets on the building itself or point cloud. You can also guide and record the point cloud by topographic relative or absolute coordinates obtained with the total station, GPS or through the observation of a point forward, a known point and behind the instrument height. This will get a nine or Cloud Virtual to which we can, for display, apply the property of the color obtained from the very intensity of the laser beam to impinge or through coaxial camera equipment or an outdoor camera for quality. In this case the point cloud was primarily used to determine the geometric elements such as large domes, arches, ribs, pilasters, etc...

With point clouds obtained we can start building volumes or maya directly through a mechanized process of self- management software point clouds, although the specific case of the vaults of the church studied has opted for a more artisanal procedure particularization consisting of each, particularized and separates each element. Obtaining the principal directions of the ribs, the shape of the plant and its stage, besides nerve section allowing us to proceed with the CAD drawing software proceed to the construction of an initial volume configured by lines or guidelines nerve to then proceed to the preparation of a new volume by simple extrusion or loft section of each rib along the guideline obtained or patterned, once completed to proceed with the cuts unions solidification set and obtain the corresponding fusions constructed to render them.

Fig. 6: Images corresponding wired neural arches and surface rendering models nervaturas model.

Fig. 7: Views of obtaining the address section of a nerve based on point cloud obtained once registered.

Fig. 8: Images corresponding to the pictures and neural modeling rendering at different vaults.

Once obtained the geometry of the nerves and obtained a solid we can proceed with the construction of a physical model, in our case concluded, for making these physical models Opted two possibilities, one through 3D printing by an inkjet printer on binder powder or the other by using a numerical control machine or drilling procedure, according to the element to be reproduced, in the case of large volume elements have chosen to 3D printing and powder injection in the case of predominantly surface or flat

elements we opted for machining by numerically controlled or milling. Being able to export the results in various supported formats such as DXF, JPEG, LAS, VRML and OBJ and more.

Fig. 9: Template made with a numerical control router sobe veneer 4 mm. And nerves profile of the vaults on point cloud.

For the analysis and study of smaller pieces has resorted to the use of feedback systems and documentation through the use of lighter and versatile photo cameras, with which we can make capturing multiple photos and mediate programs imaging usually free treat photogrammetric imaging systems direct intersection once calibrated or identified the camera, which we can also get quite dense point clouds all based on pixel camera. One time the point cloud obtained we can proceed to a mesh of the same in formation of irregular triangular meshes (TIM) which cover surfaces to which we apply the color or texture of the photograph itself, this system is the one has been used for modeling the bases, capitals, moldings and in general for all those elements ornamentals object modeling.

Fig. 10: Views of various ornamental elements modeled by mayado and texture obtained through camera.

Another way to appreciate the results is through video playback graph obtained from both the point cloud models as maya and vectorized by the engines own video display and allow us to obtain true virtual museum tours and even for the work, ranging from the most general aspect as are space, magnitude, even small and insignificant difficult to see at a glance by taking a real sense of proportion and unity.

Fig. 11: Views of the physical models made using a 3D printer in the case of the vaults and using of numeric control milling in the case of the front and niches.

5. Conclusions

The graphic documentation understand that it is an indispensable tool for the study, preservation and analysis of architecture built. So what is seen above, we can deduce the possibility of making a comprehensive record of information included in addition to the shape, color and texture model lift and thus get their virtual representation with a virtual cloud of points or the development of physical and tangible models.

The virtualization system or modeling , based on images or videos, virtual museum will provide a basis for sharing these experiences and share them with the general public through the global Internet granted and thus to value the heritage as intangible property and the building itself in question.

The application of this methodology has shown the consistency of measurement systems generally used independently, which can be seen from the early stages of architectural as lifting , their combined use is a significant reduction in the time needed to power operators overlapping tasks during data capture leveraging time intervals in which sweeps are performed with the laser scanner to take pictures that will process later by photogrammetry.

Experience noted that the combination of traditional systems and new systems architectural survey , are not incompatible, but the opposite, having to apply in most cases hybrid systems, thereby obtaining a graph accurate documentation and detailed of the various elements that constitute the proper " document " . Without data collection practiced alter or modify the physical conditions of the object (non-intrusive measurement), with a fast and accurate system, the results are easy to reference, and storage of information, which allows us to easily a check and monitor the evolution of the "document" over time. Promoting understanding of the building and its architecture. That may even be a technology or GIS and geo referencing serving turn experimental testbed for verifying and peritara building developments , checking them solve or proposals for future intervention without resorting to building.

Abstract

The conservation of architectural heritage encompasses various aspects of technical sciences. In large buildings, made and further modified in different stages with different materials and techniques, it is difficult to measure the “health” of its structure in a simple way. The monitoring through displacement gauges represents one of the less costly solutions for estimating the evolution of damage in an existing structure: evidence of damage is represented by an increase of displacements. Anyway, due to the nonlinear behavior of large constructions, it is possible that displacements are measured only when the damage is at an advanced stage. In this sense, urgent measures have to be taken for ensure the stability of the construction. A preliminary study of the monitoring system and a good calibration of the threshold displacement values is required in order to limit the uncertainty about the true damage evolution stage. At the end, a full example illustrating the strategy to adopt in monitoring an historical construction is proposed.

Keywords: Structural monitoring, progressive damage

1. Introduction

Architectural conservation has a crucial role in the modern era. The history of any country is in some sense defined by its architecture. The actual trends are focused on preservation of historical architectures and monuments.

Weaver [1] noted that architectural conservation of historic urban sites is the most important evidence of the past life style. The idea of preservation deals with issues of prolonging the life and integrity of architectural character and integrity, such as form and style, and its constituent materials, such as stone, brick, glass, metal, and wood. What exactly is architectural conservation has been defined by Stubbs and Makas [2]: architectural conservation constitutes actions and interests that address the repair, restoration, maintenance and display of historic buildings and sites or measures taken to keep the existing state of a heritage resource from destruction or change. Therefore, actions preventing decay and prolonging life are needed. This includes maintenance, repair, consolidation, and reinforcement.

The international community as a whole and, in particular, the international scientific community have a very important duty: protect the integrity of cultural heritage sites from the destructive effects of natural and man-made hazards. The most prominent factors affecting cultural heritage structures are the environment, pollution, and tourism [3-5]. Some sites with recognized cultural value have been already deteriorated, partially destroyed, or are in imminent danger due to the effects of various “stresses” as earthquakes, volcanic eruptions, floods, land subsidence, pollution and acid rains.

Engineers can help architects and all the people involved in the conservation of such objects through innovative techniques. As said, continuous deterioration plays one of the most relevant hazards for historical constructions. One strategy for assessing such continuous processes is represented by the installation of sensors able to detect unusual increments in displacements in the structure. These can

be related to progressive damage. Unfortunately, various problems occur. Preliminary to any discussion, the behavior of structures made by connected entities has to be highlighted (Section 2). Then, solutions to the emerging problems are presented. These are based on the idea of force paths in the structure. An example of what has been theoretically presented is reported in Section 4. General conclusions are, then, illustrated in Section 5.

2. Behavior of damaged structures

The response of connected structures to damage can be extremely variable. Usually, such structures are characterized by the presence of multiple load paths. In other words, once a set of loads is assigned to the elevation part of the construction, the ways the forces are transferred to the foundations is extremely variable. The presence of multiple load paths is essentially linked to the static indeterminacy of the scheme, for which equilibrium equations are not sufficient for finding the forces in the elements. Thinking about robustness, intended as the capacity of a structure not to be too sensitive to local damage, whatever the source of damage, the presence of multiple load paths is considered a powerful strategy for preventing large deformations due to local damages and, thus, for ensuring the robustness of the structure. In parallel, the robustness of the structure may be a good indicator on the possibility that the structure exhibits large or smaller displacements before the collapse. In these terms, it is important to assess whether a structure is robust or not. To discuss on the behavior of frame structures under localized damage and on the difficulty in assessing the progression of the damage, consider the structure represented in Figure 1, taken from [6].

Fig. 1: A three columns – one storey concrete frame. Two different damages are supposed to act, alternatively on the structure. The damage acting on the top right joint (indicated as grey shaded transversal black hatchings) represents the first situation. Otherwise, the plain grey area represents the second damage situation, from [6].

The example relates to a three column-one storey frame on which a uniform load acts on the horizontal deep beam. Since the system is symmetric, the bending moment in the central vertical element is null. Therefore, only an axial force acts on this vertical element. Idealizing the system as made by five monodimensional elements, say “beam elements” in a finite element software (two for the top beam and the remaining three for the columns), the degrees of static indeterminacy are 6. In this sense, as briefly explained, there are various load paths.

A main question follows: what happens if one column is progressively damaged? Since the system is statically indeterminate, the damage does not turn the equilibrated system into a mechanism. In particular, as soon as the degrees of static indeterminacy of the undamaged scheme are larger than one, the damaged scheme is still statically indeterminate (and presents more than one load path). In other words, damaging progressively one column, the remaining is able to sustain the external actions, i.e. to transfer the loads from the elevation to the foundation.

Suppose now to monitor the vertical displacement at the two mid-spans of the top beam. In the case in which the damage interests the top right joint, the resisting bending moment at that point reduces and, thus, the bending of the top beam increases, i.e. the mid-span of the right beam moves down. On the contrary, if the damage interests the cross-section of the central column, which is only subjected to axial force, the stiffness reduction is smaller. This is essentially due to the fact that the flexural stiffness is several orders of magnitude higher to the respect to the axial one. Hence, the damage progresses and the system apparently behaves as undamaged. The collapse may occur in two distinct

situations: (i) if compressive strength in the central column is exceeded and the element breaks in compression, (ii) if flexural strength is not sufficient for the additional horizontal force acting on the structure and generating bending in the columns [6].

As a result of what presented above, as much as there are alternatives in the ways the loads are transferred from the elevation to the foundations, the effects of damage can be various. There is the possibility that the monitoring of some cinematic quantities (say displacement or rotation) at the wrong point does not give any evidence of progressive damage [6].

This fact has been highlighted by De Biagi [7] in evaluating the variation of deformation work after a localized progressive damage. He generated topologically similar structures with different stiffnesses distribution. In theory, since the topology is constant in the analysis, the number of load paths does not change. Anyway, the different distribution of stiffnesses, i.e. the cross-section of the elements varies, causes the behavior of the structure to be different, once a load is applied on it. That is, if one considers the scheme into which the load path, i.e. the way the forces are transferred from the elevation to the foundation, is unique the suppression of elements belonging to the most effective (and unique) load path entails large increases in the work of deformation. In parallel, the removal of elements not belonging to the most effective load path, does not involve an increase in work of deformation. On the contrary, if the stiffnesses distribution is such that is not possible to identify the dominant load path, the effects of progressive damage on deformation work are extremely reduced.

2.1 Models for damage evolution

Damage phenomena on constructions are various and uniform approaches are difficult. Although the choice of a function for structural damage is a challenging task [8], specific approaches are possible only once damage causes are clearly identified. In order to assess structural robustness with respect to a progressive deterioration of the structural components, the damage on the structure acts at the material level. As reported in Lemaître and Chaboche [9], the phenomenon can be modelled by softening of material strength and/or stiffness. In this sense, the decrement of stiffness is governed by a reduction of material elastic modulus, from its nominal value to zero in the undamaged and totally damaged cases, respectively.

3. Monitoring for damage through displacements

The damage can be considered as an unplanned variation of the properties or of the geometry of one or more parts of a structure, which entails a weakening and, usually, negative consequences. The methods usually used in the evaluation of damage on a structure consider its static or dynamic response, or both. Previous researches shown that the former is more sensitive to damage than the latter [10] and stressed the fact that the instrumental equipment for static measures is economic and easy to install [11].

As stated in the previous section, because of the redundancy in the structural schemes, the interpretation of deflection, rotations and strains is not straightforward for a direct evaluation of the health of the structure [12]. The main problems in the usage of static data rise when the damage acts on an element that has no or fairly little contribution to structural deformation under a certain load case.

The response of the structure, under its elastic phase, is a function of the distribution of stiffnesses and the position and magnitude of the external loads. In structures with high degree of static indeterminacy, e.g. frames, the overall behavior is determined by the contribution of all the elements belonging to the scheme. For example, in a three stories frame subjected to vertical loads and horizontal wind forces, the actions at the foot of one of the columns are highly dependent upon the way the stiffnesses are distributed on the whole structure, rather than on the neighborhood of the column under consideration.

3.1 Instrumentation for displacement measurements

The best way to assess the displacements of a large construction is represented by a topographical survey. Marks are placed on the building at precise points and the position of the measuring instrumentation is clearly defined in the neighborhood of the construction (which may be considered fixed). At precise time steps, the relative position of the reference points (materialized on the construction with the marks) is measured by means of distance and angles. In order to evaluate the absolute displacement, the set of reference points has to include fixed points (say objects that cannot deform or move around the construction). The displacement of the measuring points is estimated by subtracting the positions of two consecutive surveys.

In order to get the measurement quicker, it is possible to idealize a fixed measuring gird. Concrete pillars can support topographical instruments and keeping the alignments unchanged for many steps. One of the major advantages of the possibility to fix the position at the initial time is represented by the automatic survey. The system is able to recognize the correct position and performs automatic

searching within the angular range set by the operator. In addition, the metallic marks can be substituted with crystal prisms and the procedure can be further accelerated.

4. Example: monitoring the main facade of Roman Theatre of Aosta (IT)

The effectiveness of the considerations made in the previous sections are now applied to a real example of piece of architecture.

4.1 Historical aspects

The considered construction is the Roman Theatre in Aosta, Northwestern Italy. It was built in the late reign of Augustus, some decades after the foundation of the city (25 BC), as testified by the presence of pre-existing structures in the area. There was also an amphitheatre, built during the reign of Claudius, located nearby. The theatre occupies three blocks annexed to the ancient city walls, along the Roman main road (the decumanus maximus, next to the Porta Praetoria. The structure occupied an area of 81 x 64 m, and could contain up to 3 500/4 000 spectators.

What remains today include the southern facade, standing at 22 m. The theatre is made of large parallelepipeds of “puddinga” a local sandstone with large grains. It was covered by slabs of limestone. The cavea was enclosed in a rectangular-shaped wall including the remaining southern part. This was reinforced by buttresses each 5.5 m from the other, and included by four orders of arcades, which lightened its structure. It has been supposed that the theatre once had an upper cover, making it a *teatrum tectum*.

The orchestra had a diameter of 10 m. The scene, of which only the foundations remain, was decorated by Corinthian columns and statues, and was covered with marble slabs [13].

The first archeological analyses were made in the first half of 19th Century by Promis. At the beginning of 20th Century, the facade was still covered by medieval houses and part of the area was totally covered by debris. During Fascism, the architectural shape was highlighted through the demolition of superfluous constructions and with excavations, see Figure 2. Many problems due to humidity and low temperature emerged after this intervention. The building was later restored in 2009, see Figure 3.

Fig. 2: Roman Theatre of Aosta in the Thirties during the first intervention works. The houses built around the historical monument were demolished, source Wikipedia [13].

Fig. 3: The Roman Theatre of Aosta nowadays, source Regione Autonoma Valle d'Aosta.

4.2 Damage analysis

In the following, the structure of the main facade of the Roman Theatre of Aosta is subjected to a progressive damage. As explained in Section 2.1, the damage model takes into account the reduction of Young's modulus of the material constituting the construction through the parameter d . Young's modulus of the undamaged "puddinga" is set equal to 10 GPa.

The damage parameter varies from 0 to 1 for undamaged and totally damaged (i.e. removed) element, respectively.

A frame-equivalent scheme discretizes the masonry facade. A node is set at each connection. Beams connect the nodes. The model is composed by 49 nodes and 76 beams. The cross section dimension of each beam is determined from the sizes of the real masonry structure. The self-weight of the construction is inserted in the numerical model through nodal loads. The frame-equivalent scheme has been determined from rotated and scaled pictures, see Figure 4.

Fig. 4: The main facade of the Roman Theatre of Aosta, source Regione Autonoma Valle d'Aosta.

Since progressive damage velocity is extremely reduced, each damage situation can be considered as a static case. Each simulation consider the damage progressing on just one element. The vertical and horizontal displacements of a control point are monitored as much as the damage evolves on the structure. The control point is at the top of the construction, as indicated by red diamond in Figure 5. The initial displacement, in case of undamaged element, is subtracted from the set of measurements as long as the damage evolves. This gives the possibility to measure relative displacements, instead of giving absolute values that may be prone to various measure errors. In this sense, in the undamaged situation, the monitored value is null.

Fig. 5: Localization of the control point (red diamond) and the damaged elements

The vertical displacement due to damage evolution is proposed in Figure 6. Here we show that there are damages that imply larger displacements at the control point, and others not.

The vertical displacement at the control point (red diamond in Figure 5) is plotted as a function of the damage on elements of the frame-equivalent structure. As can be seen in Figure 6, there is evidence of progressive damage only in a limited set of cases. For example, as much as damage progresses on element F, i.e. one of the main columns of the masonry facade, the displacement increases rapidly. Effects of damages on vertical elements are various. Despite the fact that a damage on the columns close to the measurement point induces larger vertical displacements, this does not appear in the case of damage on distant columns.

The horizontal displacement at the control point is plotted as a function of the damage on elements of the frame-equivalent structure. As can be seen in Figure 7, the response of the structure to damage is variable. The main effects are shown in case of damage on elements D and J. This causes large horizontal displacements after the damage reaches a prescribed value. Damage on horizontal beams, say element E, does not cause an increase of horizontal displacement.

Few considerations can be drawn:

- the proposed calculations showed that damages close to the monitored point do not always imply increase in the recorded data. Remembering the damage on element E, no horizontal and vertical displacements are measured, while the damage acts. This is due to the lack of external horizontal forces acting on the structure.
- the evolution of damage and the evolution of displacements are not linear. That is, I record a large increase in the measurements as much as Young's Modulus of the damaged element is close to zero. This affects my estimates on the real health state of the structure.

5. Conclusions

It has been shown that, in frame systems, the response of the system is governed not only by the evolution of damage, intended as a localized reduction of Young's elastic modulus, but also by the

connectedness of the elements. This implies non-linear response of the system when damage occurs on one of its parts.

This fact is important in structural monitoring. The local measure of displacements can give wrong interpretation of the real progressive phenomenon. As clearly visible in Figures 6 and 7, the response of the system does not increase to the final value as much as the damage evolves. This is due to the connectedness of the system and its capacity to redistribute the loads.

An example on a real historical construction shows this property of such structures. The best strategy we propose is to subject the structure to other sort of external loadings (say by mean of tendons) in order to activate other load paths in the structure and highlight all the possible damages.

Fig. 6: Vertical displacement at the control point as a function of the damage on vertical and horizontal elements of the frame-equivalent structure.

Fig. 7: horizontal displacement at the control point as a function of the damage on vertical and horizontal elements of the frame-equivalent structure.

Abstract

The aim of the paper is to describe the non-destructive tests performed on the clock tower of the Castle of Trani (Bari, Italy). The tower is about 9 meters high and has a square plan with a side of about 3.90 meters; moreover it is built on the principal enter of the Castle and supported by a barrel vault reinforced with an arch.

The tower, built in 1848, was realized in tufa masonry (Stone of Trani); nevertheless, during the years, it has undergone a series of interventions, in particular in 1979 and 1997 to consolidate the walls cores with armed injections and the vaults extrados with hood in reinforced concrete.

The non-destructive monitoring was realized using specific accelerometers placed on the structure for measuring the acceleration in different points. The particular squat structure of the clock tower made the traditional monitoring, with only environmental actions, the so called only-output measurements, not so safe for determining the building modal parameters. For this reason, an electro-hydraulic shaker was ad-hoc designed and realized for applying a controlled dynamic force on the examined old masonry tower.

In this paper all the phases and procedures of the experimental monitoring will be described together with a preliminary analysis of the data.

Keywords: Non-destructive monitoring, Masonry Tower, Forced Vibrations, Dynamical analysis.

1. Introduction and historical background

Trani Castle is one of the most important castles among those erected by Holy Roman Emperor Frederick II. It is placed close to the sea and its location on the edge of the town allowed to guard the entrance of the port and the access roads to the village.

Originally the Castle had a simple and functional quadrangular enhanced layout with four square towers with the same height. The clock tower of the castle (Fig.1), in tufa masonry, was added to the main entrance in the XIX century, just when the castle became a prison. With this modification of its end use, many changes underwent, but fortunately the interventions of the XIX were only superimposed to the old structures and consisted of opening and closing passages, local filling of masonry walls, the construction of new rooms, always using the existing structures to fit with the least expense to the new needs. The clock tower was built by Tommaso Moscatelli early in 1848, while the clock was built and put in place by Vincenzo Russo in 1848.

In 1976 the castle was consigned to the Superintendence for Architectural, Artistic and Historical Heritage of Puglia who started restoration works since July 1979 and finally the opening to the public of the monument was celebrated on the 5th of June 1998.

Fig. 1: The clock tower of Trani.

The dynamic behavior of the historical buildings is usually analyzed in order to evaluate its vulnerability, and eventually for designing repair intervention solutions and retrofitting to seismic actions. Retrofitting interventions on old masonry structures are quite common as these ones, like the tower under exam, have been built to resist only to vertical actions. Studies consider different kinds of analyses [1], the mechanical characterization of the structural materials [2] and intervention techniques [3-5] to improve the behavior of masonry structures. The most utilized techniques consist in non-destructive in situ tests aimed at acquiring acceleration data in specific points of the structure induced by ambient and forced vibrations.

Usually the experimental data are recorded by means of a series of accelerometers installed in specific points of the structure, and subsequently are analyzed through the Operational Modal Analysis (OMA) (i.e. [6-11]), with the aim of evaluating the modal properties of the structure. Slender structures, such as towers, are particularly suitable to this type of investigation [6-15], as they show significant vibrations also in the field of low intensity actions, like the ones induced by ambient actions. The analyzed clock tower can be considered a squat building; this circumstance has suggested to perform forced dynamic tests [15] in order to obtain more clear data. To this aim an appropriate electro-hydraulic shaker has been designed, built and used for forcing the structure to vibrate. In the paper the equipment and the experimental set up utilized for in-situ dynamic identification tests are described and an extensive analysis about the effects of the shaker on the response of the tower is presented.

2. Description of the tower

The clock tower is about 7.0 m tall and consists of three parts: the base, the clock and the hut where a small bell is housed. The base has a slightly trapezoidal shape and rests directly on the walls at the entrance to the Castle, immediately after the stone bridge that crosses the moat. The clock tower is about 4.0 x 4.0 m in plan., its structure consists in masonry walls in Apulian tufa (with a variable thickness of about 75 cm), covered with Trani stone, of about 25 cm thick. The clock part, with similar dimensions of the base, is a cubic element that has, on each facade, a division in different parts. On the main facade there is the face of the clock, in perfect line with it, while the other sides has lower-level openings.

On the last level, in perfect proportion with the underlying layers, there is a hut which was used to house a small bronze bell that, at the time when the castle was used as prison, indicated the changing of the guard, but that however it was not presented during the dynamic tests.

Each level is defined by a cornice; the one which separates the first from the second level is rounded and has no protrusions; the frame on which the hut is set is convex and presents a higher protrusion.

The artifact is accessed from the plan sets with the castle wall through an opening.

3. Description of the testing set-up

The monitoring system consists of several elements properly connected: the acquisition units or piezoelectric accelerometers with a sensitivity of about 1000 mV/g; the data acquisition system or DAQs positioned at each of the monitored level; the laptop with an acquisition software; the cables that connect all elements to each other. In the specific case twenty-three high sensitivity seismic accelerometers ICP PCB 393B31 were positioned on the four corners of the tower; using appropriate rectangular blocks for ensuring the orthogonality (see details in Fig.2). The accelerometers were

placed on four different levels in such a way to guarantee a certain alignment (Fig.3); two accelerometer were placed on the superior arch for monitoring the oscillation of the upper part, probably the most significant local modes for stability analysis. This paper will consider the data of the accelerometers aligned in the frontal side including the superior arch and registering the vibration orthogonal to the main entrance and indicated as positions A,B,C and D in Fig. 4.

Fig. 2: Details of the accelerometers mounted on the tower and the connecting wires

Fig. 3: Different levels of alignments of the accelerometers in two different sides

Fig. 4: The considered accelerometers positions A,B,C,D and the shaker position

The forced vibration tests have been performed by means of an electro-hydraulic shaker (fig. 4). In particular, the system adopts an electronic control system that governs a hydraulic pump valve (with a maximum flow rate of 40 l/min and a maximum pressure of 120 bar) and drives the actuator device to-and-fro by adjusting hydraulic power units. The shaker can apply a maximum static force of 50 kN and is characterized by a large stroke (maximum displacement of ± 100 mm); moreover the shaker has a 200 kg stabilizing mass. Due to specific limitations imposed by the Superintendence and to logistic difficulties, it was not possible to place the shaker near the clock tower. As a consequence, it was decided to position the shaker at the main entrance of the Castle without a direct contact with the turret and with a vibration direction orthogonal to the door, while the hydraulic pump was behind the actuator and connected with the two actuator chambers by pressurized black wires.

4. Experimental tests

4.1 Preliminary results in environmental conditions

The experimental tests were carried out on the 24th January 2014. Preliminarily, three environmental tests were conducted for testing the amplitude of the recorded oscillations. The tests lasted 15 minutes with an original sampling rate of 1024 Hz.

The data have been under sampled to 128 Hz and also normalized eliminating the offset of each signal by subtracting the mean value of each acquisition.

In Figs. 5-8 the three time histories for the four considered positions A,B,C,D are plotted.

From the results shown in Figs 5-8 two important considerations may be immediately carried out:

- the repeatability of the oscillations for the three different tests;
- the different amplitude of the oscillations for the four considered measure points in all the tests: the peak to peak value of the oscillations in position A (on superior arch over the turret) is around 4×10^{-4} [g], it decreases to 2×10^{-4} [g] in position B (upper part of the turret), to 10^{-4} [g] in position C (middle part of the turret), to around 0.8×10^{-4} [g] in position D (lower part of the turret). This consideration ensures a registered environmental oscillation of the superior part of the turret and of the arch nevertheless the very stocky profile of the building; the peak to peak values are consistent with the accelerometers sensitivities ensuring the correctness of the used experimental setup.

Fig. 5: Time histories in position A (environmental excitation)

Fig. 6: Time histories in position B (environmental excitation)

Fig. 7: Time histories in position C (environmental excitation)

Fig. 8: Time histories in position D (environmental excitation)

4.2 Results of the tests with the use of the electro-hydraulic shaker

In order to amplify the oscillations values the electro-hydraulic shaker has been placed as previously described in Fig. 4. The first test was carried out considering an excitation with the same amplitude and a changing frequency during the acquisition. In detail the frequency was changed from 1 Hz to 15 Hz with a step of 2 Hz manually modified every about 2 minutes. The final 80 seconds of acquisition have been done switching off the motor in order to evaluate the influence of the motor to the oscillations in the considered positions.

The results for the four considered positions are shown in the following Figs. 9-12. It is evident that the shaker amplifies the oscillations in all the positions (with a factor of 5-10 times with respect to the environmental oscillations of Figs. 5-8); nevertheless it is placed in the base entrance without a direct contact with the tower structure. Moreover, it is interesting to observe a relevant amplitude variation according to the shaker frequency variations; in all the positions the signal increases in the second part when the shaker frequencies gets to 9, 11, 13 and 15 Hz.

Finally, observing the last 80 seconds of the acquisition when the pump motor is switched off, it is evident that there is a brusque reduction of the oscillations. In order to investigate on this aspect, another acquisition of six minutes has been carried out considering the oscillations related to the effect of the pump motor only. The results are shown in Figs. 13-16 and they show clearly that the dominant effect of the oscillation is due to the pump motor. This preliminary analysis convinced the authors to use the shaker with only the accumulator power (motor switched off) in order to excite the structure avoiding the vibrations of the motor. Next section shows the results in this testing condition.

Fig. 9: Time history in position A (with variable frequency shaker and motor)

Fig. 10: Time history in position B (with variable frequency shaker and motor)

Fig. 11: Time history in position C (with variable frequency shaker and motor)

4.3 Results of the tests with the use of the electro-hydraulic shaker with only the accumulator

The preliminary analysis has been very useful for arranging further tests without any doubt about the possibility of damaging the structure and/or about the possibility of acquiring data only related to the shaker forcing action and not influenced by the pump motor effects. For this reasons, short tests were carried out using only the accumulator energy. Nevertheless the accumulator autonomy was very short and also depending by the frequency; for example, for a frequency of 3 Hz the accumulator has 110 seconds of autonomy, but it decreases to about 50 seconds for 9 Hz, to about 25 seconds for 18 Hz and to only 15 seconds of autonomy for 20 Hz. All the time histories of the tests are shown in the following Figs 17-20 for the considered positions.

Fig. 12: Time history in position D (with variable frequency shaker and motor)

Fig. 13: Time history in position A (with only motor)

Fig. 14: Time history in position B (with only motor)

Fig. 15: Time history in position C (with only motor)

Fig. 16: Time history in position D (with only motor)

It is evident that the amplitude varies at changing the frequency of the shaker; in all the positions the maximum amplitude is achieved with a frequency of 18 Hz, letting us consider that this value could be considered very close to the first natural frequency of the building. Anyway the results here discussed are meaningful as they demonstrate the applicability of the electro-hydraulic shaker for forcing the structure also if it is not applied directly in contact with the turret.

Fig. 17: Time histories in position A with different shaker frequencies

Fig. 18: Time histories in position B with different shaker frequencies

Fig. 19: Time histories in position C with different shaker frequencies

Fig. 20: Time histories in position D with different shaker frequencies

5. Conclusions

In this paper the efficacy of an experimental setup, that was *ad hoc* designed for the dynamic tests of a squat structure, is investigated. In particular, the setup has the possibility of forcing the structure with excitations having different frequencies and amplitudes; the real effect of the frequency variation on the structural response recorded at different levels of the tower has been extracted, giving useful

information on the dynamical behaviour of the clock tower. The here presented data demonstrate the possibility of the designed experimental setup of amplifying the oscillations of the tower also when the shaker cannot be directly connecting the examined tower, as in the case here discussed.

Abstract

The ancient temple dedicated to the Roman Emperor Augustus on the hilltop of *Tarraco* (today's Tarragona), was the main element of the sacred precinct of the Imperial cult. It was a two hectare square, bordered by a portico with an attic decorated with a sequence of clypeus (i.e. monumental shields) made with marble plates from the Luni-Carrara's quarries. This contribution presents the results of the analysis of a three-dimensional photogrammetric survey of one of these clypeus, partially restored and exhibited at the National Archaeological Museum of Tarragona.

The perimeter ring was bounded by a sequence of meanders inscribed in a polygon of 11 sides, a hendecagon. Moreover, a closer geometric analysis suggests that the relationship between the outer meander rim and the oval pearl ring that delimited the divinity of Jupiter Ammon can be accurately determined by the diagonals of an octagon inscribed in the perimeter of the clypeus.

This double evidence suggests a combined layout, in the same design, of an octagon and a hendecagon. Hypothetically, this could be achieved by combining the octagon with the approximation to Pi used in antiquity: $22/7$ of the circle's diameter. This method allows the drawing of a hendecagon with a clearly higher precision than with other ancient methods. Even the modelling of the motifs that separate the different decorative stripes corroborates the geometric scheme that we propose.

Keywords: Tarraco, clypeus, Augustus, geometry, hendecagon, Pi-approximation.

1. Investigation context

This article suggests the existence of a geometric model used for shaping monumental clypeus of the sacred enclosure of *Tarraco*, which are preserved at the National Archaeological Museum of Tarragona. This proposal is a result of collaboration between architects from the Technical Superior School of Architecture (ETSA) from *Rovira i Virgili* University (URV) and archaeologists from Catalan Institute of Classical Archaeology (ICAC), from the interchange of knowledge applied to photogrammetric documentation of architectural heritage as a previous step of the functional and chronological analysis of their structural elements.

The enlargement of the Imperial cult developed in provincial capital a homogenous architectural and artistic language, which was based on the monumentality of Imperial Forum in Rome. In the case of Tarraco, the attractiveness of the hilltop sets up a true religious acropolis, where, through centuries, the main worship building of the city had been superimposed. In this context, the current investigation locates, under the medieval cathedral still in use today (fig. 1e), the worship octastyle temple devoted to Emperor August (fig. 1d), built from Tiberius' period emulating *Mars Ultor* Temple. Afterwards, this *aedes* was preserved during the final transformation of the acropolis into monumental headquarters of the *Concilium Prouvinciae Hispaniae Citeriores*. So that Augustus Temple was kept in use in the centre

of a new square erected in the Flavian period (fig. 1a); image and likeness of *Forum Pacis*, in this case. So was introduced a new model of imperial urban sanctuary with formal similarity as Cigongnier in Avenches or Courseul Forum [5].

The new sacred square was delimited by a monumental portico completely made of marble from Luni Carrara and whose colonnade held up an entablature compounded of architrave, frieze and cornice. Over the entablature an attic showed a succession of clypeus with Jupiter-Ammon's figure, clearly inspired in the portico of *Forum Augustum*. Most of the clypeus recovered from Tarragona correspond a syncretic image of Jupiter-Ammon while, for the time being, the identification of another mythological figure is doubtful. A possible fragment of clypeus could reproduce a model of Medusa, although it is not entirely sure (see [6] fig. 3.5). If it is so, this model is related with other emblems of Medusa decorated in base of straight and oblique tabs [3] [8]. This possibility could be related to an iconographic programme of porticoed gallery with attics decorated by an alternation of Jupiter and Medusa clypeus, documented for first time in Flavian period (see [8] p. 575). In Tarraco, and unlike the first model of *Forum Augustum* or in the copies of Pozzuoli and Mérida, separation between clypeus would be performed through panels divided by vegetal candelabrum, as it is found in the cities of Avenches and Arles, or in the forum of Nyon (see [8] p. 567).

The analysis of the recovered fragments, either clypeus elements or candelabrum reliefs, show an average thickness around 16 cm. Regarding clypeus diameter, E. Koppel had achieved around 150 cm [3], this measurement was modified by R. Mar and P. Pensabene (1,35 cm [7] p. 135); our photogrammetric restitution shows around 160 cm.

2. The singularity of hendecagon

Planimetry of Roman architecture used to be based on simple arithmetic operations, the layout of basic shapes (triangles, squares, rectangles, circles) and their manipulation with ruler and compass (fig. 3). This allows to easily obtain derived figures (e.g. the hexagon, the octagon), as well as immeasurable proportions (e.g. the golden section ratio Φ , $\sqrt{2}$, $\sqrt{3}$).

Fig. 3: Basic geometries of Roman architecture.

Typically, central plan Roman buildings (or interior spaces) are articulated from hexagon and octagon. Vitruvius, in the 6th chapter of the 5th book, describes the laying out beginnings of a Latin theatre using four triangles inscribed in a circle, forming a dodecagon, that is, the first subdivision of a hexagon. The Domus Aurea (fig. 4b.) and the Domus Augustana have octagonal rooms, the same geometry we find in the central islands of Leptis Magna Forum and in many rooms of thermal buildings. The 4th-century villa, constructed over the Baths of Trajan (fig. 4d), has a hexagonal layout, as it happens in a courtyard of the Jupiter Heliopolitanus Sanctuary in Baalbek or the columns that surround the inner courtyard of the rotunda-mausoleum built by Constantine in Rome (Santa Costanza Church). We can consider Hadrian's Villa as the culmination of this Roman geometric articulation system for architecture: the so-called *Academia* and *Teatro Marittimo* has a plan based on an intricate layout draft by circles centered at the vertices and axes of an octagon. In the tomb of Portus (fig. 4c.) we can even identify a simultaneous use of the hexagon and the octagon in the same building: the inner room is laid out by an octagon, while the outer peristyle consists of 24 columns, the result of dividing two times a hexagon. These considerations on the large scale can be transferred to architectural decoration, with column shafts with 24 (4x6) striae, vegetal decorations with hexagonal or octagonal flowers, etc.

The use of more 'sophisticated' regular polygons, as the pentagon, the heptagon or the hendecagon, is less common, but we can give some examples. The statue group known as the Dying Gaul in the Capitoline Museum has a pentagonal diagram inscribed on its base (see [12] fig. 3.7). The tholos by the Tiber at Rome (fig. 4e), at the Forum Boarium, has a peristyle of 20 columns, probably the result of subdividing 2 times a pentagon. The so-called Temple of Minerva Medica (fig. 4f), in the Licinianus Gardens of Rome, presents a plan structured through a decagon, the first subdivision of a pentagon. We have only found a Roman building that we can attribute to a hendecagon based geometry. The tomb at Capua known as *Le Carceri Vecchie* has a circular base with 22 modules, the result of subdividing a triangle or, as discussed below, applying the approximation of Pi given by Archimedes to laying out an architectural plan: according to Mark Wilson Jones [12] (fig. 4.7d, p.75) its diameter is 70 feet, while the 22's intercolumniations of the facade are 10 feet, which leads us directly to the fraction 22/7.

We return now to the decorative element typology that concerns us here. Some of the clypeus from the Imperial Forums in Rome has a decorative crown articulated by an octagonal geometry, as we have verified in figures 2d y 2e. In both cases we have analysed reconstructive drawings published by Lucrezia Ungaro [9] (2007, p. 155, fig. 203) [10] (2004, p. 22, fig.15).

We also found the octagonal geometry in Mérida Forum clypeus fig. 2f/2g). Especially significant is the case of clypeus 2g: we have restored its geometry from the photograph published by José Luis de la Barrera [1] (lamina 83, Cat. 229), who considers that because of the fineness of its carving, and the fact of being the only Carrara marble clypeus of the whole Forum, can be attributed to a master stonemason that would set the model to follow. The clypeus 2f ([1] lamina 92, Cat. 243) is a piece almost entirely preserved; strangely, in the drawing provided by Barrera ([1] in fig. 26) the outer crown is divided in 34 parts, instead of the 32 (4x8) which can be counted in the picture.

Concerning the hexagon, we identify it in the geometry of a clypeus with *anthemion* at Pozzuoli (fig. 2i) that shows the reconstructive drawing published by Fausto Zevi and Claudia Valeri (in [13] figure 10, p. 457).

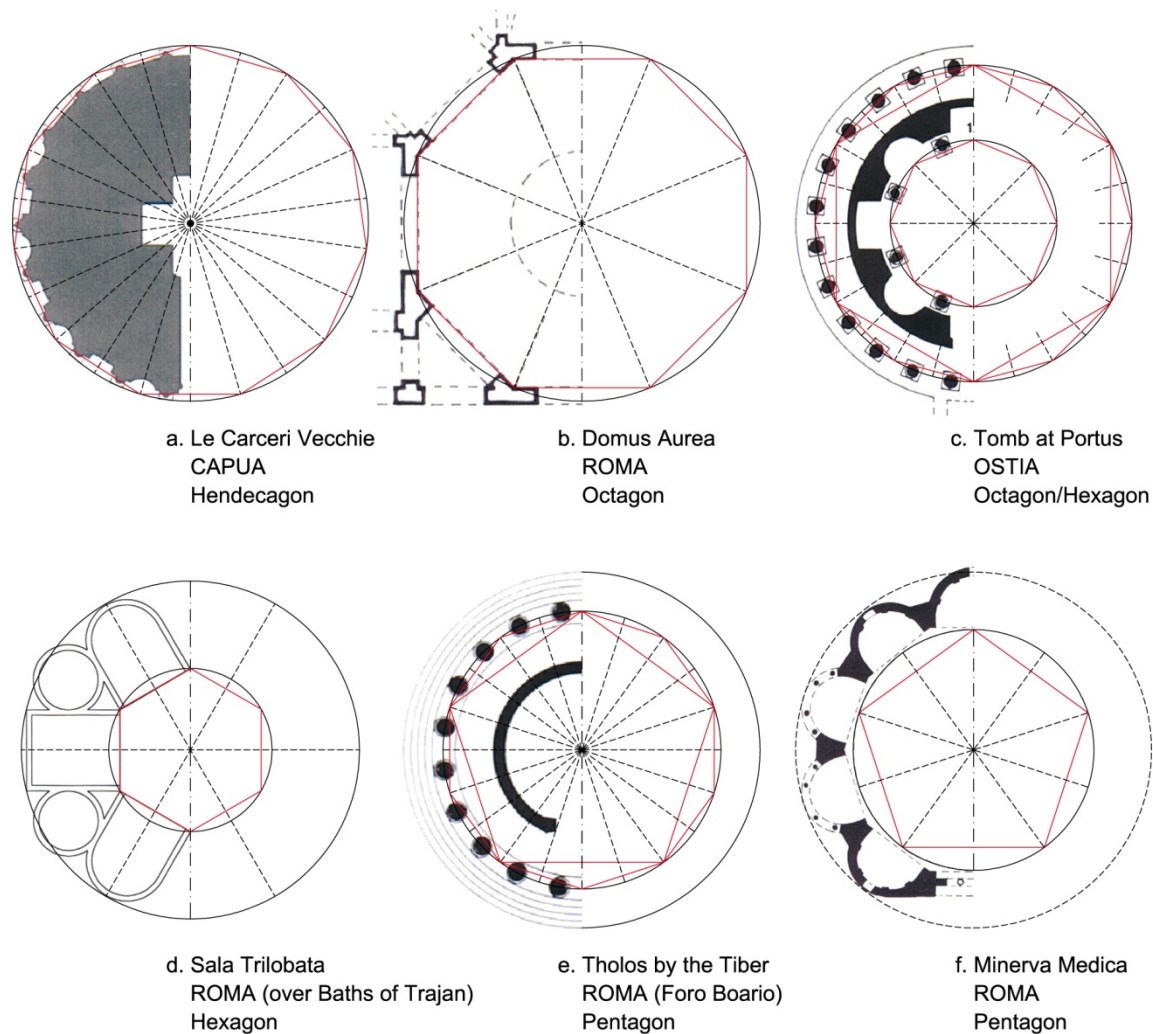

Fig. 4: Central plan Roman buildings. Key geometrical scheme overlaid to the drawings published by Mark Wilson Jones [12] and John B. Ward Perkins [11].

Can we mention clypeus based on more exotic regular polygons? Yes, but with some cautions. There is a Mérida clypeus which seems to correspond to a heptagonal geometry (fig. 2h). In the José Luis Barrera picture on which we base our geometric analysis [1] (illustration 95, Cat. 245) can be distinguished large reconstructed areas. However, we note a great uniformity in the size of the 28 pods that form the crown (4x7, two subdivisions of a heptagon), which gives us confidence in the validity of the restitution.

In the clypeus integrated into the reconstruction of the portico of the Mars Ultor Temple temenos, (fig. 2b) provided by Lucrezia Ungaro [9] (p. 154, image 202), we can distinguish two rings around the central medallion: the internal decorated with feathers and the external with pods. The second consists of 44 pods, a hendecagon divided twice.

The decorative scheme of Rome clypeus 2b is repeated on the clypeus of Pozzuoli 2c. On the basis of the reconstructive drawing published by Zevi and Valeri [13] (p. 459, image 12), we consider that in this case the hendecagon figure establish the geometry of the inner decorative ring.

Our initial hypothesis for the clypeus of Tarragona was that the reconstruction of the meanders crown shown at the National Archaeological Museum was wrong. We believed that an accurate survey of the original fragments would determine a decorative crown marking from a 12-sided polygon, a simple subdivision of a hexagon, or 10-sided, a subdivided pentagon. We were wrong.

We conducted a 3D survey of the reconstruction exhibited at the Museum through *Autodesk's 123D Catch* software, exporting the generated 3D model in OBJ format and analyzing it using CAD programs *Rhinoceros* and *Autocad*. A close examination of the original parts allowed us to determine that the pods between each meander module were arranged forming an angle between 32.5° and 33°, very similar to the 32.72° of a regular hendecagon, and sufficiently far from the 36° that would correspond to a decagon or the 30° of a dodecagon, so as not to have doubts about the figure that was used to compose the piece.

This finding led to a new question, and very interesting: how this hendecagon was laid out? We are not facing a building plan, the Clypeus is a decorative piece, yes, but its dimensions and the precision

of the execution seem to rule out a marking based on trial and error. Also has to be kept in mind that we refer to a series of quadrangular marble plaques of, approximately, $\frac{1}{2}$ Roman foot thick (14.8 cm) and about $5\frac{1}{2}$ feet sideways (162.8 cm), weighing nearly a ton. They all had to fit in the attic of the portico, and its design should articulate with the corresponding architectural modulation, while its carving obeyed standard parameters that involved an organizational template, previously to chiselling relief and repeated for each marble panel.

The exact construction of a hexagon or a regular octagon is obvious. In the first case is sufficient to mark the radius of a circle around its circumference. In the second has to be inscribed a square in a circle and then drawn the bisector of its sides. The pentagon can also be accurately plotted with ruler and compass, but with slightly more complicated operations, not obvious to someone without advanced knowledge of geometry. Does not exist, however, an exact design to draw a hendecagon [14] (nor for the heptagon and other regular polygons [15]). Therefore, to draw a hendecagon with ruler and compass it is necessary to resort to approximate constructions. In table 1, by the end of this paper, we summarize the length of the sides and the deviations from a regular hendecagon for all layouts discussed.

In figure 5 we show a first approximation, quite complex and unintuitive, that provides a construction with relatively small deviations: while a regular hendecagon inscribed in a circle of diameter $\varnothing=1$ has 11 sides of equal length $L \approx 0.2817$, with this *complex approximation* we obtain 7 sides with $L \approx 0.2828$ (a deviation of +0.37%) and 4 sides with $L \approx 0.2799$ (a deviation of -0.65%).

Fig. 5: *Complex approximation to a hendecagon construction.*

A simple approximation to the hendecagon construction involves dividing the radius of the circumference which is inscribed in 25 parts, and then take 14 to draw a side (fig.6). The resulting figure has 10 sides where $L=0.28$ (a deviation of -0.61%) and a side where $L \approx 0.2990$ (with a considerable deviation of +6.13%). According to Thomas Heath [2], this solution was already known in classical Greece, and is perfectly consistent with the Greco-Roman geometrics operations: is based on a simple fraction, $25/14$, a formulation similar to approximations of Pi proposed by Vitruvius and Archimedes. Indeed, in the next section, we will rely on the Archimedes' approximation of Pi to propose various alternative constructions for hendecagon.

Fig. 6: *Simple approximation to a hendecagon construction.*

3. Hendecagon construction combining the octagon with the Pi approximation

As we have seen, some of the clypeus from the Forum of Augustus at Rome, the reference model for Tarragona's Sanctuary, clearly present a geometry derived from octagon (fig. 2d y 2e). Apparently this is not the case in Tarragona: meanders of the outer ring of the clypeus are not laid out, as expected, by a subdivision of the hexagon or octagon. Instead we found a hendecagon defining its geometry. However, if we inscribe an octagon in its outer perimeter the diagonals appear to define with a certain precision the ratio between the outer ring and the central medallion (see right half of fig. 9).

But, how can we relate both figures? Then we recall the approximation of Pi given by Archimedes through a numerical procedure for calculating the perimeter of a circumscribing/inscribing polygon of $2n$ sides, once the perimeter of the circumscribing/inscribing polygon of n sides is known, based on the properties of the bisector of an angle of a triangle described in proposition III of book VI in Euclid's Elements.

Subdividing the hexagon 4 times, Archimedes succeeded in calculating the approximate perimeter of polygons of 96 sides (6×2^4) inscribed and circumscribed to a circle, establishing Pi value between $(3+10/71) \approx 3.1408$ and $(3+1/7) \approx 3.1429$. The upper limit can be expressed with a simple fraction, $22/7$, that fits well with the practical procedures used by Roman builders to make measurements. Vitruvius himself gives an approximation of Pi expressed in similar terms: right at the beginning of the 9th chapter of the 10th book he describes a method to calculate distances by turning a cart-wheel: if it has a diameter of 4 feet at every turn it will travel about 12 and a half feet, that is, proposes assimilate Pi to the fraction $25/8$, an approximation with an error of 0.5%. The Archimedes' $22/7$ represents an error of only 0.04%, an order of magnitude lower; obviously his work was known in the Roman world, and it is reasonable to think that was within the mathematical background available for Roman builders.

On the other hand, we can use the Archimedes' fraction to perform an approximate hendecagon construction. We have already seen that Wilson Jones [12] proposes for *Le Carceri Vecchie* at Capua (fig. 3.a) a width of 10 feet for each of the 22 facade modules, while the diameter of its circular plan would be 70 feet; namely, he directly refers to the fraction of Archimedes. Obviously, a regular polygon of 22 sides allows us to draw a hendecagon joining vertices 2 by 2, but the direct application of the fraction $22/7$ produces a considerable error in the layout. In the left construction of figure 7 we have divided the diameter of the circle which it is inscribed in 7 parts, an operation that can be easily performed with the theorem of Thales or picking a metrology that facilitates the division (e.g. the 70 foot diameter plant of *Le Carceri Vecchie*). If we mark $\emptyset/7$ along the perimeter of the circumference we obtain an hendecagon in which 10 sides have a length $L \approx 0.2828\emptyset$ and 1 side where $L \approx 0.2712\emptyset$; regarding regular hendecagon (where $L \approx 0.2817\emptyset$) we have an approximation of its layout on which 10 sides have an error of +0.37% and 1 of -3.74%.

We can refine this system subdividing the diameter modulation. If we divide it into 14 parts and we mark $\emptyset/14$ along the circumference (central construction of fig. 7) we have 10 sides where $L \approx 0.2821\emptyset$ (+0.12% deviation) and 1 side with $L \approx 0.2783\emptyset$ (-1.22% deviation).

A new subdivision of the diameter, now up to 28 parts (right construction of fig. 7), improves the accuracy, with 10 sides where $L \approx 0.2819\emptyset$ (a deviation of +0.06%) y 1 side with $L \approx 0.2800\emptyset$ (a deviation of -0.60%).

Fig. 7: Approximate construction of a hendecagon through Archimedes' approximation of Pi.

The subdivision process of the diameter of the circle may continue, getting better and better approximations to a regular hendecagon. But we stop at the second subdivision, which involves expressing the Pi approximation $22/7$ by the fraction $88/28$. For a circumference of 1 meter in diameter (Tarragona's clypeus are slightly wider, having an overall diameter of around 1.6 meters) we have, theoretically, a deviation of 2 mm in the worst side and of 2 tenths of a millimetre in the remaining 10 sides, an error within the graphic tolerances when drawing over a stone slab. The problem here would be the accumulation of errors: would be necessary to transfer 88 times on the circumference of a circle the subdivision in 28 parts of its diameter. This is where the octagon comes in. Since the numerator of the fraction $88/28$ is divisible by 8 we can adjust the laying out by first drawing the diagonals of an octagon, a trivial and accurate operation, to restart the marking of 11 modules in each of the eight arcs of a circle defined by the octagon (see fig. 8), thus avoiding much of the possible distortion caused by the accumulation of errors.

Fig. 8: Approximate construction of a hendecagon combining the octagon with the Pi approximation.

This solution provides an approximation to the hendecagon indistinguishable from the regular polygon in the laying out of a decorative piece with the size of the clypeus studied here, as can be checked in the table 1 in which we summarize the deviations of the constructions we have presented.

		sides length	deviation
regular hendecagon	11x	0,28173256	
complex approximation	7x	0,28278381	0,37%
	4x	0,27989206	-0,65%
simple approximation	10x	0,28000000	-0,61%
	1x	0,29900670	6,13%
approximation by $\emptyset/7$	10x	0,28278381	0,37%
	1x	0,27120167	-3,74%
approximation by $\emptyset/14$	10x	0,28207649	0,12%
	1x	0,27829128	-1,22%
approximation by $\emptyset/28$	10x	0,28190116	0,06%
	1x	0,28004603	-0,60%
approximation by $\emptyset/28 +$ octagon	4x	0,28190116	0,06%
	6x	0,28166933	-0,02%
	1x	0,28143748	-0,10%

Fig. 9: Proposed geometrical scheme for the clypeus, compared to the orthophoto of the piece exhibited at the National Archaeological Museum of Tarragona.

4. Conclusions

The clypeus reconstruction of the National Archaeological Museum is correct. Therefore we are facing a singular case: the use of a hendecagon to fit an architectural decoration.

The Forum of Augustus in Rome was the reference parallel for building the Imperial Sanctuary of the *Conciliium Prouincia* in Tarragona and other similar complexes, its reproduction served to transfer to the provinces a monumental architecture that exalted the Imperial cult. In the case of Rome the geometry of the clypeus that decorated the porticos was based mainly in the octagon, a common figure in the geometry of Roman architecture. In Tarragona we find a hendecagon, but we have managed to establish a possible connection between its layout and the octagon through a Pi approximation, well known in classical antiquity: $22/7$. Moreover, the octagon diagonals seem to establish exactly the proportions between the outer ring and the inner medallion, so we could consider that the geometries of Tarragona and Rome clypeus were not so distant.

Alternatively, we propose a second hypothesis for drawing the hendecagon: to use the $14/25$ fraction of the radio of the circle in which was inscribed, we call it the *simple approximation*. Finally, it could be proposed a combination of both solutions: the octagon would serve to establish the main proportions of the piece, while the *simple approximation* for the hendecagon construction would serve to inscribe the meanders ring.

Anyway, we can see how Tarragona's enclosure did not follow strictly the parameters of the original model, an aspect that is also seen in the use of panels with candelabrum as separation of clypeus, unlike the *Forum Augustum* in Rome and other monumental complex, that incorporated caryatids decorating their attics.

The fragile heritage of the second half of the 20th century

Caterina PALESTINI

Dipartimento di Architettura, Università "G. d'Annunzio" Pescara, Italia

caterinapalestini@libero.it

Abstract

The architectural heritage of the late 20th century is still undervalued and isn't recognized enough to be protected, even if including precious pieces of work. Therefore it's even more vulnerable, so it requires specific considerations about the methods of intervention for its safeguarding.

For this reason, it has been important to conduct a project in collaboration with the Ministry of Cultural Heritage and Activities, that has taken a census through the whole country that identifies the consistency of this rich heritage, of which the necessary recognition that guarantees the process of conservation has not yet been made.

Basically the study focuses on the research carried out in Abruzzo and Molise from which a first selection of buildings spurt. They are registered on sheets that identify the relevant pieces of work present in the two regions under study, through standardized methodological criteria.

This investigation, now in the phase of completion and deepening, has partly been presented to regional and town institutions through a publication, in which there are 114 localised and georeferenced architectural complexes. They are shown on synthetic, descriptive sheets that allow easy consultation released in a handbook.

The aim of the research is to focus attention on the issue, to launch a process that avoids demolitions and transformations, in many cases already carried out or underway, including the missing information about the value of such works, regarding a common heritage, which is undeclared and particularly fragile.

Keywords: Heritage, Architecture, 20th century, Documentation, Protection.

1. Research and documentation

Attention to the recent architectural heritage, which lacks historical distance that allows legal recognition, pushes to consider the social and cultural values from which it is generated. The vast post war construction production has called in an incisive manner the appearance of contemporary cities, generating new urban heritage, widely disseminated throughout the country. Small and large cities, in central or peripheral places, preserve, often unknowingly, of relevant works by important designers, eclipsed within the ordinary building fabric.

The first step was therefore that knowledge, identification of architectures and infrastructures that are important pieces to reassemble in the overall design of the protection and promotion of the contemporary in Italy.

This is the search path started in 2002 by the "Direzione Generale per l'Architettura e l'Arte Contemporanee[1], continuing with updating and integration programs, now cared for by the Direzione-Generale per il Paesaggio, le "Belle arti", l'Architettura e l'Arte Contemporanee, devoted to determining the overall consistency of the contemporary architectural heritage in the national territory. The cognitive process, derived from the evolution of regulations that overlooks the modern and contemporary architecture to enter fully into the universe of cultural heritage, has been activated to get

an overview of the different regional realities. The basic documentation needed to understand the distinctions of the different cultural areas that have not always had a homogeneous historiographical focus, which are intertwined political mechanism, geographical, and local realities , to consider in getting a shared cultural asset identification as a public value[2].

From these goals started the census of the architecture of the second half of the twentieth century got started and has already examined 17 regions, distributing them evenly preset search criteria by the “Ministero” and sought the territory in collaboration with universities, from which is derived a selection of 1,800 buildings and architectural complexes , including 300 products have been reported. The contribution covers specifically the experience conducted in Abruzzo and Molise, combining as was the case for other case studies, methodological aspects shared with the local analysis and readings that add specificity to the collective work.

The data refers to two distinct, geographically contiguous, although regional reality relate a selection of architectures, in appropriate descriptive cards, identified with standardized criteria and in relation to the territory. The analysis carried out initially by a group of professors [3] from the Facoltà di Architettura of Pescara, have faced the different study subjects with multidisciplinary contributions concerning specifically the project, and the state of preservation of the works surveyed, examined with specific references to typological, formal aspects and structural. The work done previously with field surveys, with direct investigations [4] carried out in the areas of study, was then evaluated and organized through the mentioned methodological reflections, on which was based the next phase of cataloging and critical analysis of selected architectures.

Fig. 1: Selected architectures localized for provinces

Fig. 2: Tab concerning one of the artworks surveyed.

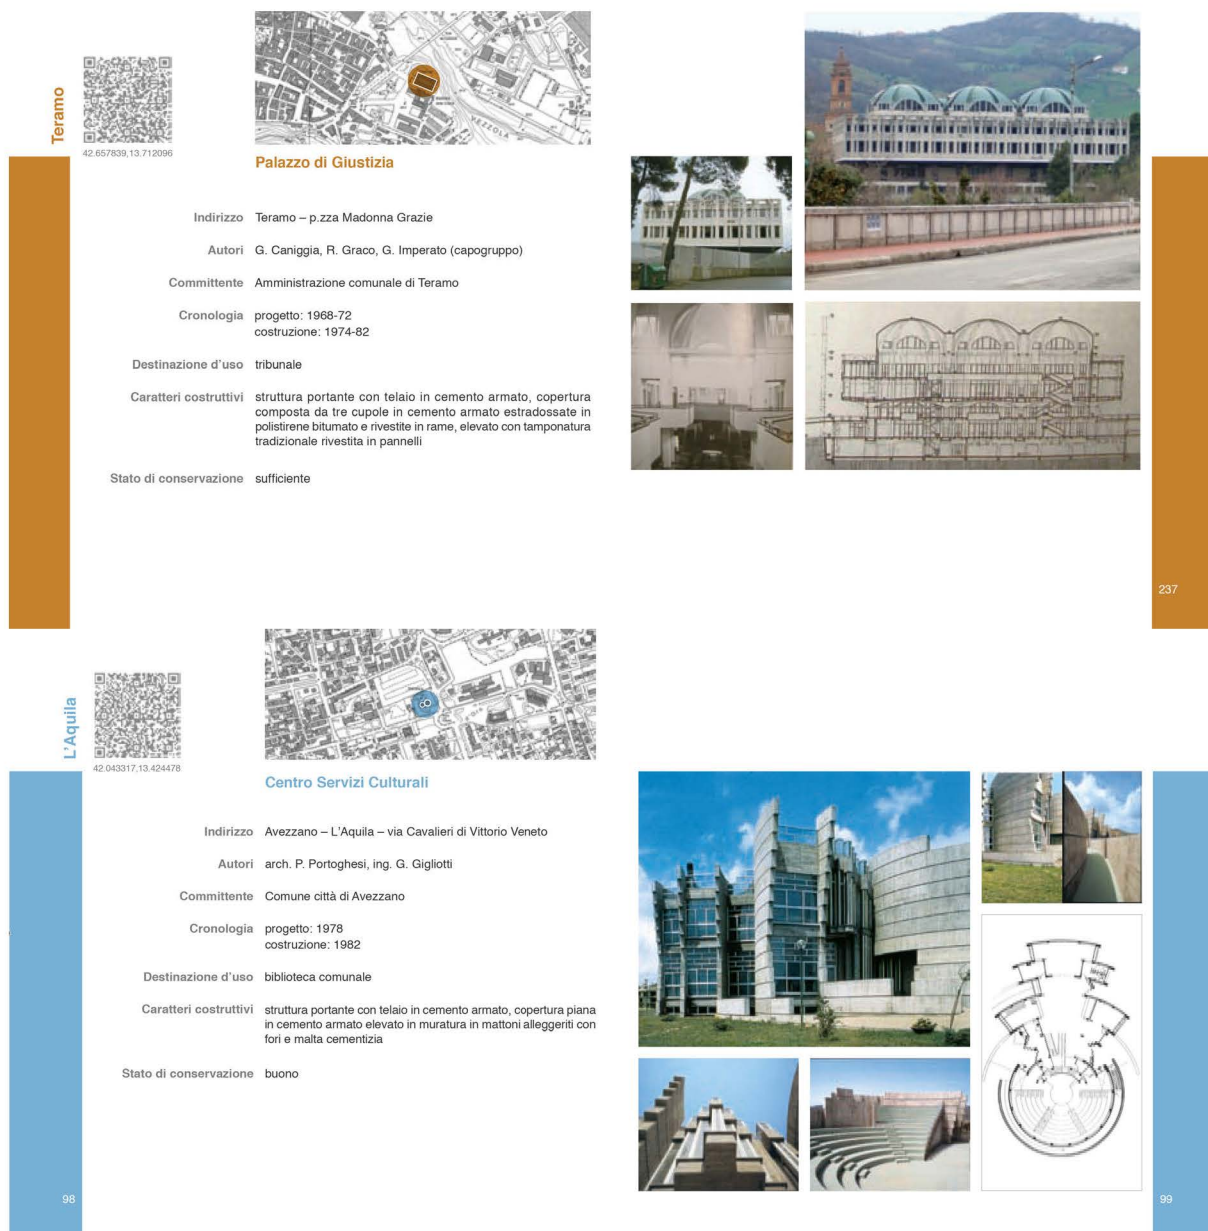

Fig. 3: Adriatic Stadium in Pescara, Luigi Piccinato 1952-56

These were transferred into a database, in a multimedia CD, delivered to the Ministry, which systematically explores the data collected during the various operational phases, through indexes that provide a reasoned system for the consultation of arguments contained in the cards.

A second operative intervention covered the spread of data collected, communicated through a publication that was spreading rapidly search outcomes subjecting them to a wider audience and to the attention of local administrators.

The idea of placing in a guide materials resulting from the local screening, manifested from the beginning, was welcomed and supported by the same promoters and coordinators of national research, which included the need to urgently provide a first level of caution on the subject, useful to initiate a process of development that avoids further dismantle and transformation, in many cases already occurred or are underway [5], including the lack of information on the values of such works .. The primary objective was to communicate the results of research offering, with the scientific support of the basic material, a comprehensive overview of the first selected architectures in the two regions. The corpus of the tabs, revised for the occasion, provides an accurate geo-referenced location, through timely references useful for tracing architecture, often little known and not always easily visible inside the city context, in many cases built in outlying or outside urban areas. The selection offers 114 buildings and architectural complexes, organized by provinces, presented in

Figg. 4-5: Selected architectures tabs

summarized descriptive tabs allowing an easy consulting communicated in form guide. The exploration of the architectural heritage surveyed is further facilitated by the assignment of the QR code, acronym for Quick Response bar, a matrix barcode which contains readable information through smartphones or web platform. Users can thus have a tool to read that provides a general picture of the second half of the twentieth century architecture present in two regions, certainly not exhaustive but necessary to protect the fragile heritage, at this moment not subject to constraints.

The publication [6], in order to gain a greater awareness on the delicate issues of safeguarding was officially presented [7] deliberately affecting regional institutions, citizens and business operators should include the management of their cultural heritage, in the normal control mechanisms of the processes transformation of the territory.

The need for conservation programs for such high-risk assets, was repeated in the activities of Superintendents of the two regions concerned by the scientific officers of the national census, by some professors of the Department of Architecture of Pescara and by curators, involved in the documentation of modern.

The work, to be considered not as a point of arrival, but a starting point for the continuation of recognition for the protection, today resumed the search for moving toward in-depth analysis on the work carried out with reference to the different areas of investigation, with readings and supplemented, in part already implemented in the volume.

This analytical investigation, in the young city of the province, takes an essential significance relate specifically to the moment of their increased urban growth, transformation and experimentation of

Figg. 6-7: Selected architectures tabs

contemporary language, as occurred in the cities of Abruzzo and Molise. Numerous public buildings, markets, schools, residential homes, examined revealed the presence of works by designers not only locally, but nationally active, selected through contests of ideas, from which are derived interesting architectures such as the church of Quaroni Francavilla (CH) or the Court of Caniggia in Teramo, the modern museum of modern art of Montuori in Pescara, to name just a few, which today constitute a fragmented and fragile heritage to be enhanced, reconsidering in the right architectural and cultural values.

Abstract

The city of Tarragona houses an important architectural heritage mainly from its past as 'Tarraco', capital of the Roman province of *Hispania Citerior*, but also from its medieval and late 19th century history. The archaeological ensemble of Tarraco was inscribed as a UNESCO World Heritage Site in 2000, but although many efforts have been devoted by archaeologists and historians to unveil and understand the history and aspect of the Roman city, many aspects remain unknown.

This is largely caused by the absence of a coherent body of historiographical material, which is today scattered across several institutions and, specially, the lack of precise and useful graphical representations of the remains and of the existing city that allows in-depth analysis and interpretations of future findings.

In recent years, researchers from the Catalan Institute of Classical Archaeology (ICAC) and the Architecture School of the URV (ETSA) have teamed up to produce comprehensive, detailed graphic materials, including a new set of plans and sections of the old city, of the grandiose areas of representation of the Provincial capital, and of the hidden structures beneath the city's surface. These have been executed with the latest technologies (fotogrammetry, laser scanning) but also with traditional methods (measurement, topography), on top of a mixture of existing materials (hand-drafted cartography from municipal master plans) and of historical and archaeological documentation.

Keywords: Tarragona, Architectural heritage. Representation. Education. Archaeology.

1 Introduction

1.1 Archaeology and Architecture: a long history together

Architecture and archaeology are two disciplines that have had a long history together and a close relationship that dates, at least, from the late Middle Ages. In the past, the solidity of structures that were "made to last" (castles and fortresses, churches and cathedrals, and so on), built mostly in stone and with durable materials, has made architectural remains an important part of archeological sites.

The first intellectuals that took a decided look backward at history, and regarded it as an "open book for architectural and historic reference were the humanists in the Renaissance. For most of them, such as Alberti, Vignola [12; 13] or Palladio [9], to name a few, the study of the Roman remains became a sort of "ritual", and they all traveled to Rome to copy, survey, redraw and interpret the remains of the old roman buildings that still were visible in the metropolis of the Roman Empire. This was an "educational primer" in architecture, history and humanism, and this pedagogical scheme became a

standard in architectural education until well into the 20th century¹ (maybe one of the last examples, now under debate, was probably Le Corbusier himself [1]).

The major written source of scholarship on architecture during the renaissance was the study of Roman building treatises, of which only Vitruvius' *De Architectura* has survived. Vitruvius' book includes the term in its title, and this term was adopted fully by the Renaissance intellectuals as the name for the discipline that was taking shape with them: "architecture"².

Archaeology, on its part, also has its origins in a few early Renaissance authors who not only took an interest in ruins (i.e. "architectural" remains) but also in ancient remains³. The first excavations with a proto-scientific method were carried out by John Aubrey, in Stonehenge and other megalithic monuments in England [2], and also in Pompeii and Herculaneum in the late 18th century⁴.

Hence, architecture and archaeology have had a very close relationship until the end of the 19th century, and probably part of the 20th [11]. For some reason, the education of architecture professionals progressively abandoned the study of history and archaeology. The reasons are many, and it is not in the scope of this paper to analyze them in depth. But we could mention, in favor of the argument, a few of these reasons. First of all, the so called Modern Movement and the architectural avantgardes approached a "new architecture" with a rupturist approach and a radical rejection of historical architecture of all kinds, be it classical, historicist or eclectic [5]. Second, a modern approach to architecture, also favored by the Moderns, substituted the study of history and traditional construction methods with the more modern building technology of concrete, steel and glass. And, last but not least, the deeper specialization trend of most disciplines, that made them abandon lesser interesting paths, like it is the case with the study of history for architects.

1.2 Tarraco, UNESCO World Heritage Site since 2000

Tarraco was the entrance port of Rome in the Iberian Peninsula. It was an ancient Iberian settlement that, due to its historical role, reached the capitality of the *Prouincia Hispana Citerior*, the largest in the Empire during the flowering times of the *Pax Augusta*. Its close relationship with the Emperor Augustus, and his exemplary role in the acceptance of the imperial cult, were the basis for the construction of the large monumental headquarters of the *Prouinciae Concilium*, the public office of half of the Peninsula. This area of 19Ha was articulated by a center of worship to the emperor, currently occupied by the medieval Cathedral, the great administrative square of the provincial forum – probably the second largest square in the entire Empire– and the Circus, defining the limit between the Municipal city and the provincial capital spaces (Figure 1). This arrangement pre-determines the medieval urbanism, and constantly reemerges in the current historical center. Besides, the Roman city of some 90Ha had a theater, an amphitheater, fifteen public or private baths and many economic urban facilities and services. This urban reality would only be surpassed after the second half of the 19th century [8].

After the decline of the Visigothic period, the city and the territory of *Tarracona* were occupied by the arab-berber invasion and, thanks to its geopolitical character, it remained institutionally abandoned for four centuries –i.e. no political or religious establishment–, as the boundary between Al-Andalus and the Catalan counties. After the Catalan reoccupation, the city recovered its urban condition, under the tutelage of the Count of Barcelona and the metropolitan Archbishop. But it never reached the vitality of other periods. Only after the debacle of the Napoleonic wars, the city gets back a socioeconomic vitality thanks to a growing port activity.

¹ It is remarkable how classical architectural education, for centuries, included a trip to Rome. For example, the *École des Beaux Arts* in Paris awarded since 1663 the prestigious *Prix de Rome*, which included a stipend and a stay in the French academy in Rome for two to four years of study, to get acquainted with the models of antiquity.

² However, Alberti's book on architecture, the first renaissance treatise on architecture, is named "*De re aedificatoria*".

³ Flavio Biondo (1392-1463) is dubbed as the first "archeologist". Humanist and historian, he published several works on the remains and the topology of ancient Rome, at the crossroads of archaeology and architecture: *De Roma instaurata* ("Roma restored"), 1446; *De Roma triumphante* ("The triumph of Rome"), 1459; *Italia illustrata*, 1474; and *Historiarum ab inclinatione Romanorum imperii decades* ("The historical decades of the decline of the Roman Empire"), 1483.

⁴ Karl Jakob Weber, engineer and architect was in charge of the first methodic excavations of these towns by commission of king Carlo III of Naples [10].

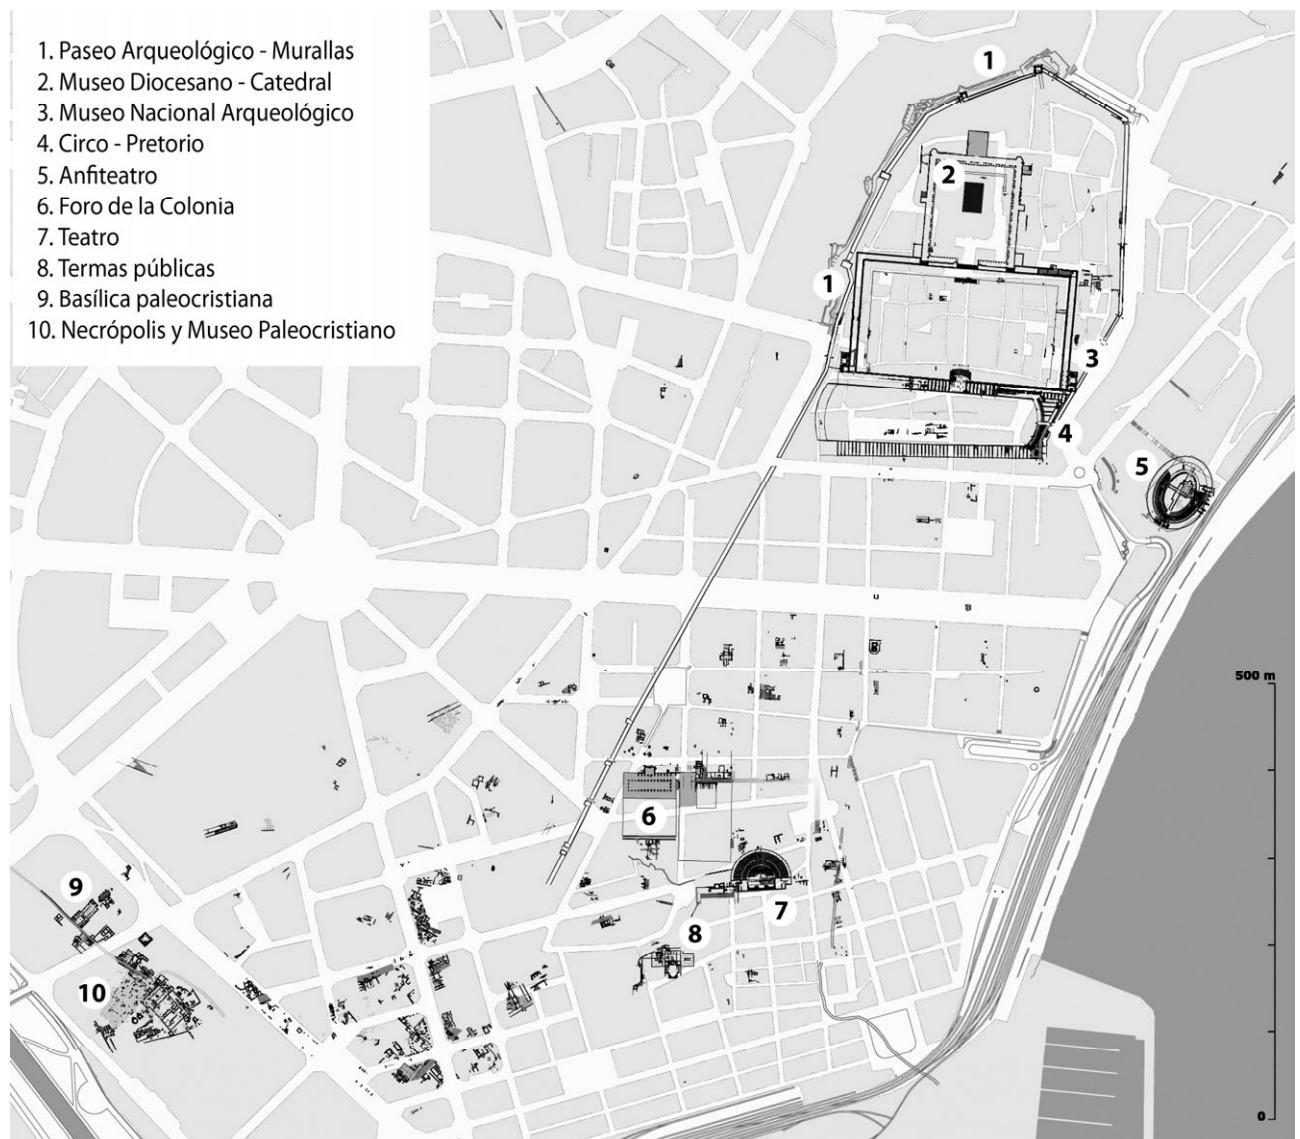

Figure 1: The scheme of the provincial forum in the Upper part of Tarraco

The first known early writings and compilations on the rich historical heritage of the city are dated from the Renaissance. The studies of Lluís Ponç d' Icart and the collection directed by Archbishop Antoni Agustí define the beginning of the interest on the local past, although the absence of stable institutions gave a central role to the concerns of local historians. The 19th century marks a definitive turning point in relation to the protection of heritage and the emergence of local institutions, such as the first Diocesan Museum, the Antiquities Museum, and other initiatives in the realm of local collectors. When Tarragona loses the status of military plaza the first great conservationist debate occurs, in relation to the destruction of the walls of the city, that constrained so far the new urban developments. A similar situation also occurred in the first quarter of the 20th century, with the discovery of the local forum and the great Christian necropolis. Finally, the debate on the conservation and restoration of architectural heritage is set in the mid- 20th century, with the rehabilitation actions undertaken by the Brigades of National Heritage (Pretori Tower, amphitheater, colonial forum, etc.). The return of democracy and economic development of the city leads to a new stage in the restoration of heritage, sometimes as an empowerment of museological enclosures, or as a dignifying of institutional spaces housed in historic buildings [7].

In the late 1990s the city felt that the maintenance of such a heritage deserved some important institutional support, and filed an application to the UNESCO. The “archaeological ensemble of Tarraco” was inscribed as a UNESCO World Heritage Site in 2000”, recognizing that “the Roman remains of Tarraco are of exceptional importance in the development of Roman urban planning and design and served as the model for provincial capitals elsewhere in the Roman world. Tarraco provides eloquent testimony to a significant stage in the history of the Mediterranean lands in antiquity”.

With or without the endorsement of the UNESCO nomination, many efforts have been devoted by archaeologists and historians to unveil and understand the history and aspect of the Roman city, but many aspects still remain unknown to date. This is caused by a number of different reasons, some of which are detailed here.

First of all, the remains are today very fragmentary and many are preserved under the present city and beneath more recent buildings. The medieval city was slowly built occupying the inside of the courts of the representation squares of the Upper part, and later the arena of the circus (Figure 1). Much of the material for the new city was scavenged from the old Roman monuments, mainly in the form of raw material to create lime mortars for construction (see also note 5). Then, the built structures such as walls, terraces and stands were used as supporting elements for new structures, and were left inside new constructions where they were modified, altered and, most of the times, damaged. Thus the original form of the city is difficult to understand and requires a very thorough understanding of the different existing structures, which are sometimes not visible.

Besides the diacronical evolution of the architecture of the city, the research efforts and archaeological tasks have been scattered across several institutions. Indeed, the agents involved in the study and preservation of Tarraco are, at least, five: the city hall of Tarragona, through its History Museum; The National Archaeological Museum of Tarragona, part of the state cultural institutions and administration; The Royal Archaeological Society of Tarragona, a non-for-profit organization established in 1844; The Catalan Institute of Classical Archaeology, a Catalan independent research center created a decade ago; and the University Rovira i Virgili, mainly (but not only) through its History and Archaeology department. The effect of so many agents has been the dilution of the efforts devoted to the study of the city. Sometimes, the differences in the respective policial agendas, diverging research interests (and, sometimes, personal confrontations) have affected the necessary collaboration relegating it to a very small thread –if any, altogether.

Finally, as a result of all these contingencies, there is an absence of a coherent body of historiographical material. In particular, there is a lack of precise and useful graphical representations of the remains and of the existing city that allows in-depth analysis and interpretations of future findings. A city like Tarraco, with so many hidden structures, built by the addition of several layers of history, and several waves of alterations and modifications, needs a solid set of drawings to be able to interpret and understand the relative positions of the concurring elements, the disposition in three dimensions of existing and disappeared structures, and to allow the crystallization of old structures into present forms to emerge.

To date, one of the best and more comprehensive record of the final state of archaeological documentation is the publication "Planimetria Arqueològica de Tarraco" [6], a systematic collection of documents and drawings, and a thorough index of bibliographical materials, known in 2004. Although this work has provided the basis for the development of a three-dimensional model with *Sketchup*, a graphic *corpus* of all the preserved Roman architecture does not exist, a visual archive that allows the realization of reliable architectural studies or, simply, the management, monitoring and control of the conservation of a heritage which is 2000 years old.

2 Redrawing Tarraco

2.1 The ETSA – ICAC Collaboration

Since its creation in 2005, the School of Architecture of the Universitat Rovira I Virgili, with its headquarters in the nearby city of Reus, has had a strategic planning that focuses on three interrelated lines: the study of the architectural heritage; the study of the local territory; and the advancement in modern construction technologies. These strategic lines inform the research lines of its professors and research groups, and therefore affect also the teaching at the school, which, besides the traditional and mandatory subjects, has a slant in these directions.

According to the school, the study of the architectural heritage has been a way to introduce interdisciplinarity into the sometimes closed world of architecture. The interaction with specialists from other areas, like art historians, and archaeologists. It is a way of bridging the traditional barriers of the architecture discipline, and reach out as architects to other areas of inquiry and offer their skills. This reinforces their disciplinary values, and puts them in contact with other valuable knowledge. On the other hand, the study of the territory connects the research to the needs of the peoples that live closer, while at the same time generating a universal knowledge that can be transferred to other areas of the world.

During the third year of the school, professors from the area of graphical representation, with an interest in architectural heritage, teamed with researchers at ICAC in order to collaborate and share skills and experiences. The architecture professionals were skilled digital draughtsmans, with

experience in research and teaching in architectural drawing, traditional C.A.D., 3D modeling and rendering, and digital imagery. They did not shy away, therefore, from all forms of new technology and its application to architectural representation. Alternatively, the professionals from ICAC were trained archaeologists, with an in-depth knowledge of historical sites and excavations, stratigraphy techniques and a background in history. Most of them came from the Graphical Documentation Unit at ICAC, and were also well trained in the use of CAD programs and digital representation technology. Besides, the team was completed with history specialists in Tarraco and its Roman and medieval past.

The first activity together was the proposal of an elective course on architectural heritage and architectural representation, which began during the academic year 2007-08 (see below for the description). The objectives of the course are threefold:

a) Use the most accurate and most modern technologies available to them in order to make detailed surveys of existing monuments and architectural structures. The limit for the use of technology was only the available budget. Furthermore, as is usual among technology lovers, the challenge to test and try out new possibilities was almost a necessity.

b) Redraw the surveyed elements, with the help of advanced architecture students, in order to reinterpret the data with architectural drawing. Redrawing architectural structures in plan and section, in 3D, and in different scales can put in context a lot of information, and allow for the comparison of elements. The reconstruction in drawing (manual or digital) or in three dimensional models of the existing (and the non existing) structures is a cheap way of testing hypothesis and combining and controlling insights. Finally, the rendition in a set of accurate drawings of the status of the present city allows the emergence of invisible and hidden structures, by inspection of the crystallized forms of the ancient remains in more modern structures.

c) Finally, putting in a historical context this graphical information, with the help of historians and academics with a good knowledge of the remains.

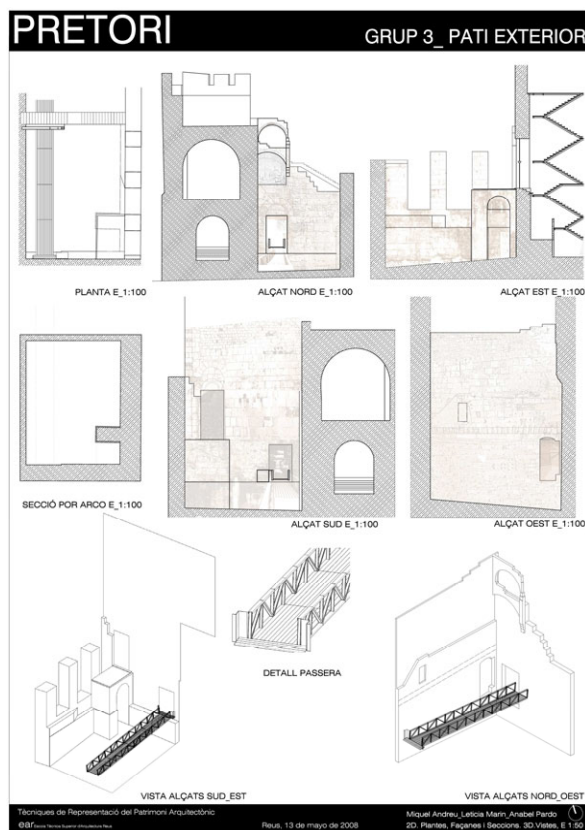

Figure 2: Architectural drawing of the Pretori Tower

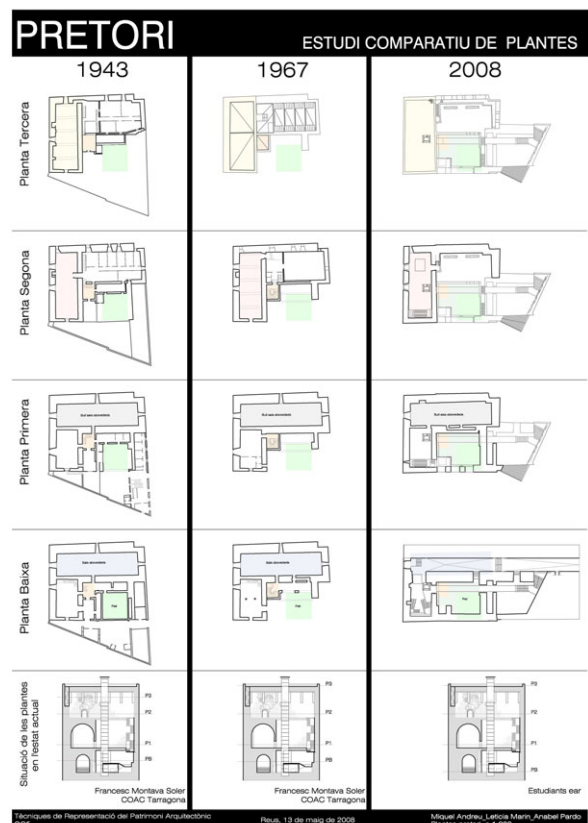

Figure 3: A historical comparative of the evolution of the plans of Pretori Tower

It is very important to stress that this elective course is not a simple "lecture course" but, on the contrary, intends to go far beyond mere teaching. While it is based on a sound pedagogical and academic basis (nothing else could be acceptable, of course), the course is, in fact, a platform that reaches into research areas, digs and experiments in real archaeological problems, and to tries out real surveying techniques. Every year, the teaching staff proposes to solve a particular representation problem, which is not naïvely selected (see below, section 2.3). Then, with the help of a group of

experts in the different areas involved, the students discover the surveying methodologies, the representation techniques and the solutions to the usual pitfalls in and around tangible surveying exercises of rather large proportions: “learn-by-doing”. For this reason, it is organized as a rather free-form atelier that knows the starting point, but ignores the end results altogether.

2.2 The area of study

By the name of “Pretori Tower”, “Castell del Rei” or “Tower of Pilates” we identify a solid building, which after 2000 years of history, and the architectural restoration works of the 1960s, is currently about 26.40m wide and a maximum height of 23 m. This is a tower-shaped body raised in the 1st century aD and performed in stonework as part of the monumental complex that housed the Concilium Prouincia Hispaniae Citerioris (commonly known by the neologism of “Provincial Forum” of Tarraco). This vast urban complex, which occupied about 12 Ha, was the result of the sum of a *temenos*, a large square of representation and, on a lower platform, the circus, the latter constituting the element of separation from the residential town. This is a scheme evolved from the Hellenistic model composed of sequence “temple” > “public area” > “recreational area” extended from the time of emperor Augustus [4], where what is now known as the “Pretori Tower” is just the southern end of the eastern cryptoporticus of the representation square, as extended stairwell and whose main function was part of the communication backbone between Circus and the perimeter of the square. This urban scheme motivated the existence of another almost twin structure at the opposite angle : the tower of the former Audiència [3] (see Figure 1, Figure 2).

Other fragments of this scheme are today either hidden beneath the city, or fossilized in newer structures. The difficulty is not so much to discover and know about their existence, but to be able to compare new and old, side by side, to ascertain their correspondence. Hence the importance of accurate drawings.

2.3 The objects of study

The course co-organized by ICAC and ETSA, named “Heritage representation Techniques”, is celebrating in 2013-14 its seventh edition, and in the last six years a great deal of information has been generated:

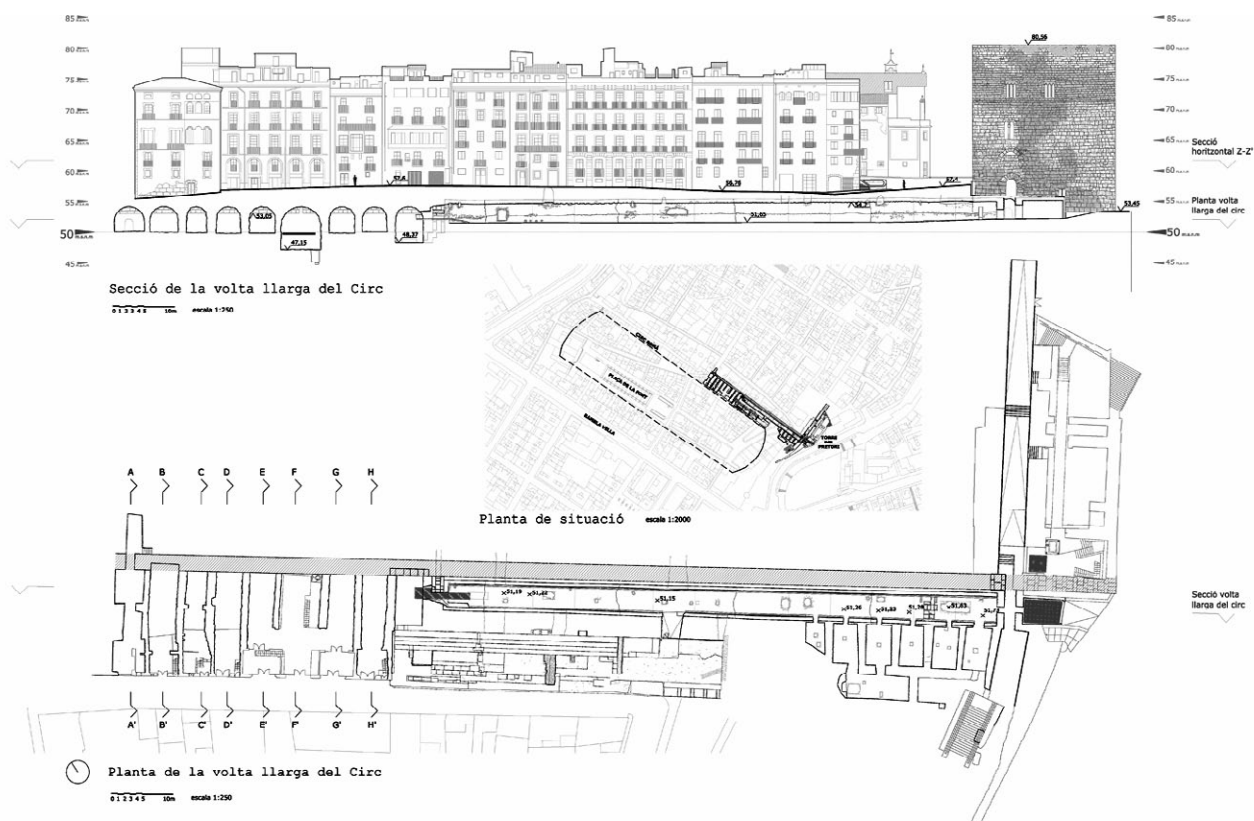

Figure 4: One of the drawings of the survey of the *Volta Llarga*, from which its main sections are cut .

2007-08: For the first edition of the course (only with a handful of students) a simple object was selected. The students surveyed in 2D and 3D the building of the tower of Pretori. The techniques were, this first time, rather conventional: topography, measuring tape, photography, etc. The resulting documents were a set of plans, sections and elevations of the building that yield an interesting representation of its complexity (Figure 2). Then, with the help of a great amount of historical documentation, in the form of plans and photographs, a historical analysis of the transformation of the building was prepared (Figure 3). Several interesting conclusions came out, like the definitive orientation of the stairs inside the building, which have been troubling researchers for a long time (not shown).

Tarragona Juny 2011

2008-09 The survey continued on the vaults beneath the Pretori tower and the circus (“volta llarga”), both on the exterior and the interior. The result is the first elevation of this space and its accurate relationship with the city above (Figure 4). Although traditional topographic techniques were mostly used, we began experimenting with 3D scanning and photogrammetry, thanks to the acquisition of a robotized total station. To complete the drawing, existing materials of the city above, we reused: old plans (hand drawn in the 1980’s, and part of the municipal documentation) and more accurate topographic materials (dating from the 1990’s) were available. These had to be redrawn, corrected, and merged into the existing information.

2009-10: Continuing with the previous experiences, the following year the survey of the “hinge” between representation square and circus was continued. Thus, the complete elevation from Pretori Tower to Antiga Audiencia Tower was completed at several levels (plan of the upper screen, plan of the hidden structures, longitudinal sections at different points, transversal sections, elevations, etc. This time, a closer study of the relationship of the hidden structures (beneath the ground) and the existing city was carried out. In particular, the position of the façades (corresponding to the medieval city wall) was accurately measured to align them with the huge stone block wall known to exist below it (Figure 5).

2010-11: Encouraged by the success of the three elevation campaigns, the team decided to move to another location and try out new surveying techniques, always in an experimental manner. The object this time were two sections of the enclosing wall of the cloister of the city’s cathedral, that have a fragment of some 30-40m of the original Roman enclosing wall of the sacred precinct (see areas 1, 2 and 3 in Figure 6, left). These techniques, coupled with topographic and traditional measurement, allowed us to survey these wall fragments, and also to locate them with great precision in Tarragona’s plan. An impressive section of the city and the hill on which the old Tarragona was built was also drawn (Figure 7).

Figure 7: Section of the hill of Tarragona (“Part alta”) through the cloister and the nave of the Cathedral.

2011-12 and 2012-13:

To continue with the works in the sacred precinct (also known as the “worship square”, or the higher square of the provincial area), the team went with a group of students to the National Archaeological Museum of Tarragona, that holds an important collection of marble and limestone fragments from several monumental zones of Tarraco⁵ (Augustus temple, worship and representation squares, forum, etc.). Most of these pieces were photographed all around and were modeled using photogrammetry techniques. During 2011-12 several pieces from the museum’s warehouse were scanned; during 2012-13, pieces from the museum’s permanent exhibition and pieces hung up on the museum’s walls were photographed and modeled with photogrammetry. The resulting 3D models were then measured, analyzed, and checked against some of the most widely known treatises of antiquity: Palladio’s *Four Books* [9], Serlio’s *Seven Books* [12] and Vignola’s *Book of five Orders* [13].

The result (Figure 8) was a thorough study of the pieces and the classical orders (in this case, a composite order), with which we attempted to make a full 3D representation of the whole decoration program of the sacred square. This attempt to a complete redrawing of the façades, plans and

⁵ It is important to remember that marble (of which all the monumental areas of Tarraco were made), and also limestone, are a mineral compound of calcium carbonate (CaCO₃). This material is one of the main sources of lime mortar. Unfortunately, most of Roman ancient and other ancient remains were ravaged to produce this construction material, and Tarragona is no exception. For this reason, very few remains of Tarraco’s monuments have arrived to our days.

sections of the whole square opened several questions, and allowed the students, professors, and collaborating experts to test out hypothesis and different solutions.

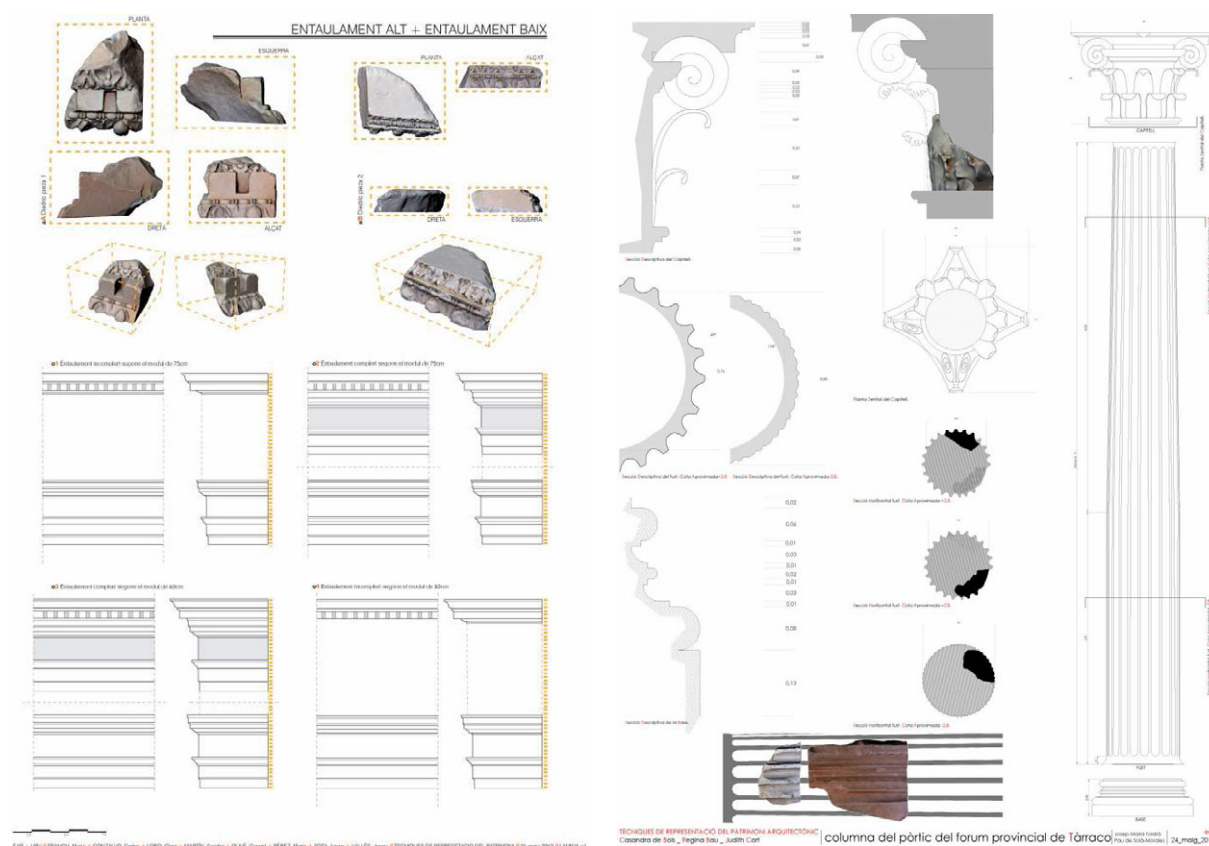

Figure 8: Two samples of photogrammetry 3D modeling of pieces from the MNAT, and an interpretation (together with hypothesis and conjectures) of the possible size and features of the resulting decorative program

3 Conclusion

With the help of fourth year architecture students, who are well versed in representation techniques, and utilizing modern and traditional surveying techniques the authors have been able to redraw different heritage remains in the city of Tarragona, the old Roman Tarraco. Learning and teaching these techniques has been fairly easy, and obtaining 2-dimensional and 3-dimensional, data-rich and accurate representations of Tarraco's remains fairly simple. Thus, from a pedagogical point of view, the courses have been useful and sound, more if we understand that we have also taught the students new ways of interacting, analyzing and understanding the history of their territory. .

But from the point of view of the professors and researchers involved in the course, we have been able to obtain valuable materials: well drawn, precise representations of historical "objects". Or, in other cases, we have been able to locate them with the use of these drawings: as the city evolves, it "crystallizes" or "fossilizes" the old city, and through good representations, we are able to undo this process. Finally, with good surveys and representations of fragments and pieces, we are able to test hypothesis or reconstruct the original city form.

In any of these cases, accurate and precise architectural representation is used as a support for archaeological and historical analysis of the past, establishing a useful interdisciplinary relationship that we hope will yield many results in the near future.

Abstract

Each river is a history, witnessing historical changes of the city. As the earliest area of urban development, the riverfront contains rich culture information, which forms fluvial culture of different regions with different features. The riverfront is an important resource in urban development, which plays a key role in improving urban environment quality, enriching regional features and promoting urban economic development. With the continuous evolution of cities, many historic riverfronts are facing with various problems caused by economic development, environment governance, cultural aspiration and etc. This paper took the Murazzi of Turin and the Bund of Shanghai as cases to compare the conservation idea and method of historic riverfront based on different contexts. Through the comparative research, this paper aimed to put forward methods to solve the contradiction between protection and development, protect the continuity of historical culture, and further carry forward the city's features in the process of urban regeneration.

Keywords: conservation, historic riverfront, Turin, Shanghai

1. Introduction

Each river is a history, witnessing historical changes of the city. As the earliest area of urban development, the riverfront contains rich culture information, which forms fluvial culture of different regions with different features. The riverfront is an important resource in urban development, which plays a key role in improving urban environment quality, enriching regional features and promoting urban economic development. With the continuous evolution of cities, many historic riverfronts are facing with various problems caused by economic development, environment governance, cultural aspiration and etc., which has increasingly become an important issue being paid great attention by international cultural heritage research.

The Washington Charter (1987) firstly proposed the definition of “historic urban areas”[1], those areas including urban historic and landscape characters in aspects of natural environment, artificial environment and humanistic atmosphere etc., which could reflect the diversity of social lives and cultures. The protection of “historic urban areas” is the protection of cultural relics and historical sites more comprehensive and integrated, as well as the protection of urban features. When it comes to “historic riverfront”, some relevant protection elements are more focused because of the existence of the river, which could be divided as: historical space organization, historical architectures and structures, biological cultural resources and unique cultural tradition and custom, according to composing elements of space structure of “historic riverfront”. [2]

This paper studied two cases, the Murazzi of Turin in Italy and the Bund of Shanghai in China, to compare the conservation idea and method of historic riverfront based on different contexts. The Murazzi is a belt area along the Po River in urban center of Turin, an area with high environmental, architectural and historical value. Likewise, The Bund is a linear open space along the Huangpu River in the center of Shanghai downtown, which has always been a symbol of the city. Both of these two cities have practices regarding to the conservation of historic riverfront, while the ideas and methods

are not always the same due to different cultural background. Through the comparative research, this paper aimed to put forward methods to solve the contradiction between protection and development, protect the continuity of historical context, and further carry forward the city's features in the process of urban regeneration.

2. Conservation practice of the Murazzi in Turin

2.1 Historical changes of the Murazzi

Turin located in northwest Italy, encircled by mountains and hills. The Po River, originated in western Alps, passed through the whole city from south to north, joined by three tributaries. Turin city was built probably in 16th century, located with a certain distance to the river. Natural terrain, slopes in the north and east to the river, enhanced the security defense system of the city at that time. Until the mid-19th century, the city developed across the Po River to the east, since this the Po became a river inside the city, in other words, the city closely contacted with the river.[3]

With the continuous expansion of the city to the Po River direction, Since 1860, the Municipal Council of Turin recognized the necessity of the order on the left bank of the Po River. Based on two purposes, regeneration and landscaping, the construction of the Murazzi began from 1872.[4] The project conducted with the demolition of old villages and the embankment along the river. Since then, previous urban fringe area converted to the most beautiful and attractive places in the city. The embankment conformed to the natural topography. The lower layer was set approximately 2 meters above the ordinary level of the water; the upper layer was built almost at the same level of urban road, with about 9 meters gap between these two levels, forming a row of rooms facing the river, most of which were rented as storages for transportation on the river as well as industries (such as laundries ect.) that need continuous clean water. (Fig. 1)

Fig. 1: Turin – on the Po River, in Lorenzo Artusio, Mario Bocca, Mario Governato, Mario Ramello, *Mille saluti da Torino*, Edizioni del Capricorno, Torino 1990, p. 128

2.2 Conservation practice of the Murazzi

The Murazzi was a belt area along the Po River with high environmental, architectural and historical value, characterized by a row of rooms facing the river, which are used to fill up the gap between the city and the river. The original function of these rooms was linked to traditional service activities on the bank: laundries, storages for fishing boats and transports etc. With the development of society and the changing of lifestyles, the traditional activities on the bank had been transformed and reduced, some even had completely disappeared. So these rooms were idle and the whole area showed a rundown scene, which even bred criminal activities. Since this, the Murazzi, experienced nearly a century of prosperity, became a “dark area” in the city, which seriously affected the image of the city and citizens’ lives.

From 2006, a renovation project of the Murazzi was implemented in order to clear off all kinds of inappropriate activities, recover the original environmental features, create a comfortable and relaxed place for the public, so as to enhance the overall space quality of the embankment. The project mainly dealing with two problems:

- ① Develop new functions in accordance with modern lifestyles to win economic benefits and improve the quality of the environment.
- ② Defense periodic flooding to guarantee the physical security of the place and personal safety of users.

Fig. 2: Schematic section of the conservation project of the Murazzi, in Gianfranco Cavaglià [et al.](edited by). *Progetti integrati d'ambito a Torino: complesso dei Murazzi del Po, via Giuseppe Garibaldi, piazza Vittorio Veneto*. Torino: Celid, 2009, p. 49

2.2.1 Riverfront space

Bi-layer space with a row of rooms facing the river was the most typical feature of historical space of the Murazzi. Because of the location, the lower layer space, close to the river surface, was very attractive while threatened by periodic flooding at the same time. (Fig. 2) In order to solve this contradiction, the conservation project proposed a Guideline against the flood risk, in which doors of rooms should be strictly selected by material and structure for excellent performance in sealing capacity, and outdoor furniture should be removable that could be removed within 30 minutes when flood came. In this way, the risk of flooding on the site was effectively avoided, at the same time the historical space feature was conserved.

2.2.2 Riverfront activities

Abundant waterside activity is a symbol of vitality of waterfront space. The conservation project was characterized by the introduction of the concept of "time" in riverfront activities, which means that activities should change over time and continue to update. Current situation of the use of the rooms was detailed investigated, then the feasibility of adding new activities was evaluated according to the spatial characteristics and regional features. The Urban Design Guideline stated: current functions and activities along the river in the rooms should not be the limiting factors of the development of other new activities, on the contrary, these activities should gradually change over time, or even be replaced; activities that may occur in the future should not only adapt to environmental, historical and architectural background conditions, but also help to improve these conditions.

After conservation, this riverfront area recovered as energetic urban space, the place for canoeing once a year, the place for fireworks show on holidays, and the place for public recreation on weekdays.

2.2.3 Pedestrian system

The Murazzi connected two pieces of important urban areas, the urban square (Vittorio Piazza) to the north, and the urban park to the south (Valentino Park). After conservation, the pedestrian system along the river was rationalized, so a continuous regional pedestrian system was formed, which improved the quality of environmental space of riverfront in urban center. Besides, in the vertical direction, the upper and lower layers were connected by steps, ramps and green slopes, providing multiple paths for tourist to get close to the river, which help people to have rich experience of urban riverfront space. (Fig. 3) The rational allocation of sculpture, structure, street furniture and other elements contributed to a multi-level and interesting pedestrian system.

Fig. 3: Vertical transportation system on the Murazzi, photographed by the author.

2.2.4 Embankment

Most part of the Murazzi was vertical rigidity embankment due to the tense space in urban center, which often generated unapproachable feeling for people. In order to make up the shortcoming of this kind of embankment, the conservation project made full use of the green part near Valentino Park to construct ecological embankment, also known as flexible embankment. In this section, the gap between urban road and the surface of the river was filled up by green space, among which interspersed pedestrian and bicycle lanes. (Fig. 4) Such linear space in urban center combined by rigidity and flexible embankment could contribute to meet the requirements of flood defense as well as increase the opportunity of close to nature.

Fig. 4: The embankment of the Murazzi, photographed by the author.

3. Conservation practice of the Bund in Shanghai

3.1 Historical changes of the Bund

Shanghai located in the extreme east of the Yangtze River Delta, on the midway along the China east coast. Huangpu River, originated from Dianshan Lake originated in the west of Shanghai, passed through the city from south to north, joined by Suchou Creek in a T shape in Shanghai downtown. The river system made Shanghai a traffic hub for land and water transportation in the area south of the Yangtze River and an important gateway to inland China from the east coast. Superior geographical location and convenient inbound and outbound transportation provide a sound foundation for the emergence and development of the city.[5] The old town was built on the west of the Huangpu River.

Then the city developed to the east, From 1850s, areas along the river were constructed by foreign settlements into “a modern city”. Until the announcement in 1990, that the land to the east of the Huangpu River was opened for development, the city developed across the river from west to east. The Bund was originally a piece of barren land along the Huangpu River outside the town. With the opening of Shanghai Port in 1843, the Bund was selected by foreign merchants to build houses and private wharfs, due to its geographical advantages. [6] The architectures and facilities developed by foreigners in the early 20th century, especially the historical buildings built in western style along the Bund, has always been a symbol of Shanghai. (Fig. 5) From 1959, a flood-control wall began to be fixed along the Bund, and be heightened for several times, from 4.8 meter to 5.8 meter until 1974. At that time, the riverfront set on the same level with the road, which enabled tourists to get close to the Huangpu River easily. From 1989 to 1993, a new flood-control wall of reinforced concrete dual-layer culvert structure was built along the 1700-meter riverfront of the Huangpu River, thereby the riverfront was raised to one-storey height above the road. In this way, the problem of flood was well controlled, the parking pressure was released as the inner space of the culvert structure could be used as public parking, while a serious of functional and environmental problems were generated accordingly.

Fig. 5: Scene of the bund in 1920s, in Shanghai Zhangming Architectural Design Firm(edited by), *Shanghai Waitanyuan Historical Buildings (Phase 1)*, Shanghai Far-East Press, Shanghai 2007, pp. 34-35.

3.2 Conservation practice of the Bund

The last reconstruction has solved problems of transportation and flood defense in some degree, but along with increasing citizens and visitors' demands for the quality of public space and activities, many problems gradually appeared. Firstly, busy transit traffic occupied a large amount of riverfront space, which increased the difficulty to cross the road and reach the riverfront. Secondly, public activity space was constraint. Thirdly, insufficient leisure facilities caused that tourists could not stay on the riverfront for a long time. Fourthly, places for appreciating the historical architectures are not enough. Fifthly, such a high flood-defense wall blocked tourists' sights towards the river.[7] In 2007, Shanghai Municipal Government started the "Bund Comprehensive Renovation Project", aimed to fulfill tourists' demands and enhance the quality of urban riverfront space. This Project initiated with the construction of a underground expressway, in which the ground driveway was reduced from 11 lanes to 6 lanes, which has released more than 40% urban space on the ground.

3.2.1 Riverfront space

The dual-layer culvert structure was the typical feature of the Bund from today's point of view. In view of problems mentioned above, some transformation has been done. The reduction of driveway on the ground expanded the space for pedestrian, so the widest part of pavement at west side of the Bund was widened to 12m. Besides, with regard to issue of appreciating historical architectures and river, some new levels were added on the culvert structure: a middle layer sightseeing floor (FL+4.7m) was added between the ground floor (FL+3.5m) and the platform of the structure (FL+6.9m), thus three-layer sightseeing space system was formed for appreciating historical architectures and leisure (Fig.

6); on the side of riverfront, concerning the difficulty to get close to the water brought by the gap between platform with the river surface, a row of platforms close to the river was constructed at intervals, which enhanced tourists' feeling of nature.

Fig. 6: Three-layer sightseeing space system, in XI Wenqin, XU Wei, *Remodeled Classic, the Centenary Shanghai Bund: Detailed Plan of the Urban Design and Site Plan of Shanghai Bund Waterfront*, in «Urbanism and Architecture», n.s. Feb. MMXI(2011), n. 77, p. 45.

3.2.2 Riverfront activities

With regard to problems of disordered arrangement of various kinds of facilities and low quality of public services, the conservation project optimized and integrated public service facilities for parking, tourist, leisure and celebration activities. Structures of facilities have been redesigned and relocated according to tourists' requirements and the characteristic of the space. After conservation, the Bund could accommodate a variety of activities, from daily recreation to celebration activities on vacations. On each New Year's Eve, a 4D light show, taking historical architectures as the background, staged on the Bund, often accompanied by an evening party. (Fig. 7) In addition, many historical buildings were protected and endowed with modern functions, such as the Gutzlaff Signal Tower was restored as a coffee bar on the ground floor and a small museum on upper floor, the former British Consulate was transformed as the "Bund history museum". The establishment of cultural facilities promoted the aggregation of cultural activities within this area.

Fig. 7: The night scene of the Bund after renovation, photographed by the author.

3.2.3 Pedestrian system

By reasonable arrangement of the pedestrian system, the accessibility to the Bund in vertical direction and the consistence in horizontal direction has been improved to a large degree. As the ground space was released for pedestrians, walking space was greatly increased. Pedestrians from west of the Bund could cross the East Zhongshan Road on the ground level directly, which changed previous embarrassed situation that pedestrians have to cross the Road through an underground passage. Besides, in order to solve problems caused by height difference between the ground and the top of the flood defense structure, many height difference treatment measures, like steps, ramps, elevators etc., has been added, connecting three layers of sightseeing platform, which increased the density of vertical transportation and provided many interesting and selective accessible paths for tourists. Thus, a safe, comfortable and natural height difference transition has been formed.

3.2.4 Embankment

The Bund was the central riverfront space in the downtown, which stretched in north-south direction and cramped in east-west direction. Before conservation, the green space distributed uneven on the bank, mainly gathered in Huangpu Park, the northernmost of the Bund where the Huangpu River and the Suchou Creek converged. The conservation project completely reserved substrate-vegetation system in Huangpu Park, and took special treatment to improve local ecology in the whole Bund area, like suitably adding arbors and making it form three-dimensional greening system with bushes, establishing tree array on the ground, setting up green wall, on the basis of ensuring public activities and showing historical scenes. Thus, the integral ecological environment has been improved to a large degree. Besides, based on the analysis on the architectures and landscape vision from the Bund, deciduous trees were selected in specific area where historical architectures were most excellent, which could provide shade during hot summer days and provide sightseeing convenience during cold winter days. In the southernmost of the Bund, the original culvert structure was replaced by natural embankment, which brought a great vitality to urban space. (Fig. 8)

Fig. 8: The embankment in the southernmost of the Bund, photographed by the author.

4. Comparison and conclusion

By comparison of Tuin and Shanghai's cases, two cities sometimes had different measures to deal with the contradiction of protection and development, while the ideas were mostly in consistent, "protecting historical site memory on the one hand, and fulfilling contemporary requirements on the other hand".

4.1 Comparison

4.1.1 Riverfront space

Due to natural terrain and historical changes, the space of the Murazzi and the Bund was different. The conservation project of Murazzi made full use of the natural terrain to establish two-layer platform for leisure and sightseeing activities, one close to the river surface which was designed to be flooded

occasionally, the other one on the same level as urban road. The space under the road was opened to the river which provided more space for waterside activities on the bank. On the Bund, the conservation project added platforms between ground floor and the top of the flood- defense culvert structure to provide multi space for appreciating historic buildings with great historic and cultural values and enjoying the scene of river. The inner space of culvert structure was opened to the urban road, used as public parking.

4.1.2 Riverfront activities

Both the Murazzi and the Bund stimulated activities on vacations and on weekdays, including cultural or traditional activities as well as leisure and entertainment, by optimizing and integrating public service facilities. The conservation project of Murazzi even creatively introduced the concept of “time” in riverfront activities, which ensured the type of activity to continuously update with time.

4.1.3 Pedestrian system

Both the Murazzi and the Bund strived to improve the accessibility to the riverfront from the city by increasing the density of vertical transportation, such as steps, ramps and green slopes or elevators etc., providing multiple paths for tourist to get close to the river. In horizontal direction, these two cases both created a continuous regional pedestrian system by reasonable arrangement of the pedestrian system to improve the quality of environmental space of riverfront in urban center.

4.1.4 Embankment

Both the Murazzi and the Bund were linear riverfront space in urban center, most part of which was vertical rigidity embankment. In order to make up the shortcoming of this kind of embankment, ecological embankment should be combined as far as possible in order to meet the requirements of flood defense as well as improve integral ecological environment. In addition, the case of the Bund also stressed that the selection of tree species should consistent with spatial characteristics, and the growth of trees should not influence viewing.

4.2 Conclusion

In conclusion, the historic riverfront concludes urban historic and landscape characters in aspects of natural environment, artificial environment and humanistic atmosphere etc., reflecting the diversity of fluvial cultures. In view of these characteristics, the ideas and methods of conserving historic riverfront could be concluded as follows:

- ① Create multi-layer space to enrich sightseeing and increase space vitality.
- ② Stimulate activities for the requalification of urban space and cultural continuity which should be continuously updated with time.
- ③ Optimize the accessibility to the river and establish continuous and pleasant pedestrian system in regional scope.
- ④ Combine the ecological embankment with the rigidity embankment for the sake of safety and ecology.

Abstract

The Shrine of Pompeii is one of the most sacred places dear to the Christian religion and its building is an expression of spiritual revival movement that was present in Europe during the course of the nineteenth century.

The proximity to the pagan city buried by the eruption of Vesuvius in 79 AD, was the stimulus for the creation of a city inspired by religious principles. These ideals, in fact, led the activity of Bartolo Longo, the lawyer by Salento who founded the new town of Pompeii.

The commitment to promote and grow a new community of men supported by the principles of faith has also been the success of the initiative expressed by the spread in the whole world, devotion to the Virgin of the Rosary.

The simple character of the architecture of the old nineteenth-century shrine was eliminated in the first half of the twentieth century, during the Fascist period, with the expansion of its size up to five times higher, making use of the technology of reinforced concrete.

The experience of enlargement of the church Pompeii was linked to similar experiences in Europe were born also to support and enhance the totalitarian political regimes that exercised power.

Keywords: sacred architecture, extension Pompeii shrine, concrete, traditional architecture

Sacred architecture end rhetoric of political

The Shrine of Pompeii is one of the most sacred places dear to the Christian religion and its building is an expression of spiritual revival movement that was present in Europe during the course of the nineteenth century. The simple character of the architecture of the old nineteenth-century shrine was eliminated in the first half of the twentieth century, during the Fascist period, with the expansion of its size up to five times higher, making use of the technology of reinforced concrete.

An case history is Pompei's basilica, where the expansion, in the second half of the nineteenth century, is a complex attempt to combine the traditional needs of worship with the most modern instances linked to the enhancement of sacred art.

The proximity to the pagan city buried by the eruption of Vesuvius in 79 AD, was the stimulus for the creation of a city inspired by religious principles. These ideals, in fact, led the activity of Bartolo Longo, the lawyer by Salento who founded the new town of Pompeii.

The commitment to promote and grow a new community of men supported by the principles of faith has also been the success of the initiative expressed by the spread in the whole world, devotion to the Virgin of the Rosary.

The Church founded by Bartolo Longo to the east of the ancient city of Pompei has been an important Marian and charitable centre since its foundation in 1876, forming a kind of Christian "New Pompeii" and a symbol of salvation amid todays positivist world.

Fig. 1-2: Lisieux, Project and statue of St. Therese Shrine; 3: statue with his author, father B.M. Richomme

The rebirth of the Vesuvian town, after long centuries of oblivion, had its symbol in the building that, by means of its Baroque style, it seemed likely to confirm the deep commitment to the spiritual connotations responsive to the needs of the territory of Naples. The result is a singular discrepancy, a sign of exceptional cultural richness, but also of Campania's resistance, wealth that characterizes the area of Naples. By virtue of it, while Enrico Alvino predisposed the project for the facade of the cathedral of Naples in a version *tricuspidata*, in the city buried by the eruption of 79 AD, the patron Bartolo Longo chose a formal language close to the Renaissance.

Fig. 4: Lisieux, St. Therese Shrine

Fig. 5: Pompeii, cast ancient Pompeian; 6: Book of extension work

In this way, the temple tended to retrieve, even visually, a golden age for Italian art and architecture. The choice is not random, but responds to client's decision to oppose symbolically to the pagan city (the *imago* of the Roman *orbis*) another that, similarly, to oppose to the first, embodying an formal prototype encoded by a centuries-old tradition.

In this way, Pompeii's experience tends to materialize the Catholic faith in a building that had a clear

Fig. 7: Rome: ancient photo of the pavilion of the Ara Pacis

Fig. 8-9: Devotional postcards to the First World War Neapolitan devotion to S. Anna alle Paludi

metaphorical character. The occasion of the increase is placed at the beginning of a decade, the thirties, particularly significant in the context of architectural reflection of the time, marked by a substantial controversy between those in charge of sacred art, about the formal aspects and materials of new buildings.

The enlargement's realization of the basilica, whose author was Spirito M. Chiapetta, fits perfectly in the cultural environment of the time: the project in fact summarizes a series of cultural and technical

Fig. 10: Plant enlargement of the Shrine of Pompeii

problems, the result of a problematic attitude towards modernity. In fact, using modern materials, the engineer showed openness towards new technologies, opposed by the client, while trying to match them with the aesthetic language of the factory

The pontifical Prelate Delegate, Anastasio Rossi, carried out work to expand the now inadequate church in the mid 1970s. The plans of Chiapetta, who had first trained as an architect and at the time was president of the central Pontifical Commission for sacred art, were assessed and revised by Gustavo Giovannoni, undoubtedly the greatest authority of the period. Giovannoni not only approved Chiapetta's designs, but produced a lengthy reasoned opinion with observations and suggestions. As has been noted¹, the recovery of that document, published entirely, shows how the problems of treating sacred spaces were considered. The change of plan, with the transformation of the original single room in a large temple with three naves, and the choice of a large dome, which barely hides the implicit reference to the previous Michelangelo, demonstrate an attempt to combine the old and modern in a project for promote the image of the "new Pompeii." Recently, the recovery of document, published in its entirety², shows how the problems of treating sacred spaces were considered. It also makes clear how the existing buildings on the site were allowed to influence the new plans.

The experience of enlargement of Pompeii's church was linked to similar experiences in Europe were born also to support and enhance the totalitarian political regimes that exercised power. In view of the personalities involved in the project, the Pompeii sanctuary provides an interesting opportunity for a detached study of the architectural design of the period.

Fig. 11: Enlargement of the Shrine of Pompeii

Fig. 12-13: Models enlargement of the Shrine of Pompeii

The expansion of the Shrine of Pompeii constituted an important initiative for the promotion and celebration of the Marian cult in Italy. It, in many ways, it connects to other significant experiences and to contemporary European efforts, in the two decades following the First World War, to rebuild the social fabric of the individual states in supporting national identity through the promotion of shared values.

In the same years in which they set up in Pompeii is the work of enlarging the small nineteenth-century church (1933-39) to Lisieux was being built, perhaps modeled on the Sacred Heart of Paris, the great basilica dedicated to the petite Carmelite nun Teresa.

To her already the Austrian novelist Joseph Roth, settling his novel in the period of construction of the church Vesuvian, had dedicated his beautiful writing *The Legend of the Holy Drinker*.

The same story seems to describe, through the protagonist suspended between alcoholism and virtuous intentions, the existential malaise of that era that needed to find a way inspired by the great social values of solidarity.

No different from the French, Italy, during the second decade of the fascist regime were activated significant works of architecture that were going to move to seal the political course of a state that, in the meantime, had also chosen to operate a policy of imperialist address.

What had happened in 1929 with the creation of the Lateran, was hailed as an experience of national reconciliation and, therefore, as a significant opportunity to undertake the investiture of political experience of the dictatorship which complete reliability.

The historian Emilio Gentile notes: «Cattolici e protestanti furono concordi nel ritenere che l'avvento degli Stati totalitari non fosse un fenomeno contingente della vicenda politica del dopoguerra, ma il culmine di un lungo processo, il prodotto della secolarizzazione e della espansione del potere dello Stato nella società moderna, che aveva costretto le Chiese ad arretrare verso la dimensione privata o a conformarsi ai miti della politica dello Stato laico. La Grande Guerra, le rivoluzioni politiche, le crisi economiche avevano esteso, attraverso la centralizzazione e la pianificazione, l'autorità e il controllo dello Stato sulla società e sulla vita collettiva, fino a sfociare nella concezione totalitaria della politica»¹.

The route, however, could not be a path through the promotion of the company's time instruments which derive directly from the religious tradition. The goodness of the individual social histories that were living in Europe in those years had to be certified by a process that as defined the historian of fascism, was to sanctify the political moment.

Among the traditional tools of communication of religious languages were identified as a priority the liturgy and iconography.

Fig. 14: Roma, Bronze door of San Paolo Fuori Le Mura; 15: Naples, Church of St Vitale a Fuorigrotta: card devotional for war in Africa

For the latter material has a special meaning very complex, almost of disturbance, the statue of St. Therese a Doctor of the Church, near the basilica French, placed in 1938 to welcome the pilgrims visiting the shrine. The work, created by the Trappist Father Marie-Bernard Richomme, shows petite Thérèse bearing in his left hand the book of the Gospel, while the right arm is stretched out in a Nazi salute to the faithful³. In Italy, otherwise, some artistic interventions, in terms of the production of functional images to the rhetoric of the party, emphasize the sacred nature of certain stories meant to legitimize the absolute value of the state.

Singular experience in this regard is that of the bronze door of the sculptor Antonio Maraini for the church of San Paolo Fuori le Mura, the work that sealed, with the delivery of that ancient Benedictine foundation to the Holy See, the highest moment of conciliation, in 1929, between the Vatican and the Italian State.

The sculpture, suggested theologically by the Abbot Ildefonso Schuster, provides a Christian interpretation of reality through the Roman figures of St. Peter and St. Paul. Just the future Archbishop of Milan will also firm believer in the educational value of works of art in the Christian reinterpretation of the archaeological heritage, pointing also to the proposed actualization of those values through the identification of the Duce as a new Constantine⁴.

16: Naples, Church of St Vitale a Fuorigrotta: card devotional for war in Africa (detail of the invocation)

17: Pompeii, Enlargement of the Shrine of Pompeii, details structural for roofing

The insistent call to the transformation of places support the opportunity of interpretations up-to-date that, in tourism's key are likely to do one with political propaganda. In fact, the Benedictine Alfredo Ildefonso Schuster, certainly the most prominent Catholic intellectual of the time, offering his exegesis of an ancient monument, he argued: «La teoria dei ricorsi storici ha qualche cosa di pericoloso, perché pretendendo di ridurre la storia, che è vita, a delle tesi, che significano dei sistemi scolastici, si corre il rischio di falsare colori, affinché un quadro rassomigli ad un altro. Se non fosse così, io volentieri paragonerei la situazione di Roma alla morte di Giulio Cesare, alle condizioni disastrose d'Italia dopo Caporetto, coll'indebolimento dell'autorità statale di fronte ai partiti cozzanti fra loro. Ma come allora la "Divina Mens" inviò Ottaviano, così anche in Italia sorse "l'Uomo provvidenziale" di genio, il quale salvò lo Stato, fondò l'Impero e diede alle coscienze italiane la più perfetta unità nazionale in grazia della pace religiosa. [...] L'"Ara Pacis Augustae", quale ora viene restaurata presso i portici dell'antica via Flaminia, per me ha un significato analogo a quell'ara dedicata al "Dio Ignoto" che si ritrova anche sul Palatino o quell'altra di cui discute S. Paolo all'Aeropago di Atene. [...] Ho detto da principio, che io temo dei ricorsi storici; ma qui ce n'è uno che balza fuori dai fatti medesimi». On February 11, 1929, at the same shrine of the Lateran which is the novella "ara Pacis" of the renewed Empire, the Legate of Pope Pius XI and Mussolini, dux of new Italy, subscribed together an fatidical agreement, recalling too closely the 'edict of Milan in 313, the Constantine peace⁵.

In closing, mention should also be a kind of tourism found in inverse relationship with the inmates entertained by Longo: «La fondazione dell'Ospizio per i figli dei carcerati, suscitò un'eco di simpatia negli stabilimenti penali di tutta Italia, nei quali Longo faceva arrivare le sue pubblicazioni [...] pubblicò una *Guida del carcerato*, stampata in 3600 copie. L'opera si proponeva di "confortare" i detenuti nelle lunghe ore di solitudine del carcere, suscitando in essi "la rassegnazione e il pentimento cristiano" [...] Il Commendatore, in una lettera indirizzata ai "fratelli carcerati" ... rammentava "a questo libro hanno lavorato i vostri figli"»⁶.

Similarly, Gabriele De Rosa, one of the greatest scholars of the Italian Catholic Movement, summed up the experience of Longo's Christian restoration -centuries later- of the ancient city Sunni buried by the Vesuvius in 79 AD.

In fact, the archaeological motivation was, however, an integral part of the creative process of the new city-although, as has been shown acutely Danila Jacazzi, the site of Pompeii has continuously maintained a continuity of frequentation⁷- since it was widely present in the insights of the founder of the new urban aggregate, especially for the significant contribution made by Giuseppe Fiorelli in the method of archaeological excavation: «Stamane dunque siamo andati a Pompei una brigata per vedere un nuovo miracolo del nostro Fiorelli, che fa risorgere i Pompeiani [...] sono morti da diciotto secoli, ma sono creature umane, che li vedi nella loro agonia. Lì non è arte, non è imitazione [...]

18: Pompeii, Enlargement of the Shrine of Pompeii

Finora si è scoperto templi, case, mura, dipinti, scritti, sculture, vasi, arnesi, utensili ed altri oggetti che interessano la curiosità delle persone colte, degli artisti e degli archeologi; ma ora tu, o mio Fiorelli, hai scoperto il dolore umano, e chiunque è uomo lo sente»⁸.

The synthesis of Luigi Settembrini reads, in the romantic the suggestion of the perception of human suffering, the track of rehabilitation which is the *specimen* urban, around which matures the hypothesis and the contextualization of the restoration to life, according to the Christian ideals of the men who lived in the desolate Valley of Pompeii.

If the contribution offered by the science of antiquity, in the approach of an intellectual renaissance as Settembrini, legitimized, together with the address of the ideological work of excavation of Giuseppe Fiorelli-which was also the first Director of Central as well as the inventor of the protection service of the monuments of the newborn Italian state- the aspirations for the creation of a unitary state, Longo's commitment expressed in ideological terms Catholic, the same expectation for which the small town of Vesuvius became an 'experimental laboratory' of new Italian sociality.

On the other hand one of the great Italian intellectuals of the twentieth century, Benedetto Croce, likened the experience of Pompeii to that previous French that took place in a small town in the Pyrenees and that assumed, for their religious content, an international reputation defining, therefore, the site of Campania as the Italian Lourdes⁹. Similarly to the case side of the Alps, is significant at the site of Campania the remarkable wealth of miraculous events, of miracles, which has also become attractors, even "tourist", to a visit dedicated to the city that was reborn.

In this regard it is of interest to note that the lawyer Longo prepare a sober and very precocious history of the Shrine of Pompeii, with the intention of providing objective data about the miraculous events that were happening around the Marian devotion in the site at the foot of the volcano. Longo wrote: «Ed invero il Tempio del Rosario a Pompei non era solo un edificio santo che sorgeva, ma era ancora un'opera più eminente, più spirituale, più universale»¹⁰, arguing, so ideological, that the construction of the Shrine coincided with the spiritual edification of the people present to religious Opera.

If, therefore, the French experience can boast a kind of literature in this regard, with the publication of statements that make the journey to Lourdes¹¹, a kind of plot exposition, with the involvement of top-class intellectuals as Émile Zola or later, Mario Soldati, or even scientists such as Nobel laureate Alexis Carrel, Pompeii relies, in a unified way, at his own architect and ideologue of the reading and interpretation of their experience through writing a history of the sanctuary which is a statement of the events related to the invocation of the unique and miraculous Marian protection and, for that reason, strong motivational tool for the option of religious tourism.

Engaging Visitors: Developing Presentation as a Tool for Site Preservation at Pompeii

Alia WALLACE

Institute of Archaeology, University College London, London, England
alia.wallace.10@ucl.ac.uk

Abstract

Often presentation and interpretation of archaeological sites are overlooked as important elements of site management planning despite their potential to aid in site preservation. This is particularly relevant at Pompeii, where mass tourism negatively impacts the site. Improved site presentation at Pompeii would help communicate the site's significance and raise awareness of conservation problems. However, for presentation to be effective it needs to be the result of collaboration between numerous stakeholders, and needs to use the site to its potential. I have assessed the current status of presentation at Pompeii through extensive visitor observations and interviews, movement mapping, and in-depth interviews with stakeholders. The results show that the current presentation of Pompeii, including visitor itineraries, signage, and guides, does not adequately orientate and engage visitors in the ways needed to make it a sustainable tool for site management. This is due to a number of reasons, including an unclear understanding of what visitors want when visiting Pompeii and a lack of collaboration among stakeholder groups. From this data the foundations for developing a presentation and interpretation strategy at Pompeii emerges; one that uses the site to its potential and creates a forum for open collaboration among the key stakeholders.

Keywords: Presentation, Interpretation, Conservation, Management, Pompeii

1 Introduction

The goal of modern site management is to ensure that archaeological sites and their associated values are preserved for future generations. The presentation and interpretation are often overlooked elements of management planning and regarded in a secondary capacity to other elements like conservation and on-going research [1,2,3]. Presentation is primarily linked to services related to the visitor experience and thus, presentation is associated with economic benefits or visitor numbers [4]. This can lead to problems in site management if the presentation is not understood alongside other elements like conservation and research. Archaeological excavations and conservation are complex and often debateable processes that play a major role in deciding what is valued [5]. Both archaeological research and excavation are interpretative choices that are 'presented' but are not often considered in presentation and interpretation theory. This gap between viewing presentation as 'entertainment' and understanding the deeper, multi-disciplinary relationships is a problem that needs to be addressed to ensure integrated and sustainable site management.

This results in an antagonistic relationship between site presentation, conservation, and research as visitors can cause decay to the physical fabric. Recently presentation and interpretation have been recognized as instruments for preservation by helping to mitigate the negative impacts caused by visitors [6], communicating the values and significance of site to various audiences, and serving as a tool for increased collaboration among stakeholders. Silberman and Callebaut suggest that the

modern social function of presentation plays an integral role in the success or failure of the preservation of a site [4]. The ICOMOS Charter for the Interpretation and Presentation of Cultural Heritage sites addresses these social roles of presentation and interpretation through standardised terminology and professional principles [7]. However, it is still necessary to look at specific case studies to test the viability presentation and interpretation as tools for preservation in real world settings.

This research is concerned with developing a deeper understanding of the visitor-conservation-research relationship at Pompeii in order to develop a foundation for using the presentation and interpretation as a tool for preservation at the Vesuvian sites (and across the globe). Pompeii is one of the most famous and visited archaeological sites in the world. Over the past few years the state of conservation at Pompeii, and the effectiveness of the current management have come into question. This has prompted an international discussion how best to manage the Vesuvian sites including, new management plans, privatization, and EU funded large-scale conservation projects. However, no amount of planning or external funding will be sustainable if the management framework in which it is implemented is fragmented and ineffective. As this discussion is on-going it is important to continue to look for alternatives. It is equally important to look at what smaller-scale changes can be made that work within the current management. It is only then that viable and sustainable changes to the management planning process can begin to be made.

This paper presents the results of research I conducted into the current presentation of Pompeii. Data was collected during a number of field sessions from 2011-2013 though primarily qualitative methods, including observational studies, interviews, and analysis of documents and text. Observational studies were conducted using three primary methods: ethnographic observations, visitor movement tracking, and recording linger-time (how long visitors stayed or 'lingered' in a certain area or property). A series of semi-structured interviews were conducted with visitors, tour guides, and academics at Pompeii. Professionals and academics were also interviewed at Herculaneum and Stabia. The literature review included studying various interpretation aids, guide books, audio guides and on-site signs. Further explanation of the full methods used can be found in Wallace 2013 [8]. From this data I have begun developing a presentation and interpretation strategy for Pompeii that would aid in the conservation of the site, as well as serve as an avenue for increased collaboration among the wide range of stakeholders at the Vesuvian sites. The results of this research show that only small, inexpensive changes need to be made to help address some of the conservation concerns at Pompeii.

2 Mindful Visitors at Pompeii

It is assumed that a good visitor experience will encourage visitors to be more aware and respectful of archaeological sites, and thus be more inclined to see it conserved for future generations. However the relationship between the visitor and archaeology is difficult. The closer the visitor gets to the archaeology (physically and intellectually) the deeper the visitor experience but this can have negative impacts on the sites conservation. Moscardo states that presentation should aim to create mindful visitor [9]. Rooted in the social cognition research of Ellen Langer mindfulness is a state where the mind actively process information and is more receptive gaining knowledge [10]. Mindlessness is the opposite and is often the result of boredom, repetition or a loss of control. There are a number of factors that can affect how receptive a visitor is including the visitors' level of interest, fatigue, heat, and size of the site. Some of these cannot be easily controlled but other factors like visitor facilities, exhibitions, signage, and content of the interpretation can be.

Visitor studies at cultural sites in the past have focused on the demographic or geographic factors, over the psychographic factors to identify visitors [11]. While demographic and geographic factors are much easier to measure, they provide limited information. Psychographic factors, like visitor attitudes and values, are much more difficult to quantify but reveal deeper, more meaning results. In this research I conducted 66 in-depth interviews with visitors at Pompeii who were primarily international. At the start of each interview, visitors were asked why they decided to visit Pompeii, and if there was anything in specific that drew the visitor to the site. Based on their responses, they were divided into four levels of motivation based on Silberberg's Levels of Cultural Tourist [12]. Of the respondents 34% were Greatly Motivated, 30% were Adjunct visitors, 21% In-Part, and 15% Accidental visitors. What these results indicate is that a majority (64%) of visitors to Pompeii visit due to cultural motivation, and an interest in Pompeii or cultural sites. However 46% of the visitors interviewed indicated that they simply visited the site due to its being in the region of their holiday or because someone recommended it but had no real interest in the site itself. This indicates that a large number of the visitors arrive to the site without a high level of interest or background knowledge.

When visiting the site, visitors have four main interpretation options available:

- using only the information provided with the purchase of a ticket (map, Brief Guide, signs and panels)
- using a guide book or travel book
- purchasing an audio guide
- joining a guided tour (either on-site or pre-booked before arrival).

Each of these provides different ways of receiving information and engaging with the site. For this research I chose to focus on visitors who were not part of an organised excursion as they often have set itineraries that are organized by their excursion company and are informed of these before arriving to the site. Of the 66 visitors interviewed, 28 used a guide book or travel book to complement their visit, including the site specific guides and general travel books like Lonely Planet. These respondents explained that they wanted the freedom to wander around site and enjoy the experience on their own. Eighteen visitors chose not to use any interpretation aids, and relied only on the information provided onsite and with the purchase of a ticket. This is limited to on-site panels, a map and the information in the brief guide which includes a small paragraph and small photos of 69 properties, although the map and brief guide were unavailable during the summer when these interviews were conducted. Most of these visitors indicated cost as a factor for not purchasing interpretation aids as well as an expectation that there would be more on-site interpretation, like signs or a visitor centre. Fifteen visitors purchased an audio guide indicating that they felt an audio guide provided more information than a guide book, and more freedom than a guided tour. The remaining five groups had been a part of a guided tour.

While those who participated in guided tours tended to feel satisfied with the information they received and didn't feel any barriers with accessibility, the other visitors I interviewed indicated a range of factors that impacted their experience. Some of these, like the heat or the size of the site, cannot be controlled—however, by addressing some of the others, changeable factors there is the potential to create mindful visitors at Pompeii and the Vesuvian sites. In this research I was interested in understanding what visitors wanted from their experience at Pompeii. The words *know*, *learn* and *understand* were present in a large number of interview responses, but they were often used with other words like *experience*, *feel*, *visualize*, *see* and *touch*. These sensory and emotive responses indicate that visitor motivations occur on multiple levels, both educational and a more personal, internal experience. Thus the presentation and interpretation of Pompeii should aim to engage visitors on both of these levels and provide visitors the tools to make decisions and be in control of their visit.

Observations conducted revealed that, on average, visitors spend less than five minutes in a property. Many visitors were observed entering and leaving in less than a minute, particularly during peak times or when they were without interpretation aids. Levin-Richardson found similar behaviors at the brothel where visitors went through the property in an average of 30 seconds, and thus were reliant interpretation aids for information [13]. With non-guided visitors, the limited time spent in an area is a possible indicator that the current interpretation is failing effectively engage visitors. Visitors to Pompeii expect the experience to be personal and interviews and observations have revealed that the current presentation does not provide the elements and information that visitors want and expect, thus does not provide the factors needed to create mindful visitors. In the interviews there emerged four primary problems with the current presentation and interpretation:

The availability of information and services: Visitors expressed how they “expected there to be more signs” and services available. As a World Heritage Site visitors arrive with a preconceived expectation of a certain level of services and information being available. The absence of information resources at Pompeii was frustrating to many visitors who were unable to get answers for some of the questions they had which resulted in an unsatisfactory visit.

The ease of use if the interpretation: By far the most common comment by visitors interviewed was expressing frustration and difficulty with finding places on-site and navigation. The lack of onsite signage, orientation, and clarity was an issue expressed by a majority of the interview subjects. The inconsistent numbering of properties, as well as English/Italian translations were seen by visitors as a barrier as they were not always able to tell where they were. Visitors with the audio guide indicated difficulty following the tour when inside a property.

The accessibility of information: Visitors also pointed out the information provided in the guide books and audio guide was too technical and that they often didn't know what it was talking about. Additionally, signs on-site frequently use Latin terms without providing a translation. Visitors felt that there was an assumption of knowledge about the site, Roman history and archaeology.

The content of the interpretation: Visitors interviewed expressed a strong interest in daily life and social aspects of the city, particularly in the people who lived there and what they did. Multiple visitors commented in interviews that they wished for more in-depth interpretation in the audio guide, and in guide books. Visitors also expressed interest in the development of the city and broader topics, such as social and civic life which is absent from the current presentation.

Visitor interest in the daily life of Pompeii's citizens can be explained by the similarities many visitors found to modern cultures and themselves. For some, this was one of the most impressive and memorable elements of their experience; many expressed awe and surprise at how similar the Pompeians were to us. One visitor, who expressed that he was not particularly interested in the site, stated that this link to modern society is essential for a visitor like himself. However, he felt that the current presentation did not provide this.

Here, they don't think about that not everyone is interested in archaeology. But they might be interested in the courthouse, or something, because it relates to their work. It works real well if it's two-way traffic, if it reflects a bit about your life and reflects about their life. And this [current interpretation] is one-way traffic. And I think that's okay for people who are interested in it but for [indicating himself], it doesn't work.

In summary, the current presentation of Pompeii does not address the expectations of visitors. Visitors find that it does not provide the information that they desire and it is neither physically or intellectually accessible to them. While this is not the case for every visitor, with around 3 million a year, it can be assumed that many feel the same way. When combined with things like visitor fatigue and heat, visitors can become "mindless." In the next section, it will be shown that many of the negative visitor impacts result from this feeling of mindlessness and could easily be addressed through enhanced presentation.

3 Visitors and conservation: a shaky relationship

In the 2011 mission report, UNESCO and ICOMOS highlighted six major conservation problems that are present at Pompeii: ordinary decay, inadequate water management, damage from ultraviolet radiation, overgrown vegetation, incompatible conservation and restoration work from earlier generations, and visitor impacts [14]. While sustainable management of the sites needs to address all of these problems this research is concerned with the visitor impacts as visitation to the Vesuvian sites increase and available resources decrease. Currently the *Soprintendenza Speciale per i Beni Archeologici di Pompei, Ercolano e Stabia* (SANP) has no effective condition assessment system in place so it is difficult to identify visitors impact but these have been better documented at Herculaneum by the Herculaneum Conservation Project. They found that visitor impacts primarily enhance decay that is already present, either through direct physical damage or by limiting the resources available for conservation work. This results in more and more areas of the sites closed each year, thereby concentrating the growing number of visitors in smaller areas and thus accelerating the rate of decay. Over the past half century, the number of properties, roads, and areas accessible to the public at Vesuvian sites has decreased by 1/3 (see Fig.1 for a map of the current distribution of open and closed areas in Pompeii). Furthermore, areas not open to the public tend to be neglected as the limited resources are diverted towards those areas accessible to visitors [15]. This is reflected in the more recent collapses on site which have been in areas that are not open to the public and receive little visitor traffic as they are not on the main itineraries. It is this circular cycle that this research is concerned with addressing. In order to identify areas of Pompeii that were impacted by visitors, as well as *how* and *why*, I carried out a number of observational studies. These revealed that there are two major areas of concern that need to be addressed; 1) visitor movement and itineraries, 2) visitor behaviour and management. All of these can have negative impacts on the conservation of the site but enhanced presentation and interpretation can be used as tool for addressing them.

3.1 Visitor movement and itineraries

In Fig. 1 the properties included in the SANP interpretation are identified. This includes on-site panels and signage, and the properties included in the audio guide and guide books. In theory the current interpretative infrastructure should encourage visitors to spread throughout the site, if they were to follow recommended itineraries provided in the interpretation (Fig.2). Visitor tracking and observation identified common visitor movement patterns which show that visitors are, in fact, isolated to a small section of the site (Fig. 3). From this, I was able to identify areas of the site that received high-medium-low visitor traffic and some of the causes for this movement (Fig. 4). The visitor tracking and observations suggest a few possible causes for overcrowding at Pompeii. The first is that many of

these properties are considered 'must-see locations' and are included in all types of visitor information and interpretation materials. Some of these properties, such as the Forum and the Theatre complex, are unique to Pompeii as similar buildings at Herculaneum remain buried. Properties like domestic houses, the Follonicas (laundries) and the baths are types of buildings that are common throughout the city. There are 515 houses in Pompeii, 93 of which contain substantial decorative elements, but only about seven are regularly open to visitors. Most guided tours consist of the highlights of Pompeii; for this reason most tours lead visitors along the same path through the site. When asked why they visit these specific places, the guides interviewed for this study replied with three main responses: 1) the popular locations are what visitors are interested in and expect to see; 2) the buildings represent the best examples or best-preserved of each type of property; 3) those buildings are open and available to visit. Guided indicated they would diversify their tours if there were alternative but often the decision on where to go varies day to day, and not always by choice. Guide 3 said, "I never know what will be open. One day I visit a house and the next [day] I take a group there and it is closed. It's always a mystery." Similar responses behaviours were recorded in other research on tour guide itineraries at Pompeii [16]. Visitors who did not elect to take tours were just as unaware of closures and as a result there was increased traffic around closed houses as visitors were not aware of closures. For example, visitors looking for the closed House of the Vettii and House of the Meander spent a significant amount of time creating higher traffic and crowding in those areas (areas 6 and 9 on Fig. 4). These houses had been closed for a number of years (though House of the Meander has since re-opened), and this could easily be addressed through active communication like signage at the ticket office. The relationship between overcrowding and site presentation is easily seen. Visitors tended to go to properties that were open thus putting more pressure on these areas. Overcrowding could be lessened at the most popular buildings if the site offered alternatives, and through clearer communication of which properties are open. The current interpretation for Pompeii is outdated and a number of the properties included in it have been closed for years. Others are open or closed depending on factors like on-going conservation work and personnel. As a result, certain houses are open irregularly, often only a few hours one day and none the next depending on the availability of on-site personnel although it is not within the scope of this paper to address the human resource side of site presentation and accessibility. Instead, there needs to be an multi-disciplinary and collaborative development of new visitor itineraries that take visitors through other parts of the site and to alternative properties. While at a site like Pompeii, there will always be times of overcrowding and visitor impacts it is possible to lessen the severity and spread the impacts throughout the site

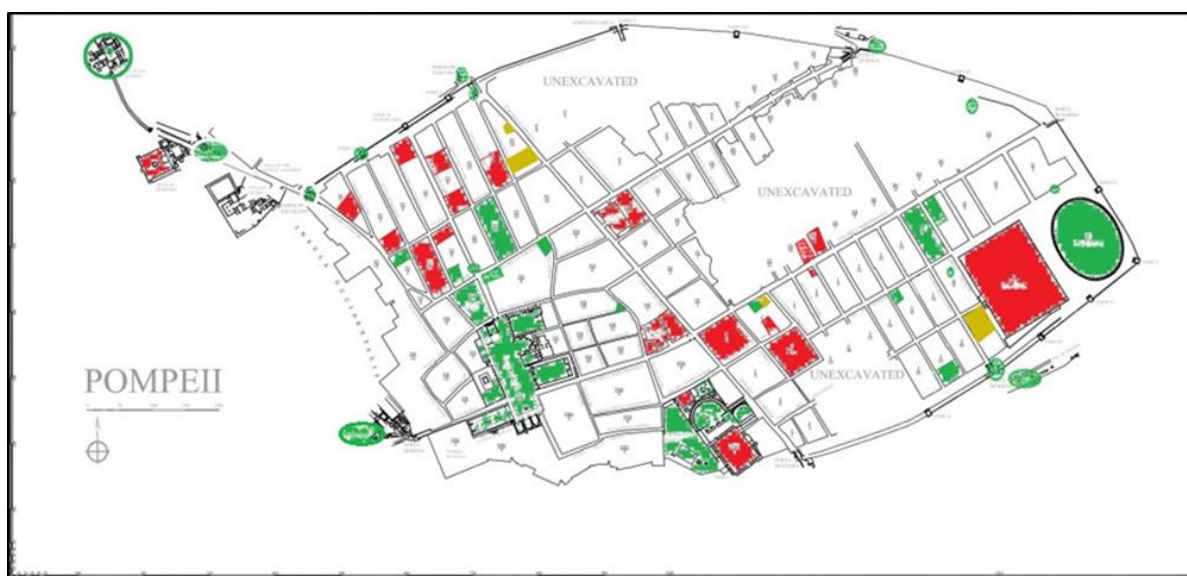

Fig. 1 Schematic map of the distribution of on-site interpretation (provided by the SANP). Green indicates open properties, yellow indicates those open occasionally, and red indicates closed properties (as of Summer 2011)

Fig. 2 GPS mapping of all on-site interpretation at Pompeii. Includes audio guide, guide book and recommended itineraries provided on map. Also includes the PompeiViva itineraries which include signs and interpretation panels

Fig. 3 Distribution of GPS tracking of the movement of 100 visitors during summer 2011.

Fig. 4 Map of Visitor Tracking. Numbers 1-5 represent high visitor traffic, 6-10 is medium visitor traffic and 11-15 is low/no visitor traffic.

3.2 Visitor behaviour and mangement

It is human nature to investigate using our senses and the tactile link to the past provided by Pompeii is important to visitors. One visitor I interviewed stated that she enjoyed being able to touch the walls and the frescoes, despite knowing that she shouldn't;

There were some you could just touch, and I know you're not supposed to but I did it. I'm a very touch-oriented person so it really brings it home [to] reach out and think about the life that painted this.

If not actively managed visitor behaviours like this can negatively impact on the conservation of the site. Ethnographic observations revealed that the most common bevahiours that can have a negative impct on the sites conservation are touching frescos and walls, sitting, standing or leaning on walls, and entering closed off areas. Visitors were also observed splashing water on mosaics to "freshen them up," as recommended by the Fodor's guide book and numerous tour guides. While most of these behaviours did not tend to be malicious, there is also evidence across the site of modern grafitti, although this was not observed in action during this research. At Pompeii, this freedom for visitors to interact tactilely with the sites is more a result of inadequate visitor management than of providing an intentionally engaging experience. Upon entry to the site, there is a small sign at each ticket window that lists the rules and regulations (n213 dated 22.01.01) for the site; the rules are also printed in the official Brief Guide when it is available. Few, if any, visitors take the time to read these regulations and the enforcement of the rules and regulations is minimal. There are a maximum of twenty-three custodi on duty at any given time. During the field observations, custodi were observed entering properties less than fifteen times, and their enforcement of regulations varied. For example, in the Follonica di Stephanus the custodi will tell visitors to watch their bags but will not advise visitors not to use a flash when photographing the frescoes. Similar variation of enforcement was also observed on guided tours, where some guides would actively enforce rules and other would not.

Fig. 5 and Fig. 6 Examples of visitor behaviours that can impact negatively on the site. Fig.5 is modern graffiti on a fresco in the Fullonica di Stephanus and Fig. 6 is a visitor standing on a wall to take a photo. Note that the area is meant to be closed off but due to a broken gate, the visitor entered.

The active visitor management is minimal at Pompeii. Visitors are kept out of certain buildings and areas by fences, barricades, and locked doors; these vary from the newer metal fences and gates to old wooden fences what are often falling apart. Inside the buildings, visitor movement is restricted by rope barriers, plastic tape or barricades. This mish-mash of barriers is often confusing to the visitor, as a broken gate can be interpreted as open or closed. Observations and interviews revealed that many visitors moved temporary barricades or stepped over ropes. When this happened other visitors would often follow. As one visitor said:

There were broken barriers and you could go into it. And to be honest we did go into them. But there were footprints before, and you know that someone else had been in there. Not to mean that this makes it any better but if they were fixed you wouldn't go, you'd obviously know that was a no-go zone.

For the most part, visitors obeyed the barriers and accepted that certain parts of the site are closed. Some visitors interpreted the locked doors as a sign that excavation or conservation work was occurring. However some visitors, the closed and broken gates also represented neglect and a lack of adequate maintenance and this left them with unsatisfactory visits.

Some of the sections were really well-preserved and well-presented and some were much more dilapidated than I expected. I think it's a fine balance between having this site as an ongoing archaeological dig and a tourist attraction and I don't think they have found that balance quite right. It didn't feel as though it was there. It did seem like it wasn't really cared for that much...I think I was expecting to be in awe more than I was. I mean it was fascinating and really, really interesting, but I don't think I was as blown away as I was probably expecting.

The negative impact from visitor behaviour and management are due to visitors being unclear as to what is or is not acceptable. Much of this damage could be lessened through active communication of appropriate behaviours, providing clearer and more up-to-date information before they begin their visit, and regulating the enforcement of rules and regulations. While an initial investment would be necessary to replace broken barriers and provide informational signs and panels, the long term

benefits would outweigh the costs. It must be kept in mind that barriers, fences, and a lack of regulations are all communicating interpretive messages to visitors, even if not intentionally. Visitors take this to mean that certain behaviours are acceptable, and feel that a distinct message of neglect towards the site that is present which impacts how the visitors experience the site.

4 Presentation as a result of ‘meaningful collaboration’

It emerged in this research that visitors feel that the most valuable aspects and elements of Pompeii are the ability to get close with the site, its openness, the ability to ‘visualize’ the city as a whole, and the intact nature of the ruins. The potential to “bring the past to life” is central to the value visitors hold in their experiences while at Pompeii. However, the current visitor experience at Pompeii does not provide the necessary elements; thus visitors are left feeling frustrated and some are even disappointed. On-site interpretation should aim to orientate, engage and inform the visitor of a range of themes while diversifying the visitor experience thematically and physically. Directional signs and more detailed maps can be used to orientate and direct the visitor, while on-site panels can provide information on a variety of different topics. However, decisions regarding signs and other interpretation materials need to consider the varying backgrounds and expectations of visitors, as well as how any changes will affect the visitor experience. While this research has provided a starting point, it is essential that further visitor studies be conducted prior to any decisions being made otherwise the results can be catastrophic to the site.

The ICOMOS Charter for the Interpretation and Presentation of Archaeological Sites says that presentation and interpretation should be the result of ‘meaningful collaboration.’ This research shows just how important that is. While there is a need for a more complex interpretation strategy that utilizes the site more effectively and communicates to the diverse audiences to the site, this cannot be achieved without collaboration between various stakeholders. Pompeii is an active archaeological site, not a “city frozen in time.” Conservation work, condition assessments, and new research should be integrated into the current on-site interpretation but the decentralized approach to site management does not encourage collaboration between stakeholders and thus hinders the development and availability of interpretive information. While visitors have shown interest in these topics, there is currently no formal requirement for researchers to make their work available to non-academic audiences. Thus those who are producing the interpretation (tour guides, outsource companies) do not have the ability to stay up to date with current information, whether new research or house closures. Most importantly, for any interpretation and presentation strategy to be sustainable it must be continually assessed and reassessed, otherwise it risks becoming ineffective and outdated like the current presentation. This strategy would require active involvement from all aspects of site management and thus has the potential to create a forum for increased collaboration, which can only benefit Pompeii and its stakeholders.

From the *pompeiana domus* to the Early Christian Basilica

Maria Carolina CAMPONE,⁽¹⁾

Abstract

According to a widely accepted theory, which considered the West, particularly Rome, the *fulcrum* of Early Christian Art and Architecture, the christian Basilica derives from the Roman. Mutated purposes and functions, it retain the original longitudinal development. The basilica has a plant common from the V century, when the buildings have a scansion tripartite: atrium, nave, sanctuary. A comparative analysis of the sources and surviving buildings shows that even in V century the problem of orientation is not generally perceived in the West and does not existing a specific terminology in order to indicate the various parts of a religious building. In light of the centrality, for the birth of early Christian architecture, of the eastern regions of the Empire, a detailed comparison between the *Pompeiana domus*, some Roman buildings and other northern Africa demonstrates how the *ecclesia* originates from the private *domus*. An examination of the two types of building demonstrates surprising analogies and explains some peculiar elements of the primitive churches, as the presence of one or more *atria* and numerous annexes, the location of the faithful in the smaller aisles, the altar at the center of the greater aisle, certain peculiarities of the apse, sometimes the absence of the roof in the nave. In forming a complex organism such as the basilica, had to intervene multiple cues and factors, but the link with the house, the *oecus* and the various environments is critical to understanding the subsequent developments of the model.

Keywords: Roman domus, early Christian basilica, paleochristian architecture.

1.1 Introduction

The studies on the early Christian architecture and its origins traditionally indicate the prototype of the religious basilica in the civil basilica of the Roman period, from which it had derived some characteristic features such as the strong longitudinal development, the presence of a porch, the use of columns or pillars to mark the aisles. This explanation, however, does not seem entirely acceptable even today, mainly because of two sets of factors: on the one hand, it would seem to take their cue from typological analysis exclusively linked to the development of a basilica in the West and especially in Rome, while industry studies have gradually recognized the growing importance of some areas gravitating around the Mediterranean basin, primarily the North Africa, in the early centuries of Christianity¹. From another, it is useful to illustrate the type basilica which seems formed from the late Middle Ages, while not explain completely the disparity of the elements that characterizes the Christian places of worship to their birth and the different geographical distribution of the same. In identifying the matrices of the Christian par excellence, the church, can't be neglected, next to the archaeological and architectural, literary sources, confirmed by recent excavations, which located in the *domus ecclesiae* the germ of the future church. As is well known, Doura Europos's plant by separation of the various liturgical rooms arranged around a central courtyard, already indicates the roads of the future typological development. With the growth of the community was inevitable that a major part of the house was reserved for the performance of the liturgy and rites, with a process of "typing" of the liturgy in a domestic environment.

Fig. 1: Doura Europos, plant

The excavations in Galilee in the last decades have shown that the *domus* of the first communities no would suffer radical changes in the planimetry even after being used as places of worship, as happened for the so-called "Peter's house" in Capernaum³.

When during the period between the pontificate of Pope Victor (190-199) and the beginning of the third century, as a result of a strong proselytizing and required by the standardized form that the liturgy was increasingly taking, the Christians began to design buildings of worship *ex novo*, the type, now supported by the practice of worship, remained essentially unchanged, with a broader articulation of interior space according to the needs of worship.

Several archaeological evidence show that, in the middle of the third century, began the decisive process of resolution formal and structural of the "place" of Christian worship, which ended in architectural types made by Constantine onwards⁴.

Even in Rome, numerous archaeological traces found in the churches "owners" suggest to the order primitive of these buildings, later overturned by the creation of a housing of Christian worship, in which however are recognizable obvious influences deriving precisely the type of *domus*.

There is one point, in any case, I want to make clear regarding the fact that, when we talk about Roman dwelling, it refers to a complex and fluid, subject to change obviously related not only to the type of society, but also by geographic area as well as by evolution in time and space. T

he evaluation of the first Christian buildings of the City is much debated, but valuable, in a vision compared with the contemporary traces of similar construction found in Syria, to shed light on the early stages of definition of future churches.

The buildings found beneath the Basilica of Saints John and Paul, the old *Titulus Byzantis*, suggest that, in the third century, under the church there would be a single building, made from the fusion of previous environments⁵.

The Christianization of the house would take place only at the beginning of the fourth century, after phase homogeneous building -between third and fourth- had turned it in a stately home.

The creation of a large room, used as a meeting place for the local Christian community, opens a window interesting on transition from private residence to a place of worship, allowing you to capture those elements that characterize destined to survive into the next basilica, in the first place the importance of *quadratum populi*, around which develops the assembly hall. In the case then of the structure in question, under the floor of the assembly hall was built a *confessio*, as a prelude to subsequent crypts⁶.

Fig. 2: Pompei, Surgeon's House, plant

1.2 Some examples of Domus: Faun's House in Pompeii

Given this premise, there is no doubt that the image-type of the *domus* can be detected in both examples, Surgeon's House and Faun's House, both in Pompeii, emblematic of the evolution of the type, the more simple the first (IV century) more complex and more late the other.

Especially in the latter, many elements seem predict the development of a basilica, with the particular subdivision into groups of environments with distinct functions and the hierarchical scan specifically between the scope public of the house (the sector to the receipt of the *clientes*, focused on

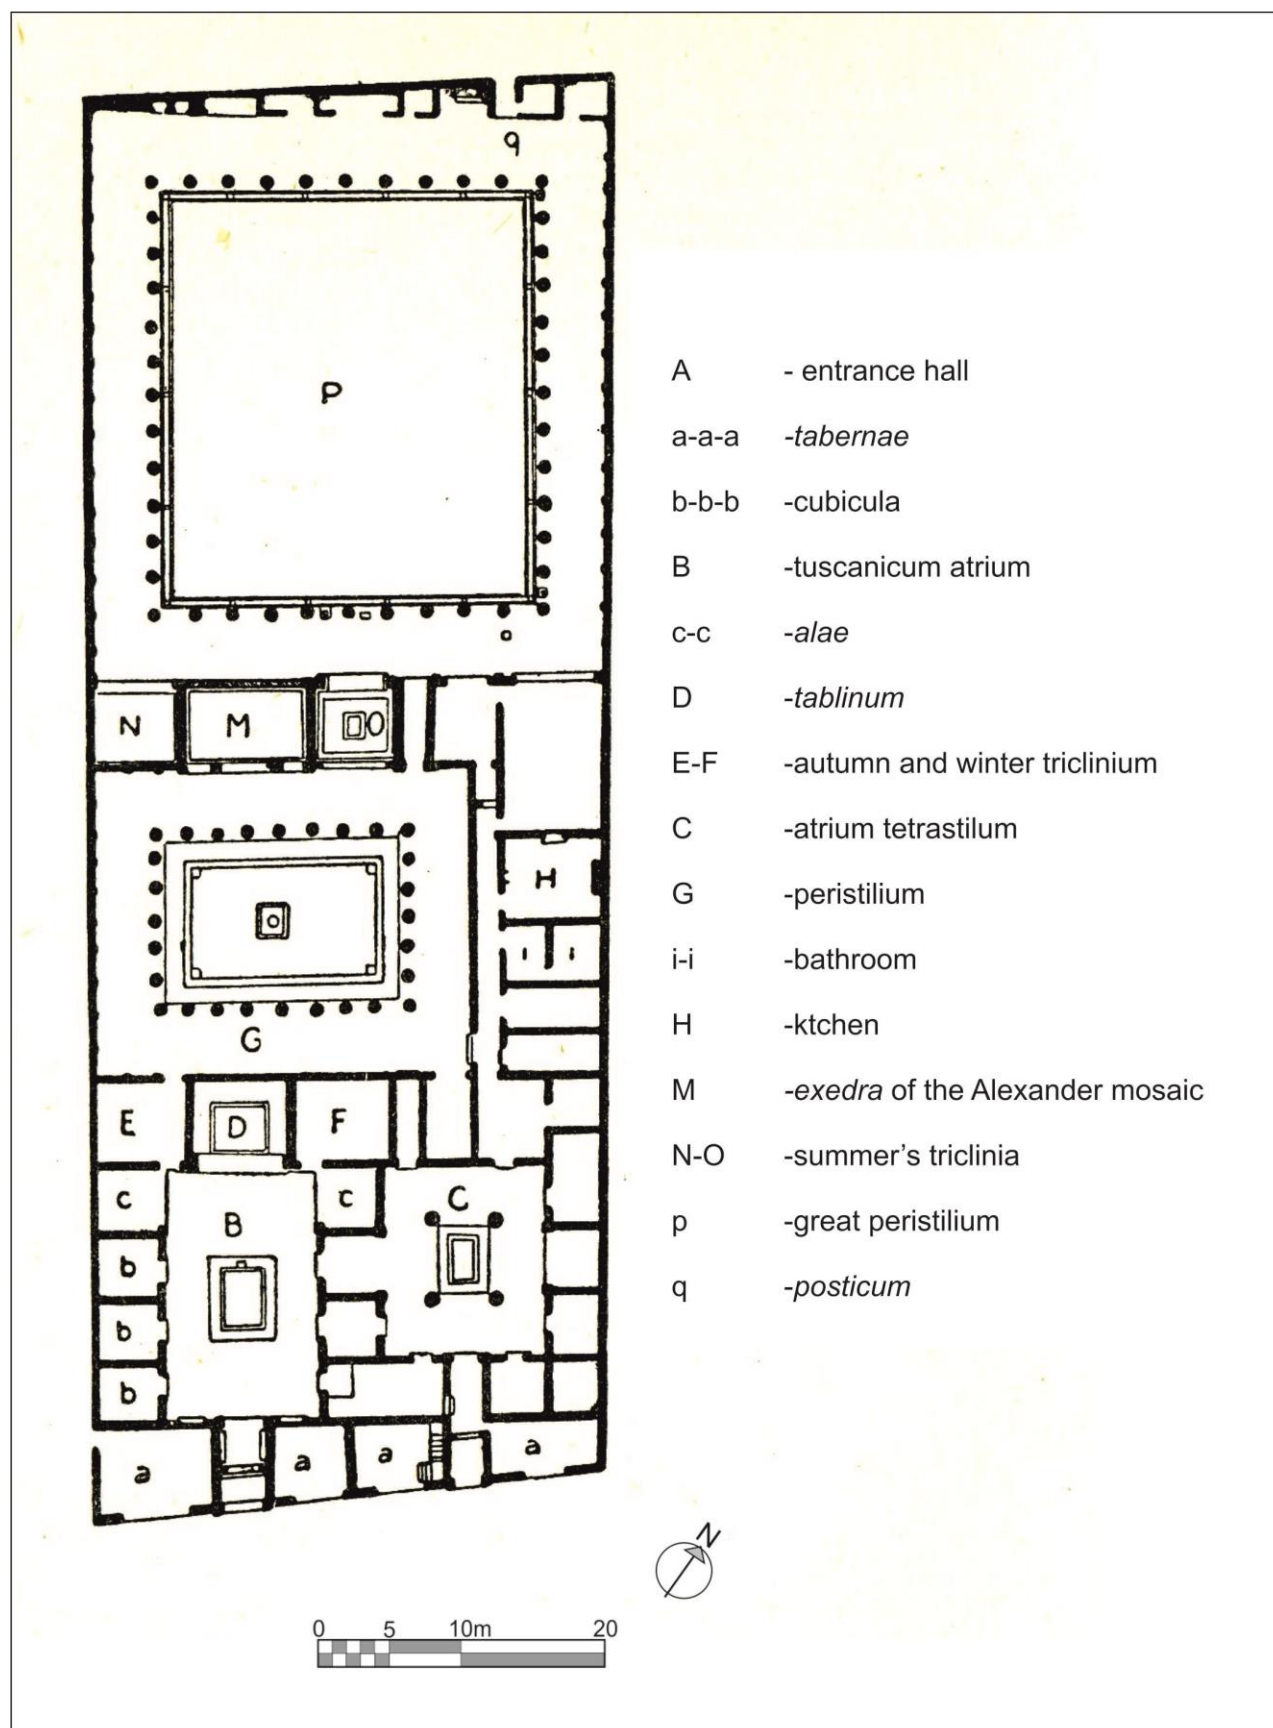

Fig. 3: Pompei, Faun's House, plant

tuscanicum atrium), a part used to welcome the guests and friends of the *dominus* (the two colonnades with their appurtenances) and a group of rooms, located in the immediate vicinity of the tetrastyle *atrium*, conceived as a private place reserved for the *familia*. Very interesting the articulation and total meaning of the ideological-decorative set of the *tuscanicum atrium*, where the two little temples symmetric of the *fauces* introduce to the *domini sanctitas*. They are real *lararia* of the public nature of the entire *domus*, which amplify the sacred character with reference to the Dionysian iconography of the whole⁷.

Fig. 4: Haidra, basilica à auges, plant

Since the *fauces* you established a relationship with the gods, but the real point of convergence of the constituent elements of the exaltation of the *dominus* was *tablinum*, in which the process of deification of the landlord touched its peak, with the raising of the floor pavement and decoration in *opus sectile*. Continuing and exasperating some peculiarities of the archaic *domus*, the houses of the historical age, just as the greater part of the buildings of the Paleochristian age, have their characteristic not only in the *atrium*, but also in plan's organization, that in fact is based on development of axes, one vertical (*fauces, atrium, tablinum*) another, in the *alae*, perpendicular.

Equally relevant for the purposes of this contribution is the set of *domus* with apse, whose reference model can be found in the development of the suburban villa in Imperial age.

Beyond the individual examples, it matters to emphasize the functional scanning of the environment, the strong emphasis of the *atrium*, culminating in the peristyle, the separation of the private areas, the presence of apses, located, for example in the case of *villae*, in the so-called *pars urbana*.

1.3 The Christian basilica

Analyzing the Christian religious buildings built since the fourth century, one can easily identify a common element: they all feature the same division in *atrium*, nave and sanctuary raised. In essence, this simple system of basic repeats that of the greek-Roman *domus*, with one entrance from the street, quadrangular *atrium* with fountain, from which it passes to a vast pillared hall and finally the *lararium*, which is more restricted. To confirm the dependence on the *domus*, is the fact that, in the face of an insistence on shared Christological symbolism related to the plan of the basilica with a transept, many of the first churches (St. Sabina and St. Maria Antiqua in Rome, House-Church of Joseph in Nazareth, Damous el-Karita in Carthage, St. John Studios in Constantinople, Constantine basilica in Jerusalem, Nativity Church etc...) were devoid of the transverse element.

Even more significant is the role that the *atrium* plays also in buildings with a central plan, as the church of Saint Lorenzo in Milan, legacy of a functional differentiation that has its roots in the buildings of the imperial era. The outdoor area of the *paradisus* inherits the "social" function of the *atrium*, in front of the nave, destined to the faithful, and the altar, where there is Divinity.

Very important to understand the structure of the pre-constantinians buildings and the legacy of the *domus*, is the eulogy for the cathedral of Tyre, crucial for reconstructing the spatial organization of the site, now destroyed: «A vestibule huge and very high rises on the side of the rays of the rising sun [...] leave a space as large as possible between the aisles and the first entry, which surrounded and decorated with four arcades, forming a quadrangular body, supported on all sides by columns. The spaces between them are closed by wooden barriers that rise up to a height appropriate, while he has left blank the middle part of the atrium [...] There he has placed symbols of sacred purifications, setting up in front of the facade the church with abundant fountains of living water flow» (*Historia ecclesiastica* 10, 4, 38-45). From the description it emerges the picture of a well-ordered house, whose walls separating pagans and unbelievers, in which the hall is reserved for catechumens, the aisles to advanced in faith, the presbytery to the priests, with a hierarchy of increasing *atrium* spaces apse, which is reminiscent of the Pompeiana *domus*.

Fig. 5: Rome, St. Maria Antiqua, plant

Fig. 6: Thugga, Trifolium's house, plant

An analysis of the first churches in the areas gravitating around the Mediterranean, which waives the pretence to choose as a vantage point in Rome and asks instead to consider all parts of the empire, can't but take into account the incredible development that the type basilica know in the current Maghreb and, in particular, in Tunisia. Here, as noted by a number of studies, especially in the site of ancient Carthage, as early as the fourth century, we find a rich harvest of churches, surprising for quantity and size⁸. The number of aisles of Damous-el-karita, (nine, eleven o'clock, but cross), Dermech I (five), Dermech II (three, but the wide central measuring 9m. X 80)-even taking into account later additions and alterations suffered by these structures-leads to reconsider the problem of the genesis and development of the church, especially in view of the evolution of local plans.

The development of the first buildings around an *atrium* or an *peristilium* (this in Africa) with the scanning of numerous annexes around this, often with the central ship positioned at a lower level than the side, as in Santa Maria Antiqua in Rome (and as in the Africans *domus* "to *peristilium*")⁹, constitutes in itself an indication of paramount importance. This church looks like a rectangular hall divided into three naves, in the thickness of the which wall back was built the apsis and on two small chapels. An entrance hall leads to the nave made from a *impluvium* (dating back to the first century a.C.) in a lower level to the two side-aisles, revealing her to be a significant example of the adaptation of an pre-existing pagan building.

Beyond, however, of a mere comparison planimetric, seem relevant the elements of early Christian basilicas, in reference to their function and use. The presence of the *trychora* for the relics in the apse in a long series of buildings reminiscent the use of such environments is made in the context of private building of Imperial age (villa of Piazza Armerina, Diocletian's palace in Split, Palace of Bosra, building of Mshatta).

The large series attested, numerically significant especially for the African area, more than useful to clarify individual cases, it may shed light on a general criterion of reference. The fact that the *trychora* was used mainly in the apse is linked to the original function of this architectural element, attested both in the *termae* and in the *triclinium* of *domus* of many areas particularly in the East.

While the very presence of triconch has urged the series of precise comparisons between the private building of the Italian area and the North African, notably as regards the so-called "peristyle houses"¹⁰, its function invites further reflection. If in fact the trilobate *ductus* appears in direct relation with the relics of martyrs and *martyria*¹¹, it also seems related to the *trychora triclinia* of the mansions of imperial age, especially prevalent in the western part of the Roman Empire.

Precisely this kind of choir is an important topic in support of the bond with the *domus*: as in *triclinia*, in the presbytery, with the exception of some North African churches- there is the altar, the holy table, or under which with which they were the relics of the martyrs.

Fig. 7: Cimitile, Basilica nova, plant

Not surprisingly, in many instances of advanced altar in the nave, was the same *ara* to take shape triconca, as for the altar of the *basilica nova* in Cimitile, of which we know the form based on the description of saint Paulinus bishop of Nola¹².

This type of building had played a major role in the civil late antiquity, adopted for the construction of sumptuous dining rooms and then transferred to sacred architecture, reserved to the chancel area, where celebrated the Eucharist, understood as "memory" of Last Supper, the more so, at least from the end of the fourth century, it is consistently associated with martyr's cult. In the most ancient examples, like the churches of Cimitile (Nola), Knossos, Concordia, Bétika, Deir el Abjad, the Roman influences are too significant to be passed over in silence, as evidenced by the lack of the transept and the *ductus* outside, corresponding to the inner, intended to be changed at a later date. It is particularly significant that the Christian altar derives from the table household and not from *ara* used for pagan sacrifices, *sub divo* in the *temenos* of the temple, particular this confirmed, especially in the East, by the name of *τράπεζα*, which normally indicated that part of the church.

Equally significant are, in the construction of the first centuries, elements ostensibly difficult to explain, such as the presence, attested in the fifth century in all the sacred buildings of Cyrenaica and other North African (Basilica of the prophets, apostles and martyrs of Jerash), and Aegean, of two rooms on either side of the entrance, almost a equivalent of the sacristies flanking the apse.

These spaces, whose function was unknown so far, can only be understood in relation to the *fauces* of the Roman *domus* and with their derivation from the domestic environments. Still in Cyrenaica they are associated with certain characteristics (chorus closed by gates, nave's isolation through another system's gates) that are reminiscent of the clear separation of the environment of the house and the central closure outside of the room private.

Finally, only keeping in mind the model of the private residence, is possible explain some types purely Africans, attested both in phase early Christian age and in Byzantine era, as the *basilicas à auges*¹³, in which the church is flanked by crushers and mills grinding of grain (in sometimes, as in Palestine, located internally next to the apse) while the intercolumns of the nave are closed by feeding or food containers.

Conclusions

The building of worship for excellence in Christian had to be realized with reference of more models, not least that of the private residence, from which the church itself took the moves. A reflection on the initial places of worship, especially in the East and in North Africa, leads us to reconsider the link between private residences and places of worship.

Fig. 8: Cimitile, St. John, trychora

The reference to the civil basilica remains a valid model to explain certain features, but must necessarily be supplemented or even excluded in some areas -as current Maghreb and Near East- in which the private *domus* was the prevailing model of reference.

The issue is complex, also due to the fact that the type of the *domus* presents significant geographical and typological varieties and therefore should be analyzed the simultaneous evolution of building's two types.

More generally, it should be noted that, since the first imperial age, is adopted a kind of architecture common to residential mansions and imperial useful to the ruling classes to express their aspirations and political and *status*.

It is possible to detect not only a model, but a development of contemporary architectural models that used the same code to express similar meanings in terms of the ideology of power.

Note

The text is preview of a larger study on the relationship between religious and private building in the Late Antiquity in course of publication.

POMPEI URBAN CENTER : knowledge, regeneration, management

Maria Antonia GIANNINO,¹

⁽¹⁾ Dipartimento di Architettura e Disegno industriale, Dottorato di Ricerca in “Rappresentazione, Tutela e Sicurezza dell’ambiente e delle strutture e governo del territorio”, Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Abazia di San Lorenzo ad Septimum, Aversa (CE)

E-mail: mariaantonia.giannino@unina2.it, architetto.giannino@gmail.com

The scientific interest and design for the urban affairs of Pompei moves from the singular nature of this city, today strongly characterized by the presence of the Ruins and the Sanctuary as well as a strategic location in the territorial framework. Proposals for redevelopment of the tourist-cultural-urban Pompei are, therefore, designed to interact with the two main poles, the ruins and the Sanctuary, making the city a *port* of cultural tourism in Campania. The objectives of a strategy for strengthening and redevelopment are numerous: - redistribution of tourism flows of access to cultural heritage and landscape; - increase of the attendance interested in cultural tourism related to the production and distribution of art and craft products; - energy saving derived from the rationalization of traffic and increase of energy production through the use of photovoltaic systems. All this through the construction of a true Urban Center that will produce information-communication-participation by activating a program of events designed to raise awareness of projects and scenarios of the transformation of this area; a cultural center to disseminate the new languages of the contemporary city; speaker and promoter of best practices aimed at increasing the awareness of the citizens and through the support to the institutions a useful tool for the construction of urban policies shared.

Keywords: heritage, regeneration, development

1. Regenerate and Preserve Pompei: strategies, methodologies and tools

“Our artistic heritage is a universal language of humanity because it is an expression of our nature, our history, and our living relationship with others.

For this reason it can be the unifying factor around which we can strengthen respect for civil and social values ,as well as economic and territorial development and the inclusion of our citizens.

The way to inform a responsible citizenry must be through education” F. Profumo

Pompei is “the representation” of our cultural heritage, and has been a UNESCO site since 1996. It is the largest archaeological site in the world. Its 66 hectares, of which 45 have been excavated and 33 are open to the public, include all of the ancient city divided into 9 regiones (districts), subdivided into 112 insulae (blocks) and 1500 domus (houses). It possesses a rich and varied artistic heritage consisting of mosaics, decorated surfaces and decorative architectural elements that are all important components of the Pompeian identity and which attracts 2,300,000 visitors each year.

Fig. 1: View from the south of Pompei. In the right foreground, the theater and the Odeon. In the center, street Stabiana, which runs through the ancient city from north to south. In the background, Mount Vesuvius.

In terms of tangible and intangible activities, the awareness that this heritage contributes to European cohesion and plays a strategic role in its development means that all forces and all attention converge on Pompei; for these reasons, protecting Pompei means that all stakeholders must assume their responsibilities. The search strategies, methodologies and innovative tools is necessary for the preservation of Pompei. Also against the continuous decay concerted action is necessary to identify, on the basis of sound scientific evidence conjugated to the prompt action for the safety of the whole area. The scientific interest and design to the vicissitudes of urban Pompei moves from the singular nature of this city, (fairly recent re-establishment after the interruption of the ancient Roman glories), today strongly characterized by the presence of the Ruins and the Sanctuary as well as a strategic location in the territorial framework. Clamped between the Vesuvius, the mouth of the Sarno and the hill chain that joins the peninsula of Sorrento, Pompei seems to claim the upgrading of urban infrastructure nodes, and answers to broad and good landscape sensitivity, to redevelop the rail-highway-parking system channel-campaign-tourist sites.

It is known that the Ruins of Pompei are one of the most visited sites (over 2 and a half million people a year according to the Superintendent), as well as the Shrine of Pompei is, for many visitors, one of the most important Marian shrines in Europe. These two sources of cultural tourism are as important as different and autonomous: ancient Pompei few visitors go to visit the new one with its Sanctuary and vice versa. So for the proposed redevelopment of the tourist-cultural-urban Pompei are primarily intended to integrate the two main poles, the Ruins and the Sanctuary (the old and the new) making the city a Port of cultural tourism in Campania region, decided to explore the main cultural tourist routes of the region (Vesuvian Area, Naples-Campi Flegrei, Sorrento Peninsula).

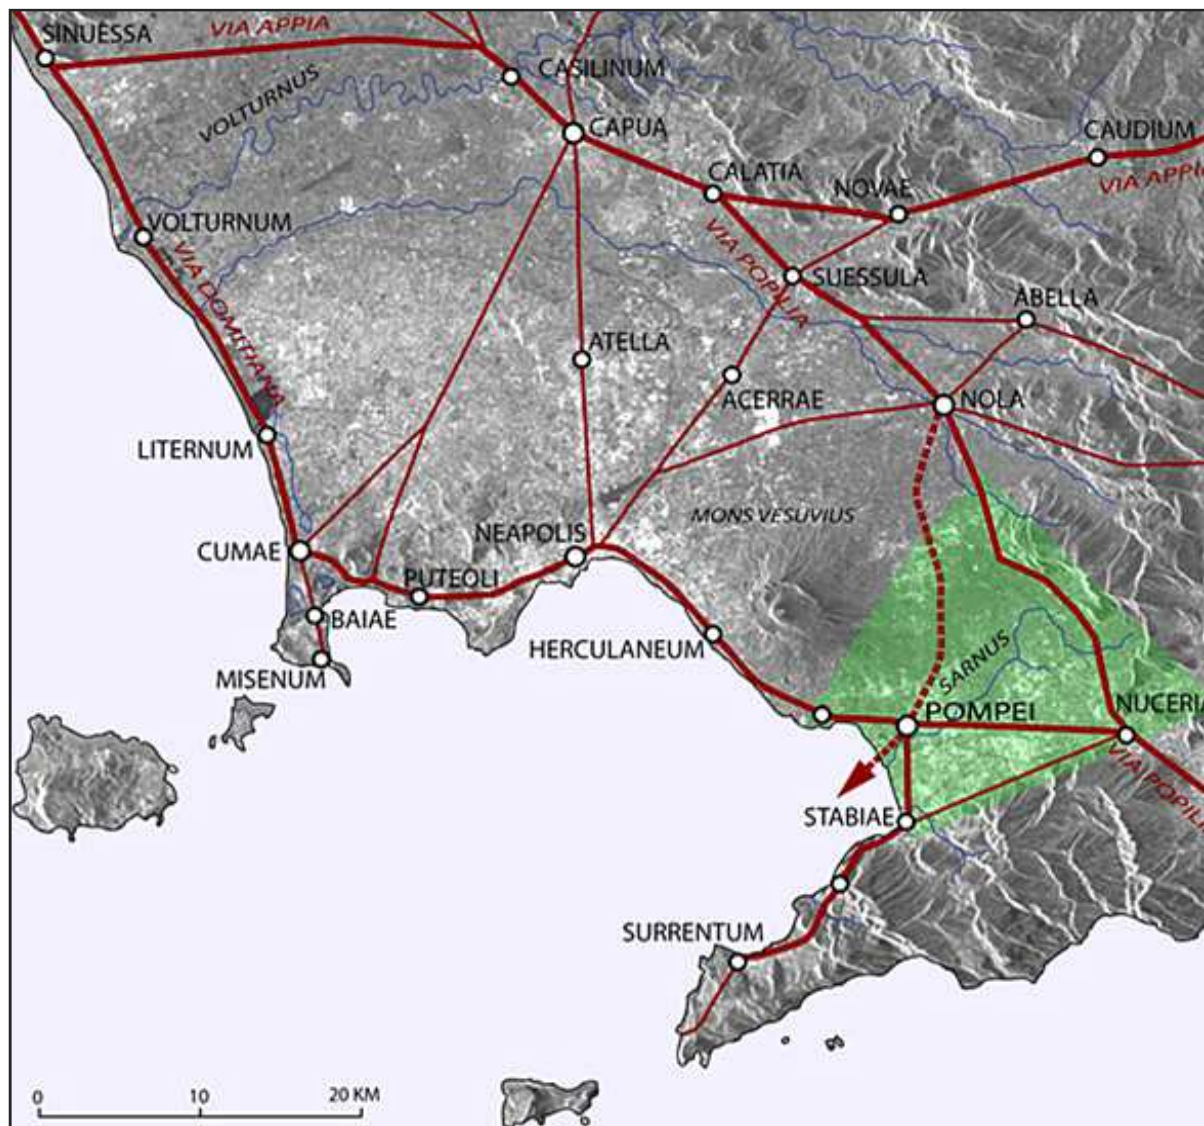

Fig. 2: Network of the main connections between Pompeii and the cities of Campania

1.2 Intervention's strategies

Radically affect the structural and preservation, protection and enhancement of an archaeological and historical and cultural heritage character of uniqueness and absolute relief leads to strategic interventions through the principle of enhanced cooperation and implements that address with reference three essential features that characterize it as a prototype:

- THE SAFEGUARD OF A CULTURAL HERITAGE OF WORLD SIGNIFICANCE AS A DRIVER OF TERRITORIAL DEVELOPMENT IN A COMPLEX AREA

Strengthening territorial competitiveness, including tourism, by means of a unified system of functionally interdependent interventions that offers prospects for growth and socioeconomic development, leading directly to the reinforcement of national and local identities.

The innovative drive of the methodologies adopted will in turn generate opportunities for the growth and development of professional skills, of businesses in this sector, and of research, by creating a workshop structure; upgrading the video surveillance system; promoting and guaranteeing conditions of transparency, participation, and control by the citizens (URBAN CENTER)

- 100% SECURITY AND LEGALITY : THE ABSOLUTE PROTECTION OF THE REQUIREMENTS OF SECURITY AND LEGALITY, INCLUDING COOPERATION WITH THE MINISTRY OF THE INTERIOR

Dealing at the urban scale with all key aspects that relate to minimising hydro-geological risks, implementing structural reinforcements for embankments not yet unearthed and the insulae; consolidating and restoring masonry and decorated surfaces; protecting buildings from the elements; and upgrading the video surveillance system.

Monitoring of the works throughout, from the analysis of the tender documents to the implementation of the works by those carrying them out; monitoring the relevant funding streams in respect of the principle of traceability in accordance with art. 3 of Law no. 136, 13 August 2010. carrying out on-site health and safety checks; checking that the rights of workers are respected.

- STRENGTHENED COOPERATION

The interests of all ministerial departments are made to converge within the implementation model: consistency of the project with EU rules on development policy; the high technical and scientific profile of the initiative; its ability to continue working towards territorial development objectives during its period of implementation; the involvement of the whole competent institutional sector at the territorial level; appropriate and efficient conditions and procedures for implementation.

2. New cultures, New languages for the city of Pompei

In recent years, new forms of architectural and urban of the contemporary city have been experienced in the valuation of the historic city, in the recovery of some structures of the suburbs and into a consolidated view of the landscaped open areas. I believe that today it is essential to deal with a critical and purposeful that part of the city, more extensive, which includes the suburbs of large cities, the urban sprawl, the infinite city, a group that can be called the city continues to the urban character that pervades. It an urban character that characterizes the ways of life of the inhabitants which does not correspond to an urban character of the spatial organization and morphology.

In this city are found new potential sites, a different conception of collective space, new types of systems that replace mixité fragmentation functionalist. In this town you can organize a new community vision based on dynamic relations and the opening of the crossing flows metropolitan and territorial conception of the project as proposed open space and time, a vision of a sustainable city that goes beyond the sum of the sustainable neighborhoods.

The languages of this city are produced in the relationships that are established through the use of the morphologies space and their interpretation.

Knowing them and encourage the design experiments I believe it is now one of the tasks of the Urban Center.

Fig. 3: Design in the built, Pompei

3. The concept of Urban Center and its applications

The obvious targets of this strategy of strengthening, upgrading and safeguarding the environment are manifold.

- Redistribution of tourist access to cultural heritage and landscape;
- Increase in attendance interested in cultural tourism linked to the production and distribution of art and craft products and a better link with the various productions of the territory;
- Energy savings derived from the rationalization of traffic and increase energy production, through new uses of photovoltaic systems and so on.

All this through the construction of a true Urban Center that will produce information-communication-participation by activating a program of events designed to raise awareness of projects and scenarios of the transformation of that territory; a cultural act to disseminate the new languages of the contemporary city; speaker and promoter of best practices aimed at increasing the awareness of citizens and institutions through support to be a useful tool for the construction of urban policies shared.

The phenomenon of the Urban Center is closely related to the metamorphosis of the subjects architects scenarios transformation of the city. The new generation, if we may so call it, of strategies for the promotion, development and commercialization in the field of urban modernity seems to favor a more sensitive approach to the figure of the complexity of the actors, with the maturation by administrations to pilot and manage increasing security mode, times, reports of dialogue between the interests and finds space.

Now passed, in fact, the traditional, monolithic model of dialectical opposition public / private due to the proliferation on the urban scene of a surprising number of actors – both quantity and characterization – the result of a partnership between consolidated entities (local governments, businesses, consortia of private banking groups, STU and joint ventures) and "emerging players" (special purpose company, promoters theme, management groups, authorities, institutions of communication and image enhancement, interest groups spread), new stakeholders that in pursuing specific missions are holders of innovative approaches both in the process of formation and stabilization of the design patterns, as in the architecture of support to the paths of realization and management of interventions.

The Urban Center can play the role of "cultural center" not only as an expression of reality brought some local perspective but also as a "node coagulation territorial", a bridge between the government of the transformations settlements and citizens, between the environment depositary of a technical knowledge and regulatory apparatus on one side and all the people and groups who live, make use of local resources and will grow opportunities.

The "territorial projects" that the Urban Center can facilitate and accompany binding appear both in the metropolitan conurbations, both agglomeration and unions of municipalities contained, for which the sine qua non for the promotion of local resources is represented by a threshold of significant critical mass that would justify and encourage virtuous forms and concrete planning.

Ultimately, the Urban centers can play a role identity to the civic community, in which the needs and intentions fragmented and geographically dispersed, forced within administrative boundaries that often have nothing to do with the different physical-spatial relations environmental, social, economic, can be put in the system and a shared strategic vision.

3.2 American Urban Center

There are three main commitments of American Urban Center: the issue of transparency and access to information; the issue of direct production of studies, research and other documents regarding the citizen development and related problems; the promotion of architectural activities directed primarily in participatory planning, in competitions' s ideas, debates about current projects.

In Europe, you perform the same tasks, although with less attention to the aspects of participatory planning and consulting. What changes the results obtained, it is the same role that the Urban Center takes in the urban context: no more third place of moderation between the parties involved as an expression of the public will. The following American cases, although arising in a social context, administrative and planning is completely different from that of Europe and, in particular, from the Italian, allow to understand the evolution, the management procedures adopted and forms of financing obtained.

These models have the general characteristics that can be taken from any Urban Center in the world, although in different conditions. Ultimately the features common to the Urban Center analyzed will be the foundation for the construction of an Urban Center in the area of Pompei.

The birth of the Urban Center in America dates back to the 70s. In this period, in fact, it happens a new phenomenon in the way urban towns typical of American cities: it begins a process of abandonment of the city center is by the population, both by capital and productive activities. This leads to two main consequences:

- remain huge brownfield sites in the city center for further evaluation reuse;

- starts a continuous and uncontrollable horizontal development towards the outside of the city, not integrated with overall planning and long-term.

In this context, forming associations of citizens who want to take action on the issues. So the union of several associations, generally financed by foundations and universities, leading to the birth of the first Urban Center: tanks of ideas in which citizenship can participate in the urban redevelopment of brownfield sites. In such structures, seeking a compromise between a number of stakeholders to bring proposals strongly directed towards a better quality of life of the city and towards greater social cohesion to internal districts themselves.

3.2.1 The SPUR: San Francisco Planning and Urban Research Association

"A community that does not plan and build the structures necessary for the life of all days remain perpetually backward; The buildings may also be towers towards the sky but their current social elevation will remain below that of an almost decent country "

Lewis Mumford - the cardinal principle of the Spur San Francisco

The oldest Urban Center is probably the one in San Francisco. It was founded at the beginning of the 900 at a particular time catastrophic for the city, the management of the post- earthquake of 1906 that destroyed the home to more than 300,000 people (out of a total of 400,000). In this situation, the social and urban, some citizens and city leaders decided to create this forum for the discussion with two primary targets: to improve the quality of housing in new buildings and to limit as much as possible post-earthquake building speculation. This first structure is a forerunner of the real Urban Center citizen (the SPUR San Francisco). Have been proposed to citizenship meetings, debates, seminars to be administrators, planners, representatives of associations have shown development projects, research, projects of buildings and redevelopment of areas. This behave a number of advantages: encourage the participation of a large number of people, prevent the request for reimbursement by the speakers in front of the brevity of the interventions, increase the ability to organize a large number of encounters though of lower dimension. In summary, the main purpose of this Urban Center is to increase the participation and information between stakeholders in order to create guidelines and policies to suggest the local administration as a result of the debate, first within the association itself , and then the public.

3.2.2 CFA: Philadelphia Center for Architecture Foundation

Different interpretation than San Francisco is the "Urban Center in Philadelphia. It was founded in 1968 and underwent a final set in 1980. Philadelphia is the city that contains the largest number historical buildings of the city, the place where was signed the declaration of independence, the first capital of the United States. This context helps us to understand the specific address taken from Urban Center. A specific project, which has been the most successful in the various editions, is aimed at nurseries and schools with objective to know the younger importance of environment and the buildings that surround them with deep historical significance through interactive features and games. A similar target is pursued towards an adult audience through an extensive activity of guided tours to the places and routes the most important of the American metropolis.

The promotion activities then pass through the drafting of city guide and a magazine that in addition to release information on the activities that the center conducts, develops the debate on topical issues in the city. Always include the major players in the process and also to exit from the local area are organized competitions for ideas and set premiums so as to involve international players, but above all to attract attention towards the heart. All these issues are, however, discussed in forums, seminars and discussions organized periodically by the property is for a public purpose expert, who for the most widely interested and for which you have to use a totally different language. The structure's staff is not particularly slim, twelve are the people working under him; the board is made up of thirty people from various backgrounds (architects, bankers, lawyers, real estate developers, brokers, representatives of the groups and local committees, experts in specific disciplines).

All the activities of the Urban Center in Philadelphia, however, revolve around the principle of importance of safeguarding the cultural and architectural history of the city is very rich.

3.2.3 CAF: Chicago Architecture Foundation

In Chicago, the situation is very similar to that of Philadelphia. The city, famous for its architectural brilliance, saw the birth of his own Urban Center with the target of increasing and spreading the architectural culture of the city, promoting it in the population, in administration and throughout the world. The town house is designed to encourage the promotion and enhancement of the architectural culture of the town and through outreach activities and discussion and through events that promote awareness and citizen participation in urban transformation. The foundation is operated as a charity that deals with the dissemination of the culture of urban design.

The public events they see a confrontation between academics, practitioners and all other stakeholders and thus to promote discussion and the creation of ideas. As in most of the cases so far seen, the main donor are the foundations as well as to the Depaul University. Like most of the UC analyzed born at the end of the 60s with a specific target: to save from demolition an architecture of Richardson very important to the city's culture. In the following years they began the training of citizenship, conscious that a greater awareness of all precious architectural heritage against the citizen would have at least the most protected in the choices of future administration. All the activities of the foundation are based on the performance of 600 volunteers who make it possible to manage the structure with a relatively low budget.

The activities of retail sales, primarily related to the bookshop, allow good economic gains. The individual accessions insignificant compared to the total revenue, as public funding. On the contrary, the development of targeted projects on commission allows additional income.

3.3 European Urban Center

The arrival of the Urban Center takes place in Europe with more than fifteen years of lagging behind the United States of America. Only in the late 80s, early 90s, they begin to arise in major European capitals of structures called Urban Center or Architecture Center, Light House, Open House, and more. These structures arise in a context of deep critical for Europe's urban areas. On the one hand there are the first brownfield sites, to regenerate completely, from there is more to the chronic lack of infrastructure, a characteristic of European cities. The growing cultural well-being, in addition, can only encourage the desire and need of citizens to understand and express their opinion about the urban change in progress.

In addition to England and France, where many Urban Center proliferate in most large cities, which create a very similar pattern linked to the spread of architectural culture as well as the facilitation of the exchange of information among its architects themselves, are two interesting Urban Center were born, in the mid-80s in the two capitals of the northern Europe known for the vibrancy of its architectural urban transformations: Copenhagen and Amsterdam. These two centers are if you want the best example of how the Urban Center will play a key role as a place for discussion and dissemination of architectural processes, leading to an effective architectural brilliance and a widespread awareness of the architectural tradition of their country. The forms of control of the two centers are different: the former is supported by private funding, the second to the government funding.

3.3.1 ARCAM - Amsterdam

With nearly ten years ahead of its main competitors in Europe, Amsterdam was equipped with an Urban Center already around in the second half of the 80s. The structure was built to interior of a building specially designed by one of the most famous Dutch architects, built right in the city center, you can count on a facade of three layers of steel and glass. The activities are aimed primarily at the general public: for adults and tourists, through exhibitions, debates, lectures, meetings with designers aimed primarily to help people understand the inspiration and the study of urban works in progress, but always trying to create an awareness and protection on Dutch architecture; training programs to young people with very accurate that you can even insert inside of their syllabus for many college courses.

3.3.2 DAC - Copenhagen

Copenhagen, like Amsterdam, is a forerunner in the role that Europe can take an Urban Center for the urban future, and not just the city. In 1986, in the central area of the port, was in fact created the Danish Architecture Center - DAC-with the aim of bringing designers and manufacturers to facilitate the building of a new city and especially to promote the techniques and culture of the growing phenomenon of environmental quality for which its Copenhagen, in later years, it will become popular in the rest of Europe.

Lots of activities specifically aimed at training the younger, with targeted activities for teachers, children, youth and college students. The DAC organizes temporary exhibitions mainly related to sustainable construction. For all these initiatives often receive government funding to internal programs that the danish government has set up with the intention of becoming the nation most avant-garde in Europe in the field of architecture. You want to access all the citizens and visitors of tests, projects, experiments about concepts that can produce novelty in the field of quality housing. All these exhibitions are created with the greatest number of possible partnerships, both to increase the funding available, both for the use of human resources in the most competent individual sectors, but especially to enhance cooperation and exchange of information among the various stakeholders. The Urban Center Danish want to make the bearer of a culture innovative architectural paying particular attention to danish and international architects, promoting meetings, workshops and discussions reserved for them, with the intention of stimulating ideas, gain knowledge from the most interesting experiences of the world. Through these operations, the future classes of architects and designers will have a greater

3.4.2 Milano Urban Center

The place and space are a dedicated element of success for the Urban Center in Milan: it is inside of Vittorio Emanuele Gallery, with an exhibition space of 160m² associated, upstairs, in offices, services, and another small space devoted to breakfast, meetings or initiatives of various kinds.

Inside the exhibition space there is a permanent exhibition that tells the future transformations of Milan, its future skyscrapers, the areas of development, all through easily upgradeable and replaceable panels that cover the walls of the room. The activities organized but are not limited to major exhibitions: there are numerous conferences, debates and workshops organized in their own room equipped of 'Urban center that can hold up to 200 people.

4. Conclusions

With the analysis of various Italian and international cases, it is seen as every urban center has its own meaning, its own type of management, funding tied to the local community.

What should be then those features for the Urban Center of Pompei? And most importantly, because an Urban Center in Pompei? What should make up for deficiencies? What targets ask?

From what emerges from research conducted in recent years, such structures may have different features and characteristics, and consequently also differ from each other significantly. In fact, next to a core activities, informational and communicative, the urban center often accompanied by events, which vary according to the culture of "doing the town" and those relating to the legal model of the order of the countries in which they are established.

Incubators of knowledge, rather than reservoirs of creativity; places of participatory democracy rather than deliberative, represent the extremes of a dichotomous schema "pendulum of interpretation" useful representation for utilizing multiple forms that urban centers are taking to coagulate the interactions between civitas and urbs, namely between brought social and cultural expressed by the community at large and the physical city.

The choices regarding the objectives must start by considering that the urban context of Pompei has experienced a remarkable liveliness in last decade. There have been many projects that have changed and marked the city and many are the ones under construction, design or even earlier discussion. Many projects, little knowledge: the public opinion today is to discuss issues and projects of which he knows very little.

In all these contexts, given the experiences of other Urban Center, which could be the role of a Pompeian Urban Center? The exhibition space could and should be devoted to the dissemination of their data and projects for the main processes of urban change. Expose projects, detailed renderings, models for larger systems will help to fuel a serious debate with all stakeholders who have a good knowledge of what will happen, costs, effects and prospects. The Urban Center can then become a place of exposure, but also a place for debate. Might have the designers of the works, the competent assessors in redevelopment projects and mobility on stage to explain to citizens, in detail, what are the interventions, such as projects, such as the measures financed, listening to the views of all.

The assessor and or the designer himself could explain, during a guided tour, the stages of progress of the construction and how it was conceived and designed his project.

The issues to think about from the outset, to define even in broad outline the characteristics of UCB are:

- broad objectives;
- how to organize and how to handle it, it will very much depend on the choices of 'municipal administration, which is the main promoter;
- on which events and which initiatives to push inner space;
- what initiatives on which to work and what's the initiatives that can attract more funding and sponsorship;
- what subjects involved;
- if you have a fixed venue (like the majority of the Urban Center) or prefer a web communication with touring events in village halls;
- communal space which allocate and what are the characteristics that a space must have to be used (which are a function of "objective that you assign);
- such as opening times and how to structure operatively adopt this service;
- that the budget be made available

The Atmosphere of Industrial Architecture: Experience and Production

Kasper ALBREKTSEN¹, Mads Harder DANIELSEN²

Abstract

During the last decades a cultural grafting of former industrial areas in the Danish city centres has been unfolding: Former industrial buildings with distinct architectural atmospheres have been transformed into cultural centres - milieus of experiences in prime examples of conservation of architectural heritage. In this integration of city and industry the houses of the industrial economy have become houses of the experience economy!

However, concurrently a conflicting tendency is unfolding at the same cities' outskirts: The construction of contemporary industrial architecture in segregation with the cities. Which qualities separate the transformed industrial architecture of the past from the industrial architecture of the present?

Could contemporary industry again contribute to the city? And which capacities are to be embraced in order to meet the demands of both industrial economy and experience economy?

This paper seeks to investigate how to create an integrated and resilient approach to contemporary industrial architecture where development and improvement is facilitated by the knowledge of the transformed industrial architecture; how to utilise the lessons learned from the conservation and management of cultural and architectural heritage; and how in the link of past and present to move beyond mere retrospective and stringent rational approaches to industrial architecture by focusing on the connection between architectural atmospheres and the creation of experiences.

Keywords: Industrial architecture, experience economy, atmosphere, peripheral perception

Two contemporary tracks of industrial architecture [1]

The current state of industrial architecture is the theme of the article *Industriarkitektur efter industrialismen 1960-80 (Industrial architecture after the industrialisation 1960-80)* by the associate Professor at Aarhus School of Architecture Boris Brorman Jensen. He states that with the transformation from industrial economy to experience economy the role of industry in the city has shifted. In this process Brorman Jensen points towards two tendencies: The establishment of new industrial buildings at the outskirts of the cities and the reintegration of former industrial buildings into the city by applying new programmes. These roles are reflected in the economic development of Danish society: Contemporary society has both elements of production connected to industrial economy and elements connected to experience economy. In this development are two tendencies – the segregation of the industrial architecture of the present and the city, and at the same time the integration of the industrial architecture of the past and the city.

With these opposite developments it seems necessary to ask: Which qualities separate the industrial architecture of the past from the industrial architecture of the present?

Brorman Jensen gives a harsh description of the state of contemporary industrial architecture as he describes the production facilities at the outskirts of cities as an ocean of anonymity consisting of introvert, concrete monoliths with lack of illusions. A focus on consumerism and minimised production

costs has according to Brorman Jensen neglected industrial buildings as an architectural area: The buildings are minimised to vapid boxes assembled by standard concrete elements with a large frame where the factory sign can be changed to match the company currently housed in the building. Brorman Jensen further states that not only the buildings are in a poor state – also the industrial areas are left to large pieces of patchwork consisting of squares of disjointed land with a cover of asphalt and grass, included a few trees and bushes in a forest of signs.

Brorman Jensen states that the dullness clearly is larger than the construction costs. As a consequence of this construction cost, low prices on land and connections to infrastructure have become the most important parameters for industrial architecture – and they are all found at the outskirts of the cities and near the highway. This tedious tendency is questioned by Brorman Jensen as he asks: “*Why must it be that boundless bleak?*”

The answer is perhaps that it does not necessarily need to be that boundless bleak; industrial architecture has since the mid-1800s played different roles in the societal development. These roles have been the focus of the Danish architect Jørgen Sestoft's investigation of the history of industrial architecture in his book *Arbejdets bygninger (The Buildings of Work)*. Together with the article *Fabrikken som arkitektur i Nordeuropa (The Factory as architecture in Northern Europe)* by the historian Caspar Jørgensen an answer to Brorman Jensen's question is approached.

Sestoft describes the history of industrial architecture through a tripartition of the industrial periods: The first industrial period from middle of the nineteenth century, the second industrial period around 1910-40 and the last period from the 1950s and onwards. These three periods also represent three different views on industrial architecture, respectively: The image of progress, the image of functional beauty and the image of pollution.

The description by Brorman Jensen is inscribed in the latter period from the 1950s and onwards with industrial architecture as an image of pollution – and focus is therefore aimed at this period to elaborate of the state of contemporary industrial architecture.

Segregation and integration within industrial architecture [2] [3] [4]

Jørgensen states that the huge construction boom after the end of World War II and a focus on getting the economy kick-started created an enhanced focus on the functional principles and mass production where function dominated and the architecture became a by-product. Through these processes the architect lost his role in the building process of industry as it evolved to the consistence of large flexible boxes of production.

These foci and the exponential use of the car and explosive development of infrastructure fostered separation and large industrial areas were therefore planned and isolated from residential areas in the rural areas with cheaper rents and lower wages. The industrial typologies became - in the words of Sestoft - a picture of pollution.

The latest period of industrial architecture can therefore be characterised as an engineer-oriented industry where optimisation and production are the key notions: Industrial buildings as an industrial product isolated from interaction with the city to optimise cost; and cooperation between architect and engineer are minimised.

To unfold alternatives to the current state of industrial architecture that Brorman Jensen vividly describes focus is aimed at the other roles of industrial architecture through history: Industrial architecture has not always been ousted to outskirts of the city - the role of industrial architecture has shifted drastically during the years since the industrial revolution.

With the breakthrough of industrialism from the mid-1800s the industry was established as building typologies dedicated to a specific function of the given industrial production. These industrial buildings were often placed without regard to overall planning, as they were located at a site where the surroundings could be utilised in the production. New settlements were often located around or in immediate vicinity of the major industries to have the workers proximity. The first period described by Sestoft has thus a high degree of integration between industry and city.

The development created new urban areas with industry at the centres: Where the cities previously had been built around the church they were now centred around the industrial buildings.

According to Jørgensen the industries created a pressure on the hierarchical architectural subdivision and the architectural profession designed several private industries.

In the end of this period the industries started to focus on optimising of production and process methods and the engineer became more and more important to the industrial buildings.

In this first period the industrial architecture was regarded as a sign of progress and the buildings of this period are characterised by integration with the cities, connection to the architectural mode of expression at the time and a change of hierarchy within architecture where production facilities climbed in prestige. The design of industrial architecture was in the domain of the architectural profession – however as Jørgensen states this changed.

In the period of 1910 to 1940 the optimisation of production developed the industrial architecture into process plants which challenged the historical rules in relation to scale and proportions: These buildings no longer contained individual workers with isolated individual machines, but greater procedural machinery, where the flow and relationship between the individual machines were crucial to the production. These buildings changed the view on industrial buildings from carriers of symbols in the historic architecture to functional buildings that intrinsic had a beauty in the emphasis of function. The functional focus facilitated a higher emphasis on engineering in the design of the building. The stringent simplicity of function and technology became part of the architectural vocabulary – architectural and engineering consideration went together as cooperation in a modernistic future-oriented perspective.

The collaboration between architects and engineers and the increasing focus on the industrial fabrication and production methods resulted in a focus on the fast-growing technology. The industry had become the flagship of the development of modern society; the building became a symbol of the future and the machine itself.

This focus on functionality and rationality simultaneously resulted in a segregation of industrial areas and residential areas – and functionally divided cities therefore arose as a result of this approach.

Where the first period of industrial architecture was dominated by the segregation of professional competency with an architectural dominance and an integration of city and industrial buildings, the second period of industrial architecture was dominated by the integration of architectural and engineering competencies, but also by the modernistic segregation of city and industrial buildings. The domains of segregation and integration can therefore be said to have exchanged places in the two periods.

The third period described by Brorman Jensen can with this in mind be described as an adoption of the aspect of segregation of the two first periods: The industrial architecture of the third period are dominated by the segregation of professional competencies with an engineering dominance and the segregation of city and industrial buildings.

When Brorman-Jensen ask: “*Why must it be that boundless bleak?*” – perhaps the solution is rooted in the embracement of integration instead of segregation: What if the industry again became an integration of professional competencies and became integrated in the city?

Could this change of focus point towards a fourth period of industrial architecture where industrial architecture again claims the domain as societal co-generator of the urban scene?

As Brorman Jensen described two tendencies already exist in the state of contemporary industrial architecture: Segregation of industrial architecture of the present and the city and the integration of the industrial architecture of the past and the city.

The renewed interest to the central location of the derelict industrial buildings and their attractive potential for future development of cities can be ascribed as the transformation from industrial economy to experience economy. The latter development described by Brorman Jensen indicates that the transformed industrial architecture has capacities suited for the unfolding of the experience economy – capacities similar to those contemporary industrial architecture needs to embrace in order to contribute to the contemporary urban development. In continuation of this consideration: Which capacities of the transformed industrial architecture are important and useable in a re-integration of industry into the cities built on the experience economy's requirements for architecture?

Lessons from the transformation of industrial architecture [5]

The capacities of transformed industrial architecture are investigated in the research project “*The Experience City*”. The research project investigates this cultural grafting of former industrial areas in the Danish cities that has been unfolding during recent years: New cultural centres deliberately linking cultural institutions, information centres and milieus of experience in act of transformation.

The Experience City focuses on the connection between the cultural centres of the experience economy with different programmes – commercial and free of charge. The motivation for the link of different cultural programmes is often of financial character as the cultural programmes alone has not been able to fund the projects. Links between educations, productions of knowledge and experience have arisen as a consequence of this in the larger provincial towns of Denmark. The research project mentions these as hybrid cultural projects and stresses the potential of these projects for more than mere entertainment and for the inclusion of diverse groups of the society.

The architecture of these hybrid projects is described as “*experience-architecture*” which reuses and reinterprets heritage of industrial architecture and lend scale and typological diversity in the transformation to facilitate the cultural programme. As Brorman Jensen the research project emphasises the importance of the central placement of the former industrial areas as they re-enter the

cities, and in addition to this the research project emphasises that the large volumes of industrial architecture also are subjects of interest for the experience economy as they are carrier of historical references. The buildings are of high spatial quality and consist of a typological diversity of labyrinthine structures that makes them a perfect match for cultural use founded in experience.

The Experience City refers to Tate Modern as an exemplary transformation with these capacities: The former power plant at the south bank of the River Thames have by Herzog & de Meuron been transformed with a prospective approach where a prosaic reuse of the industrial architecture is combined in interplay with constructive and aesthetic additions – the contrast of the melanised concrete to the elements of glass, steel and wood strengthen the narrative of the transformation where the key concept in the transformation is the preservation of the vast space of the Turbine Hall of the power plant.

In continuation of these descriptions of *The Experience City* it seems that intrinsic in industrial architecture are potentials of experience and identity that reach beyond values of production.

To unfold these potentials it seems necessary to address the challenges of the adaption by industrial architecture to the agenda of experience economy. The values of production, cost optimisation and logistical connections are essential for a production rooted in an industrial economy, but they cannot stand-alone if these buildings are to contribute to the contemporary urban scene.

To elaborate on how industrial architecture is to develop focus is therefore turned away from the demands of the industrial economy to the demands of the experience economy – keeping in mind that industrial architecture also have to meet the essential demands of production, cost optimisation and logistical connections. The element of optimisation of production will always be a key design parameter for the industrial architecture – but the further investigation of this section will not focus on means of further optimisation, but on how the industry can embrace the experience economy.

In the same way the key design parameter of integration - between both professional competencies and also between city and industry – will not be exhaustively addressed as the focus will be on which capacities contemporary industrial architecture needs to contain to contribute to urban development. To approach this focus the demands of the experience economy are addressed. Aiming attention at the foundation for the experience economy does this: The creation of experiences – and the role of architecture herein.

The design principles of experience economy [6]

The two American economists B. Joseph Pine and James H. Gilmore introduced the term of experience economy at the end of the twentieth century: The term describes an economy based on experiences as the latest successor in a row of agrarian economy, industrial economy and - most recent - service economy.

The approach of Pine and Gilmore has a commercial focus and as the maximisation of profit is the main focus not all of the considerations are transferrable to architecture. However the core of this economy is – obviously - the importance of experience and this aspect can according to *The Experience City* be utilised to shed light on the role of industrial architecture in contemporary society and to unfold the phenomenon of experience.

Pine and Gilmore operates with four experiential realms and five design principles to create experiences; the four experiential realms of the experience economy are: Entertainment, educational, escapist and esthetic. The realms are characterised by two key dimensions: The level of participation and environmental relationship; and it is in the coupling of these dimensions that the four experiential realms arise.

The experience of entertainment is characterised by passive participation and absorption as environmental relationship. Absorption is described by Pine and Gilmore as “*occupying a person’s attention by bringing the experience into mind*” as opposed to a physical involvement which is characterised as immersion. Entertainment is thus a passive absorption of the experience through the senses: The participant is an observer.

The educational experience is also a mental experience – however it is an act of active participation: The mind is actively engaged and absorption of the unfolding events occurs as the participant is actively engaging.

The escapist experience is a physical experience in contrast to entertainment and education and this means that immersion occurs instead of absorption. The result is the completely immersion of the participant in the experience as an actively involved participant – the participant is able to affect the actual performance. A level of escapism thus occurs as the participant immerse in the act of participation.

The esthetic experience is as the escapist experience rooted in a physical immersion, but is of a passive nature. The participants have no or little effect on the event or environment.

Pine and Gilmore state that the most important factor for entertainment experience is to sense, to

learn for the educational experience, to do for the escapist experience and to be for the esthetic experience.

Pine and Gilmore stress that experiences can be enhanced by blurring the lines between the four realms, and that the richest experiences include aspects of all four realms: The design of a rich, compelling and engaging experience encompass the experiences of entertainment, educational, escapist and esthetic – not necessarily at once, but emphasised differently during the process of the overall experience. Only when the interplay of the four realms is unfolded within the same experience is it possible to create “*a distinctive place*” – in contrast to what Pine and Gilmore describes at plain space. Staged experiences that unfold over a period of time need the sense of place to keep participants in the experience; the goal is according to Pine and Gilmore to create mnemonic places: Places that produce memories which will invite the participant to return to the experience again.

To design distinctive, mnemonic places which embrace all four realms of experience Pine and Gilmore list five design principles: Theme the experience, harmonise impressions with positive cues, eliminating negative cues, memorabilia and engage the five senses. Theming the experience, harmonising impressions with positive cues and eliminating negative cues can altogether be described as the creation of a consistent universe of experience – or as Pine and Gilmore state: A mnemonic place.

The element of memorabilia which is to provide a tangible artefact seems difficult to apply to architecture, but the latter principle - engagement of all five senses - continues the focus on memory: The degree of which an experience includes all senses determines how memorable the experience will be for the participant. Cues can strengthen an experience through a single sense, but also detract value from an experience if not matching the overall narrative. Pine and Gilmore stress that architectural and technical skills are needed to add sensory phenomena to experience in the creation of “*experience with senses that make sense*”.

The parameters of the creation of experiences can therefore be said to consist of the creation of mnemonic places in the inclusion of the four realms of entertainment, educational, esthetic and escapist experience and the engagement of the five senses.

With these overall aims of the experience economy it however seems necessary to ask how these parameters can be approached - which elements in the creation of experience is contemporary industrial architecture to aim at to embrace the potentials of the experience economy?

To answer these questions and to transfer the principles of Pine and Gilmore to a spatial context focus is aimed at the Danish/Icelandic artist Olafur Eliasson who has conducted in-depth investigations of the relation between the utilisation of all senses and the creation of experiences in works of spatial character.

From observer to participant [7]

Olafur Eliasson has through his work addressed the aspect of multisensory awareness within the experience economy and in the 2004 interview book *At se sig selv sanse (To see yourself sense)* he states that the commercial part of the experience industry is one of the only places of contemporary society where the individual sensory perception is the centre of focus. In continuation of the focus on sensory perception Eliasson ascribes the understanding of subjectivity as one of the main areas of his work.

Eliasson states that he approaches the mechanisms of experience by trying to dematerialise and de-objectify the work of art; the focus is a transgression from the creation of “the right experience” for the spectator through the object to allowing the subject to become constituent for the work of art: The decisive element for Eliasson is the dissolution of the clear boundary of object and subject in a process where the spectator becomes participant.

Eliasson hereby suggests that experiences arise from the dissolution of the boundary between subject and object and the change of the role as mere observing subject to an engaged participant as a consequence of the dissolution. This transgression between body and setting lies in continuation of the consistent all-embracing universe of mnemonic place described by Pine and Gilmore. This approach of Eliasson thus emphasises the active participation over passive participation in the four realms of Pine and Gilmore – meaning that the educational and escapist realms are emphasised over the entertainment and esthetic realms in the creation of powerful experiences rooted in the dissolution of opposition of subject and object.

Eliasson has focussed on this relation between subject and object in numerous projects among this The Weather Project at Tate Modern in London where the spacious understanding of the large turbine hall of the former power plant was changed by placing a large, bright, artificial sun at one end and a large reflecting mirror on the ceiling. These interventions changed the space from a cool, cold and hard entry hall of dimensions of a cathedral to a place where people grouped themselves and lay down on the concrete as the sun and the mirror created a sense of intimacy and intermission – a place to linger.

Eliasson states that in the process of the dissolution of the border between subject and object the vision is only one sense among others to contribute to the creation of the experience: Perception is connected to all areas of the body and consciousness - and that the role of spectator is only connected to vision. He states that the approach of focusing on isolated vision therefore is stridently limiting in the creation of experiences.

The call of Pine and Gilmore for engagement of all senses is by Eliasson not only emphasised, but also further extended: Eliasson seeks to create what he describes as *inertia* and thereby enhance the intellectual potential of motoric skills. Eliasson states that a reduced ability to hear, touch, see, and smell; the absence of memory or anticipation; a reduced balance etc. is highly influent on an experience. Eliasson thereby suggests that the sensory apparatus is extended beyond the classical five senses of sight, hearing, taste, smell and touch – balance, distance, sense of time and dimensionality are equally important.

Eliasson stresses that this multisensory awareness is cornered in the western world where man is regarded as a rational being and as a consequence of this the consciousness of sentiments has been placed at the very end of the course of cognition: The sentiment of the situation is understood as something successive of the process of engaging in a situation and forming an opinion of the situation. In this line of thought a sentiment of the situation is reached afterwards. The goal of Eliasson is to turn this process upside down so the sentiment comes first and the rational conclusions follow thereafter. By doing this Eliasson strives to let sentiments constitute the surroundings instead of being products of them.

Eliasson states that by reversing the approach of the rational natural science where the senses are mere receptors for the environment it is thereby possible to see the senses as producers of the environment. He states that the senses constitute the environment and through this dialog with the environment they also constitute us – a sort of double dialogue thus exists. The senses are completely relative to the situation – a new position forms a new situation and a new perspective.

The perception of experiences is thus according to Eliasson founded in the dissolution of the opposition of subject and object where the change from spectator to participant is at the centre of focus. The realms of the educational and escapist experience are thereby emphasised. The importance connected by Pine and Gilmore to the five senses is extended and in continuation of this the emphasis on sentiments in the beginning of cognition is accentuated.

As the mnemonic place, four realms and the five senses are linked through experience it seems that the accentuations of Eliasson are related to an undefined element connected to the interaction of subject and object sensed by all senses as a sentiment.

Keeping the architectural capacities of the transformed industrial buildings such as Tate Modern in mind: What is this element that also seems to be intrinsic in industrial architecture according to conclusions of *The Experience City*? And how can it be further approached in an architectural discourse?

To transfer the conceptual consideration of the creation of experience by Pine and Gilmore and the spatial consideration of the creation of experience by Eliasson into an architectural context the philosophy of Gernot Böhme, professor of philosophy at the Technical University of Darmstadt, will be utilised.

Atmosphere as a space of bodily presence [8] [9] [10]

The relation between architecture and the interaction of subject and object has been the theme for investigation of Gernot Böhme: The vaguely defined element that Eliasson addresses in his work is by Böhme clearly defined as atmosphere: In the essay *Atmosphere as an aesthetic concept* Böhme bluntly states that atmosphere is something between the subject and object.

The notion of atmosphere is by Böhme problematized as it is of a colloquial character – it is highly ambiguous and is connected to vastly diverse thing. Böhme however stress that atmosphere always concerns a spatial sense of ambience, and he therefore describes atmosphere as a prototypical “between”-phenomenon: “*Atmospheres fill spaces; they emanate from things, constellations of things, and persons. The individual as recipient can happen upon them, be assailed by them; we experience them, in other words, as something quasi-objective, whose existence we can also communicate with others. Yet they cannot be defined independently from the persons emotionally affected by them; they are subjective facts.*” Böhme continues by stressing that atmospheres are characteristic manifestations of the co-presence of subject and object.

Böhme emphasises that the character of atmospheres make them an aesthetic concept – where focus is changed from the prevalent aesthetic emphasis on what is perceived to how it is perceived; it is not about what something represents, but how it is present. This establishes a focus on sensory perception – as opposed to judgement - and Böhme thereby continues the emphasis on sentiments by Eliasson.

Böhme states that atmospheres address aesthetic as its original meaning - as the theory of

perception: *"In order to perceive something, that something must be there, it must be present; the subject, too, must be present, physically extant. From the perspective of the object, therefore, the atmosphere is the sphere of its perceptible presence. Only from the perspective of the subject is atmosphere perceived as the emotional response to the presence of something or someone. Aesthetics thus becomes the study of the relations between ambient qualities and states of mind, and its particular object consists in spaces and spatiality"*.

The concept of atmospheres thus changes aesthetics from something passively beheld into something that creates a spatial sense - objects are something that changes the room by their presence. Atmosphere is first and foremost something that recreates spatiality - it focuses on a physical presence and a sensory perception.

Böhme states that the goal of the aesthetic of atmospheres is that which lies between – the space!

The role of the architect is according to Böhme to shape space from consideration to confinement and expanse, direction, lightness and heaviness. In connection to this three notions are especially important: Radiance, impressions and suggestions of motion.

In an interview with the Danish architectural journal *Arkitekten (The Architect)* Böhme describes the rehabilitation of the senses and a rediscovery of the human body as general tendency in contemporary society as a consequence of the experience economy - the popularity of physical therapies such as yoga and t'ai chi or more physical forms as cross fit and parkour are examples of the change of viewing the body as mere object to experiencing it from within.

This tendency within the experience economy is for Böhme an evident opportunity to aim focus at a greater sensibility to the atmospheric qualities of spaces: The emphasis on experiences calls for a focus on how the human is situated in spaces and an emphasis of senses over intellect.

Böhme describes atmosphere as the core concept in the way man perceives and finds him in a room – where atmosphere is grasped by a bodily presence. Böhme therefore sees atmosphere as an obvious concept in future focus in the experience economy with the prominent focus on the user experience quality. By going from a society based on production economy to a society based on experience economy – focus has shifted from basic needs to the desire of rediscovering body and learning how it works and reacts.

Böhme continues Eliasson's critique of western tradition of cognition and elaborates on the link between a multi-sensing participant and the emphasis on sentiments in the beginning of cognition in the creation of atmospheres by architectural means. The sense of space created by atmosphere is at the centre of attention and the bodily presence is according to Böhme decisive.

Böhme states that the description of a room on the basis of an atmosphere departs from a subject's subjective description: A subject that has been placed in the enclosure and perceived the tangible presence, proportions and given elements placements in the space. By describing space in such a manner the concept of space can be described as a space of bodily presence.

As an example of this Tate Modern's Turbine Hall cannot be described by mere dimensions or the relation to the human body – the same space can be experienced in very different way even though the dimensions of space and man do not change: Where the Turbine Hall was experienced as a space of intimacy during exhibition of the Weather Project by Eliasson, the same space of the Turbine Hall radiated a sense of distance during exhibition of Sunflower Seeds by Ai Weiwei in 2010, where millions of unique porcelain sunflower seeds covered the floor of the space.

The space of bodily presence is the space which is experienced due to the spatial presence and the space which therefore is sensed with our body – it therefore has an anisotropic character as it is centred around and defined by an absolute: Where the body is.

This suggests that the characterisation of a space is determined not only by where, but also by how the subject is present in space. This experience of how the subject is present is the decisive factor for the characterisation of the space – and Böhme stresses that this can be described as atmosphere.

Böhme states that as a consequence of this architecture is classified as an art of space – and not as a visual art as it is often described: The true means of creating experiences for architecture is to create bodily awareness of the situated space.

Böhme is thus eye to eye with Eliasson as he ascribes the senses of the body decisive importance: The spatiality of atmosphere is registered by all the senses of the body as a space of bodily presence – and atmosphere and multisensory awareness is thus closely related.

The change from spectator to participant via the dissolution of the opposition of subject and object can therefore be related to the creation of space as bodily presence – and the creation of experiences within architecture is therefore closely connected to the creation of atmospheres.

Even with the connection between experiences, participation, space as bodily presence established through the term of atmosphere - the term is still at an abstract level: How are architects to approach atmospheres and sensory perception in the creation of experiences within industrial architecture? To

approach an answer focus is aimed at a protagonist of sensory awareness within architectural theory.

Atmosphere and peripheral perception [11] [12]

The Finnish architect and theoretician Juhanni Pallasmaa has during the past two decades been an proponent for a higher degree of multisensory awareness in architecture – and has in his latest phenomenological writings also addressed the theme of atmosphere: Pallasmaa describes the human capacity of grasping the essence of atmospheres as an instantaneous and all-encompassing capacity moving from the wholeness of complex and comprehensive images towards the single elements of the images.

In the 2010 essay *On Atmosphere – Peripheral Perception and Existential Experiences* Pallasmaa suggests a definition for what he denotes as experiential atmosphere: *"Atmosphere is the overarching perceptual, sensory and emotive impression of a setting or a social situation. It provides the unifying coherence and character for a room, space, place, and landscape, or human encounter. Atmosphere is "the common denominator", "the coloring", or "the feel" of the experiential situation. Atmosphere is a mental background, an experiential property or characteristic, that is suspended between the perceived object and the subject"*.

Pallasmaa states that man is cable of grasping the essence of a place before understanding it intellectually by identifying the details – and even though one is perhaps not able to speak of the characteristic of a situation a firm sense, emotive attitude and recall of the situation are still created. A greater importance is thereby attached to the immediate understanding than to the conscious analysis – and Pallasmaa is thereby in accordance with very similar consideration of sentiments by Eliasson and sensory perception by Böhme. To elaborate on how this immediate understanding is at work Pallasmaa aims focus at the multisensory awareness: Pallasmaa stress that the environmental characters are not of mere visual perceptual quality, but of multisensory qualities: An environment is grasped immediately as an overall atmosphere, feeling, mood or ambience rising from a complex fusion of countless factors. Pallasmaa emphasises in concordance with Eliasson that these factors are understood by use of more than the five Aristotelian senses as orientation, gravity, balance, stability, motion, duration, continuity, scale and illumination are involved in the immediate reading of environments. All of these elements are perceived in a peripheral manner and not as conscious observation. Pallasmaa emphasises that every significant experience of architecture is multisensory; he accentuates this by quoting Merleau-Ponty: *"My perception is [therefore] not a sum of visual, tactile, and audible givens: I perceive in a total way with my whole being: I grasp a unique structure of the thing, a unique way of being, which speaks to all my senses at once"*. Pallasmaa remarks that this description is also a perfect characterisation of the atmospheric perception.

The terms of *atmospheric perception* or *peripheral perception* is according to Pallasmaa essential for the all-encompassing and instantaneous perception of atmospheres - *peripheral perception* is unconscious, unfocused and encloses and enfolds in an embrace of atmospheric space. Opposed to this perception is the focused, analytical vision connected to perspectival spaces which leave us passive and separated from the sensed: *"Focused vision makes us mere outside observers, whereas peripheral perception transforms retinal images into a spatial and bodily involvement and gives rise to the sense of an engaging atmosphere and personal participation. Peripheral perception is the perception mode through which we grasp atmospheres"*.

The term of *peripheral perception* adds a nuance to the preceding writings of Pallasmaa: In his extended essay *The Eyes of the Skin: Architecture and the Senses* from 1995 Pallasmaa advocates for an emphasis on multisensory aspects within architecture as he states that the bias towards vision has become increasingly concerning. Pallasmaa states that this ocular bias never has been as apparent as during the past decades – architecture has aimed at creating striking and memorable visual images and has therefore become image products far from existential depth and sincerity: *"Instead of experiencing our being in the world, we behold it from outside as spectators of images projected on the surface of the retina"*. Pallasmaa continues: *"As buildings lose their plasticity, and their connection with the language and wisdom of the body, they become isolated in the cool and distant realm of vision. With the loss of tactility, measures and details crafted for the human body – and particularly for the hand – architectural structures become repulsively flat, sharp-edged, immaterial and unreal"*.

In his writings on atmosphere fifteen years after the publication of *The Eyes of the Skin* Pallasmaa elaborates on the consequences of the hegemony of the visual perception for architecture: *"Our culture of control and speed has favoured the architecture of the eye, with its instantaneous imagery and distanced impact, whereas a haptic and an atmospheric architecture promotes slowness and intimacy, appreciated and comprehended gradually as images of the body and the skin. The architecture of the eye detaches and controls, whereas haptic architecture engages and unites. Tactile sensibility replaces distancing visual imagery through enhanced materiality, nearness, and intimacy"*. The importance of the multisensory is thus evident according to Pallasmaa - however latent in the

latter statement of Pallasmaa seems to be a contradiction as Pallasmaa connects the focused vision to “instantaneous imagery” but also connects the *peripheral perception* to the ability to grasp an atmosphere instantaneously. Two instantaneously understandings thus exist – and it is therefore important to stress the difference of the instant focused visual understanding of architecture and the instant unfocused bodily understanding of architecture: Architecture as picture and architecture as atmosphere – the first creating distance and the latter creating experiences within architecture. In addition to this it seems that a paradox exists in the line of thought connected to atmosphere: Atmosphere is both related to an instantaneously understanding, but at the same connected to a gradually appreciation and comprehension of architecture resulting in slowness and intimacy. It therefore seems that intrinsic in the term of atmosphere and therefore also - according to Pallasmaa - in haptic and atmospheric architecture is two paces of perception: One that allows the human body to instantaneously and with all senses to grasp the identity of a space, place or situation as an atmosphere; and another of an inexhaustible character that cannot be grasped, but engages and unites.

Pallasmaa elaborates on this as he states that strong and overpowering atmospheres are of haptic nature – and almost have material presence as if they are embracing. In continuation of this line of thought a focus on atmosphere can be seen as the point of departure for a dismantlement of distance and segregation in contemporary industrial architecture and the creation of multi-sensory experiences within industrial architecture through atmospheres.

Conclusion

In order for industrial architecture again to contribute to urban development of cities in the experience economy the creation of experiences is a pivotal element and in this creation the terms of atmosphere and *peripheral perception* stand as the key notions for industrial architecture.

The emphasis of the sensory awareness is a consistent element by both Pine and Gilmore, Eliasson, Böhme and Pallasmaa in the creation of experiences: Pine and Gilmore advocate the inclusion of all five senses, Eliasson connects a multisensory beyond the five senses to sentiment; Böhme emphasises sensory perception in favour of judgement in the understanding of space as bodily presence; and Pallasmaa connects the extended sensory apparatus to *peripheral perception*.

The latter term stands as a designation of the way atmospheres are sensed: An inseparable relation exists between the *peripheral perception* and atmospheres which are closely linked to the dissolution of the opposition between subject and object in the creation of participation.

The creation of experiences can therefore be concluded to be closely linked to the creation of atmosphere within architecture – and the task of contemporary industrial architecture can therefore be defined as not only production and integration between city and industry - but also the creation of frames for atmosphere. These three parameters stand as the key aspects that contemporary industrial architecture need to embrace in order to again claim the domain as societal co-generator of the urban scene.

With the importance of participation introduced by Eliasson this means for industrial architecture that the realms of educational and escapist experiences come to play a key role: Where the transformation industrial buildings of the past embraces aspects of authenticity, identity and transparency the industrial architecture of contemporary society could facilitate experiences by introducing aspects of learning and recreation.

In the connection to the two participatory realms of experience the industrial architecture has the possibility to utilise the intrinsic capacities of an industrial production: The transparency of construction and process can be linked to the realm of learning in a manner where the public is not precluded from the industry, but integrated to a degree where both production and communication of production are possible in urban areas.

The inclusion of the public has in addition to the educational capacity also the possibility to create an escapist experience as the accessibility of the production can supplement the absorption of learning – to use the term of Pine and Gilmore: As the visitor moves around between the elements of production a level immersion can be created - and visitor can become participant.

These means towards the creation of experiences are bound together by the architectural means of atmosphere in the creation of a coherent contemporary industrial architecture emphasising production, transparency of production, integration with context, multisensory awareness and atmosphere in the creation of experiences within the cities.

Conservation of cultural heritage Risk analysis for protection and management

Sara Maria SERAFINI

Urban Planning Department, PhD student to University of Calabria, Ponte Pietro Bucci, 87030 Arcavacata di Rende (Cs), Italy
serrenett@email.it

Abstract

The cultural heritage, in line with directives of sustainability's European principles, should be protected to preserve memory and cultures; in this way others people could enjoy it, for a long time.

To explain exactly cultural heritage, we refer to the definition introduced with L. n.310/1964 by *Franceschini* commission: "Everything that is testimony, having value of civilization"; so a definition that extends conservation concept from punctual heritage to diffused one.

However, even today, when we think about conservation of cultural heritage, we refer erroneously only to heritage that we could found in archaeological sites, historic cities or museums; while conservation of cultural heritage should be extended to whole cities or landscapes.

Within this general framework, it's clear that conservation of cultural heritage, local and diffused, can't exist without the knowledge of sites that must be protected. For this reason, we propose to make an operative instrument for knowledge, protection, conservation and prevention.

This instrument is the *Risk Map*, it will be an informative system of cultural heritage, just like a particular type of data base, that will support scientific and administrative decisions of government, local authorities or research areas, responsible for conservation.

In this way, the Risk Map, just as an urban planning, could help to make a documentation of cultural heritage and a conservation planning.

Keywords: Risk, planning conservation, cultural heritage

1. Introduction to the method

To preserve architectural, historic and cultural heritage of a small city or a whole country, to plan and organize a series of action to safeguard and hand down it, and to make sure that future populations could enjoy it in many ways, is not only a duty, but a sign of regard, just like a caress to beauty.

The Risk Map of cultural heritage is a project of the ISCR (Superior Institute for Conservation and Repair).

The basic idea is a logical consequence of a theoretical - practical research that starts from Cesare Brandi's preventive repair concept, and go on through Giovanni Urbani's elaborations on planning conservation.

The force that is the base of the Risk Map is to protect architectural heritage and, therefore, to perform an action of cataloging.

Assuming that you can't protect what you do not know, the Risk Map focuses on a coherent set of operations such registering, inventorying, surveying and creating a database, followed by an historical and aesthetic analysis. A program of indexing and cataloging, therefore, is closely connected to principles of architectural and cultural heritage's protection.

Also, the Risk Map identifies systems and methods that allow us to program the maintenance and restoration of cultural, architectural, archaeological and historical - artistic heritage, according to their state of preservation and the aggressiveness of their environment, and why not, using a new valuation's element: a *value judgment* with specific and concrete criteria.

In this case, saying to program it's just like saying obtaining useful information to predict, and so to decide in time, which interventions we should begin urgently, in terms of response time and realization costs too; always trying to avoid losses and damages.

This behavior arises as requirement, but it becomes a necessity if we think of importance of some Italian historical cities, or if we consider the great consistency of Italian cultural heritage, the paucity of financial investments to its conservation and our duty to take advantage of all resources, in the best way, going over all kind of emergencies.

At the end of this project will be available to Ministry and Superintendents, new tools of knowledge and new analysis procedures to facilitate the supervision and monitoring of conservation's state of cultural heritage, in this way will be simple directing and optimizing conservation interventions.

The Risk Map adopts a simple schematic division of heritage in different categories (for example, palaces and villas, towers and steeples, churches etc.), to which corresponds a color belonging to a specific gradation, according to the its risk class, that is also classified in range: high, good, medium, low, very low.

The construction of the Map, and its way of representing territory's point of importance, will be further explained below.

1.2 Analysis and application of the method

The project was born, as already said, from a Giovanni Urbani's idea, based on contents methodology developed for the first time in his "The Pilot Plan for the planning Conservation of Umbria's cultural heritage" (1975). It was the first experiment of global rating, in which he extended the degradation factors's analysis to whole territory.

The importance of this type of study was dramatically confirmed by devastating earthquakes that happened in Friuli (1976) and Irpinia (1980).

That Pilot Plan was based on the registration, the georeferencing and the compilation of a technical file on the seismic vulnerability of architectural heritage at risk, in the area.

Fig. 1: Two photos that show earthquakes's effects: Aquila 2009 and Haiti 2010.

During the night of 5 to 6 April 2009 on Aquila, an unexpected earthquake destroyed almost all of the historical city, in just six seconds.

The 13th of January 2010 on Haiti, thousands of people died under rubble, because of earthquake of magnitude seven, that destroyed Haiti. Among the buildings collapsed there were the presidential palace, some hospitals and public offices. Death were estimated around five hundred thousand.

After Italian disaster, mass media echo was huge, but up still now, don't exist a real project of protection, still there are questions about combination of seismic risk and cultural heritage, although Superior Institute for Conservation and Repair have indicated the Risk Map as the best prevention instrument.

After tragedies like these, we remain with the memory of the splendor of a city, together with rubble and some pictures that we will not forget easily. We remain with a feeling of inadequacy and helplessness, with anger for senseless tragedies, that perhaps we could avoid in time, using rules and common sense.

In Italy, the earthquake on Abruzzo showed the precarious state of housing, in general, and of historical – artistic one in particular, of the whole national heritage.

Technicians of Ministry of Heritage and Cultural Activities, intersecting area seismicity's values with cultural density of a place, estimated that about two hundred fifty thousand buildings, on a total of half a million, are located in a seismic area, and only a little part of them can show off a risk assessment. The need to draw up a risk map for architectural heritage of the most important historical cities of our country is stronger if we think that Italy is a country with a high seismic risk, which is one of the most delicate and important sectors of Civil Protection assistance.

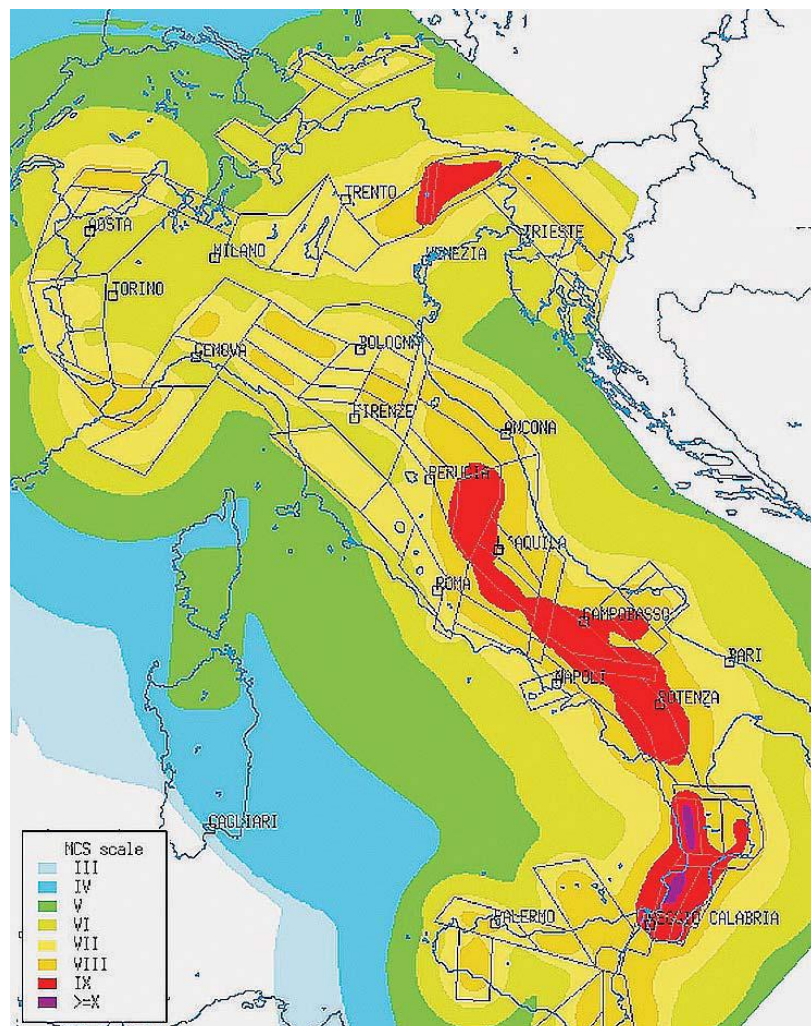

Fig. 2: Italian seismic hazard map.

The Risk Map project is very ambitious, in fact, it wants to create an information network, such as completion of work done by Superior Institute for Conservation and Repair; in this way all institutions, state and local governments responsible for heritage preservation, will have a support instrument for their scientific and administrative activities.

The concreteness of the project is the realization of a risk model, for which construction was adopted a statistical approach: the individual assets are valued as “unit” of a “statistical population” of which we want to assess the overall risk.

To build the risk model, we have identified two investigation areas, that through vector layers's overlap allow us to build two separate matrices:

- Value matrix
- Danger matrix.

Overlaying two matrices, we get the Risk Map, that will contain information about vulnerability, hazard and the proper value of each emergency diffused on territory.

The software that allowed us to operate in this way is GIS; the acronym means Geographic Information System. Thanks to this tool, we can collect, file, recover and transform spatial and no spatial data.

Essentially, GIS is a decision support system, which allows us to increase our basic knowledge of a given territory.

To make clear the operative process, we summarize the process in simple executive phases of realization; we consider three main phases:

PHASE 1: Value matrix

At this step, we collect and analyze all information about importance and value of each property. This matrix will consist of the following thematic maps:

- summary dating
- architectural quality buildings
- cultural value
- finishes building
- location of buildings and relationship with urban context.

PHASE 2: Danger matrix

At this step, we collect and analyze all information about aggressiveness and vulnerability of the environment against heritage. This matrix will consist of the following thematic maps:

- risk landslides
- risk hydraulic
- grade of crowding
- condition of efficiency and health
- static condition of buildings
- maintenance status
- deterioration status.

PHASE 3: Risk Map

At the last stage, we summarize, on a single file, all the information collected thanks to the implementation of previous matrices.

In order to make clear the process explained before, we show results obtained working on realization of Rossano's Risk Map (Calabria, Italy). We have developed the project on the basis of the three phases previously explained, considering only the historical part of the city.

First, we constructed Value matrix:

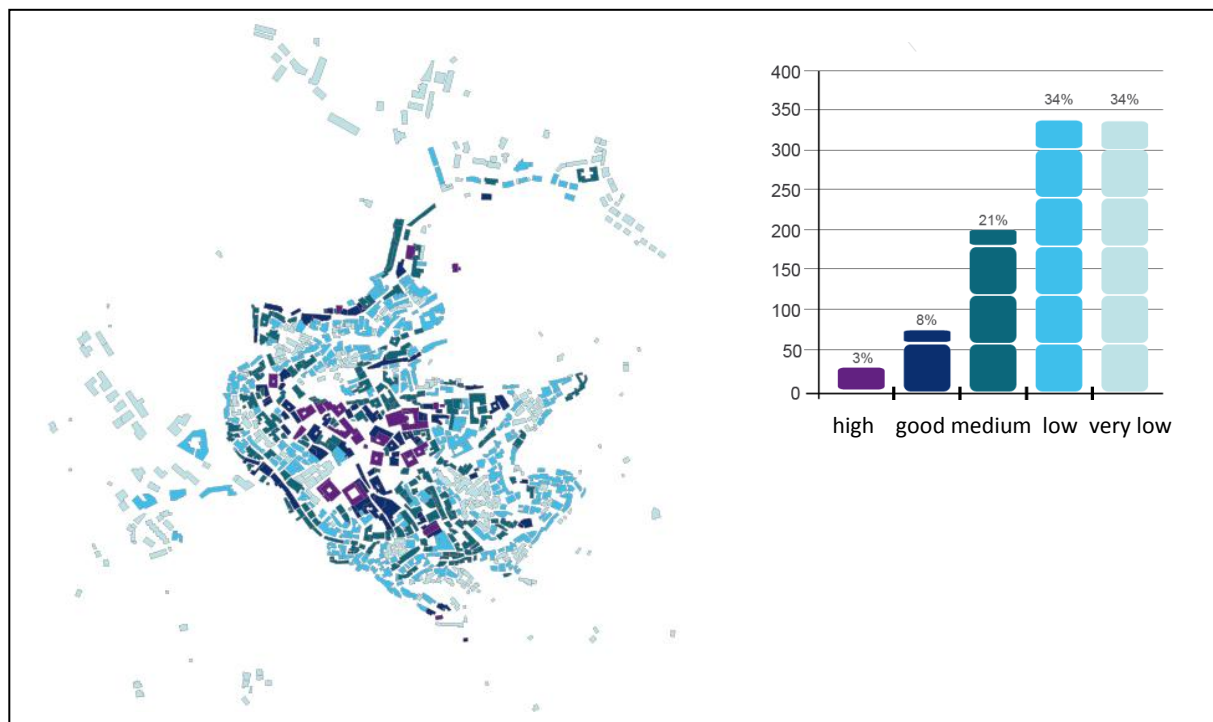

Fig. 3: Rossano (old city) Value matrix.

The matrix clearly shows that the center has a worthy state of value (cultural, architectural, etc...). Out of a total of about a thousand buildings located and analyzed, a large part of heritage, of residential category, belongs to low and very low ranges, covering approximately 32% (based on total).

In the next step, we constructed Danger matrix:

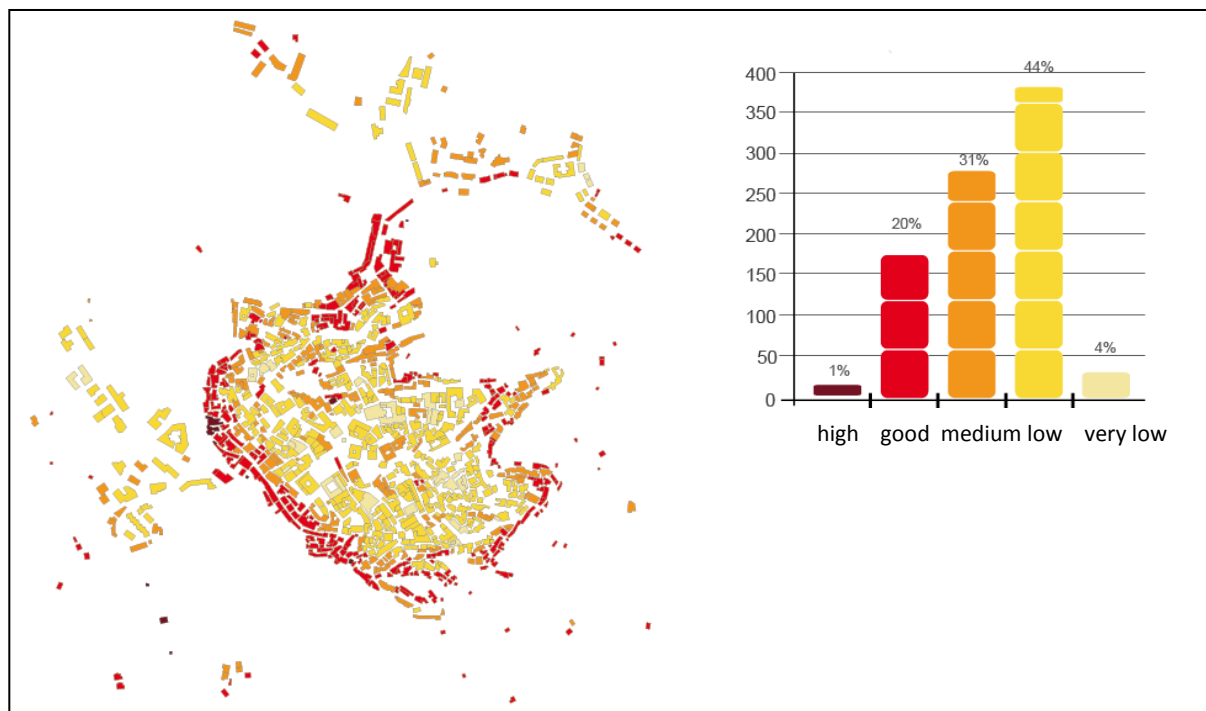

Fig. 4: Rossano (old city) Danger matrix.

The matrix clearly shows that the old city has a grade of danger (risk landslides, hydraulic etc...) mostly medium, or not very worrying. Out of a total of about a thousand buildings located and analyzed, a large part of the assets is in the low range, while the actual danger found covers approximately 21% (based on total); this percentage is still to be kept under control because it refers to many historical buildings.

At the end, we got Rossano's Risk Map:

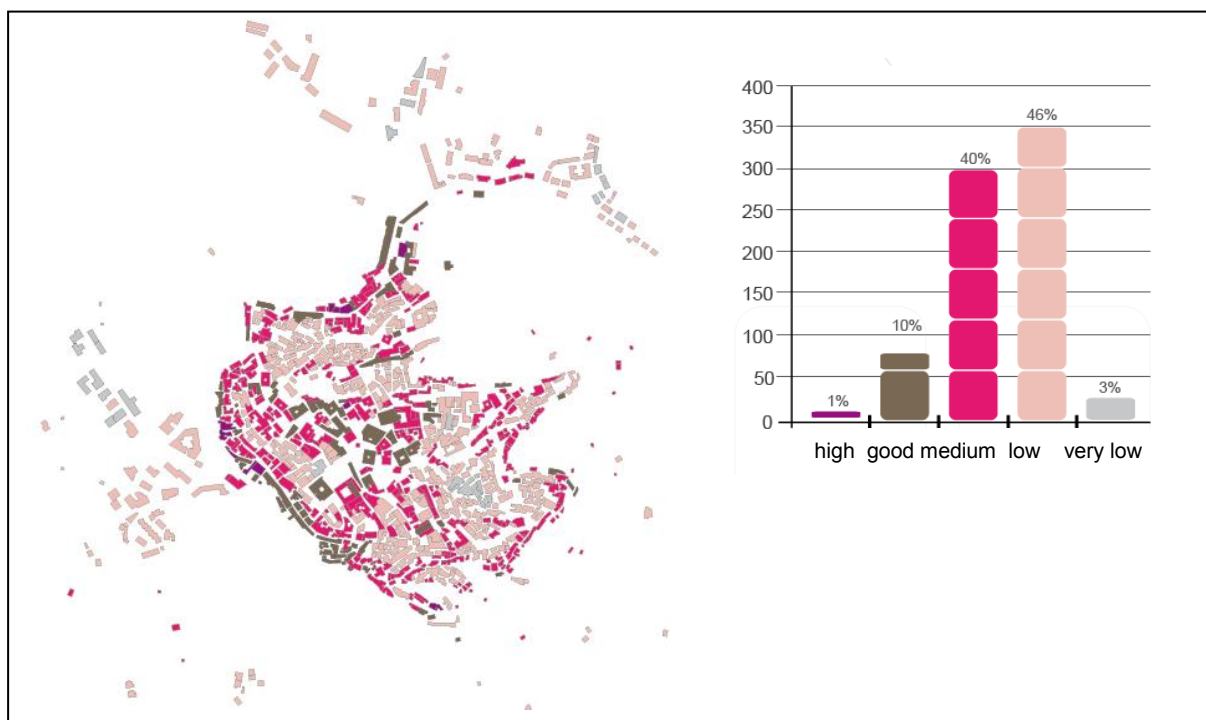

Fig. 5: Rossano (old city) Risk Map.

The Risk Map, as already said, comes out overlapping two previous matrices.
 The Risk Map, through the use of different colors, clearly shows that the old city has a medium level of risk, approximately 46%.
 However, the Map doesn't exclude the need to focus attention on potential risk issues that could occur.
 In fact, out of a total of about thousand buildings located and analyzed, the high risk covers approximately 12%, which added to medium range is more than half of housing and heritage, and so it's a result that we could not underestimate.
 At the end of presentation, it's clear that the Risk Map is an operative instrument, logical consequence of a progressive rationalization of many factors, thoroughly investigated.
 Certainly It is a kind of support for all possible actions aimed to protect cultural heritage.

TYOLOGICAL ASPECTS OF CASERIO, A TRADITIONAL BASQUE RURAL BUILDING

Abstract

The folk architecture is undoubtedly one of the essences of Basque cultural identity. It is a simple architecture, holder of architectural, ethnographic and historical, unique values; perfectly integrated with the landscape and the climate and made of simple elements and natural materials [1]. This immense heritage unifies physically and culturally the various areas of the Basque Country. The identity role of architecture is shown by the Basques' perception of the traditional house, not only as a place to live and work, but also as "perpetual being", that allows Basque man himself to perceive the historical continuity of his family, tracing the origin of house builder's last name, the founder of the lineage. Indeed houses were usually called after their builder.

The most typical expression of the above architecture is the Caserio, the characteristic farmhouse, made of simple structures surrounded by large tracts of land intended for cultivation, grazing and collection of firewood. Utility, functionalism, rationality and simplicity prevail in these sturdy, large buildings.

Caserios have been key elements in the construction of Basque rural landscape, and they are now an integral part of it. This is due to the usage of local/natural materials and the colonization of only the strictly necessary territory. The original type has been built during more than 500 years with only few variations, and the abundance of specimens still lived-in and well conserved, make the caserio a true archetype of rural architecture.

The aim of this paper is to highlight, through a careful typological analysis of a ten of caserios, the invariant features - landscape, technological and functional – of this building type. It is believed that this work can be useful for a proper preservation of this archetype of Basque traditional architecture.

Keywords: building technologies, typology, Basque architecture

1. Historical notes

The Caserio is the most typical expression of the Basque Country's folk architecture, in particular in the Vizcaya district a vast heritage of caserios is nowadays preserved. It is a simple building that represents one of the essences of Basque cultural identity, holding architectural, ethnographic and historical values. His perfect integration with the landscape joined with his own name and specific function, make the caserio a "perpetual being" that allows Basque men to trace house origin [2]. All caserios in fact, have an own name coming from topographic, vegetal and geological references about the site where the house was built, well known to the authorities and neighbours and unchanging over time.

The modern caserio, as known today, appeared in the Basque Country at the end of XV century, as an evolution of the previous medieval huts, accordingly to the new social and economical conditions.

The demographic growth, that required the conquest of new spaces, and the suppression of the usual seasonal transhumance, that forced in creating big areas for animals housing within farms, can be considered as some of the most important factors that led to the caserío birth [3].

It's possible to find out three major historical steps in the caserío typological evolution: an early Gothic-Renaissance period, from the last decade of the XV century until the middle of the XVI century; a peak Baroque period, from the second half of the XVII century to the last years of the XVIII century, and a final phase, with decline symptoms, matching with the XIX-century neoclassicism [4].

The XVI was undoubtedly the most brilliant step in the caseríos life, full of experimentation and variety of shapes and materials. The Gothic-Renaissance caseríos were very sober, without almost any furniture, and with a few rooms for family use, in a context where concepts like shame, intimacy and comfort had very little importance for lower classes. Less than a quarter of the inner surface had a residential function as the major part was reserved to stables, warehouses and agricultural machinery (such as presses). The caserío was above all a work-tool.

Between the XVII and XVIII centuries, caseríos began to be built with timbering technique: a good facade design and the careful selection of materials was a symbol of owners social prestige. Baroque caseríos were built with a modern approach, functions were well-defined and interior spaces were large and rationally distributed. Furthermore, during this period, because of a pressing demand for homes, many existing caseríos were cut into two or more shelters to be inhabited by several families of tenants.

Caseríos built during the last neoclassical period had small dimensions and humble appearance, often simple huts precariously turned into homes. In addition to these new edifications, in the XIX century the renovation of the existing caseríos started. Therefore lot of them were abandoned as well, especially the most recent ones that did not offer the minimum conditions of life and production, but that had been occupied by farmers for lack of better options [5, 6]. The Caserío architecture is a simple architecture that beautifully converses with the landscape and the climate and it is made of simple elements and natural materials. It has inspired, to the beginnings of the Twentieth Century, a new architecture Basque, that, with modern forms and different uses, develops a new local language that uses the many potentialities of the local materials and emphasizes the architecture of this typical European frontline region [7, 8, 9, 10, 11].

Currently tens of caseríos are restored every year, even thanks to public funds, but there is still no clear understanding about the true architectural values to be preserved, or about methods needed to comprehend them.

2. Typological aspects

From the typological point of view, it is possible to define some main characteristics recurring in almost all the specimens, regardless the geographic position and the historical age, that give the possibility to outline a very archetype of the rural Basque architecture. These features can be summarized as follows:

1. It's shaped in a rectangular, compact and independent block. It is a large house, without courts, patios or other outbuildings. A single unit but with specialized sections: stable, granary, mill, barn, cellar, workshop, hayloft, etc..
2. The eastward orientation of the main facade determines the position of the patio that, used for outdoor works, needed the best exposure to capture the maximum of solar light, especially in the early morning.
3. The inner disposition of rooms is unambiguously defined by the *ezkaratza* a large, central room that establishes the position of the others without any hallway.
4. There are no floors below the ground level, so no caseríos has cellar.
5. Walls, generally plastered, are stone made, assembled with coarse mortar. Corners and window frames are sometimes reinforced by freestone while timbering are made up with a massive use of wood from nearby forests.
6. The framework was traditionally made up of short and relatively small vertical timbers, which were placed in such way as to form rectangular panels, with no crosspieces or diagonal struts.
7. Roof is preferably low sloped (24° - 28°), resting on strong beams and with unfixed tiles.
8. The main door is often located on the bottom of an atrium. Sometimes there are external stairs and / or wooden balconies at the first floor.
9. The complex relationships between neighboring caseríos don't require physical proximity, clearly rejecting any possibility of sharing a partition wall or of waiving sunshine benefits. For this, houses never form squares, streets or urban groups: they are usually organized in "open swarms", formed by from seven to twenty units, designing the typical Basque country landscape [6].

Hereinafter it are examined three typical kind of caseríos.

2.1 Caseríos Oar Erdikoa, Oar Ganekoa and Oar Azpikoa in Garay (Vizcaya)

This group of tree houses, built more than 200 years ago, is located in the most depressed part of Garray. All the three buildings keep their original name, respectively Oar Erdikoa, Oar Ganekoa and Oar Azpikoa

The first one, Oar Erdikoa (fig. 1) recently renovated, holds a "neovernacular" style and it is currently inhabited.

Fig. 1: Caserios Oar Erdikoa, Oar Ganekoa and Oar Azpikoa

The second building (fig. 2) looks well-conserved and the presence of some tools in the porch rather than the inner wallpaper, made possible to state that it has been abandoned from no more than 50 years.

Fig. 2: Side view and front dimensioned sketch – caserio Oar Ganekoa

It's also clear that it has been undergone renovation works, like the painting and replacement of some fixtures. Furthermore a room has been added on the right side, determining the main façade asymmetry, even if the previous symmetry is very remarkable from the cracks in the plaster and wood beams peeking out. Except for the entrance, the whole building was closed, so it's only possible to make assumptions about this addition, evidently dictated by the need of additional space for storage of equipment and food or housing for workers.

Fig. 3: Front view and dimensioned sketch – caserio Oar Azpikoa

The last specimen of the trio (fig. 3), perhaps the most interesting, has been abandoned in not-so-very recent times, so it has not undergone any change over time, neither external nor internal. The back side (fig. 4) has two large overlapped openings: the ground floor one was for animals entrance while the first floor one for supplies storage. The choice of a masonry segmental arch (fig. 4) was perhaps dictated by economic reasons. This technique in fact is the less demanding and expensive one, even if its flattened shape and the irregularity of ashlar create a significant pushing force, that affects negatively the mechanical strength.

Regarding this, the arch has some evident longitudinal lesions that, starting from frames, spread to the rest of the structure. These lesions can be also reported to the physico-chemical deterioration of the mortar joints or to eventual dissymmetrical overload.

The plan of this caserio (fig. 5) is almost square and subdivided in four parts. A large portico entrance allows access to the home itself but also to two other independent rooms.

Fig 4: Side view, internal vertical connection and arched entrance – Oar Azpikoa

For the ground floor a direct metric survey has been carried out while for the first one, because of the precarious condition of the floor, the limited accessibility and the very poor visibility, only an indirect survey has been possible. Space on the first floor is reasonably supposed to be reserved to the sleeping area, the conservation of supplies and storage of hay and grain.

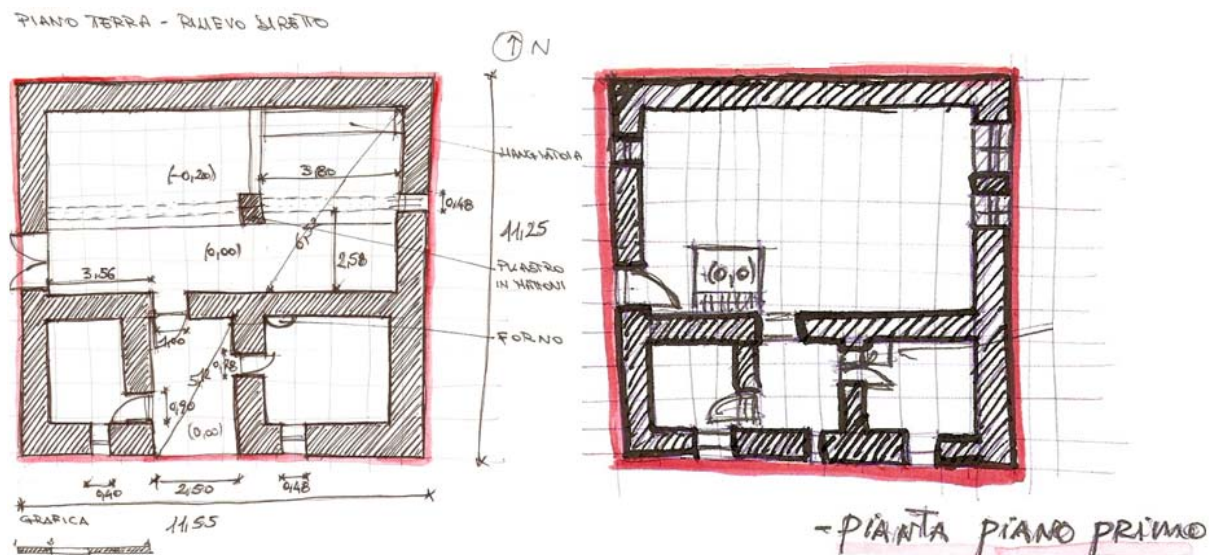

Fig 5: Metric plan of ground floor and first floor – caserio Oar Azpikoa

2.2 Caserios Ugarka and Zulaibar Beasko in Zeanuri (Vizcaya)

Last living fossil among the oldest specimens of regional architecture is the Caserio Ugarka (fig. 6), which maintains its oak wood structure and, miraculously, even the original interior layout, but some masonry reinforcement have been set up where necessary.

The kitchen, like all caserios belonging to the Gothic-Renaissance style, has a fireplace in the center of the room and vertical closures made by bulkheads. The caserio, located on a slope, has two inde-

pendent openings, one each level, ensuring a clear and hygienic separation between people and animals.

Not far from Caserio Ugarka, in the *Zulaibar Beasko barrio*, there are two very well-conserved caserios, rotated relative to one another by 90°. This rotation, jointly with the difference in the materials used, let suppose they have not been built in the same time.

Fig. 6: Front and side view – caserio Ugarka

Fig. 7: Front and side view – Zulaibar Beasko Barrio, caserio 1

Fig. 8: Front view and dimensioned sketch – Zulaibar Beasko Barrio, caserio 2

The arched entrance of the first caserio (fig. 7) is common to other specimens that date back to the late XVIII century, although in this case the arch is only a disengagement and not a porch.

The second caserio (fig. 8) is divided into two nearly symmetrical homes, probably as result of a later split into two parts of the original single unit. The reason of this partition may be sought in the pressing demand for land and homes by settlers, occurred in the XVIII century.

Another hypothesis is that the building has been originally designed to house two families: in this case it would be a rare example of duplex caserio.

2.3 Caserio Etxebarri in the Goitiz Auzoa Barrio, Mundaka (Vizcaya)

This caserio (fig. 9), of more than 300 years, has apparently not undergone significant renovations over time. Also in this specimen the two levels have two separate entrances to ensure the distinction, absent until the Baroque period, between spaces for humans and those reserved to animals.

The porch-room, like in the Oar Azpikoa caserio, allows to enter three independent rooms with different functions, probably stable, barn and kitchen (fig. 10).

Fig. 9: Front view and dimensioned sketch – caserio Etxebarri

Fig. 10: Caserio Etxebarri – porch

In 1997 an UNESCO delegation, consisting of two hundred experts from forty five countries around the world, stated that the archaeological site of Pompei is a world heritage site. Additional guarantee for any international financing, aimed at recovering both the rich existing that the submerged archaeological heritage, to bring to light (one third) through new excavations. Pompei is a town in the center of world attention because of the presence, in its territory, of rich and complex cultural-historical heritage represented by archeological site and of the Sanctuary dedicated to the Virgin of the Rosary. So in 2002 the Municipal Government represented by the Extraordinary Commission, (experience conducted personally as a Higher-level Prefectural Executive of the Municipality of Pompei nominated by the Prefect of Naples by decree of 21/09/2001 Sector n.13903/Gab.VI) has focused on technical and administrative issues related to socio-cultural aspects that characterize the Institution, to gain a correct and consonant aegis requiring the recognition of the title of "City" for Pompei. Therefore, through a study developed from historical, social and cultural point of view aiming to highlight the possession of the requirements established by the law for the acquisition of the aforementioned title, Pompeii get the title of "City" with DPR 01/09/2004.

Keywords: City, Municipality, heritage

1. Development of cultural heritage of religious interest

The Constitution of the Italian Republic in recognition of the value of religious culture, with Art. 9: "The Republic promotes the development of culture and all the historical and artistic heritage of the nation." In addition, the agreement for the revision of the Concordat between the Republic and the Holy See, in Article 9, paragraph 2, reads: "The Italian Republic recognizes the value of religious culture and that takes into account the principles of Catholicism are part of the heritage of the Italian people". So it is with the state to enshrine these fundamental tools, the Constitution and the Concordat, the relevance to the national community of the historical and artistic heritage of ecclesiastical nature, section breaks in a more general importance is attached to the cultural heritage, seen as an essential element for national identity.

Fig. 1: Areas of worship: Pompei

Fig. 2: Areas of worship: Roma

The patrimony of the Church not only have a font size to the museum, the key issue is that of their religious and worship; in the ecclesiastical cultural heritage coexist multiple dimensions and multiple elements of characterization, artistic appearance, the pier religious and spiritual significance for the local community identity that makes them the object of worship.

Therefore, the enhancement of cultural and ecclesiastical le policy for places of worship take on all aspects of the original than is the case for cultural heritage in general and le areas with a strong tourist attraction. The heritage represented by cultural heritage of ecclesiastical nature entails a great responsibility not only for the Italian parishes but also for the state and for the common people.

The ecclesiastical cultural heritage existing in our country do not end in the great cathedrals, in large convents or abbeys in history, but also in that immense heritage in a capillary spread inside of the whole national territory, in the North as in the South, in large urban areas and small towns, in the areas of hills and mountains, as in the large and small islands.

The Bishops Conference has in recent years given rise to regional councils, with expert groups suggest that the Ecclesiastical Authority measures and initiatives for the conservation and enhancement of cultural heritage, religious. At the national level, the Italian Bishops Conference has established its consultation, which, among other things, the task of creating le rules for the management and protection of cultural church; In addition to the Holy See, has developed a number of significant initiatives for the promotion of cultural heritage worldwide, constituting the Pontifical Commission for the Conservation of historic and artistic heritage and setting up a course for the training of experts at the Gregorian University.

Finally it should be noted that the bulk of the contributions that the State pays for the restoration work, and aimed at ecclesiastical heritage, although the amount of financial resources available in this field has gone dangerously thinning, after years of linear cuts that have indiscriminate characterized the public spending during these years. At this point, we must make a general remark.

Today we are faced with a new concept that differentiates the protection, conservation as true, by the measurement, reading them as complementary aspects. We can not disregard the enhancement of any, specific cultural property; because it is a historical, a clear expression of cultural identity and territorial cohesion, which is essential for the education and training of every future generation. Therefore, the protection, the conservation of cultural property, ecclesiastical or otherwise, can not be limited in the protection of the good as such, in its defense against the ravages of time or the pressures of the environment, preservation of cultural heritage leads to its enhancement and returning to the theme of the conference, highlighting a well of a religious nature means use it in liturgical practice, make it an object of worship.

Finally, a particular relevance in the issue of promotion of cultural heritage of religious interest, it should be to take on the issue of restoration and reuse of assets no longer in use or abandoned. You can not drop to the degradation of the desecrated churches, abbeys no longer monks, convents of friars free now, these are also important cultural signs of art, testimony, history and spirituality, it is not possible to neglect further. It is estimated at 100,000 le existing churches in the Italian territory, but data are lacking on the opening worship and the amount of hours that are usable by the faithful. Cultural property unplayable cultural property devalued, and even less when ecclesiastical nature and must fulfill a social function and spiritual at the same time.

Fig. 3: Church of San Francesco: Napoli

Fig. 4: Church of San Domenico Maggiore: Napoli

A church and monument, and architectural heritage, houses objects of historical-artistic (statues, ornaments, vestments, etc.) as well as having a value of religious and spiritual. The protection and enhancement of cultural heritage ecclesiastical requires care, passion, perseverance and knowledge

to fulfill a real mission, to keep intact and strengthen the descriptive characters and the cultural and religious identity of a community and of a territory .

2. Religious tourism as a factor of territorial development

Cultural tourism related supply of goods or to the use of religious places of worship is a significant factor of tourist attraction and is an essential resource for the sustainable development of the territory concerned. The attraction that exercise in general shrines and places of worship, involves a great interest in the works of art contained in it and at the same time is a real opportunity to know the area inside of which they are inserted, its cities, its cultural resources, economic landscape.

The attraction that exercise places of worship, be they large or small, is significant and very significant le increasing opportunities for knowledge, to use in a conscious and sustainable leisure, attracting tourism flows coitus and quality, not tied to particular events or placed in specific seasons. These tourist flows, these capabilities of attraction does not seasonal or episodic, can represent a great opportunity for the promotion of the local environment in which the places of worship are located and which are expressions, may constitute an important element of regional marketing, supply of territory , putting in all the system resources in a given area, enhancing the quality and making the most of the potential, even those existing in an embryonic state.

Many of the strategies for territorial competitiveness, retain a significant space to the attraction and promotion of places of worship and religious heritage of all inside of the various instruments of the tourist. In many cases, local development policies draw cultural - religious routes to promote tourism products are highly competitive and made specific improvement actions for development of regional infrastructure, political reception and accommodation facilities, policies for the protection and enjoyment, even immaterial, the cultural and environmental heritage. Also, always within the local development policies for places of worship, a specific space and increasing the relevance is taking the issue of sustainability of mass religious tourism, to prevent and / or mitigate pressures in the environment and factors alteration of church property as such. In this case, investment planning, orientation of tourist flows, time schedule of the cash flow, qualification and modernization of infrastructure, range of accommodation and dining, are all decisive factors in the action of Subjects in charge of the government of the interested public.

Also in this case, stands as a strategic consultation and cooperation among States, regions, local authorities, ecclesiastical authorities, social partners and local expression of the territory concerned. Finally, at the conclusion of this paper, a reflection of a general nature about the role and opportunities that globalization and the network can offer in the pursuit of policies for the development of local systems aimed at the enhancement of the places of worship.

3. Historic and Urban characters character Pompei' s City

Located at the foot of Mount Vesuvius, on the south side at 14 m height above sea level, Pompei is a religious center and tourist attractions worldwide to the simultaneous presence of a vast archaeological heritage unique in the world and the Sanctuary of the Blessed Virgin of the Rosary, the one reached by millions of visitors charmed by the buried city, the other, the destination of many pilgrimages. The ancient city, founded by the Oschi in the seventh century b.c., and so named in honor of Hercules (Pompei) was an important commercial hub, initially greek, then etruscan, roman and later sunni. The eruption of '79 b.c. destroyed and only in the eighteenth century began the first excavations to be able to then visit the ancient ruins.

The territory of Pompei, bordering the neighboring town of Boscoreale, Scafati, Torre Annunziata, Castellammare di Stabia, and Santa Maria La Carità, covers an area of about 1192 hectares. D'Aragona.

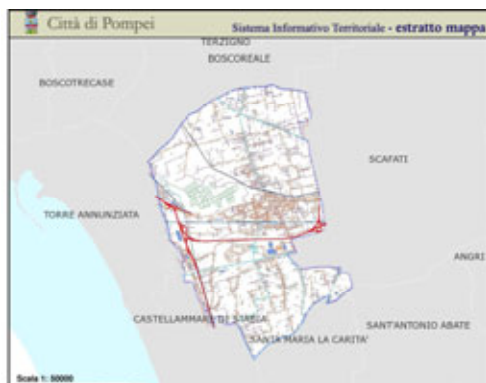

Fig. 5: Territorial Framework Pompei

Fig. 6: Square Bartolo Longo, Pompei

The current center, built around the Shrine, traces its origins to a parish community built in the early eleventh century, around the church of the ss. Salvatore, called "Field Pompeianus." Subsequently, the name of Valle di Casale, had a castle, before the feud of Luigi Caracciolo and then Ferdinando. In 1593 it became the property of Alfonso Piccolomini, but for the overflowing of the river Sarno was abandoned and later became an unhealthy area and infested by brigands. And here get there in 1872, the Lawyer Bartolo Longo, a native of Naples and Puglia Latimer who contributed initially to gather the few inhabitants scattered around the church dedicated to the Virgin of the Rosary, built the first Benefactor - Founder, beatified today and in waiting for canonization.

From that moment he became the key man for the construction of the immense charity work and childcare, in particular, that make Pompei famous all over the world and an aggregator of numerous charitable initiatives. Bartolo Longo, who has been erected a monument dedicated to him in the great Piazza, Pompei is a true bastion of faith, hope and temperance in which to believe and which to draw lessons for an authentic Christian vocation. In 1878 began the first work of the Sanctuary consecrated then, in 1891 and expanded by five times in 1938. In 1925, we project the majestic bell tower height of 80 m from the top of which you can admire the beautiful landscape of the Sarno Valley that cuts through the Pompeian territory from east to west, resulting in a few hundred yards from the Gulf of Naples.

Pompei plays a pivotal role cultural and social differences between the provinces of Naples and Salerno, and is an aggregation point between the countries of the Vesuvian area became an independent town March 29, 1928 with a population of about 7000 people, in 1930 obtained the concession Coat of arms of the civic and the Municipal Banner, with special RR. DD With the last census conducted in 2001, today the city of Pompei has a resident population of 25844 inhabitants. Since 1952, seat of the Autonomous Care Hospitality and Tourism and the Archaeological Superintendence independent, boasts two interesting museums: the Archaeological set in the Excavations, its come from artifacts including the bust of a statue of Apollo and Diana , exposed in the National Museum of Naples and Vesuvius that, set in the rooms of the Shrine near the Cottage which was the home of Bartolo Longo, founder of the Shrine of Pompei and related works, where there are exposed eruptive material, old prints, reproductions of artifacts archaeological and a plaster cast for a journey back through the centuries, the various phases of the eruption of Vesuvius. In it there are also ornaments and coins found during the excavations of the ancient city and the reproduction of the column with the famous cryptogram of the Pater Noster that, for some, testifies to the successful spread of Christianity in the pagan Pompei, already in the first century. Pompei has two great days that attract thousands of pilgrims in fervent prayer at the feet of the B. V. of the Rosary: the May 8th and the first sunday in October, both dedicated to the recitation of the "Supplication".

The Sanctuary, also home of the Pontifical Delegation, is a promoter of important initiatives socio - cultural including the Religious Craft Show, at the annual theme, held at the Institute Bartolo Longo, which takes place in the autumn and the Young Meeting scheduled to May 1 of each year, which takes place in the room meeting, adjacent to the archaeological site of Roman-Greek Amphitheater . The Pilgrim's House, located opposite the Basilica in the great square and recently renovated, is equipped with large rooms equipped for the reception of pilgrims and to facilitate the consummation bag. In addition, it is equipped with a modern living intended to conventions for n. 134 seats and room for a modern audio-visual projections; while, next to this big building, there is a modern Young Hostel with 50 beds and a theater, the "Di Costanzo-Mattiello", with 500 seats available, always committed to the artistic cast of big fame.

Fig. 7: The Pilgrim's House, Pompei

Fig. 7: Theater Di Costanzo – Mattiello, Pompei

The Archaeological Survey is also a promoter of good events and initiatives, including conferences, theatrical and musical performances that take place annually at the Amphitheater and Great Theater, adjacent to the Gymnasium of Gladiators. The Eagle's Cottage, located inside of the excavations but more recently built, is also home to study meetings and exhibitions on display.

On September 26 last year, was kicked off with great success to an important cultural initiative: an archaeological multimedia night time visit to the ruins, created with unique combination of sound, light and images, in order to make the most charming and exciting route to visit. In 1997 a UNESCO delegation, consisting of 200 experts from 45 countries around the world, said the archaeological site of Pompei, property of humanity. Additional security for any international funding, aimed at recovering both the rich archaeological heritage of both the existing and still submerged, to bring to light (one third) with new digs.

The City hall, in order to intensify the relations between the old city and the Marian city, in collaboration with all the productive forces and associative in the city and in particular of the AACST, helps to improve the reception of the tourist flow, - that the only 2001 recorded a traffic of 2,550,615 visitors - promoting and sponsoring cultural events of a certain prominent intervening with better signage and appropriate plan of roads, as well as facing the illegal building. In full synergy, the local police headquarters, State Police and the Police Station, facing the problems of public safety all over the territory.

A special program agreement made between the mayors of several municipalities, including Pompei, seen in the region of Campania, the actuator of the project about on the landfill of the existing Plant Railway, Railway Station, CIRCUMVESUVIANA (L 142/90, Article 27), located in the center of Pompei, which allows communication between Naples and Sarno, while other station device offers the possibility of easy access to the towns of Naples and nearby Sorrento peninsula.

The station of the state, in addition, a few hundred meters from the Basilica, allows easy connection with all the national territory, mainly due to the obligatory stops carried out by long-distance trains from Sicily and from all over the country and abroad. A bus service S.I. T. A provides additional easy access to Naples, Salerno and the Amalfi Coast, while the same CIRCUMVESUVIANA Company provides bus service to the connection between Scafati and Naples.

The reputation of the place has meant that important public offices were resident in the municipal area of Pompei as, the Courthouse, the Administrative Offices of the Sanitary District - AS.L. Na 5 ensures that the activities of Ambulatory Health Care, Emergency Regional Activities, Activities of Mental Health and the Family Planning. In area of the territory is, moreover, the Presidium of continuity of care night before a holiday, festive and supervision of Medical tourism. In addition, the territorial area is home to the Department of Prevention ASL Na 5 with eight Central Services and other centralized activities of the Department.

In the field of health and social care set out again: Nursing Home "Maria Rosaria" n. 100 beds and 150 authorized an agreement with admissions specialist for 8, the House of Rest "Carmine Borrelli" with about 52 seats for admission and the Pensioner "Marianna De Fusco" of the Pontifical Shrine with about 40 people in hospital.

There are four pharmacies of which: 2 central and 2 peripheral. Among the religious institutes to be counted: the Order of the Sons of Divine Fathers, daughters Dominican Sisters of the Holy Rosary, the Sisters of the Sacred Brisket, the Brothers of the Christian Schools, the Sisters of Mary Immaculate and the Secular Clergy.

The Institute for the reception of the Orphans, also founded by Blessed Bartolo Longo, has become a center of education for underprivileged children.

The Pontifical Shrine operates an elementary school, two middle schools, a vocational school and a Pedagogical High School, and also takes care of the preparation of the report "ROSARY AND NEW POMPEI", with a circulation of 260,000 copies in Italian and in English with 18,000 distribution world. The presence on the territory of the two companies, the archaeological and the Marian has led to a development of tertiary education, so as to record a capacity of 27 hotels with a total of 1078 beds and 3 campsites; 170 public houses including: restaurants, snack bars and kiosks, and the presence of four Travel Agents.

The thriving business has a three Hypermarket Supermarkets, 554 shops and 44 operators in fixed place of public areas present to the ruins of Piazza Anfiteatro, 24 stalls with shifts in Square B. Longo, 15 kiosks selling souvenirs and newspapers, about 400 craftsmen, 68 itinerant traders and residents, not for the sale of food.

The CARTIERA A.T.I., built in 1950, is a significant other industry, while the canning is fairly represented. In addition, a weekly market is held on Friday with employment of public area by 167 operators and a major wholesale market for floriculture products, among the first in Italy, helps to give a new boost to local business. The development of commercial activities has seen the establishment of six major banking branches, such as the Banco Ambrosiano Veneto, Banca di Roma, Banca Monte dei Paschi di Siena, Banca Popolare dell'Irpinia, Banco di Napoli and Banco Cooperative Credit

Scafati. There are two Clubs in the area State Educational with 14 central and peripheral plexus, two State Middle Schools with four complexes, a State Scientific high school with two buildings, a legally recognized Language High School, three and five equal Nursery Schools Preschools legally recognized.

3.1 Pompei and title of “City”

Fig. 8: City Hall, Pompei

Municipality represented by the Extraordinary Commission (experiment carried out personally as higher-level Prefectural of the City of Pompei appointed by the Prefect of Naples by decree of 21/09/2001 Sector n.13903/Gab.VI) has taken steps to focus attention on technical and administrative issues relating to certain socio-cultural aspects that characterize the body, so that it could gain a more just and consonant aegis calling for the recognition of the title of "City" for Pompei. Therefore, by resolution N. 244 of December 16, 2002 the Extraordinary Commission of Pompei calls for the granting of the title of City. Through a study on the historical-social-cultural, aiming to highlight the possession of the requirements of the rule for the acquisition of title aforesaid, the President of the Republic grants the country of Pompei the title of "City" with DPR 01/09/2004.

Dott.ssa Giovanna Cerni	<u>G</u>	<u>-</u>
Dott. Gianfranco D'Angelo	<u>A</u>	<u>-</u>

Assume la Presidenza il componente più anziano dei presenti nella persona del GIUSEPPE D'ANGELO
Partecipa il Segretario Generale Dr. Pasquale Foglia.

Il Presidente, constatato il numero legale degli intervenuti, dichiara validamente costituita la seduta, invitando i presenti a deliberare sull'oggetto sopraindicato.

LA COMMISSIONE STRAORDINARIA

Avvalendosi delle attribuzioni di competenza del Consiglio ~~del~~ Giunta Comunale, ai sensi ed in conformità dell'art. 42 ~~del~~ D.L. gvo n. 267/2000;

Vista l'allegata proposta di deliberazione relativa all'argomento segnato in oggetto, corredata dai pareri di cui all'art. 49 comma 1° del D.L. gvo n. 267/2000;

Ritenuto di dover approvare la suddetta proposta di deliberazione;

A voti unanimi, espressi nei modi e forme di legge,

DELIBERA

1. Di approvare la proposta di deliberazione, così come formulata, relativa all'argomento indicato in oggetto, che viene allegata al presente atto per formarne parte integrante e sostanziale e come se nel presente dispositivo integralmente trascritta.
2. Di non assoggettare il presente provvedimento al controllo preventivo di legittimità del Co.Re.Co. di Napoli, per effetto dell'approvazione della Legge Cost. n. 3 del 18.10.01, di modifica del Tit. V della parte II della Cost., comportante, tra l'altro, l'abrogazione dell'art. 130 della Cost. che prevede il controllo di legittimità del Co.Re.Co. sugli atti degli E.E.L.L., giusta delibera n° 6085 del 9.11.01 della G.R. inerente la cessazione da parte del Co.Re.Co. e sue Sez. di Prov. di ex L.R. n. 21/93 dell'attività di controllo anzidetta, il tutto come comunicato con nota prot. 4650/SP del 14.11.01 della G.R.C. - Ass. al Sistema delle Autonomie e Risorse Umane.
3. Di non comunicare il presente provvedimento, contestualmente all'affissione all'Albo Pretorio Comunale, al Sig. Prefetto di Napoli, ai sensi e per gli effetti di cui all'art. 135 del D.L. gvo 267/00, regolante le materie relative ad acquisti, alienazioni, appalti e in generale a contratti nelle modalità e termini di cui all'art. 133 del D.L. gvo medesimo.
4. Di incaricare il Dirigente Capo Settore I (P.R. n. 176) RAFFAELLA P.D. Responsabile del Servizio AL. N. 1012 R. D. V. ANGELO nella persona del Sig. RAFFAELLA P.D. per l'esecuzione della presente e le relative procedure attuative.
5. Dichiarare le presenti, con separata ed unanime votazione, immediatamente eseguibile, stante l'urgenza ai sensi dell'art. 134 - comma 4° - del D.L. gvo n. 267/2000.

Fig. 9: Request granted "City" title

Il Presidente della Repubblica

VISTA la deliberazione n.244 del 16 dicembre 2002 con la quale la commissione straordinaria del comune di Pompei chiede la concessione del titolo di Città;

VISTA la documentazione prodotta a corredo della domanda stessa;

VISTO il parere favorevole espresso dal prefetto di Napoli in data 2 luglio 2003;

VISTO l'art. 18 del decreto legislativo del 18 agosto 2000 n.267, e ritenute che sussistano le condizioni ivi previste;

Sulla proposta del Ministro dell'Interno

DECRETA

Si concede al comune di Pompei, in provincia di Napoli, il titolo di Città.

Romp. **MA Addi -9 GEN. 2004**

Carlo A...

Per copia conforme

IL COLLABORATORE AMMINISTRATIVO
(Sig.ra Caponera Arcieri Teresa)

Teresa Caponera Arcieri

Fig. 10: Title of "City" D.P.R. 01/09/2004

Today Pompei inspired by the recognition of the title of City granted by order dated 09.01.2004 by the President of the Republic, upon the proposal of Inside Minister, wants to aim high and look to the future, promising to exploit the huge potential offered by the territory, urging according to the intuition of the founder, once again the spirit of aggregation citizen around Christian values and civil rights. Revealed that the recalled recognition represents a moment of fundamental importance for the history of Pompei, so it seems appropriate to celebrate that title with the establishment of a special festival that coincides with the moment of relevance as fundamental as the arrival in the Valley of Pompei of the Blessed Bartolo; that the data and information specified in the above premise were the result of a close collaboration given by distinguished scholars and local historians, the City Council by resolution no. 23 of 11/08/2004, resolves to take note of the DPR of 09.01.2004 in which it was granted to Pompei the title of city, pursuant to art. 18 of Legislative Decree no. 267 of 08.18.2000; to celebrate the above title, after establishment of special holidays falling on the second Sunday of the month of October of each year to coincide with the expected date of arrival in the Valley of Pompei of Blessed Bartolo Longo, the feast which is in addition to the already known occurrences in specified narrative characterizing the emergence and development of New Pompei; to give course to the first occurrence of the above holidays falling Sunday, October 10, 2004, at the inauguration "celebration's day of Pompei City" with broad participation of civil and religious authorities at local, regional and national purpose requested; to establish that it is guaranteed a complete organization of the festivities after careful preparation of all documents, the requirements and the necessary steps.

The Walled City of Nicosia Today - The Challenge of Managing Heritage Conservation in a Living Divided City

Athina PAPADOPOULOU¹

⁽¹⁾ ICOMOS Cyprus

ath-geo@cytanet.com.cy

Abstract

Nicosia has been the capital of Cyprus for over one thousand years. It reflects the island's rich heritage and concentrates some of the island's finest historic architecture. The 16th century fortifications of Nicosia are an excellent example of the bastion system of fortifications in the eastern Mediterranean of the time. Political events during the last four decades have culminated in the physical partition of Nicosia. A buffer zone, once the most vibrant part of the city, splits the town into two parts that have been developing independently of each other, thus causing a disfunctional urban entity. In 1979, under the auspices of the United Nations Development Program the two communities (Greek-Cypriot and Turkish-Cypriot) initiated a project for a conservation and planning strategy aiming for a unified urban development. Under this objective a bi-communal team of national and international experts was formed. The Nicosia Master Plan team has since produced a common planning and conservation strategy aiming towards a reunified city. This paper presents the NMP objectives and project examples. Also, an ongoing research project, funded by the Republic of Cyprus and the European Regional Development Fund, is presented which aims at establishing a bioclimatically-based approach in the conservation of traditional buildings in the Walled city of Nicosia.

Keywords: Nicosia, bi-communal, heritage, regeneration, bioclimatic

1. Introduction

Continuous habitation of Nicosia since 3,000 B.C. has formulated the multilayered profile of Nicosia affecting present day living patterns in direct or indirect ways. The city is at the center of the island of Cyprus in the eastern Mediterranean and has been the capital for over one thousand years. The historic city's primary feature is the 16th century (1567 A.D.) renaissance fortifications which are characterized by their eleven heart-shaped bastions, three gates and ditch comprising an excellent example of the bastion system of fortifications of the time in the eastern Mediterranean. The three gates of the Nicosia walls namely, Famagusta gate (east), Paphos gate (west) and Kyrenia gate (north) obtained their current names according to the major city they led to when exiting fortified Nicosia. This significant monument, the walls, the three gates and the ditch are the primary landmark for Nicosia constituting an integral part of the city's identity[6]. The city within the walls comprises of a range of built heritage dating from the byzantine era to the early 20th century as well as contemporary structures.

Today, heritage and planning stakeholders, local authorities and the public through structured participation methods are faced with the utmost need to agree on an area scheme and management plan which will bring together all the public and private stakeholders which are involved in the future of the monuments and the city. Metropolitan Nicosia comprises eight municipalities (population about 240,000) and Nicosia Municipality which includes the venetian walls and historic city has a population of about 50,000. The venetian walls and moat together with the historic city inside the walls have been declared as "Ancient Monument - Schedule B" under the Antiquities Law since 2004. The objective of this listing was to protect antiquities and monuments however, lacking the appropriate mechanism for

implementation of this objective the listing of the historic city has proven a hindrance both in relation to the protection of heritage as well as regarding the development and regeneration of the walled city. In order to mitigate this hindrance local stakeholders are currently collaborating to develop a common framework in order to proceed with an area scheme, development and management plan for the Venetian walls and moat. The regeneration of the walled city has been a central issue for Nicosia, since 1980 and is primarily realized under the bi-communal Nicosia Master Plan (NMP) project. Having to deal with the devastating division of the city since 1964 and 1974 the NMP project has been a successful tool in implementing and promoting the integrated regeneration of the old city as well as conserving and reusing its heritage within that framework working towards a unified city.

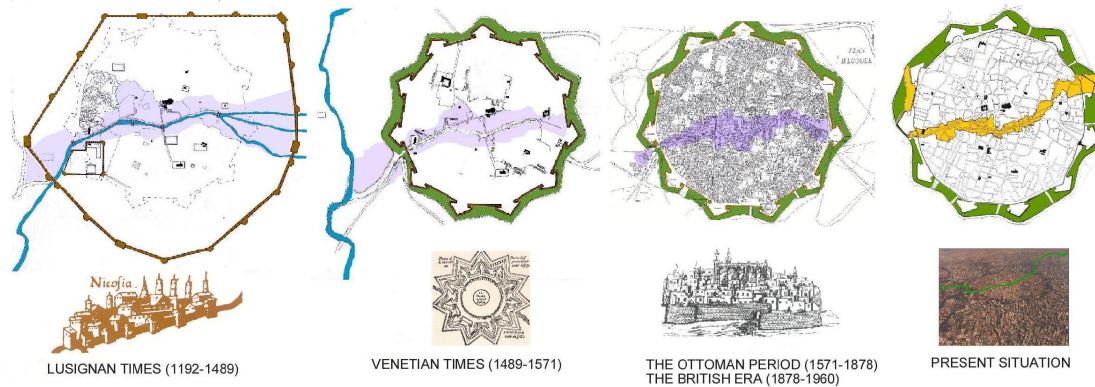

Fig. 1: Historic evolution of Nicosia (NMP archives)

2. The Nicosia Master Plan (NMP)

2.1 The Nicosia Master Plan, the framework

"In 1979, representatives from both the Greek Cypriot and Turkish Cypriot communities of Nicosia came together to assess the future development of the city they shared. Working under the umbrella of the United Nations Development Programme (UNDP), the two communities initiated a dialogue that would stand the test of time, would result in dramatic improvements in the living conditions of all the city's residents, and would introduce one of the most comprehensive planning documents of its time, the Nicosia Master Plan (NMP)"[1]. Through the Nicosia Master Plan Greek and Turkish Cypriots have been working together since 1979 for the conservation and protection of the multi-cultural heritage of Nicosia within the framework of a rational, integrated and sustainable development of the city as well as the regeneration of the historic core[2]. The major urban issues that any planning strategy had to deal with at the time were: (a) the division of the town into two separate urban parts following political unrest of 1964 and 1974, (b) the abandonment of the city's core adjoining the buffer zone, (c) the extensive urban sprawl towards the outskirts, (d) the fragmentation of responsibilities for planning issues and the multiple local authorities of the metropolitan city. At the time of the creation of the NMP planning legislation in Cyprus was limited to a law that primarily dealt with building and road design regulations. It was not until 1990 that the Planning Law was passed and put into effect. The Nicosia Master Plan documents therefore, created in the 80's were the core of the Local Plan of Nicosia which is the primary planning legislation for the city dealing with planning and heritage conservation issues. The 2004 project "The New Vision for the Core of Nicosia" evaluated the initial Nicosia Master Plan objectives and the effects of implemented projects and policies putting forth recommendations in order to improve and support the regeneration and development processes into the present and future changing circumstances. The primary axis of these recommendations is that cultural heritage is a vital asset of Nicosia and it should be at the heart of the regeneration process of the city.

2.2 The Nicosia Master Plan, implementation

From 1986 onwards, the NMP entered its implementation phase. The NMP team put special emphasis on development projects for the short and medium term, ranging from 5 to 10 years. These projects represented the backbone of the policy aiming at stimulating the physical, functional, economic and cultural rehabilitation of central Nicosia as the key to the overall development of the city. Central to implementing the NMP objectives has been the realization of ten twin priority projects in the walled city on both sides of the dividing buffer zone in order to restore and upgrade infrastructure and historic building stock to be prepared in the event of the re-unification of the city. In the late 1980's brick and mortar projects began with the two major residential rehabilitation projects in the areas of

Chrysaliniotissa and Arabahmet. Interventions during this period focused on the restoration and rehabilitation of important areas of the historic center, the improvement of traffic management and transportation and upgrading of the urban environment and infrastructure. Over one hundred projects are listed as Nicosia Master Plan projects to date. These projects have been funded over the years either by local or international funds or by organizations committed to contributing to the sustainable regeneration of the Nicosia as a whole.

Fig. 2: Map1: Metropolitan Nicosia- urban sprawl. Map2: Implementation of twin priority projects in the walled city (NMP archives).

3. Nicosia Master Plan studies and strategies

Following the first period of implementing priority projects under the NMP provisions and as the improvement of the built environment in the walled city following the NMP interventions was obvious the existence of the buffer zone as a major obstacle to the balanced development of the city continued to be a major impediment. In the meantime, the buffer zone that runs through the walled city comprises some of the most valuable architectural heritage of the historic core. This strip of land was historically the hub of commercial and social activity and possesses the greatest “gluing” potential for re-uniting Nicosia. Therefore, due to its valuable qualities the NMP implemented the study, “The survey of the buffer zone of Nicosia” beginning in 2001. The study surveyed and documented 265 buildings in this access restricted area and produced a comprehensive body of work that includes drawings and photographs of the historic buildings and recommendations for emergency support work in order to protect them until a more complete form of intervention will be made possible.

In 2004 the study “New vision for the historic core of Nicosia” was executed. The study included three main objectives, (a) Evaluation of the results of the up-to-date city centre rehabilitation approach, (b) Re-defining of a contemporary integrated planning strategy for the development of the centre, (c) Guidelines for the selection, design and implementation of urban regeneration projects. Through this process a heritage-led regeneration strategy was developed.

4. Nicosia Master Plan Projects

Throughout the years and under the provisions of the above studies and strategies several projects have been implemented in the walled city. The interventions under the NMP provisions have included urban infrastructure, restoration and reuse of a range of architectural heritage in the city, urban upgrading projects, traffic management projects as well as public awareness actions. More clearly, during the past ten years the direction and emphasis of formulating and deciding on new projects has been that of sustainable urban interventions. Issues such as managing heritage conservation together with the rest of the needs of a vibrant contemporary city for new development schemes, pressing public transportation and parking problems together with the environmental impact that energy consumption brings are a daily reality for Nicosia’s stakeholders.

Fig. 3: Restoration of Omeriye Hamam, Europa Nostra 1st Prize 2005, walled city of Nicosia (NMP archives).

Fig. 4: Restoration of façades and upgrading of infrastructure in the walled city of Nicosia (NMP archives).

The numerous projects implemented in Nicosia have been planned under the framework of the Nicosia Master Plan and Nicosia Local Plan objectives. Since 2001 funding for the various projects has come from local and central Government, USAID through UNDP, European Union pre-accession funds and European Union Structural Funds (European Regional Development Funds-ERDF, programming periods 2004-6 & 2007-13).

The historic core of Nicosia as well as its adjacent historic settlements of Kaimakli and Pallouriotissa have been the recipients of urban upgrading projects since these areas presented severe problems of decay and abandonment due to the division of the city, the feeling of instability and lack of new economic investments in these areas. The walled city is still trying to regain its identity as the central, capital city of the island as opposed to a boarder town along the buffer zone. Areas in the historic city which concentrate urban renewal projects are the Old Town Hall area, the Takt-el-Kale area, West of Ledra street area and the two connection points with the outside the walls city of Solomou Square bus transit station and Eleftheria Square which will connect the old town and the new via a north-south axis.

The urban regeneration projects include the redesign of streets and open public spaces, upgrading of public utilities infrastructure, improving of street furniture and vegetation, signage and inclusion of energy efficient street lighting as well as the restoration of building façades. These types of projects already completed have vastly improved the built environment contributing to a higher quality of life for the inhabitants and enhanced their sense of community while empowering the value of taking care of the architectural heritage as having a direct impact on the daily quality of life.

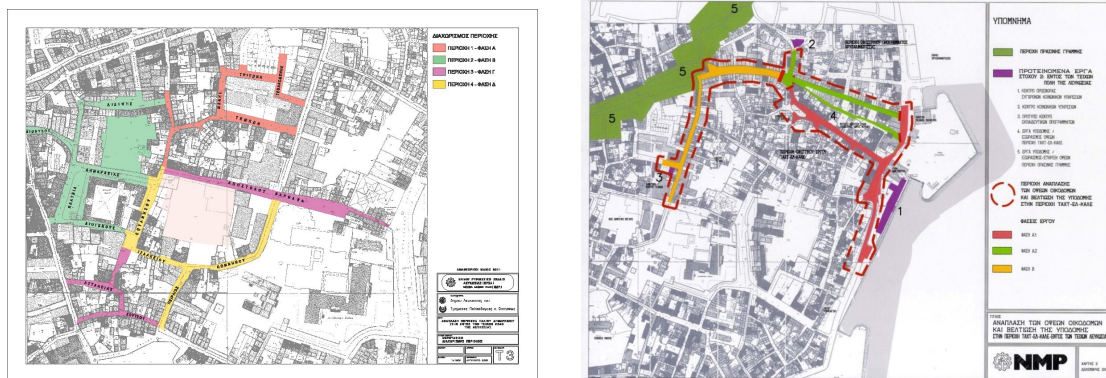

Fig. 5: Areas of urban regeneration projects in the walled city of Nicosia (NMP archives).

The inclusion of contemporary design projects within the city's historic context has been a topic of intense discussion. However, a living city encompasses built heritage from all periods of its history. A contemporary structure must be in the spirit of its own time while at the same time be in tune with the provision of the The Valletta Principles for the Safeguarding and Management of Historic Cities, Towns and Urban Areas, Article2(b), *"The introduction of contemporary architectural elements must respect the values of the site and its setting. It can contribute to the enrichment of the town, bringing alive the value of urban continuity."*

5. The Assessment of Bioclimatic Elements of Vernacular Architecture in the Historic Centre of Nicosia

In addition to the planning, restoration and sustainable urban regeneration concerns under the Nicosia Master Plan objectives, energy efficiency issues are increasingly at a point of attention in order to achieve minimize energy consumption in the city. The traditional building stock of the city presented an ideal setting for research in this field.

The research aims at establishing a bioclimatically-based approach in the conservation of traditional buildings and thus contributing to the regeneration and sustainable development of the urban environment of such a solid traditional historic core as that of the Walled City of Nicosia.

Through the study of the historic architectural evolution of the typology[3] of Nicosia it is clear that some elements that remained and have been used during all periods are: the central yard at the back of the plot, the arrangement of spaces around the yard and the prevalence of semi-open spaces (used as entrances and shelters). These elements underline the aim of the residences to adapt their dwellings to the climatic conditions of the area (hot summer, mild winter, limited winds). The dwellings were frequently arranged in compact patterns, closely built with common walls, one attached to the other, following the continuous urban system leaving small empty spaces in the form of public narrow streets and private courtyards. Thus, the vertical surfaces (walls) exposed to exterior environmental conditions are reduced and the thermal protection of the building envelope is increased. The shade between neighbouring buildings reduces the warming up of their walls by radiation. Thus, topography, geomorphology and climate are important parameters that play a significant role in the design (Le vie dei Mercanti 2013).

The selection of appropriate building materials, apart from being partially imposed by availability, is also climatically driven. The suitable use of materials in the building's envelope provides direct protection from the climatic conditions, while the materials of the buildings' surroundings contribute to the development of desirable microclimatic conditions. The materials used in the vernacular Cypriot architecture are earth and stone which are to be found in abundance in the vicinity. The traditional dwellings of Nicosia constructed with earth and mudbricks, have stone foundations of local limestone, of Athalassa-Nicosia Formation called "Stone of Gerolakos", so as to protect the mudbrick walls from the rising damp (Le vie dei Mercanti 2013).

After an overall historic and architectural investigation of the area through historic documentation and survey maps, a study of a large number of buildings from a typological, bioclimatic and construction material point of view has been carried out. The bioclimatic strategies of heating, cooling and microclimatic conditions were studied in detail. The research showed the various environmental features of vernacular architecture (central yards, semi-open spaces, construction and materiality etc.) and the correspondent bioclimatic strategies. The data collected were tabulated and encoded for comparative investigation and analysis. These recordings defined the basis for the selection of a number of characteristic buildings for monitoring temperature, humidity, lighting levels and ventilation aspects. Weather stations have also been installed in the selected study areas and in the centre of a traditional courtyard.

The analysis of the data gathered showed that special emphasis in Cypriot urban vernacular architecture was given to the cooling rather than the heating strategies. The hot climate of the area probably led to the enhancement of the cooling strategies through cross ventilation and stack effect (openings) as well as shading (pergolas, shutters, *iliakoi* etc.). The combination of shading and night cooling reduces the interior temperature, keeping it at close levels to thermal comfort. On the other hand, the rather limited heating strategies incorporated, i.e. minimum exposure of surfaces to the south and small size and number of openings in the south facades, did not allow the house to take full advantage of the sun during the winter (CIAV2013).

The monitoring of temperature and humidity levels in selected buildings demonstrated the great importance of the building materials and techniques used in the construction of traditional dwellings. The significantly lower temperature fluctuations recorded in the internal spaces with eastern, southern and western exposure, confirms the high thermal insulation characteristics of the building envelope and the thermal inertia secured by the thick wall construction materials, which offer high thermal mass (PLEA2013).

The temperature data recorded, confirm the positive contribution of the semi-open spaces as sun shading elements. Moreover the reduction in temperature fluctuation observed in all cases studied, compared to the respective temperature fluctuation of the external environment, helps towards the achievement of more comfortable living conditions within these traditional dwellings. The "portico" generally shows smaller temperature fluctuations, compared to "iliakos", due to its greater "depth". The recorded relative humidity fluctuations of the semi-open spaces are significantly lower compared to the relative humidity fluctuations recorded at the courtyard and the external environment; this indicates the positive contribution of the semi-open spaces as relative humidity regulators (PLEA2013).

According to the findings of the preliminary stage of the research, it is noticed that the occupants of the traditional dwellings often proceed to interventions in the building envelope, which alter some of the original typology features. Some of the most common interventions encountered are: (a) the closure of the semi-open spaces "iliakos" and "portio" with frameless glass elements that can be opened, (b) the closure of the small openings on the upper part of the facade, called "arseres".

Other interventions concern the external environment of the building, like: (a) the introduction of impermeable flooring (e.g. concrete floor) in the yard and (b) the filling up of the well.

The monitoring of houses with such interventions reveal that their impact is significant to the bioclimatic function of the building shell. The transformation of south orientated semi-open spaces into internal spaces has positive effect during the winter period as the space resembles the function of the green house effect and benefits from the direct solar gains. However, in cases with limited shading provisions, the effect is negative as the space is overheated. Therefore, the policy adapted for such interventions of closure of the south orientated semi open spaces is either to assure the adequate shading during the summer period or to reestablish the space as a semi-open one, by maintaining the openings of that space wide open. In this way, the cooling strategy of the cross ventilation is assured.

The small size openings, located at a considerable height, mainly on the façade on the streets (called "arseres"), contribute to the forced ventilation and the extraction of hot air from the building envelope (stack effect) during the summer period, due to the difference in temperature and density of the air (CIAV2013). Therefore, their contribution to the passive cooling is significant and their presence should be conserved.

With regard to the strategies on the microclimatic environment, the existence of water elements (wells and shallow pools) in courtyards and in the areas surrounding the buildings, as well as the watering of the plants, provide evaporative cooling during the summer (CIAV2013). Additionally, during the winter, as the surface materials (stones and/or earth) and the surrounding walls of the courtyard increase the urban heat effect, the interior temperature is higher in relation to the external environment (CIAV2013). Consequently, the materials used in the surrounding area of the building is also of great importance in a rehabilitation/restoration project.

Fig. 8: The closure of the semi-open space “iliakos” with sliding glazing panels (*biovernacular archives*).

6. Conclusions

The historic city of Nicosia constantly undergoes having to manage the forces of preserving its cultural heritage, the forces of its divided centre and the need for sustainable contemporary development. All three areas exert tremendous pressure, often times in opposite directions. The challenge of successfully balancing the three areas in order to obtain a positive outcome for the city, its inhabitants, heritage conservation and its future is a difficult task. Nevertheless, success lies in the synthesis of opposing forces and the multidisciplinary collaboration between heritage professionals, government departments, local authorities, local communities, public and private stakeholders.

In the words of Robert Palmer, former Director of Culture and Cultural and Natural Heritage, Council of Europe, *“Heritage is not simply about the past; it is vitally about the present and future. A heritage that is disjoined from ongoing life has limited value. Heritage involves continuous creation and transformation. We can make heritage adding new ideas to old ideas.”* [7]

7. Acknowledgements

The research described in this paper is based on a research programme that is funded by the Republic of Cyprus and the European Regional Development Fund (Cyprus Research Promotion Foundation's Framework Programme for Research, Technological Development and Innovation *Δέσμη* 2009-2010, *ΑΝΘΡΩΠΙΣΤΙΚΕΣ/ΑΝΘΡΩ/0609/BIE*). The Host Organisation of the programme is Nicosia Municipality and the Partners are the University of Cyprus, the ICOMOS Cyprus and the Frederick Research Institute. Special thanks to the Nicosia Master Plan team for providing access to the NMP archives.

Abstract

Roofing structures in archaeological sites are continuously subject of studies. In Pompeii there are many examples of roofing structures, built using several techniques and guidelines.

Recently, within the agreement signed between the DICAM department of the University of Bologna and the Superintendence of Pompeii about the analysis of the structures and the study of the operations of consolidation and restoration of the Insula of the Centenary, the issue of designing roofing structures of various spaces of the Insula was addressed.

In particular the attention was focused on the covering of the main atrium. Firstly a prototype of a roofing structure covering a portion of the atrium was installed. Then, precisely fitted inside the ruins by means of a laser scanner survey, the structural design of three different types of roofing structures was defined:

- wood structure with roof tiles;
- aluminum structure and polycarbonate panels;
- steel structure and corrugated steel panels.

Various three-dimensional models were developed on the real geometry provided by the laser survey and analyzed with engineering software tools to track the effect of static and seismic actions on the whole structure.

Among all the other possible ones, the solution involving the use of a restoration roof covering in lightweight material, resting on the existing masonry after consolidating the latter and creating stringcourses at various heights on the wall ridges provides a result which is less invasive visually and, at the same time, leads to an improvement in the seismic behaviour of the whole.

Keywords: surveying, modeling, analysis, restoration, materials.

1. The Insula of the Centenary

The Insula of the Centenary, the eighth in the Regio IX of the archaeological excavations in Pompeii was given this name because it was excavated in 1879, the eighteenth centenary of the eruption of Vesuvius; it is a large, trapezoidal block, tapering towards the south with a general reduction in height from north to south (see figure 1). It appears to be hinged between the western part with square insulae and the eastern part with rectangular insulae and the demarcation to the north is an important urban decumanus, the Via di Nola, and to the east and west it is bordered by two alleys, the Maialino and the Centenario, while the southern boundary, on which the Casina dell'Aquila stands out, has not been excavated yet. The greater part of the Insula is occupied by the large domus of the Centenary while there are another two building units in the south western part: a small structure, the hospitium

Hygini Firmi and the rear of a house with a peristilium whose entrance is still beneath the hill. The Casa del Centenario shows traces of a long and troubled building history; restoration work has been carried out on various occasions, also on different floor levels and with variations in the dimensions of the rooms and their intended use and significant remakes of flooring and, especially, wall covering decorations. At the time of the eruption in 79 A.D. the appearance of the house was that of a large building with two atriums and a peristilium, one of the few in Pompeii. Looking out over via di Nola, where its two main entrances were located, the domus also included a western quarter which had been vastly restored in the last building phase. The peristilium was the heart of the home and the more elegant reception rooms to the north and the south opened out onto it.

Figure 1 (the part in color) shows the zenithal view of the Insula of the Centenary and the various types of roof coverings (present up to 2010) are indicated with letters as specified below.

Original roof coverings:

a – stone vaulting (regarding the roof covering of the thermal baths; all the roof coverings of the basement shown on the right hand side of the plan in figure 1 are also in original stone vaulting).

Restoration roof coverings:

A – sloped roofs, with guttering on the southern side, with a supporting structure in wood and roof covering in imbrex and tegula;

B – flat roofs in cement and bricks, all in a state of deterioration and underpinned at the moment;

C – structures with one vault (black oecus, at the top of the picture) and vaulted and level structures (Egyptian cubicle with the level part towards the atrium) all restored with iron girders and bricks or stones;

D – bearing structures in iron and roof covering in Ondulit with finishing in copper; maintenance carried out recently.

Temporary roof coverings:

E – bearing structures in steel tubular elements and roof covering in plasticised corrugated metal.

Experimental roof coverings:

F – bearing structure in tubular aluminium profiles and roof covering in polycarbonate alveolar sheets.

Fig. 1: On the left the existing roof coverings of the Insula of the Centenary (zenithal view from Bing Maps 2010), on the right the design indications for the new, hypothetical roof coverings with a structure made of aluminium and a roof covering made of polycarbonate.

1.1 Experimental roof covering in polycarbonate and aluminium

Following sponsorship by Makroform S.p.A., today called BayerSheetEurope, it has been possible to develop an experimental application of polycarbonate sheets (compact and alveolar) for the roof covering of sectors of the Insula and also for closing up openings and protecting wall paintings and inscriptions. In particular, in relation to the study of new restoration roof coverings, the experimental roof covering of the NW corner of the main atrium (figure 2) was realised with the aim of assessing the visual effect of the partial restoration with a view to carrying out a complete reconstruction of the roof covering of the main atrium. The bearing structure (if it is positioned on the masonry, the vertical supports are necessary only for the prototype) has been made in aluminium and has the characteristics of a temporary structure which can be dismantled and repositioned, if necessary, in another place since each single constituent element can be transported manually, if required. The plinths are laid on the floor and separated from it by a protective layer of rubber. The polycarbonate sheets installed are alveolar sheets, type 16XP, bronze coloured and they cover a surface area of approximately $16,0 \text{ m}^2$. No vertical closures are present. In general the alveolar sheets have elevated mechanical characteristics, good resistance properties to fire and chemical agents and, compared to glass, excellent impact resistance with no shards formed, excellent transparency and light transmission and a higher capacity to provide thermal and acoustic insulation. In particular the technical characteristics of the 16XP sheets installed are:

- weight: $2,5 \text{ Kg/m}^2$;
- light transmission: 21% ;
- thermal expansion coefficient: $0,065 \text{ mm/m } ^\circ\text{C}$;
- protection from UV rays UV: 100% ;
- recyclability: 100% .

The sheets are guaranteed for 10 years regarding transparency and against breakage due to hail.

The entire prototype structure has the following, main characteristics:

Capacity of protection from atmospheric agents: the polycarbonate alveolar sheets filter and subdue sunlight; they imitate the appearance of the original covering and, at the same time, protect the covered area from the negative effects of sunlight and rain. The small amount of rainwater collected from the approximately 16 m^2 of roof covering is channelled into the impluvium.

Weight and transportability: the plinths in the design weigh about 560 daN, the rest of the structure, including the roof covering sheets, about 350 daN and, taking into consideration an increase due to the greater height of some plinths to compensate the subsidence of the supporting surface, there is a total static load of about 1150 daN which corresponds to a compressive stress of about $0,2 \text{ daN/cm}^2$.

Fig. 2: Prototype covering in the NW corner of the main atrium.

2. Design indications and the choice of the type of roof covering

Given that the desire to proceed with covering the most significant areas of the Insula is envisaged in the project (see figure 1 for the hypothesis with a bearing structure in aluminium and roof covering in polycarbonate), the choice of the type of covering can be subject to various constraints.

The masonry of the Insula of the Centenary is in a very delicate condition, often almost a safety hazard due to the vertical bearing capacity; this has been caused by previous historical events, natural deterioration following unearthing activities and also some consolidation and covering work carried out over time has led to further deterioration problems. All this has been made worse by the lack of regular maintenance. Therefore, even in the absence of new roof coverings, the masonry needs to be consolidated anyway, and, in particular, work must be carried out to check and improve the adhesion of the plasterwork which is still present.

During studies on new restoration roof coverings, the problem regarding the transfer to the ground of the new loads emerged immediately and consequently the choice of the type of support: should it be on top of the existing masonry or in complete autonomy, with the necessary new foundations.

In comparison to the autonomous foundations (either excavated or just positioned on the ground) it can be observed that placing them on top of the existing masonry would lead to some advantages:

- the exploitation of the existing groundwork with a transmission of loads over a greater surface area and consequently, a lower concentration of stress;
- the possibility of creating summit stringcourses, concealed in the thickness of the sacrificial masonry, on which to position the roof covering structure with a possible improvement of connections between orthogonal walls and non-orthogonal ones;
- lower impact/disturbance of vertical bearing structures.

Once the system for transferring new loads to the ground had been decided on, three types of possible roof coverings were analysed; all of them were positioned on the existing masonry as described below with particular reference to the area of the main atrium.

One characteristic common to the various types of covering is the impluvium shape; this is justified by the archaeological knowledge acquired about the part regarding the main atrium and sub-horizontal for all the others; this construction code is common for all restoration roof coverings in the archaeological area of Pompeii when the effective shape and original position are not known.

2.1 Coverings with structures in masonry and wood and roof covering in imbrex and tegula

In comparison with other types of roof coverings, as far as loads due to its own weight and permanent overload are concerned, the sole impluvium portion of the roof covering in wood and tiles (imbrex and tegula) has a weight of 76,0 daN/m² (figure 3). Then, taking into consideration other elements, the covering of the impluvium basin and the system of wooden beams and pillars, an overall weight of 12654 daN is reached.

Fig. 3: Axonometric view of section E-W of the area of the main atrium.

Fig. 4: Axonometric view from below of the N-S section of the area of the main atrium.

This overall weight, in relation to the surface area of the main atrium (equal to approximately 113 m^2), leads to an incidence per unit of surface area equal to $111,98 \text{ daN/m}^2$ as a result of the roof covering in wood, imbrex and tegula.

When using wooden roof coverings with imbrex and tegula it must also be remembered that it is necessary to build a suitable stretch of masonry (at least one metre high) in correspondence with the sides of the main atrium in order to position the main beams (the part highlighted in red in figures 3 and 4). The construction of this stretch of masonry would lead to a significant increase in stress on the original masonry due just to its weight and further stress in the event of an earthquake.

Finally, the weight of the other distribution stringcourses on the masonry and lateral elements for protection against sun-wind-water, which are the same for the various solutions, must be added. In order to make a comparison, it should be considered that the load per linear metre of a cement stringcourse, inserted into an adequate thickness of summit sacrificial masonry, in order to support the vertical bearing structures is equal to approximately 260 daN/m and running around a perimeter of approximately 30 metres (only the main atrium) contributes to the overall load by approximately 7800 daN with an incidence per unit of surface area of approximately $69,03 \text{ daN/m}^2$.

2.2 Coverage with aluminum structure and polycarbonate roof covering

The structural form used in the coverage with an aluminum supporting structure and roof covering in polycarbonate alveolar sheets, in terms of total geometry and single profiles, is the same as that used for the coverage with structural aluminum elements and roofing in corrugated metal. For the characteristics of the aluminum material, type avional 6082 was chosen, and for the roof covering, Makrolon UV 2/4-6 panels in alveolar polycarbonate (with a weight of about $3,5 \text{ daN/m}^2$).

An evaluation of loads per surface unit of the main atrium was carried out considering the following: the weight, deducted from the calculation model, only of the aluminum tubular profiles which make up the coverage (beams and small pillars), the weight of the polycarbonate central fairing (canopy), the weight of the roof covering in polycarbonate alveolar sheets, obtaining a total weight of 1503 daN and a surface unit weight of the main atrium of $13,30 \text{ daN/m}^2$.

Considering also the roof coverage which extends to all the surrounding areas of the main atrium and also to the secondary atrium (see picture 1), the total weight obtained (tubular avional aluminum elements, fairing and polycarbonate sheets over the whole area of the main atrium and part of the secondary atrium) is equal to 6405 daN which, for a covered surface of about 441 m^2 , leads to an incidence per surface unit equal to $14,52 \text{ daN/m}^2$.

In picture 5, an axonometric North-West view of the main hall is shown, with the solution in aluminum and polycarbonate.

Fig. 5: NW-SE axonometric view of the aluminum and polycarbonate roof covering.

Fig. 6: SE-NW internal prospective view of the center of the main atrium of the steel and sheet covering.

2.3 Covering with steel structure and roofing in corrugated sheet

The structured form used for the steel and corrugated sheet coverage, in terms of total geometry and single profiles, is the same as that used for the coverage with aluminum structural elements and polycarbonate roofing. For the characteristics of the steel material, those of CorTen steel were chosen, and for the roof covering, the corrugated plate of the Ondulit Coverib type (with a weight of about 10 daN/m²). The latter choice was determined by the presence of the same type of sheet, with copper finishing, used for the coverage of other areas of the Insula (type D coverage in picture 1).

An evaluation of the loads per surface unit of the main atrium was performed considering the following: the weight, deducted from the calculation model, only of the tubular profiles in steel which make up the coverage (beams and small pillars), the weight of the central fairing (canopy) in polycarbonate, the weight of the roof covering in Ondulit Coverib plate (10 daN/m² on an area of about 111 m² related to compluviate flaps). A total weight of 4206 daN was obtained and a weight per surface unit of the main hall of 37,22 daN/m².

Considering also the part of the roof coverage which extends to all the surrounding areas of the main atrium and partly also to the secondary atrium (see picture 1), the total weight obtained (tubular CorTen steel aluminum elements, fairing (canopy) and Ondulit Coverib plate over the whole area of the main atrium and in part of the secondary atrium) equal to 11891 daN which, for a covered surface of about 441 m², leads to an incidence per surface unit equal to 26,96 daN/m².

For a comparison, it is important to remember the load of the summit stringcourses that contributes to the total load for about 7800 daN for an incidence per surface unit of about 69,03 daN/m².

Finally, also the distribution stringcourses on the masonry and the lateral elements for protection against sun-wind-water, which are the same for the various solutions, must be added to the above weights.

In picture 6, a prospective internal view of the solution in steel and corrugated metal is shown.

3. Model and analysis of the new roofing structures

We need to update our analysis of the structures of the Insula in the light of the latest technical regulations (the "New Technical Standards for Construction", Decree of the Ministry of Infrastructures of 14 January 2008, and the relevant circular), and of the regulations designed to assess and reduce the seismic risk to our cultural heritage ("Directive of the President of the Council of Ministers to evaluate and reduce the seismic risk to cultural heritage with reference to the technical standards for constructions" of 9 February 2011). This will apply in particular to the structures of the main atrium of the Casa del Centenario and to those of adjacent interiors, should new roofing have to be provided as part of the restoration. This topic is always of primary importance in interventions carried out in areas of archaeological interest

Our previous explanations clearly show how aluminium and polycarbonate roofing is the best solution from a purely structural point of view, as it is less of a strain on the walls. If, however, we take into account the current state of the roofing on the Insula of the Centenary, which has recently been covered extensively using steel sheet roofing, such as Coverib by Ondulit (a multilayer, protective, steel sheet, with a corrugated profile and an external, electrolytic copper covering to guarantee a long working life, and a high level of thermal and acoustic comfort and tensile strength), we understand this opportunity of making the new roofing consistent with most of what is already in place. We can, therefore, consider CorTen steel (steel with high tensile strength and corrosion resistance which guarantees long term restoration) and sheet metal, such as Coverib by Ondulit, as being a suitable solution. On the other hand, the more difficult solution of wood and tiles would require further investigations and major structural work to strengthen the supporting walls.

The choice of materials in the project design was fundamental for load transfer to the ground. For the reasons given in the previous pages, we studied a means of resting the roofing on the existing walls, which would minimise the increase in stresses by introducing, where possible, perimeter stringcourses (with stainless steel reinforcement rods). Some of the models and numerical analyses made using commercial, finite element software are given below.

3.1 The geometric-structural model and stress analysis

We used laser-scanning technology for a fundamental survey of the geometry of the main atrium and the neighbouring interiors to provide a correct, three-dimensional reconstruction of the elevations. We divided the structural model as follows:

- model of the main atrium in its current condition, with an assessment of the tensile stress induced by its own weight and by an earthquake in both directions X and Y perpendicular to each other (with the X axis parallel to via di Nola);
- project model of the main atrium under corrugated sheet roofing supported by tubular steel profiles, with uprights resting on perimeter, reinforced concrete stringcourses, and an assessment of the tensile state from its own weight and from an earthquake in the aforementioned directions.

Fig. 7: Model of the load-bearing structure of the hypothetical steel roofing within the point cloud data.

Numerous sections were made on the point cloud data of the laser scanner survey to model the current geometry, and we reconstructed a three-dimensional model of the atrium of the Insula of the Centenary. We also made adequate models of previous restoration and salvage works, such as wooden or cement architraves and clay-cement roofing, as in the two oecii, strengthened during the project. In particular, we suggest the seriously damaged roof of the white oecus, which is currently under-pinned like so many others, be replaced with a mixture of wooden beams and planks and a concrete slab anchored to an existing, perimeter stringcourse (which will be replaced). To model the structure of the walls we used "shell" finite elements, automatically generated by the programme. The hypothetical roofing, modelled very precisely within the point cloud data (figure 7), will rest, where possible, on new stringcourses on top of the perimeter wall of the main atrium, after a reconstruction or replacement of a stretch of sacrificial masonry at obviously variable heights.

Fig. 8: Stresses Mzz for earthquake -X in its current state.

Fig. 9: Stresses Mzz for earthquake -X after roofing.

Injecting binding mixtures to strengthen the masonry were also considered.

A linear, elastic analysis was carried out. Figures 8 and 9 show the current state and the state of the project design, the tensile states for a typical Mzz stress (moment by unit of length, which represents the buckling of the wall panel under an orthogonal load on the panel itself) from an earthquake along the -X direction. A clear improvement can be seen in the stress state after roofing, due to the combined stiffening of the stringcourses and to the roofing structure itself.

From the analyses made on the model, it appears obvious how the tensile state, due only to its own weight, is not currently at a critical level, and how the increase in tensile stress, due to the new roofing, has no negative effect on the estimated torque capacity of the masonry of the main atrium. The checks carried out clearly show how the majority of the wall bays do not comply with the requisites set by the Ministerial Regulation of 14/01/08 for shear stress and combined compressive and bending stress tests. They also show the benefit of stiffening by the stringcourses, which redistribute tensile stress more uniformly and diminish the critical state of the perimeter walls of the atrium and the roofing structure. Lastly, further improvement is provided by the injection of binding mixtures.

In addition, the horizontal action forces in the white oecus are more equally divided and behave more like a box action since the floor has been replaced.

The proposed roofing rests on the perimeter walls of the atrium and becomes one with the existing structure. Even though, on the one hand, it leads to an increase in stresses, on the other, it enables a better distribution of the horizontal action forces, as a result of the perimeter stringcourses it rests on.

Finally, even though we used extremely precautionary resistances for the masonry, we will have to closely ascertain the condition of each individual wall panel, with probable local reinforcement in addition to what is already envisaged for the external facings (including work to re-adhere the plaster) and for the inner nucleus.

4. Conclusions

In the light of all this, we can see the urgent need to put roofing in place, given the frequent traumatic events in the area of the excavations of Pompeii. The roofing we have studied is an acceptable solution, as it will enable us to tackle the main problem of attempting to drastically slow down the deterioration of the walls caused by severe weather. By enabling a better distribution of the horizontal action forces on the walls, it will also contribute to improving structural strength in the event of an earthquake.

The activity done involves some aspects proper of the structural engineering: from the actual prototypal model to the mathematical model, to the analysis of data used, to the analysis of the results and their degree of reliability. A deep interaction with other teams of research is necessary, in particular for the archaeometric survey, the final effect is an enrichment of the knowledge in the conservation of the archaeological estate.

5. Acknowledgements

Under 'Insula del Centenario' Project, an agreement stipulated in the framework of 'Pompeii Law' between the Archaeological Superintendence of Pompeii and the University of Bologna, the DICAM (Department of Civil, Chemical, Environmental and Materials Engineering) has contributed sharing the knowledge in structural and topographical field.

The Authors, in particular, belong to the DICAM, ("Scienza delle Costruzioni" Section) and they deal with the structural analysis of the masonry of the Insula.

Numerical facilities have been provided by LAMC, Laboratory of Computational Mechanics of the DICAM Department. The company from Padua, Concrete S.r.l., designed the structural code, SismiCadUndici, for research. Its unusual features provide the opportunity to tackle all the phases of an analysis and testing envisaged by the recent NTC regulations of 2008 [Technical Construction Regulations], for the simultaneous use of masonry, cement, steel and wood structures.

Renovating the existing to redevelop the territory. Restoration and reuse project of an eighteen century country house in Casalvecchio Siculo (Messina - Sicily) and realization of a farm holiday center

Alessandra MANIACI, Gianfranco SALEMI SCARCELLA

Dipartimento PAU, Università degli Studi "Mediterranea" di Reggio Calabria, Italy
alessandra.maniaci@unirc.it, feangivi@alice.it

Abstract

Country houses are a very important cultural and historical Italian heritage, which represents the identity card of their own region; so their restoration is, not only, the means to preserve the Country memory but also the way to make small villages more modern, livable, source of development. This thesis project focuses on Casalvecchio Siculo (Messina - Sicily), a pleasant medieval village with a strong tourist value. The country house, dating back to the late eighteenth century, is very characteristic; it was the summer residence of a well-to-do Sicilian family and it is surrounded by vineyards and pastures. I explored and recognized the building tradition of the area through an historical and functional analysis, after that, I found geometries, materials and degradation of the building so, I proceeded with the restoration project of the existing house and I designed the addition structures such as new rooms, stables and horse riding in order to realize a farm holidays center. The project uses local materials, such as sandstone and oak wood, to build a modern architecture but linked to the territory; it contemplates both new technologies and traditional forms that integrate together with the natural environment by utilizing its picturesque landscape and the favorable climatic characteristics. The aim of the project is the restarting of the economic recovery of the area thanks to the restoration of traditional production functions, and tourist offer of hiking and wine tasting tours.

Keywords: country house, environment, territorial requalification, agricultural economy, tourism.

1. The historical farm buildings and their impact on the environment

Within the wide variety of Italian architecture, there is not only the "high" one, which has always dignity in historical culture, but also the "popular" one. Although it seems repetitive and accidental, rural architecture is actually the result of the centuries-old practice and experience that has led to the refinement of techniques and use of materials. During the twentieth century there has been a historical change of mentality and sensibility that has led us to consider rural houses as part of the cultural and material heritage of a civilization - worthy of being studied and to have the same protection and enhancement of monuments, buildings and urban architecture, considered by more and more important. Today, the study of the rural experience is important as the basis for the development of a more environmentally conscious architecture, based on the use of readily available materials and the use of low-impact machinery and construction techniques – an architecture that is "conscious" in all its phases, design, construction, maintenance, and eventual disposal.

My main goal is to investigate how the environment has influenced the architectural development in modern rural Italy and, particularly, in the area of eastern Sicily – I'll try to understand how all this is translated in the specific case of the restoration of a farmhouse in Casalvecchio Siculo, in the province of Messina, and finally, how the project of re-use and recovery of the old production functions can favor the development of tourism in a small village, and give an input to the small local production, which is currently fragmented and poorly organized.

1.1 Connection between architectural practice and local spaces

The geographical position and the wide variety of environmental conditions of the Italian territory, as well as the complex historical events, has led to the development of a remarkable breadth of agricultural scenarios: from large terraces, to allow the greatest possible exploitation of cultivable areas in the mountain and hilly regions, to the intensive cultivation techniques of the great plains with the use of large irrigation canals. Each different background has influenced the techniques of cultivation, so the rural architecture, takes different shapes and materials, and different arrangement of spaces depending on the climate, topography and cultivation. The Italian agricultural landscape as we know it, was born with the beginning of the large land reclamation plain, the clearing of great hilly and mountainous areas, large crops of trees and shrubs that included spaces wider and wider and when the lack of manufacturing resources already present in other nations, has forced the Italian population to consider the agriculture as the main activity for their livelihood.

Rural architecture is very closely linked to the territory and can be included in the history of architecture thanks to the variety of its constructive solutions. Its importance is that develops in a context of scarce resources that led the ancient builders to the study of ingenious technical and formal solutions that today are taken into account in processing of sustainable architecture, in the development of new materials and in the refinement of traditional building techniques. So why do a restoration project of the existing rather than building a new structure according to techniques and modern materials? First of all, for strictly *practical* reasons. The traditional building techniques are based on a fundamental assumption: get the maximum results with minimum effort. In this case the "minimum effort" is the use of the construction area materials, that are now called "short chain" or "zero kilometer" - materials such as stone, wood and brick, with high efficiency and that are excellent thermal insulators and excellent heat accumulators, which were chosen by the ancient builders for the ease of availability and the final result which ensured. The construction techniques are the result of studies based on the practice that have their roots in history, and which have been perfected over time to get buildings comfortable and high-performance. Then, comparing the traditional ideology with the new modern research in the field of sustainability we cannot help but notice that, in fact, their main points are perfectly superimposed. So why not take advantage from an already well-established centuries-old practice and based on it to improve it and perfect it with the new technological knowledge?

Another reason is *historical*. The study of a place is necessarily an analysis of its architecture and rural ones are very important for Italy which has based its historical economy on agriculture – there are so many cases so it is fascinating to discover how the large kind of Italian countryside has led to such different developments.

1.2 A brief history of the Italian settlements: different territories, different types of buildings

The building typologies of rural architecture, being in close contact with the land they occupy, change in shape, materials, and aggregation than that they are in the north or in the south, in the plain, in the hills or in the mountains. It's definitely impossible to give a complete and accurate description of all building types and kind of territories so I will make a brief introduction of the main Italian types and focus, then, on the Sicilian case and on the project. In Italy, from the agricultural point of view, we can identify two big geographical areas, north and south, divided by an imaginary line that can be positioned below the Tuscany. The north is a land rich in water, well drained and irrigated over the centuries, which is used for intensive agriculture, with plantations of rice, cereals and fodder. To the south, however, we find dry lands, often arid, without any type of irrigation until a few years ago, with cereal crops and forage, vines and fruit trees. As these environmental characteristics affect form and

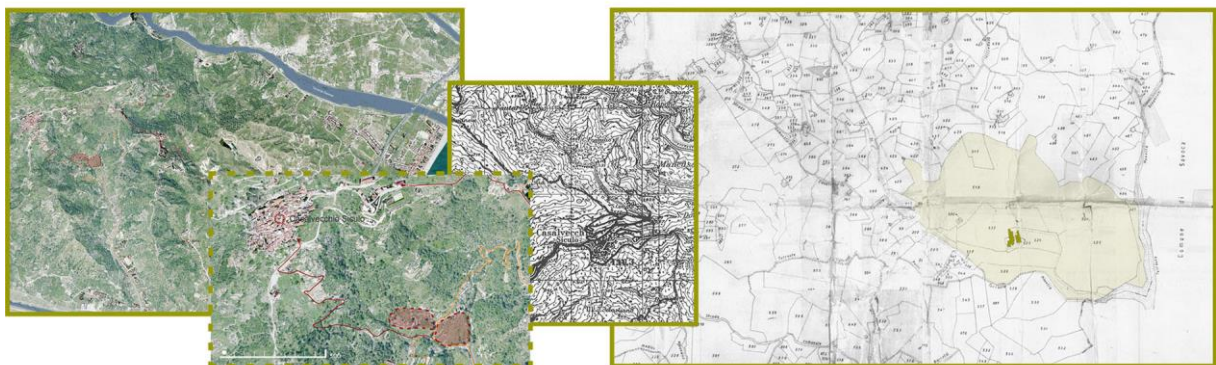

Fig. 1: Aerial photography, historical and cadastral plan of the intervention area in Casalvecchio Siculo.

Fig. 2: Study sketch of the country house object of restoration.

function? The Po valley, lush and easily irrigable, was the perfect place for a fruitful and intensive cultivation. Thanks to the adoption of the system of rotation of the earth, the heavy plow and the reclamation of land, developed large farms that had larger buildings, with U-or L-shaped, with animal shelters in the north, the houses of the factors and deposits for tools on the east and west, and the home of the conductor and the warehouses to the south. These large companies also led to the birth of the farms, called "*cassinot*" or "*cassina*" ranging in size from high to low valley.

Another example is the farmhouse – the *casa colonica* - typical of the Piedmont hills, the lower Veneto, Emilia, Tuscany, Marche and of many South areas. In this case, buildings had a unique fabric and were isolated only the pigsty, the oven, the chicken coop and shed a few. On the ground floor were the kitchen and deposits, to the first floor bedrooms.

The case of Emilia Romagna is particular, in fact, the environmental variety has made possible the emergence of human settlements very different between them. In the area of Imola-Faenza, the house is a courtyard, built with blocks of chalk, while in other areas is a threshing floor, built with adobe bricks and river pebbles and sometimes in blocks of conglomerate stone.

In the northern Lazio, in the Maremma and Tuscany, developed sharecropping. In 1400 the large estates were divided into many small farms, where the farmer paid the landlord with some of the goods of the earth. The home-based company of the sharecropper, in a dominant position respect to the farm, and sometimes enriched by architectural models such as citizen, tried to provide as much as possible to the maintenance of family farming, producing his own corn, wine and oil.

The first Tuscan country houses dating back to the sixteenth century, were usually built in correspondence of existing isolated fortifications. These, usually made of stone or brick, often had two or more levels, with the roof covered with brick tiles. To the north there were spaces for the chicken coop, stables for cattle and pig sty. Inside the farm were also oven, well, wine and olive presses, and sometimes even the furnace.

In the islands and in southern, *latifundia*, the large estates of nobility and church, was characterized by the cultivation of extensive type. The owner of the funds often resided in the city and entrusted to an administrator the management of land. South territories have, for reasons related to the above, extensions much larger than those in the center and north of Italy. In large cereal and pastoral of the South and Sicily it is common continuous grouping of all the buildings around the house of the conductor.

1.3 Agricultural lands: relationship with the modern economy

The rural house "is first of all the point of reference and identification of a certain company, its core function: and therefore is a summary of what takes place in the company. You can categorically say that the company is reflected in it: both with its agronomic organization and with its production and management relationship" (Gambi 1976). The agricultural scenery is, physically, large part of the Italian territory as well as a very important system both from the architectural, cultural and economic point of view. Throughout the nineteenth century Italy remained essentially rural. At the time of Unity, about 70% of the population was engaged in agricultural activities.

In the modern period, particularly after the Second World War, the politics of urbanization has led to a rapid depopulation of the countryside with consequent nutritional needs of the population against a diminishing agricultural laborers. This has led to overfishing of some areas and the progressive abandonment of the remaining (mostly in terms of size). In recent decades, attention to form, materials and rationality of the buildings, was replaced by the building of low-cost little inserted into the rural landscape.

Fig. 3: Plans at present of the ground floor, first floor and roof.

Unfortunately, in an already so critical context, the local government did not support the agricultural areas with an initial lack of interest of the farm buildings and a subsequent “wild” liberalization of recovery permits of old farm buildings that are now often small rural “condos” with questionable results from the architectural point of view and which are not reintegrated into a broader economic context. Recovery of rural buildings should be included in a redevelopment plan for the campaign and restocking of small villages; old farm buildings should be recuperated in accordance with their architectural, functional and contextual characteristics.

2. The Sicilian case

Historically, the dominant form of rural settlement in Sicily has been the *latifundium*: a widely large agricultural land, usually poorly cultivated and used in extensive crops often alternate to grazing, led by landowners who lived away from their lands and resided in the city. 1950's are marked by the *agrarian reform*, which imposed the expropriation of a large number of estates to divide them into smaller properties in favor of the peasants. The plan, however, did not favor the emergence of companies organized according to modern standards and instead created a large number of plots so small as to be just sufficient for the subsistence of small farmers. In these years was started the industrial development of the country through the Marshall Plan aid, and between 1954 and 1963 took place the so-called economic miracle that in a few years led Italy to become one of the major industrialized countries in the world. Since the reform, the *latifundium* has been gradually disappearing until no longer exist today, and it came to the progressive marginalization of agriculture and agricultural labor.

2.1 The shapes of the Sicilian architecture

The typical rural house has always been in masonry, in most cases to very simple structure. The more modest houses, those of the so-called “*viddanu*” were originally single cell, in which all the essential functions of housing, shelter animals, and storage, were conveyed. These houses no longer exist, in part because they have collapsed, in part because they have been modified and elevated. Instead, the wealthy farmer's house has retained its original character over time. He, known as “*burgisi*,” possessed of an estate of a certain size and possessed cattle. This type of housing differs from area to area. In Catania, it consisted of two or three rooms on the ground floor, one of which is used as a warehouse and deposit for the wagon and characterized by a large arched door.

Fig. 4: Photographs at present: north prospectus, chapel and between the two fabrics.

Fig. 5: Study sketch of the new essences park.

Trapani's burgisi home was generally two-storey, with the deposit for the wagon, kitchen, stables and stores on the ground floor and the room upstairs. Even in the area of Messina the house has more than one floor. A common feature to the whole Sicilian architecture is the rational use of spaces: various lockers were made in the walls and the tools were often hung on the wall. Common to many rural dwellings, is the cover with woven reeds and lying on the wooden beams on which were placed the tiles of clay.

The houses of the Sicilian countryside reflect the peculiarities of the environment. To better attune with the look of the agricultural landscape is probably the home country of western Sicily, almost always without plaster and built with materials from the bystanders quarries. In the Sicilian countryside, however, we also find homes that have nothing to rural areas. For example, the architectural elements of the mansions of eastern Sicily are derived from urban, particularly those from Catania and Ragusa where the owners spent half of the year.

The differences between the true rural dwellings are very pronounced depending on the areas considered. In the area of Pantelleria, the "*dammusi*", stone buildings with vaulted ceiling, were very characteristics. Particular were also the typical houses of the Aeolian Islands with regular mass and a terrace roof, representative of the Mediterranean areas. The *baglio* of Trapani, since the seventeenth century, had a dominant role in the urbanization in scattered houses; it consists of a large square-shaped building that surrounds a large open courtyard called "*bagghiu*" around which there were functional buildings (stables, warehouses, storage) and dominant was the manor house and chapel. After the agrarian reform many of them have hosted the first factories that produced the Marsala wine. Very similar to the structure of the *baglio* is the *masseria* with the same lack of homogeneity of its buildings and the appearance of a fortress. This is the only form of block present in all the provinces of Sicily. The Sicilian rural architecture, thanks to its variety, can therefore be considered as an encyclopedia of the history of all the civilizations that have ruled the island, from which you can take shapes, architectural elements and techniques, which are essential for the development of a new kind of contemporary architecture.

2.2 Materials and construction techniques

The study of masonry techniques of rural dwellings is useful to reconstruct the local customs, social and geographical characteristics, the nature of the construction materials and processes, from installation, to finishes. The attention to the historical architecture and for its preservation is essential to prevent demolition, replacement and restoration in style which break with the Sicilian history. The study of techniques becomes, therefore, a further advance knowledge at the service of the conservation and is essential as a preliminary diagnostic phase. To know the distribution of voids within a wall section or the number of garments that form a structure, is a fundamental indication to intervene with an appropriate consolidation.

In the rural buildings type, the facing wall varies in accord to the kind of material that offers the area. The system with squared elements is often used when easily machinable materials are nearby available. The differences in the use of building materials, especially affecting the choice of technique to be used. Commonly, around the island, there is the adoption of the wall texture in squared rows but in the area between Messina and Catania, the squared masonry is replaced by the mixed one. The walls are built with carved elements of variable size in height. The elements used do not comply with standard sizes but vary in order to allow a greater economy in the shipyard, allowing the recovery of more modest pieces of material.

The types of masonry are many: with *square blocks* used for the entire prospectus and often left to face view, with *mixed elements* such as blanks built with fragments of brick or river stone and almost always plastered, or the more modest homes walls made of stone combined with mud. The square stone was also used for hollow masonry and was often used, with other irregular elements, to compose the inner face of the walls that were expected plastered. The foundations were deep and rested on a strong ground. The average thickness of the walls was between 50 and 70 centimeters.

Fig. 6: Photorealistic image of the overall project.

3. Case history: restoration and reuse project of an eighteen century country house in Casalvecchio Siculo (Messina-Sicily) and realization of a farm holiday center

In reference to the above, the project aims to work on a farmhouse in Casalvecchio Siculo, a small medieval village in eastern Sicily, in the province of Messina. The restoration of the building aims to the recovery of historic property, dating back to the late eighteenth century, particularly interesting from a historical and formal point of view. Typical of rural dwellings that have changed over time, even in this case there is the aggregation of original cells with more recent others that have occurred over the course of two centuries, and it was decided to preserve as a witness of the historical events that have influenced the current shape of the building and the succession of the different construction techniques and new materials.

The project main goal is the creation of a productive, educative and touristic center. For this reason it was decided to restore the old features, such as wine production, and integrate them with new ones, respecting the traditions of the area and its agricultural characteristics. The massive presence of citrus trees on the property, which are currently untapped, inspired the production of citrus liqueurs, such as limoncello, typical of Sicily. The plan expected to restore the oven and use the remaining spaces for the creation of stands for wine tasting tours and as a basis for external producers, in order to encourage local production. Project interventions will be designed, as much as possible, to restore and recovery the original typology through the use of construction techniques and traditional materials such as stone and wood, in agreement with the necessary safety adjustments of the artifacts.

3.1 History of Casalvecchio Siculo

Casalvecchio Siculo is a small village with 887 inhabitants in the province of Messina in Sicily. Located on Mount St. Elias at 370 meters above sea level, the village is 39 kilometers far from Messina, 5 from Taormina and 20 from the *Ionian coast*. According to the topography, the country has typical medieval features, with a succession of narrow streets that intersect themselves and unfold in underpasses typical of medieval Spanish and Arabic.

Casalvecchio is very ancient: it already existed in the Byzantine era with its Greek name *Palachorion* that mean “old farmhouse” or, in Italian language, “*vecchio casale*”. The country has achieved a remarkable demographic growth up to the 1930’s when there were almost 5000 inhabitants. Subsequently, some of its fractions were removed. Therefore, the village underwent a progressive reduction in the number of inhabitants for a process of emigration due to lack of work. Periodically, during the summer, Casalvecchio is repopulated thanks to the return of migrants.

The site of Casalvecchio, that is one of the most charming little town along the Ionian coast of Sicily, has a strong tourist destination, thanks to its breathtaking views and its particular natural value. Casalvecchio is a great tourist destination and it is suitable for hosting important events and it is able to integrate with the surroundings and constitute a source of great curiosity for tourists. Therefore, as part of the restoration of the rural house, new structures have been designed to integrate the original ones, to give birth to a farm holiday center.

3.2 Analysis of the building type

The country house consists of two buildings, the first, which has one level, had productive and remittance use, the second had residential purposes. The building, dating from the late eighteenth century, with additions dating from the Second World War, has a *slope house* typology (*casa di pendio*). This is a typical form of rural settlement, both spread and centralized, which uses the slope of the ground to eliminate the staircase connecting between the two floors of the building. The house is

above the rustication which included the oven and wineries. In front of the main building there is a second fabric, similar sized, with the fold, the stables, the barn, the drying and the production of wine. Fold and barn exploit the slope of the land having, the first, the entrance to the valley, and, the second, on the mountain side, with a gabled roof and small windows. The main fabric also includes a chapel containing niches for dead people, used until 1806, the year of the entry into force, in Italy, of Napoleonic edict of Saint Cloud that prevented the burial of the dead within the city walls. Interesting feature of the building is the rational use of spaces; there are several lockers, made in the walls, in many rooms. Another feature of the house is the presence of large outdoor spaces, that were exploited through a circle columned structure originally covered by a pergola, now collapsed, used as a resting place during the summer.

The compartments are delimited by load-bearing walls with a thickness of 55 cm; the division of the interior is made with light partitions in wooden barrels, covered with rough coat of plaster and finishing, structurally independent from the masonry. The walls of the facades have many openings, especially in the one level building, to allow access (usually a separate access from the ground floor and first floor) and to give adequate lighting to interior compartments – conversely, interior walls have few openings between rooms. The productive building has five cells, two of which are added after 1945 - four rooms have their own entrance in order to witness the functional differentiation between them. Additions have a lower internal height than the historic building. Therefore, in this structure, we can find: to the east, two adjoining *stables* with masonry mangers; to the south, a *room for pressing grapes* which contain a large masonry tank connected to a smaller pool of circular shape, in which flowed the wine must; to the west, a *depot* and a *drying room* with a separate entrance. Outside there is a brick and concrete small structure used as a *chicken coop*. The second building, on two floors, includes different functions. It contains - according to oral sources and by analyzing the type of construction and materials – a stratigraphy of additions over time. At the ground floor, from nearest to farthest respect the main entrance of the building, to the north, there are: an independent room of which we do not know the original function; the masonry *oven*; a four rooms *residence*, is a state of decay because of the collapse of roof; next to it there is the *wine cellar* and another room probably served as a *warehouse* and the *chapel*. The main entrance of the first floor is on the opposite side respect the ground level and it is accessed by an external staircase. Here there is a second residence, probably the manor house, consists of 7 rooms including entrance hall, kitchen, two bedrooms, a bathroom (added in 1950 approximately) and a lounge and with two balconies (south and east). Outside there is another compartment of which the function is unknown and probably, originally, flanked by another local, now collapsed.

From the structural point of view, foundation is probably deep and rest on a resistant ground. The thickness of the walls is between fifty sixty centimeters. The walls are entirely structural, mixed and double row, with transverse elements of connection. It consists of a large stone blocks base arranged horizontally to a height of about 50 centimeters beyond which the stones become smaller and are integrated with bricks, either whole or in fragments and with pebbles. The masonry is tied with lime mortar. At the openings, both windows and doors, there is a strengthening through frames of solid bricks. The mostly used stone for decorative details exterior is *yellow sandstone*.

Fig. 7: Photorealistic images of the restoration of the existing building, new stables and horse boxes, bar-restaurant and new room buildings.

Fig. 8: Example of the possible routes: educational, hiking trail and eno-gastronomic.

3.3 Analysis of the degradation and restoration

The building has a widespread degradation that involves the walls, the roof and the windows. The set of degradations and failures detected is mainly due to lack of maintenance. The house is abandoned for nearly fifty years and the progressive degradation caused a partial loss of the roof and of the floor of the second level. In addition, because of the malfunction and the partial lack of drainage channels that led to the decay of the supporting structure of the roof, over time, slight cracks were formed in the walls, and a masonry collapsed. On the outer surface of the facades, the lack of maintenance has caused, locally, the disintegration of the plaster, and when the latter failed, the disintegration of the joints and the progressive loss of mortar and elements of integration (brick, pebbles) between the stones of the masonry. The main actions that are planned for the restoration are: the reconstruction of parts of the floor, walls and roof collapsed, the integration and consolidation of the support plates of the shell, and the consolidation of the wood and iron fixtures.

3.4 The reuse project: expectation about its impact on the area

The reuse project involves the restoration of the original house that will include local for wine production, wine cellars, furnace and production of citrus fruit liquors such as limoncello and mandarinello. These activities will be supported by educational paths and hiking trails, and for this reason, in the historical building will be located offices, information center, bicycle rental and hiking equipment. There will be a small excavation of 2 x 5 meters in the entrance hall in accord to the placement of stairways and elevators, before non-compliant, for the upper level access. The new buildings consist of 8 new fabric that contain 10 rooms for overnight, oriented according sunshine/shading, ventilation and the enjoyment of the view of the landscape; each room is served by a small patio sheltered by sliding brise-soleil panels. Another part of the project involves the construction of the bar-restaurant with 70 seats inside and 150 outside, with an adjoining office. There will be a park of essences, with tree-lined avenues, each of which will have a different tree species. Within the park there will be shelters and portals made of COR-TEN steel. The stables are designed away from the center, in addition to the barn I plan stalls for horses and horse riding. The other activities planned for integration of these routes are bike rental and hiking equipment. The residences will be restored and integrated with new rooms with separate entrance, included in the new park and they will be serviced by a bar-restaurant. The chapel will retain its original use. The projects of the barn, stables and citrus storage consist of very simple volumes: the brise-soleil system entirely covers the buildings, creating a sort of boxes. These are closed at the bottom by perimeter walls that are interrupted up to 3 meters in height; at this point the wall is interrupted and the structure of wooden beams continues to support only the brise soleil which leave the top of the buildings completely open, in order to favor ventilation and the passage of natural light. The stable consists of the stockyard, the tool sheds and the barn. The citrus storage consists of a large open area and a office. The particularity of the brise-soleil band, open to the top, allows, in addition to natural ventilation also the passage of light from the outside to inside and reverse - the interior lighting, in fact, is visible on the outside of the buildings making them illuminated boxes during the night.

4. Conclusions: objectives and expected results

This project is an expedient that start from the restoration of a farmhouse with its area of relevance to fit into a broader context of urban redevelopment of a historic city such as Casalvecchio Siculo. We expected that the restoration of the old production functions can be a base for small local producers, now disunited and with little chance of expansion, for a more united development that spreads like wildfire and can allow a pleasant village to become a strong touristic attraction – a village that can offer not only its natural beauty, but also cultural tours and small excellence productive activities, exploiting the agricultural products of very high quality, offering by a rich territory like Sicily. Even if the project intervenes on a specific building, it wants, however, to be an attempt to integrate the wide surrounding area. It is a basis for cooperation between operators in the region, whether they are

farmers, small producers, local and municipal authorities. Specifically, the functions of the old and new tourism center will convey into three main *routes* in order to offer a big range of targeted services and that, in this case, I will use to better illustrate the real purpose of the plan.

The first of the three paths is *educational*, that is targeted to both tourists and the many schools in the district. It is run from the new stables and horse riding, continues with a visit to the production places (processing citrus fruit, wine, cheese and oven), to finish to the essences park in which there are small ways flanked by several native species of trees. The main purpose of the route is to provide an alternative education for children in the area, who have few opportunities to enjoy nature, that can be instructive, challenging and fun at the same time. The second is the *hiking trail*: riding, cycling and walking; inside the farm was expected, in fact, the hire of mountain bike, and hiking equipment. This type of activity also involves the remaining inter-municipal territory, in fact the historical centers of the main towns of the area can be easily reached, so these tours range from the natural to the historical territories. Finally we have the *eno-gastronomic* route of the products of the farm (wine, citrus marmalade, limoncello, bread, cheese), it use the considerable spaces of the farm to include a stand area that can be used by local producers to advertise their products. In conclusion, this intervention is not isolated but is part of a rich territory from a historical and productive point of view, but that is today, unfortunately, underused. The project, of course, may not contain all the useful functions to the economic recovery of the area but it want to give an example from which the area can start for a wider program of planning – an intervention which going to affect growing parts of the territory in order to create, in collaboration with stakeholders, a large scale plan that allows an economic recovery but that does not distort the intrinsic characteristics of Sicily.

Abstract

A work in progress for the establishment of the Museum of the City of Reggio Calabria according to the use of methods, techniques and tools for digital documentation of cultural heritage represented by fragments of pre-earthquake Reggio, from the National Archaeological Museum, given in custody to the Mediterranean University of Reggio Calabria, on the occasion of the renovation of Piacentini building.

With the Unité Mixte de Recherche CNRS / MAP (France), the "Mediterranea" has embarked on a teaching experimental activity for a renewed idea of enhancement of the architectural and artistic heritage, with particular reference to the lost city after the earthquake of 1908 giving strength to a new professional skills in the field of communication and promotion of cultural heritage. This project was developed with the aim of collecting the fragments of a city reduced to zero by the physical and oblivion disaster, which aligns with the common notion of resilience (a concept which refers to the ability of a community to rebuild the equilibrium conditions as a result debilitating external events) and to create shares of thought and memory among individuals.

The use of experimental softwares developed by the MAP Laboratory of CNR has allowed the surveys of several stone artefacts and the subsequent processing of the acquired data aimed at the construction of interactive 3D representations for digital documentation which will form part of the exhibition project.

Keywords: memory; 3D models; virtual museum; virtual reconstruction

1. An idea to build a virtual museum of the city (FF)

In July 2013, within the framework of the European Project MIUR "Messaggeri della Conoscenza", with Livio De Luca, we shared the scientific responsibility for the educational/scientific project *Methodologies, techniques and tools for the digital documentation of built heritage* in which about twenty students of the *Mediterranea* University have experienced a detection protocol with SLR camera equipment, data processing system Tool and Acquisition Protocol for ENhancing Artifact Documentation (TAPENADE) and 3D modeling.

The procedure was applied to some fragments of Reggio before earthquake, from the National Archaeological Museum, and held in custody at the University of Reggio Calabria during the renovation of the Piacentini building.

This experience proved to be of great scientific openness to the results produced, both for the technical skills acquired digital, for communication projects for cultural heritage that have sprung up.

The field of cultural heritage is an ideal field of application for digital experiments related to the historical and archaeological heritage, and in our case involves the disciplines of visual representation and communication, aimed at creating virtual catalogs, at the museum with prototypes of parts historical heritage, achievements in anamorphic and specific sections dedicated to virtual reality and augmented reality.

The *Mediterranea* University in May 2013 has been in temporary storage, a collection of over 200 architectural pieces found or saved from demolition in the city of Reggio Calabria and the surrounding area after the earthquake of 1908. The collection of "fragments" architectural and sculptural, held until April 2013 in the holdings of the National Museum of Archaeology and unknown to most people, is now kept at the *atelier* of the former Faculty of Architecture and set up as a temporary exhibition in collaboration with the Tech Office of the University, under the direction of the Superintendent of Archaeological Heritage in the Region of Calabria. It is a heritage of Reggio's memory that emerges after a long silence to ask the attention of scholars and citizens to witness the history of the city and revive awareness of the materiality and physicality of "pieces" directly from the buildings disappeared, witnesses to the quality of architectural history and building of the city until the nineteenth century.

A set of documents that can be profitably connected and "crossed" with the cognitive data from other "fragments" of the city's history, those made from less valuable papers, drawings and projects are preserved in the Archives of State and the Historical Municipal Archives.

The collection gives an account of the relevance of a documentary heritage that reveals the potentialities of the possible interaction of the same - for the purpose of historiography that museological - with material evidence architectures disappeared. The series of exhibits is due to urban history from the sixteenth century, both the architectural and sculptural elements that graphic testimony and documentary Reggio stem primarily from the late-eighteenth and nineteenth centuries built after the earthquake of 1783.

Taking this opportunity, presents itself today the opportunity to study with more knowledge of the history of town planning and building cities, leading to a true reconstruction "virtual" Reggio before 1908, and, above all, the creation of a true Museum of the city, assisted by a virtual catalog of the pieces recovered.

Fig. 1: A neighborhood of Reggio in an image after December 1908

To Reggio Calabria, a *Museum of the city* should aim to collect the fragments of a city reduced to zero by the disaster by the disaster and physical oblivion , an event of enormous scope that was accomplished in a period of a few minutes and that changed that part of the world that would never be the same again.

The earthquake of Reggio and Messina, more than a hundred years after its occurrence , it reads like the paradigm of discontinuity and loss of memory that seems to afflict modern man , and particularly for this section to design a virtual disappearance of the city , it means creating a documentation center and orientation of cultural tourism , it means a place devoted to the city on the city, what was there and that does not exist today if not through those fragments with a careful reading of semantics can be re- arranged in a spatial dialogue capable of giving thickness town living. A pole documentary and public dissemination of culture, a place of identification and selection , by the scholar , or the lover of the tourist places to visit and discover virtually. The realization of the survey and modeling of the findings of the destroyed city also arises as a starting point to help change the approach to culture and knowledge for all citizens, particularly, for example, the teaching of cultural heritage in connection with educational institutions and universities that will use structured pathways to areas accessible through the use of interactive multimedia equipment.

Fig. 2: Phases of acquisition of a photographic exhibit

One hundred years later, the architecture that has reshaped the face of the city destroyed, and perhaps even the soul, has always maintained a bond that postpones housing to those organizations that had settled over the centuries and that the earthquake has cleared. The bodies of the city (which is lost reconstructed) describe the morphology of the territory and the new image that you have set up, compared to the old one, highlights the inevitable differences for a reconstructed identity. The catastrophe in this way can be interpreted rather than a point of failure or crisis as a turning point or new opening phrase . The reconstruction of Reggio and Messina formed inevitably an opportunity to review the strength of local identities , to address his injuries and the laborious reconstruction, to put in the yard of the a-seismic houses construction techniques and new technology of reinforced concrete, the urban conceptions population centers, but - much more difficult and require - the restoration of memory and identity of places.

This ability to find a positive reactive power, able to recover memory and regeneration, aligns with the common idea of resilience, a concept that refers to the ability of a community to rebuild the equilibrium conditions as a result of external events in order to create debilitating shares thought and memory among individuals and groups protagonists of constructive changes in contemporary society and therefore the virtual museum is part of this good practice giving strength to a new professional skills in the field of communication and promotion of cultural heritage. The use of experimental software developed by the MAP Laboratory of CNR has allowed the survey of several stone artefacts and the subsequent processing of the acquired data aimed at the construction of interactive 3D representations for digital documentation which will form part of the exhibition project.

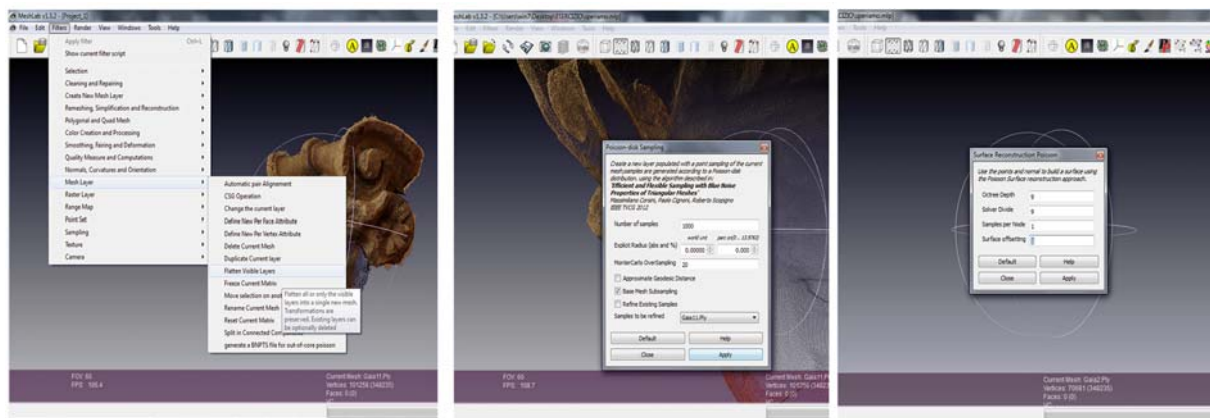

Fig. 3 / 4: Stages of development of the model and its representation of the overall (student A. Balestrieri)

2. Experimental methodologies and tools (LDL)

With the aim to assist this project from a methodological and technological point of view, CNRS MAP laboratory is providing experimental solutions for the digital surveying, modelling, structuring and representation of the studied artefacts. Our contribution starts from the idea that even if today one can use new (and sophisticated) tools, specific requirements coming from the architectural documentation and conservation fields remain and need the development of “intelligible” representations. In this sense, the alignment of the emerging techniques to the conventional codes of the architectural representation is a main issue of our approach. In this way, an important issue of our approach aims to introduce a methodological dimension able to bringing out the importance of the “interpretation” of the geometric nature of architectural shapes. This purpose is firstly oriented to the definition of relevant techniques of spatial data acquisition, geometric description and visual and semantic enrichment (see sections 2.1 and 2.2). A second issue relates to the architectural documentation (see sections 2.3) and the development of informative systems at an architectural scale. We consider that digital models can be used as “interfaces” for accessing to various kinds of cultural heritage data: firstly, the ones related to the building current state, secondly, the ones related to its geometry interpretation and finally, the ones concerning the formulation of assumptions on its past states.

2.1 Acquisition protocols for automated Image-based-modeling

With recent advances in automatic processing of photographs, several solutions are available today to automatically generate 3D point clouds from a set of non-oriented images [Bundler; Microsoft Photosynth; Autodesk 123D catch; ARC3D]. These solutions are mainly based on computer vision methods and allow the production of 3D representations also starting from images acquired by non-experts (without knowledge on photogrammetry). While providing access to some satisfactory results from a visual point of view, these solutions have the major disadvantage of the overall reliability of their metric results [Remondino et al., 2012]. Nevertheless, in the field of cultural heritage, the strong geometric and visual consistence of a 3D representation is an essential condition for the documentation and analysis of heritage artefacts. Within the framework of the [Culture 3D Clouds] project (a cloud computing platform for 3D digitization, documentation, preservation and dissemination of heritage artefacts), the CNRS MAP laboratory, in collaboration with IGN, INRIA and Telecom ParisTech, is coordinating the development of image-based acquisition protocols for the accurate and effective 3D reconstruction of cultural objects. Unlike the approaches mentioned above, mainly based on the identification of general rules for image acquisition (overall acquisition configuration, image overlapping, etc..), the general approach that leads the development of these image processing procedures is based on the analysis and classification of several types of artefacts (buildings, facades, interiors, bas-reliefs, sculptures, etc.) as well as of several graphical representation purposes (sparse and dense point clouds, textured meshes, orthophotography, etc.). For each specific acquisition protocol, an automated processing workflow is developed, by defining an ideal setting for camera calibration, bundle adjustment, multi-view stereo correlation, surface generation and visual enrichment [Martin-Beaumont et al., 2013].

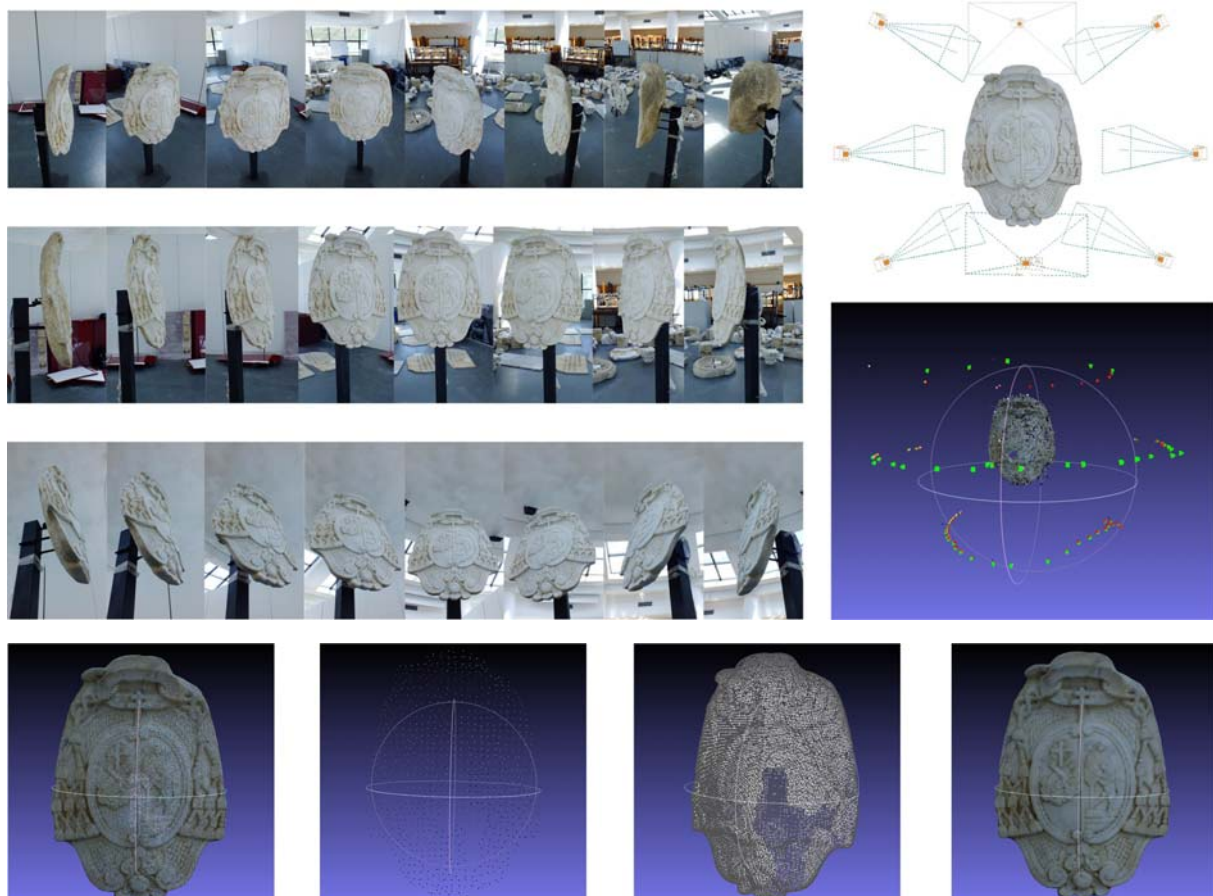

Fig. 6: Surveying project (student M.G.I. Bruno)

2.2 Reasoning from semantics to geometry and vice-versa

The introduction of new acquisition and processing protocols has given rise to new research perspectives. The opportunity to combine records, geometric analysis and characterisations about several artefacts could also be used for developing new approaches for shape classification and interpretation. The availability of flexible solutions for collecting morphological data on masses of

artefacts allow considering the shape analysis as a fundamental moment for reasoning about the relationships between geometry and semantics and in a bidirectional analysis approach.

In the first case (from semantics to geometry), the idea is to explore ways to insert architectural semantics within the surveying procedures, by associating them with dimensional information [De Luca et al., 2007]. This would allow an immediate reading of dimensional parameters corresponding to architectural concepts that characterize the artefact. This kind of approach can provide great advantages in the 3D reconstruction process. A correct (and knowledge-based) interpretation of data prevents the production of unrealistic architectural shapes and would provide models linked to specific vocabularies and grammars. In this context, significant efforts on formalizing typical architectural elements can be carried out, including the study and re-interpretation (in the context of the digital modelling domain) of architectural treatises (description of typical shapes, compositional rules, constraints of positioning and orientation, principles of scaling, etc..).

In the second case (from geometry to semantics) it's necessary to investigate solutions for the shape segmentation but also the issues related to semantic annotation. We recently started working on a shape analysis method combining a bottom-up approach [Lo Buglio et al., 2013], in which the meaning of the elements comes from the combination of a low-level, and a top-down morphological analysis, which takes advantage of pre-structured knowledge. This kind of approach is therefore based on the identification of generic models that can integrate multiple instances (e.g. objects belonging to the same stylistic trend) by bringing out common morphological features by means of the identification of semantic /geometric classes.

Fig. 7: Steps of the protocol (student R. Idone Cassone)

2.3 Semantic-driven structuring of 2D/3D/4D representations

With the aim of designing a methodological framework for the representation of buildings based on their morphological description, we introduced the principle of point of view as a concept determining the structuring of semantically-enriched 3D models [De Luca et al., 2007]. A point of view includes three aspects: the use of a vocabulary to isolate elements from the building; the identification of a relevant logic for the regrouping of these elements in a coherent unit; the choice of a type of representation able to extract from the gathered data the information necessary to the analysis. In line with these principles, we build around the morphology of the building a description model defined by three distinct levels: semantics, structure and representation. This three-levels description confers an important degree of freedom in the exploitation of the data resulting from the surveying

phase: starting from the same geometrical model, one can work out various semantic descriptions by exploiting a multi-representations system. Moreover, our model of description is not only used for the structuring of the three-dimensional model and its possible representations, but may become the common denominator for the establishment of bilateral relationships between the morphology of the object and heterogeneous documentary sources. By basing on the definition of this model of description, we started the [NUBES Project] that focuses on the development of an information system at the scale of architecture [De Luca et al., 2011], taking into account the relations that can be established between the 3D representation of historic buildings (shape, dimension, state of conservation, hypothetical restitution) and heterogeneous data concerning various domains (such as the technical, the documentary or still the historical one). The main purpose of this project is to allow users to organise multiple representations (and associated heterogeneous data) around a semantic description model with the goal of defining a web information system for the multi-disciplinary analysis of heritage buildings. The NUBES platform will be used within the framework of this collaboration as a general web database for collecting, annotating, enriching and presenting the results of this on-going project on the Museum of Reggio Calabria.

BUILDING INFORMATION MODELING FOR STRUCTURES

Ingrid TITOMANLIO

Department of Architecture and Industrial Design, Second University of Naples, Aversa (CE), ITALY
ingrid.titomanlio@unina2.it

Abstract

The computerized graphic software, takes over to the old method of hand graphic drawings. Now, thanks to the Building Information Modeling methodology, the different professionals involved in a project, can interact during the phase of ideation, planning, computation, structural analysis and realization of a work.

Using B.I.M., the exchange and the acquisition of information becomes easier. The target of this paper is the analysis of the integrated and structural planning, which represents the foundation for the success of a design project. The actually legislation about technical, imposes the need to operate in a multi-tasking environment.

The designer interfaces with the structural and plan engineers and with the employer to face the preliminary work before it starts. The virtual realization of a plan, through the 3D model is important to make visible an object, before to make it concrete, studying its plant design, its spatial, functional, morphological, and structural dimension, and, of course, its aesthetic.

On the B.I.M. model working, in concrete, the competences of several professionals who cooperate to the same target (for example, the planning of a new work or the recovery of the current one) and the methodology mix the 3D representation with the structural data.

In this paper it will be analyzed the interaction between the structural analysis and the virtual representation field.

Keywords: Building information modeling, structures, structural analysis

1. Introduction

Since 1800 in Europe the structural engineering theory was developed. It was a discipline different by the architecture understood as aesthetic representation of buildings. Only in modern times it lost the dualism between these two disciplines: representation and structures.

They began to penetrate each one into another one and they become both indispensable for the success of a quality architectural design.

The architecture discipline adds to its historical significance also that relative to the structural parts of the building and the engineering discipline adds to its known significance, the formal aspect of the architectural structures.

The knowledge evolution of the constructions techniques and building materials has led to the formulation of appropriate software for the calculation and verification of structural seismic response of buildings. By using sophisticated software for structural modeling, it gets to predict the impact of the earthquake on the buildings. This system is part of the building information modeling methodology.

By B.I.M. model, the materials, the shapes, the spaces, and especially the relationships between parts of a building are represented.

Creating a single working platform, the architecture and engineering disciplines involved in one building design began to talk the same language.

It was created a knowledge network able to share in real time the technical data of the building to the different actors involved in the design process.

The interaction between the structural, the functional and the aesthetic elements into modern design software, represents a serious challenge for many graphic programs, but B.I.M. differs from the others one thanks to its ability to compare and interchange data. Structural computation programs have interfaced with graphics programs just after B.I.M. creation.

The method developed is able to working different players on a single computerized platform. Data entered shall respect all common features present in simple 2D graphics programs, up to the most advanced structural calculation [1].

The B.I.M. model exceeds the simple graphical representation of structure in three dimensions.

The older defined a B.I.M. like this: "B.I.M. is a software application, for some it is a process for designing and documenting the building information, for others, it is a new approach to practice and advancing the profession which requires the implementation of new policies, contracts and relationships between project stakeholders".

The most recent definition of B.I.M. is "a model of virtual intelligence able to build in 3D. An intelligent format that can be used to develop constructive solutions to optimized risk reduction and to increase the value before committing a design proposal focuses on the design perspective" (Woo et al., 2010)

But the official definition credited to the National Building Information Modeling Standards (NBIMS) is:

" ... A digital representation of physical and functional characteristics of a facility. B.I.M. is a shared knowledge resource for information about a facility, forming a reliable basis for decisions during its life cycle, defined as existing from the first conception to demolition. B.I.M. is a shared digital representation founded on open standards for interoperability. A basic premise of B.I.M. is collaboration with different actors at different stages of the life cycle of a facility to insert, extract, update or modify the information in the B.I.M., to support and reflect the roles that stakeholders ..." (NBIMS, 2007) .

In this paper it creates the opportunity for two disciplines such as representation and structures to find an efficient and common connection point. The B.I.M. platform is able to answer, at the same time, to the architectural and structural needs.

2. Building Information Modeling

Jerry Laiserin popularized and standardized the term B.I.M. as a common name for the digital representation for constructions. In 1987 the GraphiSoft already identified this technology as "Virtual Building". Later Bentley Systems named it "model of integrated projects" and Autodesk as "Building Information Modeling" (Figure 1).The B.I.M. as Computer aided modeling is an innovative way to manage the project.

Fig. 1: Example of school building virtual design by Ingrid Titomanlio

Building Information modeling methodology starting from the digital graphic representation in three dimensions of the construction is able to arrive to the management processes of the model, production, communication and structural analysis.

Each one of building components contain parametric data that describe the attribute included in 3D model process.

If one of building component change, every part of the design linked to that will change.

The benefits create by using B.I.M. platform is because several databases are interface and connect together.

The actors are involved in the design process and they can simulate the negative or positive interactions and to interchange the data.

On B.I.M. platform, each element is drawn, not with simple lines, but with structural elements; geographically, spatially and quantitatively characterized, as well as, by geometrical lengths, thickness, volume, materials, lighting, stamina a.s.o....

This methodology has advantages: it avoids mistakes, the constructive elements are drawn only once and they can visualized in all views, if you make a change during a processing phase, it automatically modifies the element in all views that it is generated.

Comparing the traditional approach to the design and the B.I.M. method, it is observed that the first one visualized the building elements as vectorized lines geometrically represented but the second one adds to this characteristic the economic and textural attributes.

By using B.I.M. process there is not loss of data during the design phase and it can be visualize the building vulnerability in three dimensions [2].

In Europe facilitates the management of contemporary design and it is a multi-disciplinary approach to facilitate the identification of the spatial geometry, of the surveying, and about the quality and quantity of materials building components (Figure 2).

Fig. 2: Architectural BIM modeling Belgrade Plaza, Coventry, UK - by XSCAD work.

3. B.I.M. and structures field

The B.I.M. method definition is not universally accepted by scientific society that have different point of view about this technique.

In 2007 the GSA (General Services Administration) published this definition ... "Building Information Modeling is the development and use of a multi-faceted computer software data only to document a building design, but to simulate the construction and operation of a new facility or a recapitalized capital (modernized) structure. The resulting Building Information Model is a data-rich, object-based intelligent digital representation and Parametric structure, which sees adapted to the various needs of users can be extracted and analyzed to generate feedback and improvement of the design structure." The development of the technology has increased the need to enlarge the knowledge design field and to improve the connection between different skills to create a virtual multiple dimensions design [3].

To introduce the B.I.M. methodology in structures fields is experimental research experience.

The B.I.M. is the link ringing between the representation and structures fields.

Thought this model, each building structural elements are related to each other and the final design is an integrated solution of different disciplines (history, structures, representation, environment).

The platform on which different competences work on is unique. One element is visualized at the same time by structural skill and by representation skill [4].

The process in three dimensions is planned with all the elements which change information, in order to adapt the geometric survey of structures to the model for the numerical analysis (Figure 3).

In the knowledge process, the first step together with the historic phase is the survey.

Today by using laser scanner equipment, the building survey is become very good.

From the structural point of view, a building can also be known during the inspections, and the data to record are different than the simple relief of the geometric state.

Detecting the roof of a building, it is necessary to write down the geometric data, in the plane, and in thickness, to identify the thickness of the various components of the roof, the quality of the material which it is made, the role of the roof (terrace, support, partition and the existing connection between this element with other structural parts of the building).

It is very important to proceed to acquired correct information to realize the digital structural model.

The right approach doesn't start only from geometric data detected.

Data entry requires an high level of concentration. Several technicians who work to the same project, can work simultaneously on local models stored on their computers, updating them periodically with an up - to - date information from the central model. This phenomenon is named cloud computing, in which data, and therefore the software, resides in a remote location. The technical staff access to the template and use cloud-based design software as a service (SaaS) to work on it.

The data detected in situ are important for the purpose of a structural model, to prepare a linear or nonlinear analysis, and to evaluate the influence of the confidence factors (related to knowledge levels LC1, LC2 and LC3 that reduce the average values of strength of materials construction).

Fig. 3: Structural model – King Barbaro Palace in Porto Torres - Italy

To investigate the entire building and to store more data for 3D structural model, the laser scanner technique is not enough. It is necessary to implement the knowledge phase by using non-destructive equipment such as ground penetrating radar, the cover-meter, thermo-cam, endoscopic, sonic and ultrasonic penetration and if it is required and it is possible, undertake to destructive investigations. It proceed with the input process definition to study structural system when the geometric data is ended.

The impact of the forces on the structure and the mechanical connection that describe the mechanical acting of the material are expressed by mathematical model.

In this step, the B.I.M. become very important because emerges over traditional CAD approach and give to each structural element a complex identity.

4. Structural modeling

To evaluate the performance of buildings and to harness a range of useful information for the purposes of architectural choices, man designer adopt the digital modeling technique.

The structural model of building allows to obtain feedback on various assumptions on the design and during different stages.

The parametric modeling allows the technician to make to enter modifies in order to make the result efficient.

The correct representation of the structural elements of building is important because on cultural heritage and on the high complexity buildings is not sufficient to draw up a linear analysis but it is required non-linear procedures based on the comparison between the seismic demand and the capacity of building in terms of displacement.

The knowledge phase is the first step on which is based the process of structural modeling.

When the overview of results of all investigation are compare, the project coordinator choices the best design solution that has the benefits of all the disciplinary approach.

Before to realize the construction, it is fundamental to schematize and to analyze the structural model (Figure 4) by using B.I.M. methodology [5].

Traditionally, the structures of architectural and interior design objects were digitally represented by the CAD in two and three dimensions by lines and curves subsequently extruded.

These systems represent the structure as a geometry independent of the reference environment.

Today, with the data models "object based", structures modeled also describe entities that are intangible with CAD; for example, the costs, the concept of a gap in the area and, such as accident or acoustic insulation, energy loss of the building [6].

The survey as geometric representation is only a feature of many others contained within a structural model. If the use of traditional CAD geometry data is considered, anyone realizes that the information is insufficient to define geometrically a structural model. All phases, thanks to the B.I.M. system are accompanied by various and consistent documentation and which also fit in the economic field, in terms of calculating the actual costs, spending on the construction of the work and the amount of financial resources for the maintenance of the same.

Fig. 4: Structural model – Teti Maffuccini Palace in Santa Maria Capua Vetere - Italy

The Building Information model is able to represent a such quantity of information of building targeted to one specific purpose (structural analysis, environmental impact analysis or energy, acoustic analysis, cost analysis, a.s.o....).

The B.I.M. technology which facilitates the involvement of more professionals on the same project by associating these various stages of the modeling work process.

The model geometrically generated in 3 dimensions by AutoCAD, can be read by Midas/GEN, and can be taken back by AutoCAD after making changes or implementations. Without the necessary conditions to frame the B.I.M. system and when the process of structural modeling of an architectural work or a design object is started, it needs to generate a mathematical model that represents the artifact.

By the complexity of cultural heritage and modern buildings it is necessary to reduce the structural model of the architecture to the essential and thanks to the variety of the B.I.M. process, models of accuracy at different levels even to define different levels of analysis and investigation can be created. There is no single structural model but as many as are the aspects to be evaluated and for which a structural analysis, therefore, should be performed.

Generally, the structural model includes steps and data from other 3 types of models: the geometric, the loads/actions and the material/mechanical ones.

The latter is the most important because it associates the material to each structural element, and characterizes their structural behavior under loading.

5. Conclusions

The B.I.M. model presents clear advantages comparing to the Computer Aided Design method: saving money previously invested to create a prototypes, and decreasing building mistakes, as a consequence, corporate profits has risen.

Design approach is flexible, modifiable and applicable in each single stage.

The analysis of an architectural project involve many disciplines, for this reason, there are more information to manage and store. This is the input to invest in more powerful and complete equipment. 3D CAD models are viewers software and they can still be used for detailing some phases of the project, despite the central role is done by B.I.M. technology. However, this mode, must immediately be the starting point of the basic model.

Physical characteristics of a digital project are analyzed by simulations, this, helps professionals and entrepreneurs to display different and future scenarios for free. Each technician involved, can make decisions and change some characteristics of the project.

B.I.M. and Structural Modeling: Application on Cultural Heritage

Ingrid TITOMANLIO,¹ Giuseppe FAELLA²

^{1,2} Department of Architecture and Industrial Design, Second University of Naples, Aversa (CE), ITALY
ingrid.titomanlio@unina2.it¹, giuseppe.faella@unina2.it²

Abstract

The seismic safety of cultural heritage cannot be managed through the structural analysis only. First of all, the knowledge phase concerning construction technique and materials properties becomes strictly necessary. The Building Information Modeling (B.I.M.) is the concrete method allowing the peculiarities of the architectural/restoration design and the structural counterpart to be simultaneously contemplated. In fact, in the B.I.M. methodology for structures all the features of the virtual model are suitably contemplated.

In this paper, the B.I.M. for cultural heritage is dealt with, outlining its main steps (inspections, measurements and surveys, non-destructive investigations, integrated structural modeling and s.o.) and configuring the new B.I.M.4S&D methodology. The latter is shown through the application to a historic masonry building.

The numerical structural analysis of the existing masonry building is a relevant key since it must simulate what already exists and what arises from in-site testing and evaluation, avoiding falling into contradiction and trivial errors. Finite element method (FEM) is then used in the structural analysis for evaluating the safety of buildings subjected to static and seismic loads. The FEM method, in fact, is flexible and takes into account anisotropy and lack of homogeneity of masonry material. Furthermore, the finite element method lends itself to a more or less complex computerization, and it intrinsically has all the features interfaced with the digital geometric survey.

Keywords: Building Information Modeling, Structures, Cultural heritage, Structural analysis

1. Introduction

The analysis methodology of cultural heritage proposed in this paper combines the architectural representation of buildings with its structural behavior. Initially, in fact, the engineering history differently marked "skeleton" and "musculature" of building. This meant to divide the representation and the structural fields.

Today, the B.I.M. methodology allows creating a very refined and reliable structural model, which is the common pattern among building representation and structure. The technology can be applied to different types of buildings and design furniture. It manages several parameters and reduces graphic processing time [1].

Before analyzing the application to a representative existing historical building, it is necessary to introduce the needed pre-cognitive phase and highlight the support provided by survey through laser scanner in this pre-processing phase. And it must also be emphasized that not all the needed information for creating the three-dimensional structural model rises from the laser scanner survey. The level of knowledge of the geometric structure must be in fact achieved by using non-destructive testing, too. Only after these steps, the structure can be modeled and loaded, and its behavior and safety can be assessed. However, many historic structures need a most multidisciplinary approach and intervention for their retrofit, in order to prevent further damage or their loss.

This paper highlights how important is to overcome the mutual segregation between the various specialized fields, emphasizing the true concept of multidisciplinary restoration, and focusing primarily

on the relationship between representation and structure: the proposed B.I.M. 4S&D methodology acts with an inter-disciplinary approach between very different skills; and one of this is the preservation and the reuse of the building. For this aim, different professional archaeologists, historians, structural and geotechnical restorers must consequently be involved.

The use of the B.I.M.4S&D methodology in structural modeling of cultural heritage for assessing the seismic safety of masonry buildings is illustrated with reference to the Teti-Maffuccini Palace (Figure 1) in Santa Maria Capua Vetere (Italy): the details of the needed and performed analysis are presented in the following paragraphs.

2. Seismic safety and Cultural Heritage

The configuration/conservation design process currently describes the representation–structure binomial, since the information communication technology (ICT) has been introduced in the field of cultural heritage as digital form of communication. In the architectural field, the same digital representation phase is usually carried out to achieve the three-dimensional model, derived from the cloud of points generated by laser scanners [2].

The conservation is not, anyway, an action aimed only to the slowdown of the degradation, but also the act of valuing, guaranteeing the assurance of the resources needed. And a multidisciplinary approach now allows unifying the professional competences that formerly did not talk to each other, typical of a professional Taylorism, introducing the relationships between professionals who interact and become guarantors of knowledge. In this context, the border point between representation and structure comes out from the cloud of points and the FEM modeling, and it is caught by using the Building Information Modeling. The preservation of cultural heritage depends, first, on the nature of the materials of which the buildings are made: for example, bricks have a different behavior from volcanic rocks. But, even if in a different form, on the surface, all the rocks are vulnerable to atmospheric agents (humidity, wind, rain) which accelerates the building decay (Figure 1). With regard to the static safety issue, and specifically materials and techniques to use, it should be noted that today there is a revival of traditional materials and techniques.

A naive use of modern materials, giving the illusion of stability to the architectural and archeological heritage without compromising the aesthetic appearance, was the origin of the diffusion of materials for decades considered "modern", such as concrete, which are instead characterized by a high incompatibility. Modern materials, in fact, have been often the cause of a greater damage, not only to the values of the historicity of buildings, but also to their survival and, paradoxically, their stability, thus worsening the overall static performance. Their use seems to have failed right where it should be strong, that is, effectiveness and durability [3].

Fig. 1: Teti Maffuccini Palace in Santa Maria Capua Vetere

The more and more recurrent need to analyze and restrict the seismic risk accelerated the research and the use of valid solutions for improved performance of buildings under earthquakes. Today the choice of materials and techniques, once more modern, is significantly wider, because many new materials have been introduced in the restoration, such as composite materials, whose technology is more or less widespread and established. The choice of material and technique should not be obtained from an ideological vision, based on fundamentalist foreclosure for materials and contemporary techniques, but rather by a careful examination of the characteristics and properties of the building to be restored, its materials, its problems and its structural types. A choice that allows to design the retrofit with moderation, using compatible materials and techniques, to achieve a balanced outcome, in compliance with all the requirements of restoration, not least compatibility, reversibility and recognition of the interventions, and to keep the architectural unity and the meaning of the restored building.

The question, at this point, is whether the characteristics of new materials and new techniques are able to ensure compliance with the above requirements, also in reference to the demand of seismic safety. It is also wonder how a proper restoration can achieve the objective of maximum conservation of tangible and intangible information of buildings in accordance with the preservation of the original static behavior, minimum intervention and maximum reversibility; and then as the use of these materials may help to avoid repeating the error made by the indiscriminate use of reinforced concrete: it was not able to ensure the historical continuity and the expected increase in performance, especially during seismic events, because of its chemical and behavioral (static and mechanical) incompatibility. To provide a comprehensive answer to these questions, it is increasingly evident the need for an evaluation computer tool that is able to reproduce in detail all the available (multidisciplinary) information and allows users to make multiple comparative evaluations between the different possible solutions. In this context, there is the proposed B.I.M.4S&D methodology.

3. Structural modeling by B.I.M. in four dimensions

As demonstrated by the analysis of the historical evolution of design techniques, the avant-garde era is moving forward very quickly. For this reason, it has been tried to improve the research in the weak point of the chain, i.e. the point from which the graphic representation of the building goes to its structural modeling. Thanks to B.I.M.4S&D methodology, the weakness becomes strength and acquires the characteristics of a patent.

The benefit of using this methodology, in addition to the huge savings in time and cost and strong containment of possible errors in the design and construction stages, it is certainly the easier management of a single model.

B.I.M.4S&D is an active process of structural modeling, consisting of a connection between multiple disciplines. Any decision taken in a topic area is evaluated on the common model to all disciplines and interfaced with all the structural, engineering plants, environmental and restoration solutions.

Exchanges of information and communication on project planning become simpler on a single shared platform, on which the design pattern can be updated independently by different designers who use different computer machines. With the proposed approach, every decision about the design is more immediate, because the model works in a very similar way to the reality, even though it is a virtual model. Each element is associated with all the information needed to describe its behavior in the structural model and the constraints of the neighboring nodes [4].

The modeling of structures is well managed by the new software B.I.M. in four dimensions, which also works in the numerical simulation phase, allows to import any changes (concerning any planned intervention), following the results verification. The B.I.M. model also allows a rather fast definition of the forces acting on the structural model. Once the information is imported into the structural software, geometry and forces will ultimately set automatically. The aforementioned connection for the realization of three-dimensional FEM model and for the structural analysis has been developed at the time, with the software MidasGen of MIDAS Information Technology Co.Ltd.

4. Structural modeling by using new B.I.M. methodology: application to Teti Maffuccini Palace in Santa Maria Capua Vetere (CE) - Italy

Teti Maffuccini Palace (Figure 1) is located in Santa Maria Capua Vetere. The town center occupies the area of ancient Capua, a territory made of volcanic ash, called "felix" by Romans because of its fecundity. The Palace dates back to the nineteenth century and is subject to both archeological restrictions and architectural constraints because of its location and architectural qualities.

The building, built in 1839, initially belonged to the family of the lawyer Filippo Teti, as shown by the plaque on the arch of the main entrance, and subsequently to the Maffuccini family. The Palace was initially composed by three adjacent buildings: actually, the Municipality of Santa Maria Capua Vetere

has the desire to reuse the building as Culture and Legality Pole.

The Palace is a 4-story masonry building and has a C-shaped plan. The second floor is the "noble" one, all the rooms are decorated with paintings both on plaster and paper which adorn the Sicilian vaults and the walls. On the main building there is, in the central part, one further small story which consists of a single room used as lookout; over this small room there is a further panoramic room, accessible by a timber staircase. The roof of the entire building is realized through different pitches that intersect and engage each other, creating a network of ridges.

The in situ survey features that the portal with a depressed arch, located at the center of the façade, has two ribbed ionic columns on its lateral sides, that at the moment "are anchored to the rear wall by plates with wooden planks secured by plugs". On the ashlar arch of the entrance there are two effigies, while on the keystone there is a plaque indicating the construction year. The ground and first floor façade presents a ribbed union of horizontal stripes and simple cornices around the openings. The ones of the second floor present several ionic columns surrounding each opening, decorated with molded cornices, surmounted by triangular gables; on the central opening, above the portal, there is a fanlight. At the top of the main façade there is a jagged ledge which forms the eaves of the pitched roof on D'Angiò Street.

The entire structure of a building is usually graphically represented by a drawing in three dimensions. Figures 2 show how the Teti Maffuccini Palace was decomposed in structural parts and then modeled by FEM for performing an structural analysis. The digital survey and the cloud point generated by the laser scanner allowed achieving a refined integral 3D modeling of the masonry structure of the building, in which all the main structural components were included: the model reproduces the actual geometry and peculiarities of the structure, considering the various irregularities that characterize it.

The integration provided by non-destructive instruments, such as pulse (ultrasonic or sonic) velocity testing, surface penetrating radar, infrared thermography, cover meter testing and endoscopy technique, allowed to define and characterize the parts of the building that were not visible to the naked eye. The thicknesses of the walls, for example, were detected with the laser scanner but they were diminished of the thickness of the plaster from both sides. So, thanks to the interaction of the multi-functional instrumentation, the B.I.M. model of the structure was realized.

Fig. 2: Teti Maffuccini Palace: B.I.M. model and structural model

Fig. 3: Teti Maffuccini Palace: first three modes of vibration

The masonry walls were modeled by using the “equivalent frame method”, identifying three types of elements: masonry pier elements, spandrel beam elements and rigid beam elements. The masonry piers and the spandrel beams were modeled through one-dimensional elements with bilinear elastic perfectly plastic behavior (as required by NTC 2008). The pier-spandrel intersection panels were modeled as infinitely rigid beams.

A lumped plasticity model was used in the pushover analysis: the pier elements and the spandrel elements were represented by beams with plastic hinges at the ends. The properties of these hinges were assigned according to the code requirements and were different for piers and spandrels. The shear strength (dependent on axial force and bending moment) and the bending strength (dependent on the normal stress) of each element is maintained constant up to the limit values of the relative displacement between the ends of the deformable part of the element itself. The achievement of the maximum displacement determines the loss of the element capacity to endure shear forces or bending moments but not the axial forces.

The other structural elements were modeled by beam elements (with all the member forces N , M , V activated) or truss type (reacting only to the axial force N).

The floors were treated mainly as a load. Therefore the analyses were carried out without imposing the floor constraint by rigid diaphragm, with the exception of the first three levels.

For the purposes of the pushover analysis, the soil-structure interaction was not taken into account so neither the ground nor the foundations were modeled and the structure was considered as fixed at the base. In order to simulate the structural behavior after the strengthening, in addition to the retrofit interventions, the vaults thrusts were removed since absorbed by the designed tie-rods.

Figure 3 synthesized the first three modes of vibration of the Palace, with reference to the structure after retrofitting: all the modes show a moderate tendency of the structure to activate torsional response under seismic input [5,6].

In the pushover analysis, according to the NTC 2008, two different distributions of the horizontal forces were increased for both the main direction of the seismic input. Specifically, a distribution with forces proportional to the static ones and a uniform distribution of forces (to be understood as derived from a uniform distribution of accelerations along the height of the building) were considered.

The pushover analysis were performed in displacement control, increasing the displacement of a control point, chosen at the height of 18.25 m (upper level where the palace has a significant planimetric extension), until reaching the ultimate conditions.

According to the Italian National Seismic Code, the maximum capacity in displacement of the building structure at the ultimate limit state (SLV) was identified on the capacity curves in correspondence of a reduction in base shear equal to the 20% of the maximum one. The capacity at the operative (SLO) and the damage (SLD) limit states was computed at the achievement of a pre-fixed inter-story drift.

The seismic analysis confirmed what already foreseeable examining the main characteristics of the building, namely the configuration somewhat irregular both in plan and in elevation, the discontinuity of masonry walls along the elevation, the presence of numerous vaulted structures whose thrusting forces are not always well contrasted, the poor quality of the building structures and their state of preservation. Based on the above, it was possible to establish the type of intervention to be performed and its location for achieving seismic improvement of the building. In respect of requirements for cultural heritage, the strengthening solution, which was assumed for increasing the seismic capacity, tried to make the most of all the resources of the building [7].

The following Figure 4 shows, as an example, the capacity curve of the strengthened structure subjected to a uniform distribution of forces and the graph in ADRS format corresponding to the main limit state checks in terms of displacement, as required by the Italian National Seismic Code: the verification at the ultimate limit state shows that the structure capacity is equal to 21.9 mm while the demand is equal to 18.3 mm, which corresponds a safety index equal to 1.19 [8].

Fig. 4: Teti Maffuccini Palace: verification by the capacity spectrum method

5. Conclusions

The geometric-architectural configuration largely determines the way through which the seismic forces are distributed within a building and influence the relative magnitude of these forces. Masonry buildings allow to place greater emphasis on such a complex and fascinating study from a scientific point of view, because they are not made by standard procedures, as the steel and RC structures.

The Italian cultural heritage has a wide range of construction techniques, well diversified and not completely deciphered. Often, even mistakenly, the seismic damage suffered by masonry buildings has been associated only with faulty construction techniques. But the damage is often related to improper morphological conception of the structure, to the poor quality of materials and the superfetations that have modified the original arrangement of the structure without any type of retrofitting.

Many masonry buildings have shown, however, how many years it is possible to maintain the structural integrity despite the ravages of time and of natural events. This shows that the ancient building techniques, combined with practical experience, have resulted in good rules of construction.

All this implies that the structural restoration or consolidation design should cover many issues and that everyone should be lumped together in the structural model. The applications of the technology B.I.M.4S&D in several existing building structures, such as the one presented in this paper, showed the actual effectiveness of the methodology: all geometrical investigations carried out by sophisticated tools have enabled the verification of the survey archive data and the reliability of the in-situ measurements. The non-destructive tests have allowed to better characterize the individual component parts of the structure. All this has led to a high accuracy of the structural model, in a sophisticated and comprehensive process generated in four dimensions. In short, the participation of different professionals has resulted in an integrated B.I.M. model in which each element has been fully characterized by geometric, material and mechanical properties.

The proposed methodology in research has led to strongly combine two fields of architecture: representation and structures. The development of an integrated multimedia platform that includes all the needed structural information, analyzed from different disciplinary and scientific points of view, is part of a broader research that is in progress at the Department of Architecture and Industrial Design of the Second University of Naples.

Urban forms and architecture in the hydrographic landscape of the Sarno's valley

Andrea SANTACROCE,

Department of Architecture and Design, Second University of Naples, Aversa, Italy

info@sdgrstudio.it

Abstract

The nocerino-sarnese's plane is marked by the river course and by a complex and intricate hydrographic network of smaller canals, ditches and brooks. From the protohistoric period, this hydrographic network has been an critical environment factor to govern and regulate. During the last few years I have been interested in the urban and topographic development of Pompei's area, among Moreggine, Castagnaro and Messigne hamlets.

This urban structure has radically changed through the modification of the river Sarno's track and the Bottaro creek. It can be read as an lengthened territorial system, a strip that comes from the construction of the large walled enclosure of Bourbon's powder keg, marked recently by the beams of the railroad tracks and the motorway.

We redesigned the River Park system starting from the changes of the shape, trend and design of the Sarno's massive water infrastructure. The topics are suggested by the surveys and studies made by the Basin Authority and the Regional Park of the River Sarno, and they are bound by regimentation and recovery of riverbeds and to enhancing green interstitial spaces between the existing urban areas. So we try to bring back into the architecture domain the solutions connected with hydraulic engineering, turning defenses and safeguards against the flooding, into form factors of the landscape, into redesign systems of green spaces, which also define the shape of the new Park architectures.

Keywords: river, urban, topography, landscape

1. A theoretical position about the landscape

This essay aims to study the Sarno river system as a great work of hydraulic architecture and as natural element generator of urban forms that have settled over time in these places. The landscape and the settlement of the Sarno's valley have always been influenced by the relationship strictly dependent on the river. The birth and the development of urban centers is derived from the symbiosis between the structure of the land and construction of artifacts, the same for the main architecture type of this valley. The landscape is conceived as an essential component of the architecture. It 'true that all disciplines who have studied the city and the region have exacerbated the use of this term in an indiscriminate and generic way. In architecture, this hypertrophy can be stopped by following the construction. We do not care about landscaping as decoration, arboreal furnishing, or ephemeral element, very fashionable lately. We study what allows the landscape outside and inside the town to be an infrastructural system. There is an Italian attitude to relate the architecture to the landscape, that binds to the own idea of landscape transformation. There are some topics on which the change of scenery involves specific problems of architectural type. This occurs when the landscape, which is the background or scene, comes into the architecture, when the landscape solves an specific problem becoming the material of the architectural design. The dry stone walls that surround the property in the

south countryside, the terracing and the *prevoli* of the Sorrento coast, basements, flooring, stone embankments of the rivers in historic cities, the tree-lined and suburban country walks, are all those infrastructure that interact directly with the architecture and characterize the landscape. In an essay on the relationship between nature and the city titled "The four architecture elements of the territory", Carlos Marti Aris rises the question of gradual countryside conurbation around the city. He says: *"The transformation of our environment is determined with a rapidity and intensity increasing, and, at the same time, dramatically accelerate the phenomena of occupation and use of land. The metropolitan structures grows and expand while nature is moving away from us and becomes inaccessible. It takes an inexorable fate, the gradual move towards a complete artificiality of the territory."*¹

The River Basin landscape of the Sarno's valley has changed over time through successive transformations of its course and of the infrastructure architecture type. The mills, tanks, ditches, dams were an articulated and complex built to harness water power; but also the crosses, the bridges, the adjustment of the banks, the riverside, the rows of trees provide use both infrastructural and public pleasure. The system that grew up around the river Sarno has always been based on the relationship between single natural element to the territorial scale and multiple architectural elements to the urban scale. We act on the structure of the landscape through the settlement principles. The different steps of the landscape project produce chain reactions: the relationship that develops between the farms, the boundaries and the plowed fields in Puglia, or between the docks and the buildings of tuna traps with the coastline in Sicily and, in general, between an infrastructure system in a large scale and its intersections. The study of this system wants to rediscover the potential of these places and a working method to be applied in a possible redevelopment of the river Sarno, starting from the possibility of reconnecting the river to the city subway. In recent years the city has built denying the presence of natural elements so that the hydrographic nature of the sites come into contact with the urban places, both residence and public spaces. So the river becomes the place where the architecture takes ownership of the nature and defines a specific water character, a landscape built on the water.

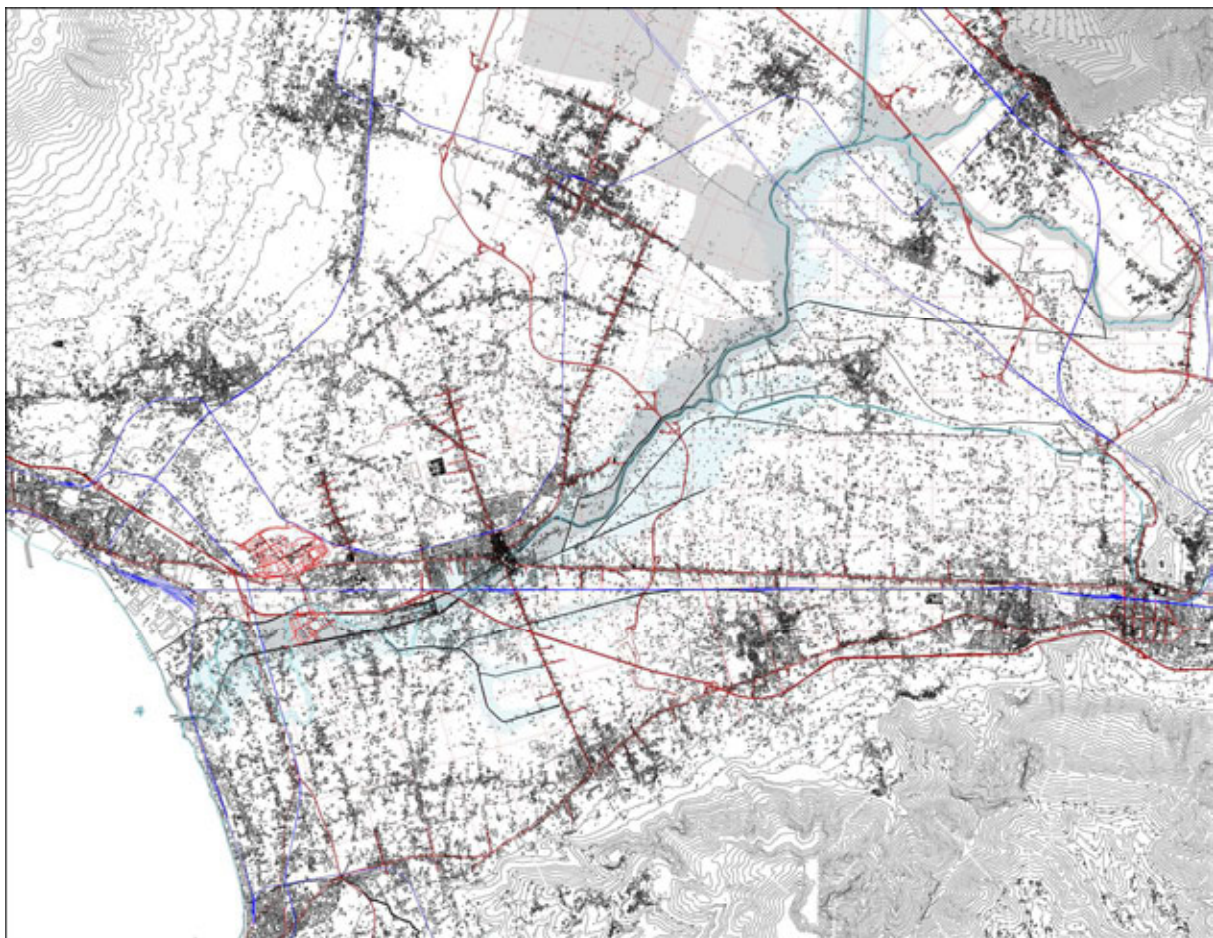

Imm. 1: Hydrographic and archeology structure: red for Pompei, Moreggine (the Roman port) and Nucera with connecting roads; blue for the winding route of the old river; black for the current route of canals and rivers

Then, as Carlo Alessandro Manzo says, in an open, discontinuous, polycentric and disjointed system, as the Sarno valley becomes important the set of open spaces and natural elements that participate in the design of new settlements with a role not accessory, but structural the project. *'Landscapes built and landscapes natural, built silhouettes and blank spaces, are antinomies of the same compositional problem, effectively summarized in the successful expression of the relationship between figure and ground.'*²

2. The urban form

The idea of the historic city, compact, monocentric, made of parts defined, is now outdated. The urban areas have merged with the territory and because they extend to the countryside, and for the re-naturalization of the internal parts. This new identity, which I call the '**landscape city**', is a city that has branched out in the territory completely merging with the landscape. It is characterized by discontinuous and open parts, moreover, it has not more geometric figures able to describe it but elements of different scales that are interwoven between them: neighborhoods, green wedges, infrastructure, residential areas, historic towns held together by agricultural plots, in our case by centuria, by orographic system and the historical axes. As in most of the suburbs of Italian cities, even the urban form of the Sarno Valley has vanished in a conurbation widespread among industrial buildings, residential buildings, countryside and infrastructure and it is impossible to define the limits of the contemporary city

The valley, until the beginning of the postwar period, was shaped by a system of urban centers that revolved around the river Sarno connected by two historic streets the '*Consolare*' and '*Poupilia*'. The rapid and uncontrolled urban expansion since the war resulted the almost complete sealing of urban centers through the draft and filamentous road network connection.

Imm. 2: Urban structure , infrastructure, the Sarno river park (gray), the areas of constraint flooding (blue)

This large part of the Campania region between Vesuvius, Lattari Mountains, the Sarno Mountains and the coast is crossed by the river that cuts off the Sarno valley into two subsystems, the first that revolves about the province of Naples, the other on the Salerno's one. Despite this administrative division, agro Nocerino / sarnese has a landscape, architectural and urban design unique due to the presence of dense hydrographic network, which has no comparison with other sites, both for the strong relationship with the primary crops as a productive resource. The architecture and the rural residences undergo a change in the relationship they establish with the ground due to the depth of the water table. That's why next to the river, historic houses do not have basements and have two floors, on the slopes of the mountains tall houses have basements dug into the layers of gray silt and one floor above ground. The complex network infrastructure, local and regional one, crosses over that territory, overlapping indiscriminately to urban presences, to paths and natural emergencies. Foremost the highways Naples - Reggio Calabria and Caserta - Salerno, which join near Nola, and the State Railway which runs along the old consular road: they accentuate the division into separate bands and parallel to the trend of the river. The historic territorial system, made of poly balanced by river line, is now virtually unrecognizable. The offshoots of urban centers exploded in a pulviscular system of residences and warehouses, and the system of linking roads is a filamentous network that urbanize the campaign.

3. Hydrographic structure and architecture

The urban and topographic evolution of the valley is inextricably linked to the shape and pattern that, over the centuries the imposing structure of the river Sarno took over, in spite of man's will to govern it. The plain is marked by the river and by an intricate network of hydrographic minor canals, ditches and streams, which has represented since the protohistoric period, a critical environmental factor to govern and regulatory. That is why since 1998 this territory, which extends over an area of about 715 square kilometers, with a population of 1,300,635 inhabitants (ISTAT 2000), has established the Sarno Basin Authority; in 2003 the Campania Region has recognized institutionally the Regional Park of the Basin and River Sarno, which is an institution that has a policy of development and land conservation through the enhancement of environmental river route of the historical, cultural, archaeological. The main course of the river is approximately 24 km long and originates from three sources at the base of the mountain range of Pizzo d'Alvano (named Palazzo, Marino and Foce) and flows into in Castellammare di Stabia.

The Sarno, in the Middle Ages called Dragon because of the unfolding of its sinuous course, today is almost entirely artificial for the reclamation works that have rectified its natural course. Originally, the paleolithic village of Longola, near Poggiomarino, was made from wooden huts on stilts to elevate themselves on the waters of the river and on swamp. In the Roman period, the city of Pompeii owes its development to its own strategic position about the Sarno. The presence of a River Port in the locality Moreggine, makes the city a great emporium for the Nocerino, Acerrano and Nolano hinterland, and constituting the center element on the economy of the whole area³.

The oldest representation of the river, appears in the Tabula Peutingeriana, dating roughly between the twelfth and thirteenth centuries, represented his tortuous path that runs alongside Pompeii and flows into the sea near Castellammare⁴. To analyze the structure of the territory before the upheavals of nineteenth century, one can study a design in 1789 entitled *'Pianta Topografica per dimostrare tutte le acque che compongono il fiume Sarno'* (Imm.3) and a notarized document with a map of 1828 entitled *'Cenno sull'origine delle acque del Sarno'* (Imm. 4). In both the maps we can see information about the arrangement of the villages, the path of the river, the roads, the type and the cultivated areas, some significant points such as bridges, mills, canals. In particular, in the second historical paper, it is emphasized Scafati's village with the Mother church and the old bridge.

Imm. 3 e 4 : '*Pianta Topografica del Sarno*', 1789 and '*Cenno sull'origine delle acque del Sarno*', 1828

It is the only urban center of the plain which has its historical roots on river water, developing a direct relationship with it. The bridge, the system of locks and channeling of water, the Palace Meyer, the profile of the Cathedral, the gardens of the Villa Comunale, the island of the mills form the urban system that characterizes the city, and it is also the most significant point to cross the river Sarno in the plain. Here you can feel the direct relationship between the city and the water, through the bulkheads and mechanical systems that were actuated for the overflow, the design of the fine edge of the channel walls of lava stone, the remains of old mills, part integral to the design of retaining walls, houses built on the edge of the river. In the Middle Ages, right in this area were built some Religious Architecture significant for our study because it placed in close relationship with the river: the church and the cloister of the Cistercian Abbey of Realvalle, were built by Charles I of Anjou in the village of St. Peter north of Scafati to celebrate the victory at the Battle of Benevento in 1270, and the church of the Virgins of Santa Maria, built in 1524 right next to the 'Pons Sarni', is defined by historian Gaetano Pesce a 'church on the river'.

Imm. 5 e 6 : 'Guaches' of 1686 and painting by Jacob Philipp Hackert from the '700

This urban system is represented in an 'gouache' of 1686 and in a painting by Jacob Philipp Hackert from the 700, in which also highlights the relationship that is established between the Roman bridge, the Scafati Cathedral and the river. There is a rich iconography of the nineteenth century that depicts some urban aspects of the Sarno's river landscape. During this time, the baroness Nathaniel de Rothschild with Leon Vernier (Imm. 7) paint the views of the Scafati houses to the Paris Salon: you can see how the residences live in close relationship with the river and the houses are built on rampant arches in order to raising the floor on the river level, the accesses are directly connected to the river, used for the transport of goods and quick shifts. In a faceless design of the first half of the

900 (Imm. 8) is drawn a charming glimpse of a house, in a place not well defined, between two bridges. The house is set on two levels, such as rural houses, with the lower floor used as storage and in closely with the river and the upper floor used as a residence. It is thus to form a hybrid space between the house and the river that looks like a transposition of a rural court on the River, a riverine courtyard , probably used as a landing place and working.

Imm. 7 e 8: Lithography by Nathaniel de Rothschild, 1886, and the anonymous design of the first half of the '900

The plain slopes gently toward the sea with an average slope of 0.1%, by drawing a trend of the river slow , winding and invasive. Such a environment system has favored the development of industrial sites that used the water driving force. The mills, textile mills, paper mills, cotton mills, textile industry, structure themselves in relation to the wide availability of water resources and the unique topography of the area. The section that comes from the mountain to the sea, with a little difference in height, the numerous hydraulic interventions along watercourses that took place over the centuries, have changed the regime of river beds causing frequent flooding. The Mills of Scafati (Abenante, Piscitelli, De Sio), Mills on Bottaro to Moreggine (Imm. 6) and the Persian Bridge (Imm. 7), until the nineteenth century, were the engine of the valley's economy. They were managed by the lords of the estates and allowed for the production wheat barley and maize as real industrial structures that used the water power of the river arranging themselves on its banks.

Imm. 10 e 11: Two anonymous paintings from the collection of the Duke of Guevara in the first half of the 900: Mills Bottaro and Bridge Persica

From nineteenth century, the structure of the hydrographic basin is related to the navigability of the river, to the activities of new industries and canalization works and drainage made by Borbone. So the wide area near the city center of Scafati, at the old bridge and the nearby railway station, was used for the creation of a remarkable factory for spinning, destroyed at the beginning of 900. From the entire structure remains only the residence of John James Meyer, industry's founder, which now houses the Town Hall. At the beginning of the nineteenth century Ferdinand II decided to build between Scafati and Pompei, a new powder factory to replace the existing one in Torre Annunziata. The great enclosure of the Royal Powder Magazine⁵ becomes a strategic intervention and of fundamental importance for the redesign and reconfiguration of the channel Bottaro and of the river main course. These works by grinding and channeling for navigation, permanently altering the original directions of development of Scafati's city towards the sea.

4. Study Area and methodological approach

In 1980 J.N. Baldeweg, in the PhD in design at the ETSAM Madrid, studies and detects the Canal of Castile since its conception in 1753 by King Ferdinand IV to the restructuring plans of some mills. He supports that it is necessary the rebirth of the life of the channel, even if partial, first of all for the restoration of its landscape value, although it should strengthen functions other than those which once were the priority.

*'The rows of trees are one of these. The Trees planted along the banks of the canal are important, not only because they can be exploited as a source of timber, but because they are a significant feature of the landscape. The lines of trees that follow the course of the canal have a visual and emotional function. They form part of the identity of the landscape and are the visible mark left on the land by an old ambition.'*⁶

In 1991 Francesco Venezia, within a broader pilot initiative of the Region of Valencia for the recovery of the old town of Alcoy, works the arrangement of the riverbed of the canals Barxell and Molinar. He starts from the idea to bring the theme of hydraulic arrangement in the architecture domain, of turning defenses and safeguards against floods and flooding in form factors of the landscape. *'The project studied a series of sections of controlled flooding, with the aim of keeping intact the natural course of the meanders.'*⁷

Fig. 12: Identification of areas study: 1 Moreggine, 2 Gunpowder, 3 Center of Scafati, 4 Abbey of Realvalle

Our research, based on these considerations, proposed the structural and identity reconnection of the territories crossed by the Sarno. It articulates with a large-scale project, addressed in the 2009's Prin coordinated by Carlo Alessandro Manzo, that uses the river Sarno as a territorial hinge; he proposes a hypothesis of urban expansion of the centers of the valley concentrated over strings that cross the river and some specific hypotheses developed for Seminars, Workshops, and recent studies carried out in close relation with the water system. We designed a map of this last system (Fig. 12) are shown where the study areas of strategic interest. Among these is the area of Moreggine (1) has already been studied for the workshop "Cross Pompeii"⁸ edited by Emanuele Carreri.

Moreggine's area is located in one of these systems, complex urban groups formed through the interweaving of elements of various kinds over time. A convoluted tangle of filamentous infrastructure strings as rail and highway, a system of overpasses and underpasses crossing point of the underlying soil, the extent of the land drawn by creeks (Bottaro), from the river Sarno, from farm trails, from cultivated fields. Balance the weight of residential buildings superimposed on a new system of connections, host a network of paths, propose new relationships between urban areas and redefine the plot of agricultural park: a system of subways which crosses the A1 allows a higher permeability north and the excavation area and a system of bridges, of which only one driveway, allows the crossing of the Sarno, linking the market area with the band south of the River.

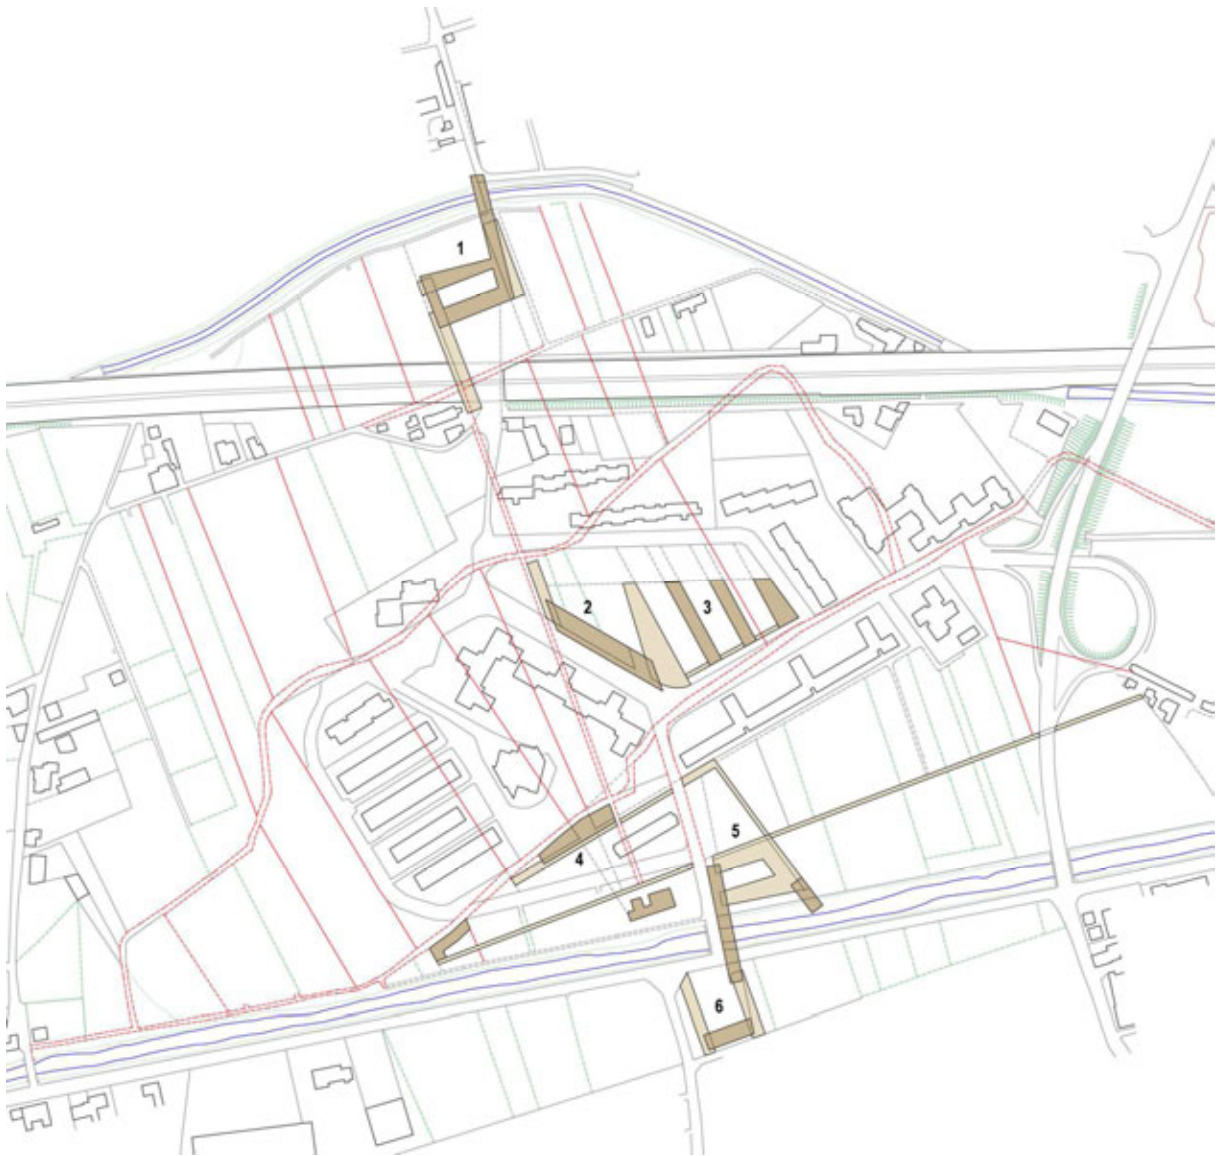

Fig. 13: Master Plan of Moreggine's area: 1 archaeological museum, 2 civic center, 3 school campus, 4 library, 5 market area, 6 environmental research center

The project of redesigning the area of "*Real polverificio Borbonico*" (2) rests on these same principles and starts from a feasibility study in 2009 which provided for the transformation of the site into 'Polo of culture and applied research, of hospitality and wellness , trade and terziario advanced. ' The project aims to create a cultural link with Pompeii, in order to attract tourist flows of archeology enthusiasts and devotees of the cult of Mary, as well as those coming from the Sorrento Peninsula and the Amalfi Coast.

The years of the Royal Gunpowder in Scafati were characterized by severely damaging events, such as to cause the suppression of the activity and the conversion of the building, in 1930, into the Institute of Experimental Tobacco. Now we have only the representative part from of the original building, recently restored. Today, the cultural center is composed of a main building made as C on three levels with a courtyard and a small pavilion, the church and the exedra of access to the gardens. The new urban system, that revolves around the historic precinct of gunpowder, is like a pivot for the systems that, from Pompei to Scafati, connect to the banks of the river Sarno. For Moreggine the two axes that cut from north across the infrastructure systems, and the Waterways have the task of repairing the degraded portions of the city to the south. The project addresses some urban issues starting from the directions of the Plan. The areas identified are inserted in a complex system and try to give a new strategic strength to the gunpowder large enclosure. The draft plan is organized through a few operations: it marks the roadsides with new vegetation (green wedges), introduces a system of special residences for students, researchers and young couples; it reorganizes the research activities of the Institute of Experimental Tobacco; proposes new green areas which relate with the system of the Sarno River Park.

Fig. 14: Master Plan of *Polverificio Borbonico*: 1 craft manufacturing center, 2 research center on crops, 3 residences for researchers, 4 university center, 5 historic core, 6 park facilities, 7 special residences, 8 school of art (theater, music and dance)

Abstract

The design of strengthening interventions on historical buildings is complex due to the numerous uncertainties in terms of geometric and mechanical properties. In addition to this, interventions must be critically examined in relation to their effectiveness and to their impact on the conservation of the assets. Accordingly, also in consideration of collapse mechanisms typically observed in historic buildings, a cognitive research must focus primarily on the history of the building, the geometry of various structural elements, construction techniques, as well as material degradation.

Difficulties typically connected to knowledge are often in relation to available resources and the invasiveness of the research to be performed, this making necessary to compare by means of posterior models based on the observations and experimental verification of the mechanical behavior of the building. Accordingly, in the field of seismic strengthening interventions, dynamic tests, experimental modal analysis techniques and FE modeling may play an important role. The first two contribute to knowing the actual health state of the historical buildings, while the last is useful to evaluate, since a preliminary design stage, the effectiveness of the interventions.

The present paper proposes a rationale for optimizing seismic safety measures and interventions, along with the description of the interesting case study of the bell-tower of the Fossano.

Keywords: masonry structures, dynamic tests, pushover analysis, FE modeling, safety measures.

1. Introduction

Masonry bell-towers are very diffused in Italy and represent an important portion of the built Heritage to be preserved. For this reason their seismic assessment against earthquake appears to be of relevant importance for historical, social and artistic reasons. A main issue in the seismic behavior of these structures is the influence of the axial stresses induced by gravity loads, whose value is often of the same order of magnitude as the ultimate compression of the masonry. Hence, structural failure can be driven even by a moderate increase in stress level, which can occur also during low magnitude seismic events.

Several studies have been conducted in the past to investigate the invasiveness, the long-lasting quality and the efficiency of different strengthening interventions [1-2]. In this field, an important role is played not only by analytical aspects, but also by the development and validation of innovative materials and systems for conservation and strengthening. The optimal design of a strengthening intervention becomes particularly difficult when operating in urgency regime and when some temporary safety measures and interventions must be done. In spite of their being fundamental for the safety of the structures, provisional interventions can have a different impact on the quality of the structure.

The distinctiveness of each bell-tower, due to masonry chemical and mechanical characteristics, stress concentration and existing cracks, makes its strengthening as unique and specific case study. Therefore the assessment of the static and dynamic behavior and the choice of the best intervention require a validated numerical model [3-7]. On this model the possible interventions can be modeled and the different effects on the structural behavior can be investigated. The availability of a validated and verified model of the structure complies also with the need to evaluate in advance the effectiveness of an intervention, so avoiding unnecessary ones.

The present paper proposes a rationale for optimizing seismic safety measures and interventions, along with the description of the interesting case study of the bell-tower of Fossano (Cuneo, Italy). Four possible strengthening interventions have been investigated and evaluated.

2. The structure

2.1 History of events

The bell-tower of Fossano Cathedral, placed in Manfredi square, was built in XIV century for want of the family Acaja. The family Acaja, established their domination on the city of Fossano, added an symbol of their authority in the square that accommodated all the emblems of the power, providing the church of Santa Maria and Giovenale of a bell-tower [8]. This church was demolished in the later centuries and in the same place the present church was built. The Cathedral is bigger than the previous church consequently the bell-tower nowadays appear less majestic than it was at the beginning (Fig. 1).

The bell-tower, conceived originally as a fortress with embrasures oriented in the direction of the doors of the fortified city, underwent important changes in the centuries reaching the current features. An important modification was imposed in the XVI century when the spire was substituted with the octagonal crowing designed by Giovenale Boetto. Now the bell-tower with an overall height of 46 meters has a square cross section and a octagonal belfry. The thickness of the walls is 1.5 meters constant up to 35 meters and decreases at 0.5 meters at the belfry.

Fig. 1: Plants (a) the old church (ochre); the present Cathedral (black); the bell-tower (orange) (b) The bell-tower and the Cathedral nowadays.

The spatial organization has changed over time, as reported by the chronicle and by the historical analysis. This organization, as shown hereinafter, does not find correspondence in the numerical model of the structure. It is reasonable to assume that the first strengthening interventions of bell-tower, as reported by the documents, occurred after the earthquake that struck the territory of Fossano in the 1887. The seismic event caused important vertical cracks, still visible, therefore interventions of consolidations became necessary. The interventions consisted in the filling up of the staircases “intra muros” with masonry having good mechanical properties and the introduction of three levels of steel ties-rod at the heights of 14, 24 and 32 meters, respectively. The first intervention was a preventive measure: indeed the new masonry wall would have acted as a prop if the external walls were failed. The ties-rod instead have the aim to avoid further crack opening so giving rise to a box behavior to the structure. No other interventions are reported by the consulted sources until the 2012 when provisional additional ties-rod were placed inside and outside of the bell-tower to avoid the further crack opening. The visual impact of this temporary safety measure on the bell-tower is important, as shown in Fig. 2. This notwithstanding, ties represent an effective safety measure in view of permanent interventions.

Fig. 2: The bell-tower after the provisional safety measure (2012).

2.2 The mechanical property of the masonry

The mechanical properties of the masonry at the different levels of the bell-tower were assigned an estimate based on the updated numerical model and were then confirmed by core drilling tests. The updating of the FE model was carried out from ambient vibration data [9]. Data were acquired using accelerometers conveniently placed on the bell-tower. The core drillings has shown a unequal masonry at the different levels of the bell-tower. Starting by the examination of the samples and utilizing the precedent experimental results on other structures, similar for geography, materials and age of construction, the strength of the masonry at the different levels was fixed. Based on the results of core-drilling tests and visual inspection by means of an endoscope, the characteristic value of shear strength was assumed equal to 60000 N/m^2 for all the masonry. The compressive strength, instead, was assumed to be 2000000 N/m^2 at the lower level and at the belfry, while for the other parts of the bell-tower the poor quality masonry resulted in an estimate of ca. $90\text{E}04 \text{ N/m}^2$. The elastic properties of the masonry, Young modulus and Poisson coefficient, were taken equal to the “parametric values” obtained by the updating of the FE model. The values for each homogeneous masonry portions (Fig.3) are reported in Table 1.

Masonry portions	w (kN/m^3)	E (MPa)	ν (-)
01_bell-tower	20	2.69E03	0.3
02_bell-tower	20	1.32E03	0.3
03_bell-tower	20	1.25E03	0.3
04_bell-tower	20	2.47E03	0.3
05_est-link	20	5.00E02	0.3
06_south-link	20	5.00E02	0.3
07_floor	22	1.80E06	0.3
08_roof	26	1.00E04	0.3

Fig. 3: Discretisation in Homogeneous portions.

Table 1: Density, Young modulus and Poisson coefficient of different masonry portions.

2.3 Seismic assessment of the bell-tower in its original state

The choice of the best intervention for the seismic protection of the bell-tower requires a knowledge on the present condition of the structure, whose current state was investigated by linear and nonlinear analysis carried on the validated FE model [10]. In the linear analysis the seismic action, combined with the gravity loads, was applied at the numerical model in order to evaluate safety levels with respect to in-plane bending, out-of-plane bending, and in-plane shear failure modes. Safety assessment carried out on the tower has shown that the lower safety factor is at the middle height of the bell-tower where the mechanical characteristics of the masonry are worse. The linear analysis was followed by a pushover analysis to determine the ultimate seismic acceleration of the bell-tower. The pushover analysis is carried up to the collapse, in correspondence of which the structure shows an expended cracking and crushing. The pushover control point was placed at the highest floor of the structure as shown in the Fig.4. The displacement-acceleration curves depend on the direction of the seismic action as shown in Fig. 5. This asymmetric behavior is due to the connection of the bell-tower to the Cathedral along two consecutive orthogonal walls and to the asymmetry of the structure caused by the presence of the old staircases “intra muros” filled up by good masonry in the 1887 (Fig. 6).

Fig. 4: Position of the pushover control point.

Fig. 5: Acceleration-displacement curves of the bell-tower at the present condition for four orthogonal direction of the seismic action.

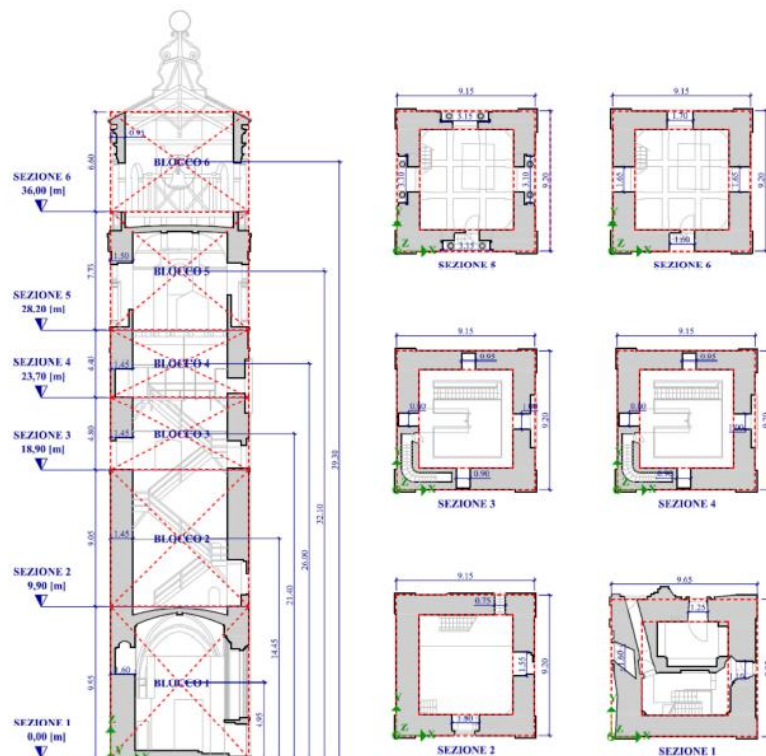

Fig. 6: Cross and horizontal sections of the bell-tower.

3. The interventions

3.1 Description and modeling

Four different solutions were considered: reinforced concrete liners, a reticular system made of vertical and horizontal FRP fibers, an auxiliary steel structure and grout injections.

The reinforced concrete liner is a common technique used for the reinforcement of ordinary structures. Its use for the seismic protection of the cultural heritage is limited due to its invasive nature. Such an intervention, in its current version, would wrap the original masonry walls with two thin layers, internally and externally, covering the architectural characters of the structure. To limit the invasiveness of this strengthening intervention, the reinforced concrete layers have been confined to the most vulnerable parts of the bell-tower, and an auxiliary steel structure has been designed for the belfry protection. The reinforced concrete liners have been modeled as shell elements with homogenized mechanical properties. The auxiliary steel structure, instead, was modelled in the FE model as an additional frame (Fig. 7).

Strengthening and retrofitting of existing masonry buildings with externally bonded FRB fibers is a technique that has been used extensively in the last years. The large interest in using these materials for seismic protection is related to some favourable properties: no mass and stiffness increase, low impact, reversibility and durability. The strips of FRP can be easily removed by a thermal treatment. Many researchers studied the behavior of strengthened masonry elements for in-plane and out-of-plane failure mechanisms [11-12]. The effectiveness of the intervention is related to the quality of bonding of the FRP reinforcement to the masonry [13]. Furthermore the de-bonding failure is extremely serious because it is a brittle failure. Due to its negligible stiffness of FRP fibers compared to that of the bell-tower, this intervention does not affect the seismic response in case of low magnitude earthquakes. Among the numerous types of FRP, carbon fibers were chosen (thickness of 1 millimeter, density 1780 Kg/m^3 , Young modulus 300000 MPa). In the FE model the carbon fibers are introduced as additional vertical and horizontal elements (Fig. 7) with linear constitutive law.

The intervention with an auxiliary metal frame, placed inside the buildings, reduces the tower's seismic vulnerability because the connections between orthogonal walls warrant a box behavior of the structure, increase the stiffness and the dissipative capacity. In more detail, a steel auxiliary spatial frame was considered as a viable strengthening measure for the bell-tower, and the FE model was modified accordingly (Fig. 7).

The injections of grout is widely used nowadays to reinforce damaged masonry. This technique basically consists of the filling the voids and/or the cracks inside the walls by injections of new mortar, in order to restore their continuity. The saturation of the cavity therefore permits to homogenize the masonry behavior. The injections must be preceded by some investigations. The dimension and the distribution of the voids, as the correct choice of the grout, according to the typology of the wall texture [14-15], assume particular importance since they can determine whether or not the reinforcement is effective. However, the effectiveness of this strengthening technique can be evaluated precisely only after its execution by means of ultrasonic tests. In case of uniform distribution of the masonry voids this technique does not affect stiffness distribution, hence the relative contribution of each member to seismic resistance remains unchanged. Furthermore, this type of intervention has a limited impact on a structure's architectural characters and features. In our case, injections would be reasonably designed so as to produce an increase of mechanical properties in poor quality masonry of the intermediate level of the bell-tower. Accordingly, the FE model was modified by setting a uniform value for all mechanical characteristics to the values assumed for the belfry, also in order to simplify the analysis. In real practice, these assumptions should be confirmed by ultrasonic tests performed after the intervention.

Fig. 7: Modified FE models: (a) reinforced concrete liners ; (b) FRP reinforcement ; (c) auxiliary steel structure

3.1 Multi-modal and pushover analysis

Multi-modal analyses were performed on FE models of the bell-tower after introducing modifications to take into account strengthening interventions. A comparison of the main modal quantities, before and after the interventions, is reported in Table 2 and Fig.8.

	1° Modal frequency		2° Modal frequency		3° Modal frequency	
	Absolute increase	Relative increase	Absolute increase	Relative increase	Absolute increase	Relative increase
Reinforced concrete liners	0.355	27.5%	0.410	29.7%	1.375	39.5%
FRP fiber	0.039	3.0%	0.042	3.0%	0.099	2.8%
Auxiliary steel structure	0.175	13.5%	0.158	11.4%	0.198	5.7%
Grout injections	0.277	21.4%	0.315	22.8%	0.968	27.8%

Table 2: Absolute and relative increase of the first three modal frequencies after the interventions. (The values before the interventions are 1.292 Hz; 1.382 Hz; 3.481Hz).

Fig. 8: Modal shapes for different strengthening interventions: (a) reinforced concrete liners; (b) FRP fiber ; (c) auxiliary steel structure; (d) mortar injections.

The multi-modal analysis was followed by a nonlinear seismic (pushover) analysis. The displacement-acceleration curves obtained by the pushover analysis are reported in Fig. 9.

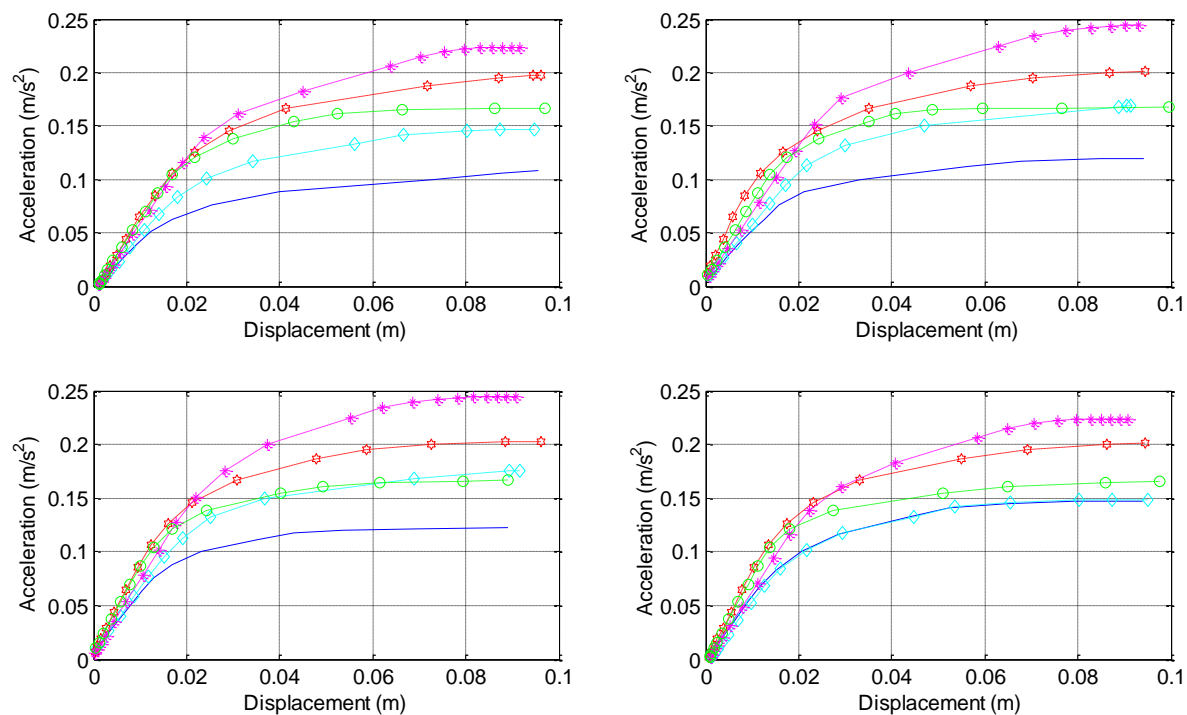

Fig. 9: Comparison of acceleration-displacement curves of the strengthening intervention — present condition; — reinforced concrete liners — FRP fiber — auxiliary steel structure — grout injection for different directions of the seismic action (a) + X direction; (b) - X direction; (c) + Y direction; (d) - Y direction.

The pushover analysis shows how all the considered interventions bring to an increase of the ultimate limit acceleration of the bell-tower. This result is confirmed for all combinations of the horizontal seismic actions. The relative resistance increase is generally equal in the two directions, except for the intervention with concrete liners. In fact, the design of liners was not able to correct the asymmetric behavior of the structure. The average increase of the horizontal ultimate limit acceleration of the bell-tower for the different strengthening interventions is reported in Table 3 together with the average increase of the stiffness, as obtained from the FE model.

	Increase in resistance (%)	Increase in stiffness (%)
Reinforced concrete liners	+ 61 %	+ 27 %
FRP fiber	+ 40 %	+ 3 %
Auxiliary steel structure	+102 %	+ 13 %
Grout injections	+ 39%	+ 20 %

Table 3: Average increase in resistance (in terms of ultimate limit PGA) and in stiffness (from FE model).

Assuming to select grout injections as strengthening intervention, which is a typical choice in low seismicity areas, safety levels with respect to in-plane bending and shear, and out-of-plane bending of single masonry panels (e.g. see Fig. 10 for the lower level). The seismic assessment, which was based on the experimentally validated model, showed that safety factor decreases of 6.04% relative to diagonal failure, increases of 13.82% relative to in-plane bending and decreases of 31.85% relative to bending out-of-plane. The lower level of safety, compared with the original state, is to be ascribed to the increase in seismic loads. In other words, the greater mass due to grout injections involves an increase in seismic loads that is higher than the corresponding increase in seismic resistance.

Fig. 10: Single masonry panels for the lower level

4. Conclusions

The seismic strengthening of Heritage buildings calls for the integration of structural requirements with other aspects related to their historical and artistic quality. This work has presented a procedure to investigate the effect of different seismic retrofitting interventions (reinforced concrete layer, FRP fiber, auxiliary steel structure, grout injections) on the bell-tower of Fossano Cathedral (Cuneo province, Italy). The seismic performance of the interventions has been evaluated based on an experimentally validated model. The experimental validation was realized by assimilating into a FE model data acquired during a modal testing campaign, as well as results of core-drilling tests and visual inspection by means of an endoscope. Information acquired on vibration modes and material properties allowed for using the model both in a linear and in a nonlinear field. The model was then modified so as to consider the different interventions. The seismic assessment, conducted in the assumption of grout injections, showed that some safety factors may decrease after the intervention, this being ascribed to mass addition due to grout injections. In this connection, it is important to stress how the provisional nature of safety measures realised in 2012, despite their temporary unpleasant effect, were appropriate as they potentially allow for a more accurate and cautious selection of the optimal intervention.

Abstract

Cultivars: cultivating culture in art, third prize in the Competition "ARS - Art that creates social employment", sponsored by Accenture Foundation with a special mention from the Italian Ministry of Heritage and Cultural Activities and Tourism, is aimed at the development of a system to build places of the heritage of Campania with agricultural activities and food, generate employment for long-term social, in the Abbey of San Lorenzo *ad septimum* at Aversa, in the Mostra d'Oltremare of Naples, in the ancient city of Pompei.

Children, citizens, tourists become "travelers" and are invited to participate in workshops in creative exploration. The workshops are divided into three phases: historically, the Architecture is lived - not seen with paths dramatized; naturally, the garden is explored through agricultural operations of planting, harvesting, creatively, *diaeta* the ingredients of the Mediterranean - Unesco heritage - are collected and processed in laboratories in the gardens of cooking in a convivial. The project is a response to EXPO 2015 which calls for a major emergency AAA Architecture, Agriculture, Food. CULTIVARS integrates three factors relying on food vector.

The project includes the implication of associations and third sector organizations in the activities of creation and management of green spaces and laboratories and the involvement of design students in the project of memorabilia that will be marketed.

Keywords: diaeta, cultivars, art, social, design

1. Introduction

The competition "ARS. Art that creates social employment", sponsored by the Italian Foundation Accenture, for project ideas, "is aimed to accept proposals for planning, implementation and management of services and products that, by using the Italian artistic heritage as asset, give as a result the creation of sustainable social employment.

This is a non-profit foundation which is only intended to promote the most important and significant experiences about innovation as a value of great advantage for society. The main subject of Foundation activities is innovation, both in its technological, scientific and managerial aspects, and in its positive role in promoting economic, social, and cultural development. The Foundation is able to achieve its institutional aims even through a strong commitment to search for a networking with other foundations, institutions, companies and organizations. In fact, this Foundation wants to act as a catalyst to collect not only economic but also intellectual efforts by third parties in order to obtain a real promotion of innovation and its applications.

Project ideas must be suitable to realize services and/or products to valorize built heritage with adequate utilizations, with the purpose of:

- To increase visitors of the chosen artistic heritage
- To make accessible parts of the artistic heritage which today are not
- To increase cultural services for visitors (guided tours, educational workshops, audiovisual tools, ...)
- To provide web services
- To create services to integrate the artistic heritage with local marketing (accommodation, transports, events, cultural tourism, etc.)

The ideas will have to create employment, supporting the development of skills and know-how with positive results for production chain and for the Country. In particular, they must:

- be characterized by a strong innovation and originality and, at the same time, take into account the real feasibility and the economical aspects;
- be sustainable over time
- allow the gradual aggregation of new subjects (non-profit organizations or public and private organizations).

Our intention is to privilege the projects concerning monuments whose cultural and economic potential is today untapped and the ideas which provide a co-operation between institutions and different organizations. The winner project must be realized and managed by a non-profit organization which already exists – and which has already given assent to the realization – or to be created with the following requirements:

1. To be economically sustainable
2. To adopt a scalable business model (which can give more services and/or to a larger number of users) and repeatable by leveraging on the investment that is the object of the present competition for project ideas
2. To be non-profit
3. To adopt high standards of Corporate Social Responsibility (“CSR”) that is, for example, managerial and communicative transparency, sharing of the value with the
4. stakeholder, respect for environment, ...
5. To include an assessment of the effects of externalities on the territory/country (accessibility, skill enrichment, improvement of the conditions of residents, infrastructures, economic activities, do not pollute, etc)
6. to contribute to the cultural growth of community” (www.ideatre60.it CONCORSO ARS ARTE CHE REALIZZA OCCUPAZIONE SOCIALE).

2. Cultivars design

Cultivars: cultivating culture in art, third prize in the Competition "ARS - Art that creates social employment", sponsored by Accenture Foundation with a special mention from the Italian Ministry of Heritage and Cultural Activities and Tourism, is aimed to valorize a system of places of build heritage in Campania territory.

For the participation in the competition we have chosen two monuments: the first one is the Abazia di San Lorenzo ad Septimun in Aversa and the second one is the Mostra d'Oltremare in Naples. Both places have been selected because they are a historical and architectural highly prestigious heritage not completely appreciated from a tourist point of view even though close to the main tourist flows (historic centre of Naples and Caserta Palace). The Borgo San Lorenzo is in Aversa. In addition to the late-gothic church, also the seventeenth-century building, which was the accommodation of Benedictines, is part of the monumental complex. This build has a large two-level cloister (one of the few examples in Campania) and today it hosts the Department of Architecture and Industrial Design of the Second University of Naples. The wide wall also surround San Lorenzo Garden, a garden of agriculture used for a long time as a parking and the turned again into garden orchard open to schools and managed by the association Orto di San Lorenzo.

The Mostra d'Oltremare was inaugurated in 1940 in 36 pavilions on 1.066.197 square meters. It is a large multifunctional park equipped with 720.000 square meters of a prestigious tree, architectural and artistic heritage, which merges precious architectural works and urban gree, The Mostra, with its urban scheme which is almost unchanged from its birth, has its international value. In both complexes, surrounded by walls, the green spaces and the land are structural elements within the architectural project: these characteristics allow the integration of the touristic and historical value of the buildings with the possibility to develop activities and services linked to culture and “cultivations” of the Mediterranean diet and of Campania wine and food panorama.

Cultivars has been preceded by actions concerning culture, nature and environment, the dissemination of products and projects and respectful initiatives that valorized cultural, rural and natural environment and propose to safeguard the rural, handicraft and wine and food local heritage, even through agreements and co-operations with public and private companies in the organization of training activities for a culture of a new rural and urban agriculture which improves the territory: from the realization of the garden/orchard in the Abazia di San Lorenzo in Aversa, to 2011 with the Oscar Green of Coldiretti Giovane Impresa, to the cultural and educational initiatives directed to all schools, through creative and sensorial multidisciplinary workshops that stimulated the knowledge of elements and processes of agriculture and healthy diet. Also SUN students and researchers also contributed to extramoenia initiatives to organize educational gardens in schools.

These are the results on May 2014:

- Involvement of 1000 students of the university course in Design and Communication for Fashion;
- Participation of 370 Campania schools;

3. Historically, naturally, creatively

CULTIVARS is aimed to activate a group of services in the selected architectural complexes to strengthen their attractiveness for tourism. The starting point is to turn tourists who passively consume their time and space into travellers who live and positively interact with places. The Building heritage must be an active and alive heritage which produces, (softly) changes and interacts with travellers. The project includes the utilization of green spaces to create gardens and settlements of urban agriculture that can be the core to realize workshops on the culture of the Mediterranean diet and Campania food and wine. The workshops will take place in three levels:

STORICA_MENTE (HISTORICALLY): it is oriented towards the knowledge of the artistic and architectural context through a narration of places, the history of monuments and their connection with the land. A “widespread museum of work” will be able to improve and facilitate the access to information through digital resources and tools.

NATURAL_MENTE (NATURALLY): it includes workshops on sowing and/or harvesting, according to seasons, in the gardens and green spaces of the monumental complexes, to know the key elements of the Mediterranean diet.

CREATIVA_MENTE (CREATIVELY): it is a workshop which allows travelers, in a convivial dimension, to learn to transform products who have been cultivated, harvested or sowed in the gardens and the green spaces of the involved areas. The project includes partnerships with third sector bodies to develop extramoenia agricultural services aimed to improve green areas. This model is scalable for other regions and architectural complexes containing areas to be turned into gardens and workshop spaces.

Through various meetings and workshops this project is a network of third sector branches that can be involved both directly, in the management of artistic complexes and services, and to map skills, resources and new “art areas” in which to implement the CULTIVARS model for new services. Meetings and workshops with the third sector actors will be an opportunity for socializing in which to identify the necessary skills to set up the staff of experts who will plan the workshop contents and will train the operators. The project includes small operations to improve green areas, with the co-operation of associations in the different territories. These areas, called “tissues of urban agri-cultures”, will be widespread in the cultural approach of the project and will also have the task to promote and communicate the initiative. The third sector will be also involved in the development and production of memorabilia designed by design students and to be sold in the shop; partners who have handicraft productive skills will have the opportunity to apply for the production of memorabilia, even by networking to integrate their skills. In the final part of the project there will be workshops to identify new art spaces where to implement CULTIVARS services and laboratories and create partnerships between subjects who can manage the initiative in the territory.

The project provides partnership with professional tour operators who are directed to an international public, as well as partnership with tour operators of cruising and hotel sector. This activity will be taken into care by the project marketing referee. Through CULTIVARS the different tour operators will be able to improve their offer by proposing a new and involving kind of travel which combines the artistic and historic dimension with the food and convivial one (which is strongly attractive for the foreign market and not fully exploited!). This offer is highly competitive in South Italy tourism, where advanced services for accurate and not trivial experiences are rare. The valorization of architectural works such as those of the Mostra d'Oltremare with specific services for language targets adds value and competitiveness and shows an unusual vision of architectural heritage in Campania. The project CULTIVARS provides the development of a system of reception and services for cultural and linguistic targets with ad hoc communication and digital supports. Partnership with university departments of foreign languages and cultures and conventions encouraging students traineeship will allow an offer which is qualitatively adequate to the international market.

The project develops web and new technologies through different solutions.

1) The project provides the creation and the installation of interactive video projections stimulating the user through a recreational and creative approach on three thematic levels corresponding to laboratories: *storica_mente* with artistic and cultural contents; *natural_mente* which concerns the garden care and management; *creativa_mente* with interactive installations stimulating the use of garden elements and artistic contexts for the virtual creation of products, recipes and narrations, suggestion. The installation will be dynamic works changing according to seasons and the intervention of users who can add and modify elements or information. 2) Widespread digital museum: the architectural complexes and their green spaces

Fig. 13: Naturally.
Fig. 14: Creatively.

Fig. 15: Contents.
Fig. 16: "I CANTIERI DEL SAPER FARE".

will be enriched with elements allowing, through smartphones and tablets, to use contents which will strengthen the access to information. 3) Web platform will be helpful both in managing the organizational phase, through reservation and services customization, and contents presenting CULTIVARS art places and exploring Campania and Mediterranean agri-food issues. This platform offers contents extending the user's experience, making accessible photographs, productions, contacts created during the user's real presence in CULTIVARS (For example the user can see the growth of the young plant he contributed to plant or cure).

4. The worksites of know-how

The project CultivARS considers the period of start-up and building of spaces and services as the opportunity of developing training laboratories for tutors and operators, the worksites of know-how. Training activities will be directed to tutors and operators and will be based on the action learning that is training combining theory and practice. Construction and activation of the spaces and the services will be the training worksite where operators will face critical issues and will find solutions in a participatory way. The worksites of know-how have three thematic levels that are parallel to workshops: Storica-mente: this worksite concerns the valorization of the two selected monuments, therefore it will be focused on: the dissemination of contents referred to artistic places, the development and the dissemination of the contents in language for the international users, the development and the dissemination of the contents in language for the special users (lis and different abilities), the installation of the work museum and of information and communication materials. Natural-mente: this worksite is focused on the creation and valorization of green spaces and urban agriculture within the two artistic contexts; basis and elements of the agricultural technique on-site, typical Campania agro-food, the design of garden and green, field preparation and creation of the urban garden. The participants in the training activities will receive the qualification of "urban farmer" and can be involved in maintenance and management of gardens and green space. Creativa-mente: this worksite is focused on the activities and contents of cultural and educational laboratories: the development and management of workshop contents, the development and management of the support for laboratories, the creation and setting up of laboratories.

The activation and maintenance of spaces, the co-operation in the management of CultivARS workshops will be entrusted to social cooperatives or third sector bodies to build processes of work inclusion involving at least 50% of operators with different abilities or coming from difficult situations. The operators will be trained in the phase of start-up and will receive the professional qualification of "Urban Farmer". Through some "special editions" of workshops, the project CultivARS is aimed particularly to emphasize the involvement of people with sensorial disabilities (both as users and as operators): for example, deaf persons will be directly involved in the tour of art places and in services for laboratories for deaf people, events in LIS (Italian Language of Signs) will take place. Blind persons can be involved in sensorial workshops about taste and touch. All laboratories will be open and accessible to people with different abilities, a specialized tutor will follow the activities of special users. The project CultivARS will also facilitate some micro-operations for the valorization of green or agricultural spaces in all Campania, these "tissues of agri-cultures" will be activated in partnership with associations of the third sector that are active in the involved territory, in the selection of partnership to activate policies and practices directed to the work integration of persons from so-called "poorest categories" will be an advantage, as well as to involve poorest categories in the identification of those who will produce memorabilia.

5. Best practice to Pompei and for the world: International Interuniversity Master [diaeta mediterranea: landesign/ali-ment-azione]

The project CultivARS has seen in the ancient city of Pompei the possibility of its development through the knowledge of the ancient city which admirably combines not only archaeology, architecture and art but also agriculture and food and investigates the roman house as agricultural company ante-litteram.

Like the "diaeta", the space of the roman house designed to reception and relationship, the International Interuniversity Master [diaeta mediterranea: landesign/ali-ment-azione] of the Department of Architecture and Industrial Design SUN and of the Department of Pharmacy UNISA is the place of re-formulation of the relationships between man and environment, food and health, land and design, content and container, of the research and scientific innovation for the development of products and service of the food production chain: [ali-ment-azione] ali = creative ingredient + mente = scientific ingredient + azione = productive ingredient.

Through an educational new model [landesign/ali-ment-azione], with a multidisciplinary approach, participants will be trained to the management of the food production chain in its formal and functional, medical and nutraceutical, food and wine and culinary, anthropological and symbolic, economic, environmental and emotional aspects.

Participants will receive the qualification of EXPERT IN MEDITERRANEAN DIET aimed to the work integration in companies of agri-food, nutraceutic, gastronomic, design, fashion, tourism sector and to the constitution of new agricultural enterprises and of green economy.

Fig. 17: A stake holders network to support the communication, the promotion and the development of the project.

obiettivo: "dal cucchiaino alla città"

- Il Master è teso alla formazione dei primi **ESPERTI IN DIAETA MEDITERRANEA**. Come la "dieta", spazio della casa romana destinato all'accoglienza e alle relazioni, il Master è il luogo della ri-formulazione dei rapporti tra uomo e ambiente, cibo e salute, terra e design, contenuto e contenitore, della ricerca e dell'innovazione scientifica per lo sviluppo di prodotti e servizi della filiera di produzione del cibo: [ali-mentazione] ali = ingrediente creativo + mente = ingrediente scientifico + azione = ingrediente produttivo.

piano didattico

- Attraverso un modello didattico innovativo [landesign/ali-mentazione] i partecipanti saranno formati alla gestione, con un approccio multidisciplinare, della filiera di produzione del cibo negli aspetti formali e funzionali, medici e nutraceutici, enogastronomici e culinari, antropologici e simbolici, economici, ecologici ed emotivi. I prodotti risultanti potranno implementare nuovi circuiti e supporti di distribuzione e vendita.

sboocchi professionali

- I partecipanti acquisiranno il titolo di **ESPERTO IN DIAETA MEDITERRANEA** finalizzato all'inserimento occupazionale in aziende dei settori agro-alimentare, nutraceutico, gastronomico, design, moda, turismo e alla costituzione di nuove imprese agricole e della green economy.

Abstract

The rich Arab - Norman architectural heritage of Palermo is, in its manifestation of different forms of art, an exceptional and unique result of a cultural syncretism. It describes the city as a privileged gathering place of the West Christian culture with the Eastern Byzantine Empire and the Islamic world in the twelfth century.

The serial nomination of the 'Arabic - Norman itinerary of Palermo' includes monuments holding inside a unique mosaic wall and pavement decoration as one of the major artistic features of its outstanding value.

Starting from the 'Management Plan' presented in December 2011 for the nomination in the World Heritage List of UNESCO, the present contribution reflects about the opportunity to include issues related to the preventive conservation management of mosaic decoration within the strategies of management plan or to relegate this topic exclusively into a specific conservation plan.

Through a comparison study with other World Heritage Sites from Sicily and from the international context, the paper investigates the opportunity of an interaction between the management plan and the actions for protection and maintenance of the heritage material essence.

The case study of the Arab - Norman itinerary as complex ensemble of sites seems to ask for the management of a coordinated and integrated system of protection of this exceptional and fragile decorative technology that goes beyond the occasional event of a massive restoration site.

Keywords: Arab-Norman Architecture, , Mosaic decorations, Management Plan.

1. The nomination of Arab-Norman Itinerary of Palermo, Monreale and Cefalù

The nomination process started on 1996 when the 'historic centre of Palermo, Botanical garden and Monreale complex' had been inserted on the national tentative list. The nomination partially changed in 2001 with a proposal named 'Palermo and the cathedral church of Monreale'. However, in order to better follow recent UNESCO strategies, the proposal changed once again towards a more historical theme and a wider territorial context, including also the cathedral church of Cefalù. Therefore, since 10th October 2010 the itinerary 'Arab-Norman Palermo and the cathedral churches of Cefalù and Monreale' is on the World Heritage Sites (from now on WHS) Tentative List of UNESCO.

The nomination is about a complex ensemble of different site typologies running from cathedral churches to civil constructions also involving three different municipalities: Palermo, Monreale e Cefalù.

The statement of its Outstanding Universal Value describes the Arab-Norman heritage as the legacy from the socio-cultural syncretism that characterized civil and monumental architecture as well as fine arts, during the Norman Kingdom (XI - XII century). The cultural elements from byzantine and Islamic period that were still present in the ordinary reality from previous dominations, had been mixed up

together with local and north European components generating an *unicum* and endemic cultural configuration. [1]

Being quite ignored by the national historiography, Arab-Norman heritage has been studied by several eminent foreign scholars (Lazarev, Goldsmith, Otto Demus, Kitzinger) probably inspired by travellers like Goethe, Guy Maupassant or travellers from the *Grand Tour*, like Viollet Le Duc, that used to reproduce their visual experiences by suggestive and often, detailed drawings.

The nomination recognizes three out of ten possible eligible criteria imposed by UNESCO: criteria I, II and IV.

Fig. 1: Territorial context (source: Google earth).

Together with the two outskirts cathedrals, the 'inventory' of the candidate properties constituting the Arab-Norman heritage of Palermo includes eight monuments.

Those properties have been selected within a range of 23 Arab-Norman sites settled in Palermo and described in chapter one of the Management Plan [2]. Following the UNESCO criteria – integrity, authenticity and state of conservation - three categories have been determined in order to distinguish properties feasible to be part of the nomination. The A1 category holds the eleven properties of which features respond to UNESCO requirements. The A2 category includes four properties described as needing for 'management and infrastructural interventions'. 'Due to the lost of original elements' the remaining eight properties are classified in the category B as inadmissible to the Arab-Norman Itinerary.

However, the management plan contains historical information e data about the whole series of Arab-Norman properties. Apparently the inclusion on the WHL is not approached as an opportunity limited to the areas holding the eleven nominated properties. In some case a succeeded nomination as WHS, could generate a great risk through the increase of the gap between nominated sites and the rest of monuments. This also prompts to a stronger exclusion from touristic routes, preservation actions and general care. On the contrary, the overall future perspective of the nomination aims to include the rest of Arab-Norman heritage as well as the historical city centres, into an integrated system of safeguard, conservation and evaluation set up around the UNESCO label. In such a sense, the Management Plan seems to evocate a holistic vision in which 'individual monuments and historic buildings are only part of the larger ensemble of the heritage resource' [3].

However, the complexity of this nomination presents some critical points mainly concerning two issues: the geographical extension with related problematic and the lack of homogeneity within individual monuments in decorative features, use, fruition and social contexts. Section three will go deeper in these problematic relating them with the setting of a management system. (V. Megna)

2. Preservative management system of mosaic decorations: the past and the present

2.1 The past

The first of three criteria selected to define the outstanding value of those monuments named to the WHL regards their mosaic decorations. The criterion (i) of UNESCO refers to the site as 'a masterpiece of human creative genius'. Referring to the description given in the Nomination Dossier 'the Byzantine mosaics of Palermo, Cefalù and Monreale are among the most important and best preserved examples of mosaic art Comnenian. In Particular, the mosaics in the Cathedral of Cefalù are a supreme example of mosaic art. The muquarnas painted wooden ceiling of the Palatine Chapel

in Palermo is an artefact unique in the world, its combination of constructional expertise with the elegance of its forms and decorations mark it out as a masterpiece'.

Fig. 2: Table of nominated sites including mosaic decoration (by V.Megna).

The excellence and the quality of mosaic decorations that today we admire in the Arab-Norman heritage should be interpreted looking at high technical and artistic skill of Byzantine artists who worked in twelfth century, together with the skills of further figures operating within the mosaic yard. In this regard close similarities have been recognized between the Norman constructions and those in Constantinople, confirming their Byzantine character. The Admiral George of Antioch brought in Palermo Greeks mosaic artists, who probably worked in the Palatine Chapel and in the Church of Saint Mary of the Admiral – build by the same George of Antioch. They were joined by new workers also from the Byzantine Greece, which gave birth to the great mosaic decorations of the Cathedral of Monreale, in the reign of William II. [4]

In mosaic yards the starting point used to be a paper model, part of the collections of drawings that could be in the form of "cartone" or "book of models" from which artists could draw the iconographic repertoire of both sacred scenes and individual figures. Starting from the "cartone" preparatory drawings were produced impressing the fresco mortar later filling them with colour backgrounds that served as a guide for the subsequent laying of mosaic tiles proceeding "day by day". The personnel at the cutting of glass tesserae also do not work in the laboratory but in situ under the close direction of mosaic master that selected the type of tiles to be cut during the day. Inside the mosaic yard different figures used to work side by side covering a specific role: painter, mosaic worker, cutter. [5]

Given the quality and the high level of these Byzantine mosaics recognized over the entire Mediterranean basin, such decorations had been the object of attention and systematic 'maintenance' over the centuries. From the history of restoration works related to Arabic-Norman sites emerges as the mosaic tradition in Palermo has always been alive and active thanks to the numerous and frequent maintenance performed through the handing down of knowledge, even over families' generations. From the early restoration works until those from the twentieth century is possible to detect continuities and discontinuities in executive modalities and techniques carried out in construction site. Since 1345, extensive restorations of mosaic decorations in the Palatine Chapel are recorded over the centuries together with the names of the mosaic artists. [6] However, these interventions often aimed to remake or embellish entire portions of the mosaic in which restorers often changed also the subject of representations. In the sixteenth century, the medieval craft tradition was already lost and interventions on mosaic decorations started to be carried out in basic way, being poor in aesthetics and technique quality and therefore recognizable. [7]

This is the case of Monreale cathedral where in the sixteenth century a restoration site had been directed by Master De Masi Oddo, founder of a dynasty that worked to the cathedral for more than a century. During the interventions ceramic tiles which technology is far from the Byzantine tradition had been arbitrarily added. [8]

Restoration works from eighteenth century recorded the contacts between Palermo, Rome and Venice. Indeed in 1753 the mosaic artist Mattia Moretti came from the Vatican City, for restoring the mosaics of the Palatine Chapel. He established within the Chapel a mosaic school on the model of the Vatican Mosaic Studio, being its director from 1753 to 1779. In the school different figures involved in different roles and tasks within the organization of a mosaic yard were trained. The mosaic conservators trained in the school learned about medieval art and techniques becoming specialists in the imitation of ancient Byzantine style and able to carry out simple additions or entire figures. In nineteenth century, the renewed interest in the Middle Ages, the in-depth study of ancient periods and the desire of stylistic restorations invaded also Palermo.

The Palatine school trained the largest mosaic artists engaged in Sicily in the nineteenth-century restoration yards of Palermo Arab-Norman heritage: Rosario Riolo and Bonanno Zuccaro brothers. They achieved so high levels in quality that 'deserve the acclaim of foreign and domestic artists and archaeologists' [9] not only for the results of mimesis but also to refine of the execution technique. During the second decade of the twentieth century the restorer engineer Francesco Valenti will be the successor of the superintendent and architect Joseph Patricolo, the pioneer that in late nineteenth century started actions for the protection and restoration of Arab-Norman monuments. The restoration works conducted by Valenti on mosaic introduced the technique of strappo - tear – of mosaic layer from the substratum then followed by its re-adhesion, and the use of what at that time was considered as the most innovative and reliable material: the cement. It has been used to make the mortar being armed with wire anchored to the substrate with nails on which mosaic tesserae were inserted. [10] (C. Spallino)

Fig. 3: Mosaici della Chiesa di Santa Maria dell'Ammiraglio, dettaglio della cupola. (Ph. C. Spallino).

2.2 The present

The long and complex history of mosaic restorations that have taken place over the centuries highlights the extreme fragility and vulnerability of the Byzantine mosaics that are an integral part of architectural systems. Despite the vicissitudes and interventions, Caesars Brandi about the mosaic decoration of the Palatine Chapel, stressed their 'undoubted formal coherence, the quality of which, in spite of the restorations, renovations and triumphs of diversity of mastery, rather than school'. [11] This formal coherence is also found today in the church of St. Mary's of the Admiral as well as in the Cathedral of Cefalù and Monreale, whose mosaic have been restored since 1960 until our days certainly with a conservation vision but always under the pressure of emergency assets caused by pending risk conditions. This typology of restoration work is the most common and informs also the most recent restoration works. The Palatine Chapel was damaged by the 2001 earthquake. Its restoration was funded by the German patron Wurth. Works for the conservation of mosaic decorations have been carried out from 2003 to 2008.

The recent restoration of the Church of St. Mary's of the Admiral, ended in December 2012, for the first time applied on the mosaic decorations the *quality control procedures* during executive phases of work. In this procedure the chief for 'operating quality control' is in charge of writing a plan that provides the necessary information to carry out a controlled management of the restoration site. The plan defines and programmes inspections, control procedures for materials, control procedures of the site construction activities, the plan for diagnostic analysis and all necessary documentation forms.

Today, the rigorous documented record of materials, construction techniques, methods of intervention and preliminary investigations carried out in the mosaic decorations of the Church of St. Mary's, is an issue of fundamental importance in order to optimize future maintenance operations and thereby ensure the preservation of the site.

In order to replace this traditional logic of post-damage interventions with a vision of maintenance practices and preventive conservation planning specific structures have to be created and charged of mosaic maintenance and conservation.

The old *Fabbriceria* of the Cathedral of Monreale and the *Fabbriceria* of Palazzo Reale in Palermo, founded in November of 2010, represent the institutions responsible for the conservation and

enhancement of the same architectural heritage hosting them. The art.37 provides of the Rules of the National Association of *Fabbricerie*, states that one of the aims is to 'provide for the costs of maintenance and restoration of the church and outbuildings and stable administration of the assets and offerings intended for that purpose'. This impose to these institutions a very high financial commitment and management. The rules also make explicit reference to the principles of preventive conservation as a common strategy to be taken into account 'tending to the prediction of the damage and to be implemented by programming controls on works and actions carried out in accordance with the logic of minimum intervention (....) a system of preventive practices so to postpone the need for restoration'. [12]

Beside the related heritage preservation, the new *Fabbriceria* of the Royal Palace of Palermo aims the development and promotion of the Norman period in Sicily through a long- term project to be developed starting from the Royal Palace, as a pilot project and later applied to all Arab-Norman emergencies 'in view of the development of a conservation management and enhancement plan, involving the whole Arab-Norman heritage, being the Royal Palace the urban and geographic epicentre'. [13]

Apart from the two *Fabbricerie*, for remaining nine sites included by the nominations, ordinary maintenance works on the mosaics are in charge of the owner. Just in the case of extraordinary measures the Regional Superintendence of Cultural Heritage has to be contacted and asked for carry out the interventions. Unfortunately, the general lack of economic resources often leads to a rebound of responsibility which in turn generates waiting situations referred which the heritage is the only victim. (C. Spallino)

3. The criticism of 'Arab-Norman Palermo and the cathedral churches of Cefalù and Monreale' itinerary Management Plan

3.1 Management critical points

As mentioned in section one, the setting of an efficient management system concerning the 'Arab-Norman Palermo and the cathedral churches of Cefalù and Monreale' itinerary could be complicated by the specific features of the nomination.

One of the critical issues that increase the difficulty in managing the proposed heritage sites is the set of territorial differences. The three municipalities involved in the nomination have different spatial dimensions, administrative references and social attitudes. The amount of inhabitants differs from 653.790 in Palermo to 38.562 in Monreale and 14.393 inhabitants in Cefalù. [14]

As 'itinerary', this nomination does not involve only the single properties and their buffer zones but embraces the connections – spatial, cultural, social, economical, infrastructural etc. - within the three urban centres.

The wide extension also involves a large range of private and public 'stock-holders' that are responsible for the maintenance and the management of their own properties. This makes the assessment of management system even more difficult encountering complex bureaucracy processes and different expenses modalities.

The Management Plan for the nomination partially dedicates the forth section to the analysis of economic and touristic resources of the three municipalities. A wide and very detailed range of data about urban and territorial infrastructures, demography, economic structures and activities, tourism dynamics and trends as well as indicators for tourism supply and demand, are provided from accurate urban studies both in urban and territorial scales. An introductory chapter provides an overview on local and regional administrative systems together with conservation and urban planning instruments and policies.

Within the existing Sicilian WHS, also 'Aeolian Islands' and 'Late Baroque Towns of the Val di Noto (South-Eastern Sicily)', Including different urban centres and their Management Plans afford the same issue. Nevertheless, previous studies highlighted the difficulties in matching times and modalities of local ordinary planning with WHS Management Plans, especially within the Sicilian context. [15]

The inclusion of several municipalities involves different local ordinary planning tools (i.e. three different master plans for each city). The study of those Sicilian WH sites demonstrated that above mentioned criticism make management plans inefficient in achieving the foreseen objectives, being unable to coordinate different planning instruments so to also reach the objectives (i.e. the tourism deseasonalization).

Moving into the scale of the single properties, further critical points lie into the different features of individual sites as well as in their actual state of use, conservation and fruition. The richness in internal or external decorations cover a wide range going from its total absence (i.e. Admiral Bridge) to a massive presence (i.e. Monreale Cathedral). Furthermore, the material of decorations can be difference holding a variety of mosaic tesserae – some of them made by glass paste some by stone or

ceramic - ceiling woods and *opus sectile* mosaic floors and 'lambris'. Those differences will consequently lead to various problematic issues asking for different actions.

Some of Arab-Norman monuments included in the nomination procedure still keep the original use (i.e. all cathedrals are still used for regular religious services) while others either have today a different use (i.e. the Royal Palace hosts the Regional Parliament) or do not hold any specific function being only part of touristic routes (i.e. San Cataldo church). Some monuments (i.e. Admiral Bridge) are settled in neglected contexts or are outside both to city historic centre and tourism paths. Furthermore, remarkable differences in fruition modalities and amount of visitors are between monuments already intended as sightseeing which also prompt a variety of tourism-related pressure impacts. (V. Megna)

3.2 The role of conservation within the Management Plan

In order to guarantee protection and conservation actions concerning WHS, as stated by the 1972 UNESCO Convention [16], in 2002 the Budapest Declaration established Management Plans as part of required documents for new WHL nominations. Three years later UNESCO Guidelines made the required Management Plan a compulsory document also for previous nominated WHS.

The present study will point out the role that an integrated conservation system plays within the Management Plan focusing on the outstanding resource of byzantine mosaics hold in the Arab-Norman itinerary. It will highlight the dichotomy between theoretical principles informing the concept of Management Plan and their interpretation in the specific case of the Arab-Norman nomination.

UNESCO did not provide for specific guidelines for WH sites Management Plans as it was taking into account the specificities related to each States Party concerning culture, environmental, economical, social conditions as well as legislative and administrative systems.

Therefore, in 2004 the Italian Ministry together with the National Commission for WHS provides for a 'Model of Management Plan'. The text structures the plan into five planning levels and related strategic plans [17] :

PLANNING LEVELS	STRATEGIC PLANS
- Assessment of monument value and state of conservation	- Assessment
- Preservation and Conservation	- Protection
- Cultural Evaluation	- Participation
- Economic Evaluation	- Development
- Monitoring	- Marketing

The preservation and Conservation level is developed into work-plans that concerns: a) definition of safeguard measures chronologically defined and ordered in specific sequences for individual objects to be protected; b) directions to address urban planning tools to the needs of heritage sites; c) executive plans for material conservation. It is also stated that the state of conservation has to follow damage typologies detected in the Risk Charter of which methodology comes from the Italian Minister of Cultural Goods and Activities and the ICR - Central Institute of Restoration -. It is suggested the comparison between damages surveyed in individual sites in order to detect the frequency and the eventual causes of damage phenomena and to address conservation intervention plans. Ministerial guidelines underlines as specific features of each WHS nomination can invalidate practices set up for a different case. Nevertheless, for any kind of nomination, from individual site to territorial nomination, it is stressed that efficient management is usually guarantee by a preventive conservation vision.

In order to ensure an efficient and faster system to carry out the WH Arab-Norman nomination procedure, a new management structure has been defined. Therefore, the 'Fondazione UNESCO Sicilia' took in charge the drafting of the Management Plan.

The Management Plan for the nomination of Arab-Norman Palermo and the cathedral churches of Cefalù and Monreale', officially presented in 2011, shows a double order of anomalies. The first one refers to the general structure of the plan while the second one concerns specifically the vision and the concept of conservation that informs the whole text.

The plan is structured three 'cumulative' planning levels:

- Heritage knowledge, protection, conservation, enhancement plan
- Action plan for social, cultural and economic research and enhancement
- Communication and territorial marketing plan

Except for the 450 pages of Aeolian Islands MP, compared with remaining four Sicilian World cultural sites Management Plans, the 560 pages of this text seem an anomaly. Indeed, the massive gathering of data and information provided within the document does not really match with the general purpose of being a practical and operational tool. The structure is not pointing out clearly the main operational sections. Provided information about damage analysis, risks, objectives, actions, financial resources, indicators etc. are not synthesized together in order to offer the reader with a general framework and a

clear management tool. The vision informing the Plan is slightly present within proposed interventions and operational guidelines as well as a coordination in management system, is missing.

The 'Fondazione UNESCO Sicilia' provided expertises setting a specific team for the Management Plan reporting. The results from a project promoted by the CNR within National Program Research (PRIN) on monitoring efficiency of Italian WHS Management Plans, underlines that the lack of managerial skills within MP team (contrasting with a wide presence of architects) contributed to the lack of measurable indicators thus with the inefficiency of the plans [18]. It suggests that the involvement of certain expertises within the drafting process of management plan have influences on the general structure and vision of the document as well as more specific issues.

This would, for instance explain the in-depth analysis on historical issues, intangible culture as well as on urban and territorial studies.

Now, 'since conservation is an essential part of the management process, the theory guiding conservation actions must be understood and used by the multidisciplinary management team' [19], the absence of conservation experts appear rather bizarre.

Despite several statements included in the text remarking the relevance of monuments preservation and conservation as objective of the plan, a real focus on this basic seems to miss.

Data about the state of conservation concerning single monuments are fragmented and repeated into different sections of the plan. They provide general information referring specifically to short or long time restoration works. However, the state of conservation never refers to a synthetic analysis of physical and material conditions and specific deterioration conditions related to the peculiarity of individual site. A table summarizing risks analysis for each of the site settled in the three municipalities define three different risk impacts: physical, fruition, environmental impacts. It is detectable a prevalence of 'high' physical risk factors investing 7 out of 11 nominated heritage sites while only one site, where restorations works were carried out during the drafting of the MP, is evaluated as low-risk. However, the table is missing in related explicative text about criteria and procedure leading to 'High-Medium-Low' risk assessment. The same assessment has not later consequence in a conservation program proposal.

Following the risks analysis, a synoptic table provides an overview relation between intervention areas, objectives, actions and expected impacts. The words describing the intervention areas – conservation, protection, 'valorizzazione' – enhancement - are used inside the matrix in an ambiguous way. For instance, the word 'conservation' used together with the word 'protection' refers to actions concerning maintenance operations, monitoring net and conservation state monitoring, while used by herself indicates actions for visitor management. Also the term 'monitoring' used several times within the range of actions has not clear reference to a specific contexts and the relative meaning results unclear.

The list of actions related to the 'state of art, protection, conservation and enhancement plan' reveals an exceeding of actions in security field (remote distance control systems, security personnel, video security) as well as in visitor management. Despite this, few actions are referred to maintenance

This aspect is highlighted by the related specifications that should follow in next paragraphs. The phrases 'ordinary and extraordinary maintenance' as well as 'systems for monitoring the conservation state in short and long terms' are only repeated without any development. It is the same for the proposal about a pilot project concerning the development of Arab-Norman heritage risk charter that is inappropriately referred to the objective concerning 'security enhancement'.

In these terms, a best practice within Sicilian WHS is the Management Plan of 'Villa Romana del Casale' that refers to the archaeological park of the roman villa and to those of nearest municipalities [20]. Furthermore, it includes exactly the same action concerning the 'systems for monitoring the conservation state in short and long terms'. The action refers to the same objective – enhancement conservation and monitoring related activities – and it is close defined by a table that concerns: the general vision of the plan, the planning field, objective, action, description, stakeholders, financial source, expected impacts, monitoring indicators.

On the whole, aspects like a simplified bureaucratic procedure for the management of the interventions, specific actions related to the specific features of each site, detection of ordinary financial sources, etc. are never taken into account by the plan.

The lack of a priority scale within the list of actions does not allow a planned strategy for budgeting. The real needs of heritage sites are revealed to be less relevant than achieving the opportunity for found programs.

Although it is evident that contemporary economical crisis, national cutting founding and local economical dislocation made the availability of financial resource a basic issue for cultural site management, the MP does not take into account available economical resources or budgeting programs concerning fixed and unexpected costs. Above all, the presence of different actors in charge of management site – municipalities, Sicilian Region, Catholic Church etc. - could face a different in economical availability for affording maintenance expenses and following management guidelines.

Founding programs often concerns extraordinary and big-scale restoration works while very few programs are suitable for sustaining preventive conservation or ordinary maintenance.

A recent newspaper article informs that UNESCO Sicilian Foundation will get a fixed contribution (€ 0,30 cent) for each ticket sold and also a further fixed average (€ 0,80 cent) for inhabitants from each the three municipalities [21]. In those economical supports, it is likely suitable the budgeting for an ordinary found concerning ordinary and fixed expenses related to maintenance but also to security and communication.

The Management Plan of a further Sicilian WHS serial nomination – Syracuse and the Rocky Necropolis of Pantalica – includes an excellent example of tables where each action has individual evaluation of related costs. It is also specify which will be the eventual financial source. The table goes deeper defining expertise needed, human, technological and infrastructural resources, phases and timing for realization. Referring to indicators it also defines periodic controls. [22]

Sicily hosts five WHS classified as cultural site while the Mount Etna is a natural site. Like the present nomination those related to Aeolian Islands, Syracuse and Pantalica, Baroc Towns of Val di Noto, are serial nominations. Despite same mentioned good example of Management Plan, the 2013 Dossier from Legambiente association highlights that all WHS show a dramatic situation concerning threats related to their conservation [23]. WHS label and related Management Plan does not seem to guarantee the preservation of the site and the development of the surrounding socio-economical conditions, especially if the nomination is approached as an ending point instead of a responsibility action toward the whole humankind. (V.Megna)

4. Mosaic decoration Management: future proposals

Once problems and complexities for the definition of a management plan that involves eleven sites within a large itinerary have been identified, it should be emphasized as the conservation of mosaic decorations is an issue somewhat lacking in the Management Plan.

Given that the apparatus of Byzantine mosaics satisfy one of the UNESCO criteria for the WHL nomination, that they are vulnerable and fragile also in the light of an increase in the tourism impact, that the presence of several stakeholders and the involvement of different public and private actors responsible individual sites, a Management Plan must be a "guide" for the conservation management of the precious Byzantine mosaics held within the nomination sites. A correct interpretation and adaptation of National Management Plan guidelines as well as further best references concerning the preparation process and its implementation phase would be aware of not negligible complexity of WH sites management. In order to be an operational tool, the management plan should include a strategy of integrated and coordinated actions that relate to the conservation of all mosaic decorations within the Arab-Norman itinerary. The Management Plan should contain take into account the Outstanding Universal Values of the application to the World Heritage List and should provide guidelines addressed to the overall of involved sites under the auspices *Fondazione UNESCO Sicilia* as the coordinator entity for operational actions of preservation and management.

The actions concerning in the Management Plan knowledge and research fields will be engaged in the collection and systematization of so far gained information on the mosaic decorations through the realization of thematic databases, promoting the integration and interdisciplinary nature of the information. A careful digital collection and systematization of data is necessary to bring together into a single tool historical and technical information as well as diagnostic results. For each site, the use of detailed geometric surveys, graphic and iconographic supports will allow a deep approach to single detected areas of mosaic surfaces. Each of those areas will be referred to constituent materials, techniques, laboratory data thus reconstructing the history of the restoration through summaries and scientific mapping to better address future interventions.

Management Plan's guidelines should take into account the need to optimize the monitoring activities on the mosaic decorations by establishing diagnostic plans, permanent detection systems of environmental conditions, and the definition of specific risk maps that assess the level of vulnerability to the aggression of environmental territorial factors. This wealth of information will then be available to different areas of interest of the scientific community helping to promote multidisciplinary debate.

The implementation of existing data must also be supported by the application of quality control procedures for all future maintenance and restoration works concerning mosaic decorations. The documentation of those works will raise a wealth of information about materials, construction techniques, intervention methods, cycles and phases of individual processes, preliminary investigations thus taking full advantage of the architectural knowledge for the optimization of future maintenance operations and ensuring the preservation in time of the site itself.

The mosaic maintenance plan is in fact based on the actions of knowledge and research and is the real operational tool for actions of conservation and protection. Through the establishment of protocols shared by all sites of the Arab-Norman itinerary is possible to define different types of instructions for carrying out the inspections and the different procedures for periodic inspection of the main damage factors. This allow to preventive uncontrolled dynamics of pathologies or damage factors.

If these protocols are defined according to the principles of quality control "measurable" indicators will be established leading to specific "corrective" actions. Taking into account also the expected increasing of vulnerability of both wall and floors mosaic surfaces in view of a tourism high-impact, protection measures for the mitigation of risk, must also go through the application of *ad hoc* protocols that are specific to individual sites. These include for example the periodic assessment of values detected by the environmental thermo-hygrometric monitoring control which is necessary for the conservation of mosaic decorations. In this regard it is necessary that *Fabbricerie* of the Cathedral of Monreale and the Royal Palace in Palermo together with the other actors responsible for the management of individual sites become the real protagonists of the maintenance actions through the adoption of shared protocols.

The Foundation UNESCO Sicilia through its control and supervision, considering the itinerary Arab-Norman in its complexity, will periodically define a "program plan of interventions" in the short, medium and long term in consultation with individual operators. It must also operate on the inspection of individual manager decisions.

The expansion of such existing structures must also take place through the review of internal human resources by adjusting the composition of the team responsible for the actions of protection with the inclusion of specialized figures. The procurement of financial resources is necessary for the establishment of permanent laboratories and teaching facilities that may become the point of reference for the restoration of Byzantine mosaic. Here, the scientific community will be able to share a unique and constantly updated documentary heritage about mosaics. Considering the actual Management Plan may be that this last proposal could flow into the ambitious project only mentioned in the plan for the Arab-Norman itinerary, and called 'City of Restoration'. [24] (C. Spallino)

5. Conclusion

The present contribution had as starting point the search for preventive conservation and maintenance strategies concerning byzantine mosaics within the Management Plan prepared for the inclusion in the WHL of 'Arab-Norman Palermo and the cathedral churches of Cefalù and Monreale' itinerary.

The investigation of this specific topic encountered several difficulties due to the unclear structure of the document. The lack of a close examination of preventive conservation programs providing guidelines for coordinated and integrated extraordinary maintenance and restoration works of those sites included in the serial nomination highlights the inappropriacy of the plan.

Management Plans certainly ask for multidisciplinary contributions and interests coming from different academic fields are more and more increasing. Economic, management and tourism disciplines are approaching the topic of cultural heritage from a specific point of view. Nevertheless, the 'physical preservation of sites nominated as the world's most important non-renewable resources, need special care and efforts to redress the imbalance between our needs' [25] (see tourism increase, economic development) and its protection (referring to its material not just to security issues). Without physical and material preservation of tangible heritage all expected result lost their existing sense.

The fragility of mosaic decorations, holding an outstanding value, certainly ask for specific maintenance and conservation procedure coming from an active conservation system – see *Fabbricerie* -. Therefore, planned financial resources should be used in order to define the most efficient conservation management system for those decorations. Existing structures (*Fabbriceria* di Monreale e *Fabbriceria* di Palazzo Reale) could be strengthen while a new structure could provide for mosaics maintenance of the remaining sites (Castle of Zisa, Chiesa di Santa Maria dell'Ammiraglio, San Cataldo). Of course coordination within the management system of individual sites should be guarantee through guidelines under the auspices of the Foundation UNESCO Sicilia.

Paesaggio: Paesaggi culturali

Abstract

Mediterranean area has been marked by connections between wine, economy, landscape and culture. If it is true that first few sips of wine were those of the peasants of Anatolia, the cultural assumptions behind the idea of *Wine Terroir* implies a rich network of identities at the intersection of land, and heritage varieties and products.

There are many connections between architecture, landscape and identity, which could be analysed with different interpretations. The key issue is the concept of "*terroir*", that in every place involves a network of meanings arising from the intersection of landscape, grapes vines, products and economy. The rural culture, with a social structure of family type, over the centuries has helped to preserve the integrity of different environmental contexts.

A specific example is the case of the recovery of Pompei ancient Winery that are productive today, in which is evident the importance of maintaining a recognizable environmental impact of historical heritage signs connected with nowadays productive landscapes towards innovations.

Keywords:

Landscape Heritage; Local Production; Wine Culture; Local Identity

1. Wine landscape and Mediterranean Connections¹

There are many relations among architecture, landscape and Old Roman identity which still nowadays influences the terroir. In a broad sense the entire Mediterranean region has always been connoted by a relationship among wine, economy, landscape and culture. In this paper we focus on how the Mediterranean area has been marked by these connections, discovering how this area, its grape varieties and its products are united in a unique relationship. The role of Roman expansion confirmed this relationship. Ancient Rome had a pioneering role in history of wine. Its influence on the viticulture moved from Italian land toward a wider extension. So the Mediterranean Sea could be considered as the cultural assumptions which is behind the Wine Terroir, implying a rich network of identities at the intersection of land, heritage varieties and products.

The term "terroir" is an idea that was born at the origin of the wine world. The physical characteristics of the chemical soil and the geological one, such as those of the climatic and exposure aspects, shall be regarded as essential conditions for having a high quality standard which is strictly depending on a given spatial system. So the terroir is the basic condition for obtaining those products which we, in the common sense, define "real products". In this prospective it is important to describe the features that characterize the terroir, studying the effects on the products.

The idea of "typicality" is then born at the intersection of spatial data and anthropological factors and, speaking of wine, it includes the territorial traits, on one hand, and the cultural traditions and methods of cultivation on the other one. This idea is then extended in a broad sense because the world of wine can be one of those steps to regain territorial identity. The operational strategy, in wine landscape culture, generally borrows many approaches from other scientific fields and analyze the derivatives that influence the architecture of the wineries and ultimately the declinations of the environmental planning, into the interaction with the places and the people.

These considerations change the notion of earth into something more compound than soil, characterized by a movement of energy that reminds us the idea of eco-museum complexity. Many French eco-museum experiences have connected winery spaces inside wide landscapes, respecting the identity of each different little space. The two main reasons for the establishment of an eco-museum in fact is the need to rebalance the environment of a place and a willingness to work for the recovery of traditions that have developed in the same place. These characteristics make southern Italy winery areas particularly suitable for eco-museums in order to promote tourism and sustainable identity.

A marginal place has good chances to be easily adapted in a composition of peculiar united mosaic with an attitude towards flexibility, if we operate with a framework of variable conformations of landscapes that have to be recovered.

The renewal of intrinsic value of a Landscape should start from a method based on an appropriate relation among elements of small size, as it was usual in the Mediterranean tradition, with a strong durability of differences, which become an identity character for the landscape of a place.

Specially in order not to totally cancel the distinctive feature of the identity of southern places, specific measures are to be adopted not only as regards the specificity of the product, like it frequently happens with autochthon wineries, but also with regard to perceptive aspect of places. However, the most relevant coming out focus is that the best choices are the ones that found a balance with respect to the perceptive rules. At a first glance one might argue that a polarization would lead to a decrease in the intensity of identity. This claim rests on the ideas that a synthetic idea would emerge in a landscape, but there is a relation inherent the correspondence of wine economy and wine landscape aspect: the recognition of a specific historically founded traditional economy corresponds also to a special organization and, if the economic structure is fragmentized, an homogeneous landscape asset design seems better

¹ Francesca Muzzillo

suited to describe reality of big economic standard and it is not often apt to be reapplied in southern contexts.

An innovative approach should offer the opportunity to enhance the cultural identity of local communities, urging the integrated conservation of the evidence of fragmented economic reality, respecting on one side the production processes and on the other side the natural ecosystem.

Notwithstanding the inherent difficulties, there are hidden opportunities in old Southern Italy rural wine landscapes as they maintain a sensible attention to the environment which moves onto the natural environment level and onto the human behaviour level with the same attitude, an attitude towards adaptability, accommodation, contextualization.

Here, in Southern Italy Roman footmark is still strong. It connotes the quality of products that into southern reality is very often bound to the extreme variability of grapes. In fact onto the double planes of landscapes, on one hand, and of wine tasting, on the other hand, we could try to determine common denominators of landscape organization and wine identity.

2.Wine Landscapes in Architecture and trough the history²

The concept of landscape in Architecture is seen as a natural setting rather than as an inert atmosphere, mostly changed and transformed by men; the reading of the territory has always taken place according to aesthetic criteria without considering the fact that the landscape is also conditioned by the changing of economy and by the evolution of technology.

In our century human activity has already significantly altered the landscape, so that it could be hard to identify all the significant variations occurred in a short time. However, in many situations, it is still possible to detect the main aspects that bear witness to our past and, therefore, offer the opportunity to set in motion the most appropriate protective action. Therefore, we'd better modify the landscape in which we live only if we are really aware of the value of our cultural and historical heritage as well as of the environment.

Sometimes, the new identity that landscape gains through the changes is carried out by the human being, who re-interprets the landscape according to his or her own sensitivity.

So many are the elements that interact and merge into one single result, which is obviously eclectic; for this reason, Landscape is a very complex entity, made of tangible descriptors as well as abstract ones, such as culture, history and traditions. The landscape contains the history of its people, while its shapes and lines are the concrete sign of human intervention, which has made the environment productive. The archaeologists say that the territory is like a palimpsest upon which all human activities have left some trace. Of course, it is very important not to forget that, with the passing of time the Landscape has often changed its physiognomy, for better or for worse, alternatively becoming the place of disfigurement (think of natural disasters or the disfigurement of our countryside in times of famine). However, the first element in charge of the landscape's change is always the work of man: the landscape becomes the mirror of human action, which turns a large part of what we call natural into artificial.

The above-mentioned concepts lead us to an important consideration, namely the ability to understand the uniqueness of the landscape and its quality of non-transferability. Landscape mutually reacts to human activities and natural environment. About the specific topic of Wine Landscapes, full enhancement of modern wine production, conforming to the morphology of the landscape, as well as to its history, is advisable especially since a vineyard gives a hard to replace and almost inimitable identity to the landscape itself. Topography, climate, and soil cultivation techniques that are imposed from time to time, are programmed for specific environmental realities.

The landscape has been created from man, making it both productive and aesthetically appealing. In few words, man becomes one of the main actors of the landscape.

Perhaps for this reason, the value acquired by wine landscape over time can be defined as a sort of "territorial imprinting." It is through the architecture of vineyards that the landscape

² Fosca Tortorelli

takes shape, providing its wines with peculiar traits, becoming the basic value for economic processes and the synthesis of a multiplicity of relationships.

The structure of the Italian viticulture/wine system is due to the territory, intended in its physical, anthropic and cultural dimensions, and to the ecosystem, meant as quality of the landscape and of the vineyard environment. It has been repeatedly stated that the viticulture landscape is made up of sets of colours, but it is also true that even the smallest details of the vineyard can revive distant landscapes, which are continuous or hidden. We can recover this concept in the case of the farm called Amastuola (fig. 1).

The attentive viewer will note the differences with the passing of seasons and the enduring charm of the intimate vitality of the vine; landscape should therefore be lived and touched with our hands.

We have said that the landscape is synonymous with culture, history, and nature, and if it is true, this means that its appeal is given by its physicality, by its diversity. In this logic, landscape is a notion deeply linked to spatial and chronological variability.

The farm, mentioned above is located within the agro Amastuola Crispiano, on a plateau above sea level in the homonymous district, and is in an area dotted with farms since the late medieval age.

Fig. 1: Picture of “Amatole’s garden vineyard”.

Luxuriant Mediterranean vegetation characterised the surrounding area, with pine trees and the Mediterranean marquis, which create a set of aromas and flavours. Vine cultivation in this rural area is an ancient practice: grape seeds and Greek amphorae have been found during archaeological excavations.

The buildings of the farm, which are not currently used, have been renovated to avoid deterioration and to encourage tourism industry and cultural development in the whole area. The winery is underground. The barriques and barrels area, also underground, once open to the public, will be the starting point for amateurs visits to wineries and tasting and the centre of initiatives in cultural tourism, sustainable mobility paths, rural receptivity.

Is also meaningful the design of Amastuola vineyard /garden that has been highly valued from many perspectives and received several awards, among which one for the “Good Practice for the recovery of agricultural landscapes no longer productive ” and for the "Good practice for the protection and enhancement of the agricultural landscape also for tourism purposes. "

It can be considered as a unique case of harmony between production and aesthetics. The vineyards were planted on the basis of the design thought of the great landscape architect Fernando Caruncho.

Also the colour had an important meaning in his work; in addition, 1,500 olive trees, items recovered as historical monuments were relocated in 24 islands organically positioned over the surface of the vineyard and along the historic streets of the Farm, featuring the project with the contrast between the green and silver of the olive. Bright green waves of the vines. Philosopher and gardener at the same time, Fernando Caruncho drew for the first time the entire agricultural landscape as if it were a garden. When designing a garden has the task of

combining the human and the natural, not only to realize a correct and beautiful to behold, but to achieve that purity and simplicity that is built into the nature of things.

The geometry becomes the grammar of the garden itself. In fact, it is precisely through this sensitive geometric design that, coming to Amastuola, and along the long avenue flanked on both sides by olive trees, the visitor can grasp - seeing them parading by side - a kind of silver grey wall that, gradually, it composes and decomposes. The purposes of this project, reported as a case study, designed to stimulate, promote and induce a different conception of the landscape, which recovered fully its value and its potential in proposing the environments and the national wine industry.

Another important example is close to our place and is strictly connect with our roots.

If we recognize that the wine in the Mediterranean is so closely tied to a specific identity construction that, in the past, incorporated the building processes to the quality of the food product. Therefore the quality of the product was linked to the way of constructing both typological/building that of the material used.

The land is one of the connecting elements of identity construction and in this area it is distinguished as a sustainable building material, if we think of the raw land, effective bioclimatic point of view, both as a basic element of agriculture, both as a modification of the soil, carried through altimetry variations made to communicate in a manner appropriate for the processing stages with those of production. So, for the interconnections of different types of knowledge that are integrated around the "wine", the tests may not be much of a practical nature, but cultural, as projects of multidirectional network between existing reality.

The ancient Pompei is comparable to a metropolis of culture, business, merchants and trade since right before the eruption of Vesuvius, it was an important trading centre between Rome and the Roman provinces. Vineyards and wineries abound in the city and surrounding areas as leading manufacturers of fine wine, which played a key role in the culture of Pompei.

In 1996, Mastroberardino was mandated by the *Government department responsible for the environment and historical buildings* of Pompeii to conduct research in an open-air laboratory.

The objective was to investigate and discover the originally used variety of grape, the techniques of wine production in ancient Pompeii investigating it prospective nowadays.

The various botanical studies, the discovery of some casts of the support poles and the roots of the vines, only give confirmation of how and where the vines were grown.

From the study of the writings of Plinio il giovane and the frescoes found on the walls, have been identified many specific varieties.

The project to restore the ancient techniques of cultivation of vines and reintroduce them in Pompeii has resulted a success. Piediroso ancient grape vines, Sciascinoso, and Aglianico have been planted in the same areas cultivated in antiquity. These vines grow on the soil of Mount Vesuvius and Pompei's soil is the is ideal.

Today, the total area of vineyards in Pompei has become of approximately 0.60 acres divided into 15 lots, in which the experimental vineyards were planted using ancient traditions. Regarding the properly architectural aspect, in that area was found in the cell transformation and processing of grapes, with the press and channels that carried the juice in ceramic underground jars (dolia) for the collection of the must.

Another interesting area is that of "Oste Euxine" (Figure 2), or experimental vineyard, which has an area of 300 square meters, in which we find the screws of eight different cultivars, choices always following the bibliographic and iconographic studies.

Fig. 2: Picture of “Oste Eusino” vineyard within the archaeological area of Pompeii.

The choice of these case studies has been done just to stimulate, encourage and induce a different conception of the landscape, which has recovered its full value and potential, also emphasizing the fundamental relationship between the history and the wine and consequently the strength of the relationship between nature and culture.

Promotion and conservation of cultural heritage through the institution of Tourism Clusters in Campania

Antonella MARCIANO

Department of Architecture and Industrial Design, Second University of Naples
a.marciano@unina.it

Abstract

Promotion and enhancement of cultural heritage is now increasingly related to an integrated planning of the territory and to a careful political governance. This paper aims to analyze the potentialities related to the newly created "Tourism Clusters", provided by Italian laws involving parts of the coastal area of Campania Region.

"Tourism Clusters", are "large areas" organizations from the urban point of view, because each area may include several municipalities, and large parts of territory. They are based on open consultations, through which public and private actors work together for the economic development. First clusters, each having its own characteristics, have been identified and delimited after a phase of listening to the stakeholders. The goal is to create a new structure that supports tourism and economic development consistent with the mechanism of "Tourist Local Systems" as defined by a regional law still under discussion. In this paper we will describe the potentialities of the Tourism Clusters in Campania Region, the resources made available in order to speed up European Structural Funds expenditure and, first of all, the possible effects on actions for protection, enhancement and promotion of cultural heritage.

Keywords: (Cultural heritage, Tourism Clusters, tourism policy, competitiveness)

Past experience: Cultural Regional Routes

Campania Region suffers strong competition with other countries even less rich in landscape and cultural heritage, but being most active and organized to promote their resources by intercepting considerable tourist flows. The competition with other routes is more complicated for the inland areas, already marginalized and in many cases affected by the phenomena of migration with consistent depopulation. Countries which due to the scarcity of employment opportunities and no economic perspectives have to deal with the effects of depopulation with many of their young people being forced to leave. Negative factors are the high rate of unemployment, a fragile and pulverized production structure, anchored to traditional sectors with small firms, poor infrastructures, scarce quality of public transport. A past experience developed by the Campania Region in accordance with the European Multiannual Financial Framework 2000-2006 has been the territorial development program related to some "Territorial Integrated Projects", a set of inter-sector actions, coherent and integrated with each other, that supported Cultural Regional Routes. These represented one of the main tools the Campania region has chosen to implement development strategies, in order to ensure a high concentration of the available financial resources.

Territorial Integrated Projects are a tool for local development policy, in full compliance with EU regulations. They support the integrated design, aiming at tangible and intangible interventions in a territorial or homogeneous thematic area. The strategy of the design revolves around the definition of a core idea "idea-strength". The Cultural Routes help economic development, pointing to interventions along a physical path and that could coincide with a tour.

Among the positive effects of the Cultural Regional Routes there was the expected action of the communities around their cultural and environmental assets, stimulating involvement and interest. But they did not inspire either durable network mechanism or a long-term marketing strategy planning. Actually, there is not the desired economic growth nor local development.

It has happened that financing the recovery of some monuments or helping individual companies for the mere fact that monuments to be restored or companies to be supported were all physically situated along a certain route within a specific territory, has not produced a critical mass sufficient to provide a new development. Small tourist centers have been strengthened, individual companies were supported, but they remained unrelated to each other and the local context.

The objectives of this old regional programming pursued a deep idea of urban renewal. Redesign underpins new routes and new virtual development where this was slowed by critical and problematic factors. On the other hand, the old EU funds program tried to involve a lot of inland and less populated areas, without neglecting coastal areas. This was a positive and ambitious goal. A number of other initiatives were implemented following the 2007 - 2013 programming in favor of the regional economy and the environment, while the regional programming attached to the multiannual financial framework 2014 - 2020, is still in its early stages.

Structural Funds coming from Europe are a great opportunity that we often fail to fully grasp. Meanwhile, the Italian government established the model of the Tourism Cluster (Tourist District) by law, which already is interesting and valuable in itself, but it may serve to operate in an appropriate manner and focused European Funds available soon.

In this light and shadows scenario, tourism clusters model seem to be a promising perspective.

The purpose of this paper is to analyze whether the concepts of cluster or industrial district can be adapted to the concept of the Tourism Cluster as it was conceived by Italian law, and what perspectives may arise from this.

Clusters and Competitiveness: from the model of the industrial cluster to tourism cluster

Michael Porter of Harvard University twenty years ago gave us a remarkable definition of cluster. He defines clusters as: *"critical masses in one place of linked industries and institutions--from suppliers to universities to government agencies--that enjoy unusual competitive success in a particular field."*[1] This concept, that has come to be regarded as a strategic tool for local economic development, was proposed in 1990 and has attracted much attention from politicians and academics.

While noting some differences, as we shall see later, this territorial model of industrial origin can be extended to tourism industry, so as to use the model of the industrial cluster for tourism cluster or tourism district.

The cluster is intended as a new governance system applied to a given territorial bounded space, controlled by parameters such as the development and exchange of knowledge, their interrelation and all the elements that make an area unique and unrepeatable.

The skills and baseline requirements that characterize a cluster are: the fundamental link between local production and territory, the definition of a quality standard for goods and services, the exchange of knowledge and skills, the ability to increase productivity, (access to information, access to institutions and public goods), strategic complementarity between different sectors, innovative capacity, (aggregates of businesses are often more careful to understand the needs of the market compared to individual operators); the ability to create new companies (spin-offs); to establish a strong physical and information infrastructure to sustain regional economy; developing local talent with a strong educational system, knowing that universities and specialized research centers are the driving force behind innovation in nearly every region. Specialized talent and training are more important than abundant labor.

It would be especially important a strong presence of the public sector to support the production, with an advantageous tax regime for firms.

The competitiveness of the system will depend on the presence of elements such as a suitable system of cultural and recreational facilities, a well-integrated social system that participates in the development and last but not least, a strong marketing strategy. According to academic definition, cluster is a *"geographically proximate group of interconnected companies and associated institutions in a particular field, linked by commonalities and complementarities"*[2].

In broad terms, clusters are concentrations of firms that work in synergy on the basis of their geographical proximity and their interdependence, joining forces of different companies and promoting productivity of individual companies in the area, encompassing innovation and growth, and finally stimulating new businesses for the cluster's expansion [3].

Within the cluster, individual enterprises can co-operate and work together and positively contribute to innovative processes, facilitate relations with other institutions and channel knowledge and information, they can also compete directly with each other. The cluster's virtuous operation suggests

the ability of the stakeholders to work together towards a common goal. With respect to globalization, we can affirm that belonging to an innovative cluster becomes a real advantage for regional businesses in the tourism sector, particularly small and medium enterprises (SMEs). Supporting factors and resources such as infrastructure provide a firm foundation upon which a destination's tourism industry can be established.

Clusters create an environment outside individual companies that accumulate knowledge, relationships, and motivation which are key competitive advantages. For each cluster, logistics support and linkages are necessary for the success of a particular sector [4].

For example, the provision of quality tourism experience is the goal of developing a tourism and hospitality cluster. It requires not only quality attractions, but also efficient "*complementary businesses such as hotels, restaurants, shopping outlets, and transportation facilities*" [5].

In the long term, all firms in the cluster can provide and enjoy mutual benefits to and from one another. It is composed of participants from throughout the tourism value chain, including government agencies, tourism promotion authorities, private sector associations and individual firms.

Among the determinants of an Italian tourism cluster, we have to put cultural heritage and landscape. Core resources and attractors such as culture and history can be the fundamental criteria for which visitors choose one route rather than another.

Campania Region_The Territory and Tourism clusters as a competitive edge

Regional economy is made up mostly of small tourism enterprises that have to compete on the world market, and under globalization, competitiveness is essential for the survival of small firms.

In order to maximize their competitiveness, firms of inter-related sectors are invited to join clusters to better meet consumer needs, foster relationships with other institutions, contribute to innovation, and facilitate technology development for their own knowledge and information needs.

This opportunity is provided by the recent legislation related to cultural and tourism clusters, currently aimed solely at coastal areas.

The cluster approach is increasingly being employed for tourism development. Indeed, the Tourism Clusters share some similarities with Industrial District model, that complies with firms' tendency to localize in the same region, and the Cultural District model based on the integration in the same region of cultural activities, cultural heritage and landscape, all determinants that identify a territory[6].

If the integration of Small and Medium Enterprises is widely developed in the industrial cluster, it is necessary to investigate how much that model is transferable to the development of the tourism, and describe what may be the differences between Industrial economic structure and Tourism Cluster.

While product manufacturing is driven by the linear logic of the value chain, with the distinction between production, distribution and consumption, the tourism is driven by the logic of the constellation of value given by a simultaneous interdependence of individuals which define and make up the tourist offer. The local community and the territory are transformed from "passive" resource into "active" resource [7] .

In this sense, the element that really differentiates the tourism cluster by the academic definition as it has been conceived by Porter is the deep link with the territory.

In our definition, the tourism cluster defines a very large group of businesses that have a special dominant in common: the territory and the landscape, the environmental and cultural context in which they feed on and derive their reason for existence. Binding firms with a given territory is far more important than the characteristics of similarity among the enterprises. It is the land, the place, the landscape that creates the basic framework within which businesses can grow.

It follows that local community is a source of supply, a factor of co- production. With regard to the territory a Tourism Cluster may include one city or region or an entire country or even a number of neighboring countries. The size of a cluster depends on the recognition and identification of a given territory that for some characteristics (prevailing economy, geographical and morphological features) can form an homogeneous unit, and at the same time a summary of diversity.

Maybe this is the most important focal point, the design of the area, knowledge of the boundaries, the identification of its salient features, identification of potential cluster partnerships. The second step is how to join existing tourism stakeholders to form an effective cluster, and finally how to organize clusters into sustainable business practices. Government can have a significant influence on the business environment, both positively and negative. It is on this point that Campania region is focusing to improve the contribution of institutions to the tourism industry. We can now imagine how new important perspectives may be opened in Campania, with the approval of the new law on tourism, currently under discussion, which includes important innovations on the harmonization of the tourism offer, quality improvement and regulatory interventions. In this context, clusters are considered as innovation drivers at a regional level and we can now hope for a better dialogue between regional stakeholders and the creation of a new stronger public - private partnership.

Set up of Clusters, the legislative framework

The new law on tourism clusters is the legislative framework. The rules on Italian tourism clusters are set out in Law no. 106, July 12, 2011. Article 3 of the law provides for the possibility of setting tourism clusters in the coastal municipalities aiming at redeveloping and revitalizing national and international tourism, enhancing the development of the areas and sectors of the cluster, improving efficiency in the organization and production services, ensuring legal certainty and guarantees to firms that operate with particular reference to the investment opportunities of access to credit, simplifying and speeding up dealing with public administrations.

The steps

The process of establishing a tourism cluster starts with a bottom-up initiative. In this first phase, local associations were formed promoting local authority the establishment of the cluster, and at the same time opening a public discussion with all local operators. Organizers might start with meetings involving tourism stakeholders at the most. Every person directly or indirectly involved in tourism should participate. As clusters develop, trust, awareness, and cohesiveness grows, while existing tourism firms are often too focused on their own business to consider the larger tourism industry. One way to build trust is work together in trade shows, study tours, public meetings and even involving medias.

The formation of the idea of the tourist district is based on the knowledge of the characteristics of the local context, explored through the study of the socio - economic and structural values.

Although the process of establishing a cluster does not require a strategic analysis and planning of the territory, the promoters of the district should start from an analysis of the area and its features, before proposing a logic definition of its physical constraints. Thus, it is useful to consult the address provided in the institutional planning, in order to assess the compatibility of the strategic vision with the decisions made at an higher scale.

Any individual or group can approach the legislative body of the Region and request that an area be studied to determine its significance under a Tourism profile. The promoters should include the public, the business men in the process from the beginning, as soon as the decision is made in agreement with the local municipality. Educating the public about the significance of the proposed cluster is a primary responsibility of the promoters. Including the public and the business men in the process will help to increase their understanding and participation of the cluster designation.

In Campania, the proponent committees were formed by creating promoting associations, representing the main local actors. These associations have submitted the request for the establishment of the cluster to the municipality they belong to.

If the local municipalities approve the request , each one of them adopts a resolution, an act , that expresses the common will to participate to the cluster. So each municipality has to adopt the requested resolution within the chosen territory.

The Region's role

The delimitation of clusters (Distretti Turistici) is fixed by the Regions, once listened to the stakeholders through a decision-making Services Conference which is a discussion between representatives of the institutions involved, Municipalities and Associations.

In this discussion a representative of the Ministry of Economy and Finance also took part. The final report of the Conference has an official value, and it is used as a basis by the regions for establishing the district.

The regions issue an establishing decree that is transmitted to the Heritage and cultural activities and tourism Ministry. Finally, the Ministry decreed the establishment of the district in accordance with the approved territorial delimitation and in accordance with the matter discussed in the previous phases. Even if Law no. 106, July 12, 2011 does not provide for a timetable for carrying out all the phases of the process, it have been overcome in few months, from June to December 2013. To date, 12 Tourism Clusters have been already delimited, all the decrees were issued by Campania Region in December 2013. The first four approved by the Ministry of Cultural heritage are: Distretto Litorale Domizio *Domitian Coastal District* (including the municipalities of Cellole, Castelvoturno, Mondragone, Sessa Aurunca), Isolaverde *Green Island* (including the entire isle of Ischia with its six municipalities), Golfo di Policastro *Policastrum Gulf* (including the municipalities of Vibonati, Sapri, Ispani, San Giovanni a Piro e Santa Marina) Penisola Sorrentina *Sorrento peninsula* (Massa Lubrense, Mete, Piano di Sorrento, Sant'Agnello, Sorrento, VicoEquense).

Effects and results

The "Tourism District" is a new legal figure officially recognized, which can work in autonomy for the tourist development of public and private organizations that belong to it. A bottom-up approach, from companies such as major players in the tourism sector. The District has a streamlined body that has the mandate to manage the identified initiatives, being able to take advantage of important benefits: The Tourism Clusters are according to the law "zero bureaucracy zones".

Zero Bureaucracy zones are the evolution of the Urban Free Zones introduced by the 2007 Finance Act (Law no. 296 of 2006), drawing on the model implemented in France, intended to promote the economic and social development, even with the interesting mechanism of exemption from some taxes on person and buildings (IRAP and IMU and exemption from contributions on salaries of employees, mainly in the cities of the South). Subsequently, with the art. 43 of D.L. n. 78/2010, the above Urban Free Zones have been fully replaced by so-called Zero Bureaucracy Zones (ZBZ), extended to whole Italy with the stability law (Law no. 183/2011) on an experimental basis until 31 December 2013.

Today the applicable law is as follows Art. 43 D.L. 31 May 2010, no. 78, converted with amendments by Law on July 30, 2010, no. 122; art. 14, Law 12 November 2011, no. 183 (Official Journal no. 265 of 14 November 2011). Therefore, for new production initiatives established after January 1, 2012.

The enterprises will have hard financial incentives through changes in the tax regime. It is well known that in Italy one of the reasons for the lack of foreign investments lies in the presence of heavy

constraints, long waiting times for permits, numerous laws to be respected not always easy to interpret. Within the cluster all of this is ridden out and at the same time facilitated. Eventually we might get a Cluster tax policy, where within a framework of transparency and equal treatment, and on the basis of the principle of mutuality, the taxes are paid by cluster in a scheme agreed with our Tax Agency. In the tourism clusters State branch offices will be present and active and will deal with tax and contributions. They will be active points of single coordination of the activities of tax agencies and Social security (INPS), (Social security, Revenue Agencies, State Property Office, regional Offices of the Ministry of Cultural and Environmental Heritage, etc), which allow companies in the district to solve any matter pertaining to such institutions, submit claims, receive provisions. A facilitated access to regional, national and EU contribution is permitted to member companies by the opportunity to make submissions and administrative proceedings through a single collective proceeding. The financial resources could be assigned directly to the mayor responsible for the territory or to the Cluster. Today the financial resources, i.e. European Union structural funds are managed by regions, provinces and municipalities.

In this case all the firms have to establish a network, and the districts will be able to certify that each of them gets the right to access to the contributions.

In general we can state that a public intervention in the tourist sector is needed for two fundamental reasons: first, to finance tourist public goods, structures and infrastructures needed to complete the tourist product and to increase the competitiveness of the whole destination and for which the private market fails; second, to help coordination among private firms supplying different goods and services.

Transferability

A model will be considered a good practice if it can be adopted elsewhere, because a central aim of the project is to assist others to improve their own practice.

It seems that the Campania Cluster project can be considered 'transferable', because it has got some characteristics such as common goals related to some core themes eventually not so linked to the specific country, the *Financial requirements* are transferable and repeatable, Legal and institutional requirements are the same in other Italian regions.

Turism Clusters and cultural heritage

Where Turism Cluster is formed and where destinations are located are two important and influential factors. The main resources that draw tourists to destinations are the core resources and attractions, classified as natural resources such as beaches, mountains, and landscape in general, and heritage and cultural resources, such as historical towns, monuments, museums. These are called by economists Dwyer and Kim (2003) endowed resources [8]. It is clear that the main resources of the newly created twelve Clusters are endowed resources, Amalfi Coast, Cilento's Landscape or Ischia Isle are undoubtable very rich in historical heritage and have got a very well known environmental resources.

With the establishment of the cluster, the Campania Region, entrepreneurs, companies related to the tourism industry and all turism Cluster actors are forced to work together.

When all actors cooperate with each other, the tourism cluster is more likely to succeed in achieving tourism

competitiveness in a global market and in turn contributes to regional and national prosperity [9] .

Producers are made up of the private sector that provides products and the public sector that manages endowed resources. Suppliers support and add value to core resources and attractions by providing complementary products [10]. To complete this framework, we are waiting for law "Organization of Tourism System" 's approval.

The draft law "Organization of Tourism System" also provides that a Regional Commission should identify the "tourist homogeneous territorial areas" in accordance with the provisions of the instruments of regional planning; tourist homogeneous territorial area is an area delimited within the region's territory, in which the local tourism system, such as an association of public and private entities, operates for the development of the tourism economy of a given field of tourism in areas characterized by the presence of an integrated tourist offer of the excellence of heritage tourism, cultural and environmental, of local agricultural products, and wine and local crafts [11] [12]. As stated in the recent academic literature, the Local Tourist System (LTS) [13] may be considered a particular case of Marshallian Industrial District . Through the definition of LTS, the policy maker can take into account the complexity of tourism, characterized by a strong heterogeneity of goods, services and subjects involved; secondly, LTS helps promote a stronger coordination between the public and the private sector, by identifying an homogeneous territory and recognizing its importance in tourists' decisions; thirdly, through the LTS the policymaker can analyze the externalities and promote the idea of cooperating networks in a context of local development. The systemic nature has also been

recognized by the Italian legislation (Legge Quadro sul Turismo, no. 135/2001) [14] by means of the creation of an economic policy instrument, namely Local Tourist System: *"We call local tourist systems, homogeneous or integrated tourist environments, which comprise territories also belonging to different regions, and which are characterized by the integrated supply of cultural, environmental goods and tourist attractions, including typical agricultural and local handicraft products, or those characterized by a widespread presence of individual or associated tourist firms"* (National Tourist Law Reform, Law 29 March 2001 no. 135) [15].

The design of Clusters could be harmonized with the *"Tourism homogeneous territorial areas"*, as expected in the Law "Organization of Tourism System".

The law, pending approval by the Campania Regional Council, provides for specific powers to municipalities, such as "competence exercise in the field of tourism, with particular regard to the performance of the following duties and functions:

- a) promotion of local tourism systems,
- b) activation of the structures of information and tourist accommodation (IAT);
- c) harmonization of public services, opening and closing hours of shops to meet the needs of tourist flows;
- d) organization of base tourism services relating to the reception;
- e) implementation of administrative procedures in the field of accommodation;
- f) transmission of data relating to the tourism facilities available in the municipal area of the IAT.

From this the link with the Tourism Clusters. It is assumed that the definition of "Distretti Turistici" (Tourism Clusters) must necessarily be in keeping with regional planning in the area, identifying areas that have common characteristics and homogeneity both from the point of view of cultural heritage and environmental tourism [16], and according to the structure and territorial offices organization being competent in the area, as well as in the socio-economic profile of the population and characteristics of companies operating in the area, even in order to delineate intervention strategies based on common goals and widely shared by public and private institutions.

Conclusion

The Campania region was the first region in Italy to introduce the Tourism Clusters or *Distretti Turistici* as defined by the Law. The process has not been concluded, because the Region has proposed 12 districts and not all of them have already received the final approval by the Ministry of Cultural Heritage. It is therefore a process being currently still in progress. We expect, however, important developments: the unity of the territory covered by the cluster, the enterprises will be facilitated and will work in a coordinated manner. They will get tax privileges and concessions in all the paperwork. The territory in which they grow will become an economic subject itself, the site of a new development. This will have serious implications for urban planning because firms tend to bind more strongly to the territory on which they are born, and in which all of them share together what we define "the tourist offer". This will strengthen the sense of belonging and also the care and respect of the territories. The proposed global tourism offer will have a stronger and more uniform image.

The creation of the tourism clusters shapes the economic framework within which a network of companies moves. The territory, the cultural and environmental heritage are creative parts of this scenario. One of the pillars on which it rests is in fact the creation of a community that is more aware, able to attract investment, generate growth, but most of all a community that moves within a landscape, with all its assets, a source of economy, the glue and the reason for the existence of the cluster.

Abstract

The aim of this research was to study a part of the Trgovski Dom, a relevant building by Max Fabiani, realized in the beginning of 1900 in Gorizia, actually in a great state of degradation.

The first step was the survey of the theatre, subdivided in three parts: the entrance, with a staircase, the main hall – in two levels, parterre and gallery – and then the space for artists, with the stage, the dressing rooms, a large underground space as warehouse, and an helical staircase to connect all the parts.

The main space is the double-level hall, where the spectators take place. Connected by a second staircase, it expresses very well the design idea of the author.

The second phase was the geometrical analysis and the comparison between the drawings resulted by the survey and the technical ones produced by Fabiani himself. Some differences were revealed, such as a different configuration of the staircase in the entrance, a variation in the distribution of the technical spaces, the presence of a small tower in the position of the helical staircase, going to the roof of the building.

After the survey and the geometrical analysis, we started to reconstruct the digital model to simulate the interior space before the restoration of the building, to understand better the Fabiani's thought for a theatre space.

Keywords: Architecture, Survey, Representation, Max Fabiani, Gorizia

1. The Architecture of the Trgovski Dom

This research intended to analyze the building called Trgovski Dom, designed and realized by Max Fabiani in Gorizia, in the beginning of XX Century. The building was thought to be a kind of "Commerce House" – this is the translation of the Slovenian name – placed in the middle of the town, at the intersection of Via Verdi with Via Petrarca, and having the side façade exactly in front of a public garden.

Before starting to describe the building, it is necessary to speak about the architect, because in this case he creates a very interesting architecture, having his aspect derived by the Wiener Secession artistic group.

Maximilian Fabiani was born in Cobidil, near San Daniele del Carso, in 1865 and died in Gorizia in 1962. He studied architecture at the Technische Hochschule in Vienna, where he met Otto Wagner, who in that period was one of the major professors and architects. Fabiani collaborated with the studio of Wagner between 1894 and 1898, understanding the spirit of the new conception of architecture proposed by Wagner for his own projects, under the general idea of the Secession art, which was formed by painters and architects exited from the Academy of Arts, to join an autonomous group.

As we know the spirit of the Secession artists was to combine all the different aspects of arts – painting, sculpture, decoration, architecture – creating a Gesamtkunstwerk, a kind of total work of art showing all the different artistic applications to realize a masterpiece. So architectures were rich of decoration and details to express the new vision of art that could be created by the designer. The Trgovski Dom was based on this typology of ideas, and its configuration is very diverse from the other ones in the town.

Fig. 1, 2, 3: Perspective drawing and two historical photographs of the Trgovski Dom.

As its name is written in Slovenian language, the main destination of the building was a commercial center for Slovenian people staying abroad. But during all the XX Century, the function changed a lot, also for the political events there were before and after the two World Wars. Started in 1903 – the date of the approved design by the Major of the local Municipality – it was built in 1904, and after the end of the First World War it was attacked by the fascists, that in 1926 destroyed all the offices and furniture there were inside, changing also its name in “Casa Littoria”. The building was used by their organization for political and social meetings. Then in 1933 it was bought by Fascist Party, remaining until 1945 of the same property.

Fig. 4: Front drawing by Max Fabiani of the Trgovski Dom with the development of two façade in plan.

After the liberation of the partisans, it became the Ljudski Dom (People's House), opened to Italian and Slovenian people for developing cultural associations. From 1950 to the end of 1980 it was used by the National League, to organize social events and cultural meetings, using also the very beautiful theatre hall that Max Fabiani has designed inside the building. After this date the building was only partially utilized, and the theatre was not used at all, leaved in a great state of deterioration. The project is configured into two blocks, everyone of them parallel to the public street located in front of it. The intersection is resolved with a corner hinge, with a circular roof upstairs. A third block is present, in which there is a small theatre, generating a small courtyard inside.

The main subject of this research was the survey and the digital reconstruction of this theatre hall – called Petrarca Hall – in order to simulate a virtual renovation of it, studying the impact of new functional organization of spaces, the use of materials and the illumination, before starting with the physical restoration of this architecture.

Figg. 5, 6, 7: Photographs of the actual state of the building: corner view, main entrance of the Petrarca Hall, detail of the ashlar around the door (from left to right).

2. The survey of the Petrarca Hall

The Petrarca Hall is a small theatre, opened on Via Petrarca and structured in three spaces: the first one is the main entrance, with an eleven steps' staircase, leading to the main hall and upstairs through another staircase.

The second one is the main hall, divided into two vertical levels. It has a length of 16.60 m and a width of 11.80 m with an elevation of 7.60 m. Two pilasters at the end support the upper floor, that is organized in the shape of a horseshoe.

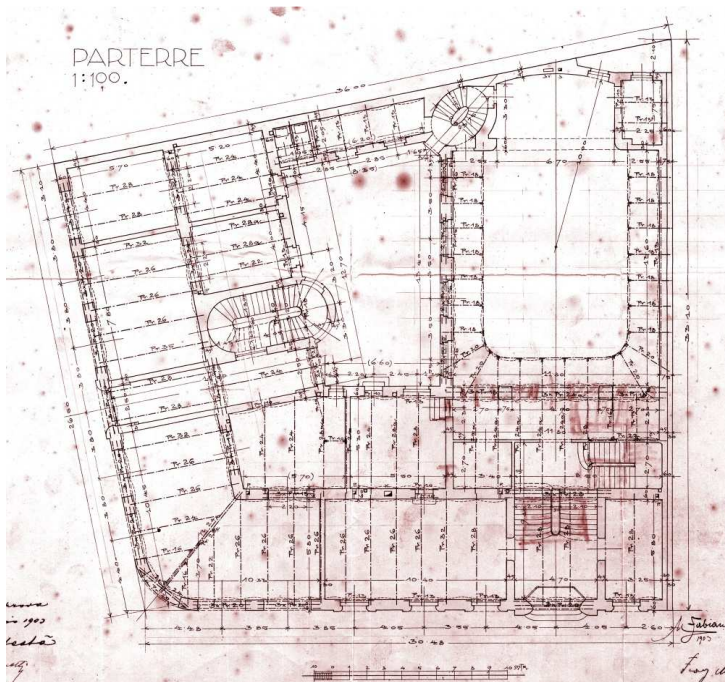

Fig. 8: Plan of the ground floor of the Trgovski Dom (drawing by Max Fabiani).

Figg. 9, 10, 11, 12: Views of the interior space of the Petrarca Hall: entrance, hall towards the stage, back view of the hall, first floor towards the stage (from left to right, from above to below)

The third one is the stage, located in front of the main hall, with an height of 1.40 m from the ground floor, having some other spaces next to it, such as the backstage, the dressing rooms and a warehouse under the stage.

Another interesting architectural solution is expressed in the ceiling, that is composed into a series of squares, that show the horizontal structure of the space.

Figg. 13, 14: Graphical restitution of the front side and the first floor of the Petrarca Hall after the survey.

As we said before, the interior state of degradation, with broken glass, floors disconnected, the presence of dead animals – birds and rodents –, strong smell of paint and gasoline coming from the underground, obliged us to protect our body with special protective suits and face masks, deciding to concentrate only in few days the activities of the survey in order to avoid any possible negative consequences for our health. All the spaces behind the stage were really small, and it was impossible to use advanced instruments such as theodolite or total station, but we only could use pocket laser rangefinder and other small survey tools.

Then, the survey was done in a direct way, verifying the dimensions signed on the Fabiani's drawings. An internal polygonal network and a series of trilaterations allowed us to control every measure, integrating the information with the ones coming from the survey.

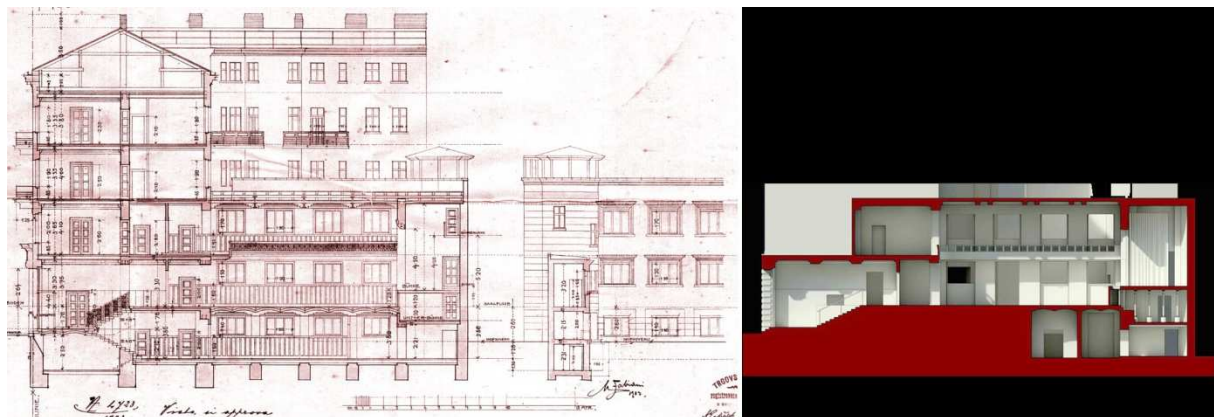

A relevant architectural object was the elliptical helical staircase located behind the stage, used as a technical vertical connection among the three different levels. In this case Fabiani resolved a very complex situation, having only a small part of the space to use, but considering it a significant portion of the whole building. Analyzing it, in fact, we can comprehend the architectural philosophy of composing of the author, who was able to enrich also some technical elements, that results very armonized with the rest of it. This kind of staircase was used by him in some other designs.

After the phase of surveying, we translate all the data into drawings – plans, elevations and sections – preparing the information for the next step that is the construction of the digital model for the final simulation.

But before starting modeling, we analyzed all the drawings – the Fabiani's ones and the one coming from the survey – to compare them in order to find significant analogies and differences to understand better the architect idea of the project.

3. Geometrical analysis and comparison of drawings

The main 3D geometry of the space is a parallelepiped, having a rectangular basis and two corridors upstairs against the side walls. The windows are located only on the left side and they allow the lighting of the whole hall. From the comparison of the drawings we have found some relevant differences between the design and the actual state. In particular the main staircase of the entrance as a different configuration. Fabiani, in fact, drew a double staircase, to go upstairs and downstairs. Now the staircase is only for going upstairs, but probably the actual solution was realized by the architect itself, with a variation of the design during the construction.

Figg. 15, 16: Comparison between drawings: longitudinal section by Max Fabiani and rendering of the actual state (from left to right).

Some other differences are in the underground space: in fact it is divided in more parts, separated by an interior wall, and there are different ways to reach it. It is due, perhaps, to the subdivision of the building during its history, and for different uses.

From the original drawings we can find also an interesting solution over the flat floor, that now is not present anymore: a small tower with a pitched roof and an exterior refinement with horizontal slabs, exactly located over the helical staircase. We can suppose that the first intention of Fabiani was to create a way for going outside from the theatre, maybe to be used in some particular events. Although there is no trace of this solution in the building, we can hypothesize either they never built it, or – as it was partially destroyed during the War – that this tower was built but then not realized after the destruction.

Figg. 17, 18: Digital simulation with Texture Mapping and Global Illumination algorithm of the main entrance and the hall towards the stage.

4. Digital reconstruction

The next step was the 3D digital modelling of the building, trying to mix the survey data – measures and photographs – with the ones from the original drawings.

The graphical primitives used were mainly the vertical and horizontal extrusions, composed with Boolean algorithms for generating holes (such as windows, doors, etc.) and unifying the single parts together. Some detailed elements required some advanced algorithms to describe with great precision the decoration.

For example the railing of the upstairs balcony, or the one of the elliptical staircase were constructed using a loft procedure that interpolates variable sections along an extrusion path, adapting the morphology to the measurement taken from the survey. As shown by the rendering images, there is a strong similarity with a photograph, thanks to some details that usually are not considered during the 3D modelling phase of an architecture, such as the handles of the windows, the small lamps on the ceiling, the curtains with folds.

After having generated the 3D model, we decided to control the quality of the representation using Global Illumination algorithms for the simulation of the natural light. This procedure allowed us to simulate not only the direct light coming from the windows, but also the indirect illumination of the walls that are not touched by the sunlight. So the typology of shadows, and the quality of chiaroscuro are really impressive and very similar to the reality.

The last step was the application of texture maps and the realistic simulation of the space. We decided to refer to the photographs taken during the survey, and reply the same visualization as if it was already restored.

In particular we used colours and materials – for example the same strips of wood present in the floor, but as if they were cleaned – to have a verisimilar perception of the appearance of the theatre, finalized to prepare a sequence of frames for generating a simulation: a virtual visit to this architecture by a spectator, who arrives to see a performance with actors in the flesh.

Figg. 19, 20: Digital simulation with Texture Mapping and Global Illumination algorithm of the back of the hall and the view from above.

Fig. 21: Digital simulation with Texture Mapping and Global Illumination of the Petrarca Hall.

5. Video animation and 3D real-time simulation

As we have introduced in the preceding chapter, the construction of the digital scene was finalized to simulate a real perception of the space. In particular the idea was to present the research to a public audience, by involving the visitors into the new configuration.

To have a real experience of it, we decided to use two different technology: on one hand a simple animation – generated compressing about 5,000 frames into a video; on the other one a 3D stereoscopic real-time navigation.

As the animation do not contemplate a particular reorganization of the file – in terms of illumination, application of materials, and so on – but only a key-frame structure to give the software the required input for generating automatically every single frame, we prepared the screenplay thinking to a person entering the place from outside, as if it was a spectator, arriving finally on the stage, as if it was transformed into an actor. The 3D real-time simulation, on the contrary, needs a further preparation of the model – reapplying new compatible textures and studying the illumination setup, as it uses different computing methods to process the digital model. So we have to reconsider all the model, for seeing with a stereoscopic system that simulate the human way to perceive a real scene.

Fig. 22: Frames from the video animation.

Fig. 23: Real-time simulation of the Petrarca Hall in the 3D Showroom in Area Science Park (elab. Arsenal).

Acknowledgments

This research was scientifically directed by the Dean of the Faculty of Architecture of the University of Trieste, Prof. Giovanni Fraziano, The survey and the 3D visualization were directed by Alberto Sdegno: in particular Silvia Masserano did the two-dimensional drawings and the geometrical analysis (Chapter 3) and Dimitrij Pozar prepared the 3D model and all the rendering images. Both of them were involved in the survey phase. Chapters 2, 4 and 5, were edited by Alberto Sdegno. Finally the real-time simulation was done in Area Science Park in Padriciano by Arsenal, and presented with a 3D stereoscopic installation during *èStoria, VIII International Festival of History*, held in Gorizia between 18 and 20 May 2012, inside the space of Petrarca Hall. We would like to thank Piero Miceu and Marco Jez of Arsenal, for their collaboration to the 3D real-time simulation.

Abstract

In the range of actions for the safeguard and conservation of cultural heritage, present computer technology confirm the crucial role of survey among all activities aimed at exploitation, recover and enhancement. As a working group we have carried out a research project, for many years now, on the themes about 3D survey; in particular we are testing the use of mathematical algorithms and programs as an additional tool, in the surveying photogrammetric process, for data mining and interpretation. Among our working experience related to archaeological survey we present a test on the use of the software *Mathematica* for new data processing on *Villa dei Misteri* in Pompeii. In particular we develop some algorithms which allows the semi-automatic extraction of the sections as well as planar surfaces contours and texture mappings (masonry walls, plaster or fresco walls, mosaic floors). The present goal is to complete the data already acquired, developing a speed working methodology which allow the different analysis, such as constructive or stratigraphic, using a 3D GIS, which links 3D objects to data.

Keywords: 3D Survey, Archaeology, GIS, Algorithms, Stratigraphy

1. Introduction

Over the last few years, 3D surveying has taken centre stage in the phases of study of monuments, and generally of archaeological sites and territory, raising a series of questions about the quantity of data that can be automatically acquired, about their management, interpretation and restitution (graphic or not). These questions seem even more delicate in the application of these techniques to archaeology, and they call attention to some points about which there is a lively international debate: the first point concerns procedures and the way they contribute to knowledge in such complex and stratified contexts; a subject that refers to the need to make the different skills interact in order to determine the most suitable methods for answering specific questions. An attempt to manage the application of the new instrumental surveying methods to archaeology is included in the Declaration of Seville [1], in which the need to substantially differentiate procedures according to the contexts in which one works and to the goals one sets, is highlighted. The Declaration also refers forcefully to the question of interdisciplinarity. The process of interpretation and evaluation of acquired information has to correspond to a specific and coherent semantic reading and can't disregard a specific and conveniently focused goal. As previously mentioned, the use and management of 3d models in archaeology requires a continuous debate among professionals working in different sectors, to correctly direct the project of measurement taking, data reading and selection. In this sense, the described operational methods can be considered part of the knowledge process. The second topic of discussion pertains to the efficacy of surveying automated procedures in the presence of bare masonry, absence of sharp edges, different states of preservation of structures, etc. The need to create a three-dimensional model, constructed from a scanning with a 3D laser scanner, seem unavoidable, for the possibilities it offers in terms of dimensional control and for the graphic immediacy. However, especially in the study of archaeological architectures [2], interpretation

problems can arise in the transition from the point cloud to the creation of triangulated meshes: as is well known, the point automatic reduction can modify considerably the morphology of objects, misleading their correct reading [3]. Therefore, even in a period of time in which the possibilities offered by the 3D laser scanner would seem to direct the debate in the opposite direction, it is our opinion that the idea according to which direct survey is necessary and irreplaceable, since it is a moment of objective comparison with real objects, has grown stronger. On the one hand, then, it is necessary that the quantity of information that one chooses to acquire be of quality, that quantity and accuracy in data collection be proportioned to data complexity; on the other hand, it is necessary to bear in mind that the following interpretation phase can't disregard the direct knowledge of what is being surveyed. On that basis, survey procedures discussed here can certainly be considered effective in archaeological contexts. The third topic concerns the advantages offered by using semi-automatic procedures for detecting and drawing different levels and quantities of information, for example, the stratigraphy that characterizes the wall surfaces, included the sections that characterize them. The possibility of producing a three-dimensional model, from a point cloud, and of determining 3d elements to which linking alphanumeric information, integrates – in the archaeological field – the operation of storage and retrieval of data linked to single wall stratigraphic units. In this context we present a research which concern the creation and application of specific mathematical algorithms to the point cloud to extract some 3d elements in a semi-automatic way. In this article we will describe the adopted procedure highlighting the advantages that it can offer.

2. Case Study

Our test site is a masonry portion of the Peristyle of Villa dei Misteri in Pompeii, surveyed in 2006 by an interdisciplinary working group of the Dipsa of the Roma Tre University, whose members are Prof. Diego Maestri – scientific supervisor– the authors (Marco Canciani, Giovanna Spadafora), Prof. Rodolfo Maria Strollo and the archaeologist Domenico Esposito of the Soprintendenza Archeologica di Pompei [4]. The survey carried out in 2006 was made integrating instrument and direct techniques, through the use of photogrammetric software for section drawing and masonry surface characterization. The aim of the survey carried out in 2006 was to have the geometric and spatial knowledge of the Villa, in which no measurements had been carried out after the surveys conducted by Amedeo Maiuri who, in 1931, published: a ground plan, a phase plan and a section.

Fig. 1: Villa dei Misteri. View of the 2,5D model (photogrammetric restitution of the elevations with some sections)

Fig. 2: Villa dei Misteri. View of the Large Southern Portico.

Our research was aimed at acquiring a wide and up-to-date knowledge of the above-ground structures of the Villa, included the roofs built during the last century and the outer perimeter. Later, in 2009, we were given the task to update drawings, surveying the new arrangement of the terraced levels that surround the Villa and some archaeological remains emerged during the works of slope stabilization and of construction of the new access to the area: some columns of the Large Southern Portico and two old roofs belonging, respectively, to a southern and a northern room of the Villa. In all, we produced: a general planimetry of the excavation area, plans, elevation drawings and some sections at a scale of 1:50. For the purposes of our research, whose first results are presented here, we

produced an image-based three-dimensional model, following procedures which connect several frames and render a point cloud on which it is possible to construct a textured mesh. These procedures need to be accurately checked and produce optimal results if they are integrated with data obtained through measurements carried out with other methods; in this case, we already had a series of data accurately surveyed in 2006, to which we referred to compare and evaluate the adopted procedures.

Fig. 3: Villa dei Misteri. Section of the Large Southern Portico (at left) and the kitchen (at right).

3. Related works

3D surveying techniques produce a large amount of data: point cloud, mesh, texture, etc. [5] [6]. In Archaeological site, the data collection is greater because the information to be acquired are more complex. It is very important organize this kind of data (picture, text, documents, ecc.) for example to integrate information gathered in previous excavations [7]. To combine 3D survey, spatial analysis and data, we use an Information System [8] but there are more examples of AIS (Architectual Information System) [9] [10] [11] in which the three-dimensional model of the building is connected to a database. In this work we use a 3D GIS to collect information about stratigraphical unit (S.U.) as in the study of Drap: "Going to Shawbak and getting the data back" [12]. According to our previous work, in this paper we talk about algorithms to extract section directly from point cloud [6] [13]. The next step of our research is how to introduce a semi-automatic segmentation process to define 3D object linked at database. Many algorithms have been developed for the segmentation of point clouds, less studied are methods to segment point clouds without creation of surfaces [14] [15]. Usually this kind of segmentations are used for airborne Lidar systems in wich points were grouped by using variation of the X Y and Z coordinates [14]. Many studies use the Douglas-Peucker algorithm [16] and produce short and long segments typically for distinguishing roofs from other surfaces. In our case study we need a similar segmentation of point cloud, so we use the variation of first derivative to have different objects that may be useful to identify the stratigraphical units.

4. The proposed methods and procedures

The method we propose tries to keep innovative and traditional survey methods together, starting with the assumption that survey procedures have to combine quickness and accuracy characteristics with real object correspondence and representation.

3D survey systems make it possible to obtain a survey that satisfies the first two conditions, concerning quickness and precision in the data acquisition phase, following a partially automated process, whereas traditional direct survey enables the fulfillment of the second two conditions, allowing, in the data processing phase, a description of the object most significant details, on the basis of a representation possibly more similar to the object.

The three-dimensional object, firstly processed as point cloud and later as textured triangulated mesh (realized by image-based and range-based procedures), and detailed through its particulars direct surveys, is the **core** of the whole process.

It is possible to extract both the dimensional data and the intrinsic features of each element from the object in every phase of the process, and it is also possible to link additional textual data. This method integrates and reprocesses the documentation produced in previous excavation campaigns, pursuing two specific goals: on the one hand, to organize data according to a GIS-based classification related

to single elements and, on the other hand, to develop the graphic restitution using new information and different procedures.

The Geographic Information System is structured on the basis of a series of 3D elements (environments, masonry walls or its specific layers), geo-referenced in a system of spatial coordinates, which are made to correspond to a well-structured database. The system that we have adopted, has been developed within the Revit software (by Autodesk) where it is possible to connect 3D objects (point clouds or triangulated mesh elements each), to a structured database and perform the queries on data.

This system allows to support the analysis normally performed in the field of archaeology, in particular those concerning the critical survey [17] [18] and analysis of the stratigraphy of the masonry walls [19] [20] [21].

Compared to the GIS systems now commonly adopted in the archaeological field, referred above, which substantially use two-dimensional objects (orthophotos, 2D cad drawings, such as [22]), the method we propose, following the one studied by P. Drap, [12] uses objects that maintain the three-dimensional information during the whole process. For example, a construction layer of a masonry wall is defined through a 3D object, whose visible parts are defined with a textured triangulated mesh, and, the parts of contact with other layer are bounded by a flat surface. 3D elements describe built structures such as masonry, floors or coverings, broken down into single parts related to specific components, such as wall stratigraphic units, architectural elements and details etc. The database is structured on the basis of the forms provided by the Soprintendenza Archeologica di Pompei and organized according to records, related to the single components, and fields, concerning specific features.

3D data processing allows the implementation of the graphic restitution, through a feature extraction process, based on algorithms described below, and focused on three features: sections, surface contour and masonry textures. The sections, useful to define the path in the depth of the elements (according to the algorithm, referred in [13]), are processed on several planes developed perpendicularly to the plane of the element's largest surface. The contour, applied to continuous surfaces of wall and floor structures (for example, plaster layers, frescoed walls, floors and mosaics), makes it possible to define the extent and structure/shape of the elements referable to flat surfaces, with constant thickness and section. The masonry texture, useful to define the construction type and the typical size and profile of bricks and mortar layers, is extracted according to the procedure that uses the algorithm described below.

The procedures of our proposed method can be divided in three distinct phases:

first a **data acquisition phase**, obtained through: a topographical survey for the general reference frame and the orientation of the specific surveys; a photogrammetric process of several images of each defined element (wall, floor, architectonic detail); a traditional direct survey for the architectonical details.

Secondly a **data elaboration phase**, which consists of: definition of the reference system as deduced from the topographical survey; specific photogrammetric georeferenced models restitution; models segmentation in elementary components; features extraction; planes of sections definition and their profiles; 3D GIS definition through the links of the 3D components to the corresponding database.

Finally a third **phase of graphical restitution** which is referred to: 2D graphics elaboration with respect to the chosen section planes; 3D elaborations, with thematic analysis, using GIS queries.

5. Algorithms for features extraction

As previously mentioned, our goal was to create a mathematical algorithm able to detect, automatically, areas with plaster or fresco fragments on walls, to draw the relative cross-sections and to obtain a redrawing of the unplastered masonry portions.

We have implemented some algorithms for segmentations of walls at different levels of accuracy, detection of contours and brickwork weaving using smooth section curves.

Smooth section curves are calculated directly from the point cloud [6], without the use of a triangulated surface, using a regular plane parametric curve which fit the closest points projected to any given plane.

We have started calculating a reference plane as close as possible to the largest wall layer: first we find vertical sections of the wall and take a segmentation of each section detecting high and low derivative intervals; secondly we select the longest intervals with almost constant value which should belong to the largest layer. Finally we take the best plane for the longest intervals of all the sections.

Given such a reference plane we have recalculated and segmented, with higher accuracy, the wall orthogonal sections taking one axis along its normal (see fig. 4). Using the segmentation procedure we are able to detect different wall layers for which we calculate contours and inclinations with respect too the reference plane (see fig. 5).

Fig. 4: Orthogonal parametrical sections: the blue dots represent high derivative along the section.

Fig. 5: Wall layer contours: background colors represent different distance from a reference plane.

Another algorithm is related to the analysis of brickworks trying to detect differences in brickwork weavings starting from brick detection. The problem of detecting singular bricks is not easy to solve (see for example [23]): we have tried several solutions starting from a given picture (see fig. 6, 7).

Fig. 6: Binarization of a wall picture.

Fig. 7: Some brick detection.

We have implemented a rough procedure to detect some of the bricks or stones in a given picture: We produce a segmentation of the picture looking for morphological recognition of some pattern: starting from a binarization related to a convenient threshold for a defined distance from a chosen color (see fig. 6). This procedure needs to be polished and optimised (see fig. 7).

We are studying a more efficient way of integrating different methods for edge detections in pictures and point clouds, using the information on color gradients and point normals which are present in a textured point cloud of the given wall.

6. Representation

Regarding the representation, just because the problem that arises isn't only of a technical or technological nature (related, for example, to accuracy or detail definition) but it's rather a **problem of selection and interpretation**, we have explored this aspect, trying to support this process of filter and interpretation of data.

Whereas on the one hand **three dimensional models**, organized in a GIS, allow an easy and immediate consultation, presenting a simulation of the real object, being more and more close to the

object; on the other hand, the **two-dimensional drawing** makes it possible to give a description of the object, which is more commonly understandable and more selective, highlighting, from the huge quantity of data, some specific features, relating to the section plane and the elements in projection and excluding other ones, for an as focused as possible data interpretation.

The proposed graphic elaborations are developed entering two series of data: the first one is related to the extracted features (characteristic sections, masonry or floor surface contours and textures, in order to describe in detail and spatially the represented elements; the second series concerns data connected to elements and is filtered according to specific themes (masonry types, wall stratigraphic unit, historical dating, etc.).

The **first graphic type**, referred to the structure's geometric-dimensional description, is developed in 2D along the choosen section plane using the orthographical view of the texturized model. Moreover on this model we insert several information extracted by semi-automatic procedures, which we propose, such as: some sections elaborated *in situ*, which are useful to underline the differences of surface depth, contours for layer or different wall elements detections, wall textures necessary to classify different type of constructions (see figg. 8, 9).

Fig. 8: Section drawing superimposed with the orthographic view of the 3D model.

Fig. 9: Detail with section *in situ*

The **second graphic type** refers to the structure's analytic studies and is developed in a 3D environment, using data linked to each element to produce a graphic of analytic type on which one can define the specific features selected in the database fields (see figg. 10, 11).

In this way our works highlight, directly on the 3D models, the analyzed classifications (for instance different wall stratigraphic units), without the bi-dimensional reduction with the necessary perimetral redrawing on a plane.

7. The achieved results

Over the last few years, our research group has constantly pursued the purpose of obtaining a graphic representation of the surveyed object that could focus all collected information on it, through a system of signs that can be immediately interpreted.

Fig. 10: View of the 3D model with some highlighted elements

Paradoxically, this purpose, which architects specialized in survey have always had, has been made more complex by the amount of data that nowadays are at surveyors' disposal. The process of selection of what has to be measured doesn't take place anymore upstream but downstream, shifting the problem of the selection of what has to be taken into consideration and then represented, from real space to virtual space.

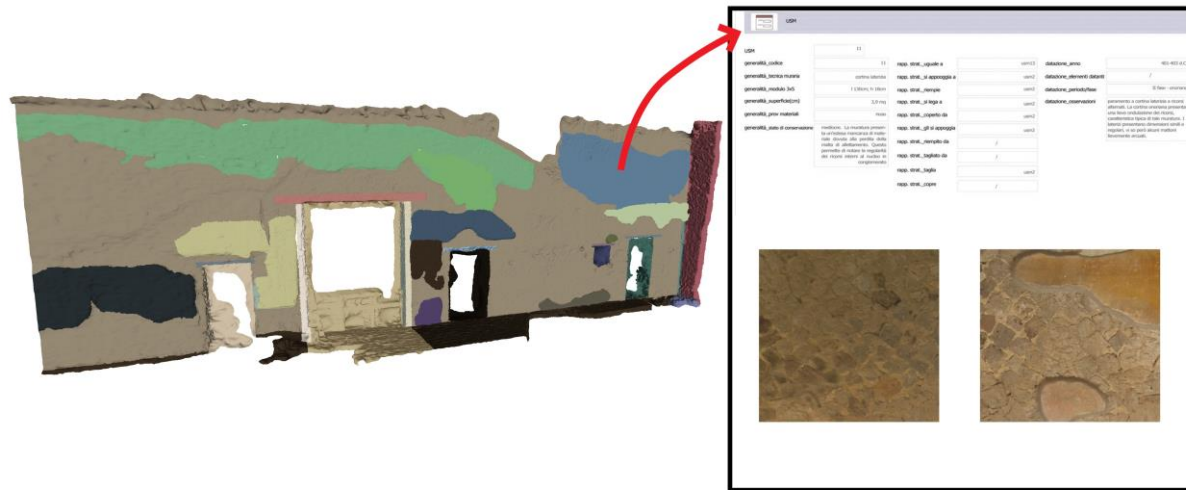

Fig. 11: View of 3D model of the masonry wall with an element linked with data form.

The point that is essential for the specificity of our field of expertise is, instead, to work in order to obtain a graphic representation which expresses just the interpretation of data, i.e. which is the result of a process of analysis, selection and synthesis of complexity and not the reproduction of the status quo. The graphic representation process is, then, an essential moment of summary and control based on conscious choices which determine what to discard and what to represent.

In this sense, we are working to create a semi-automatic system of extraction of the plastered surface contours and redrawing of the masonry types. The “semi” prefix reduces the predominant use of automated processes and claims the fundamental role of an accurate evaluation.

Also for the redrawing of the masonry type the aim isn't – and couldn't be – to slavishly redraw all components, but to detect the type and the main constituent elements (such as the size of bricks and of mortar layers). It isn't possible not to recognize that the extraction of these data – also useful for the relative dating – reduces the time it takes to produce a two-dimensional drawing and to count.

We agree that IT tools haven't to be considered as displaying tools any more, but as information and content gatherers [3], letting the two-dimensional drawing have the privileged role of summarizing and representing the complex analysis and interpretation work that was done.

⁽²⁾ robertamontella@libero.it

Abstract

To be a member of UNESCO, a site must be an extraordinary example of an architectural and landscape group, or it must be rich in geomorphological process, which represents a typical period of human history or of an anthropological culture.

Survey suggest a comparison between two topics. Among them, one is already part of UNESCO and is recognized as best practice. This site is analyzed whether through architectural, landscape and cultural characteristics or by analyzing both strategies and retraining interventions, together with sustainable promotion interventions which are brought about.

The other site, which isn't in UNESCO yet, is chosen in order to recognize all the typical characteristics able to highlight the promotion of the heritage.

Once checked out the standards from the best practice, a management strategy is supposed to be done also in the second one, which involves not only the technician but also the inhabitants.

Keywords: Avola, Alto Douro, UNESCO, cultural tourism, heritage

1. A potential candidate: Avola, Siracusa, Italy ⁽¹⁾

Going back to the date of reconstruction of the different centers of the Val di Noto, following the 1963 earthquake, it is important to consider the architectural and urban, agricultural and landscaping character, to enter the town of Avola in the list of centers valley.

Therefore, it is interesting to identify the many qualities that characterize this site to create the basis for a useful research to understand and highlight the real possibility of its desirable insertion of UNESCO sites already existing in the south-eastern Sicily.

The eight towns in south-eastern Sicily included in the list of UNESCO World Heritage sites, and members of the Val di Noto, are: Caltagirone, Militello, Catania, Modica, Noto, Palazzolo, Ragusa and Scicli, all rebuilt after the earthquake of 1693.

"They represent a considerable collective undertaking, successfully brought to a high level of architectural and artistic fulfillment. Keep within the late Baroque, they also describe particular innovations in urban planning and construction of the city."

To enter these cities in the world heritage, it is necessary that they represent "a remarkable testimony to the exuberant genius of late Baroque art and architecture and the 'development project to be an example in this area permanently at risk of earthquakes and eruptions from part of Etna."

Unfortunately, as emerged from the research and collected in the results that follow, the site of Avola, identified for its extraordinary scenic beauty and the uniqueness of its formal urban plan as another possible candidate to be included in the list, it was not considered suitable to be inserted between the other centers heritage of the Val di Noto. Avola, a town flat wet to the east by the Ionian Sea, is surrounded to the north-west by the Iblei chain, is located about 40 m above sea level. Its territory lies between Cassibile and Asinaro rivers.

Fig. 1: Territorial framework of Avola in Sicily, Italy

Its name originally was *Abolla* or *Abola*, of Arab origin, after it became *Castrum Hiblae* or *Castrum Abulae*. The Arabs have also changed the name of *Hybla* in the *Ab*, the Normans in *Abola* and, finally, with the Angevin have definitely changed in *Avola*. Then, the city has become marquis under Aragonese rule and remained so until the earthquake of 1963.

The present town is built in the early eighteenth century, after the destruction of the old Avola. In sixty years, the new country-city center, since 1756, has indeed become a much more extensive reality.

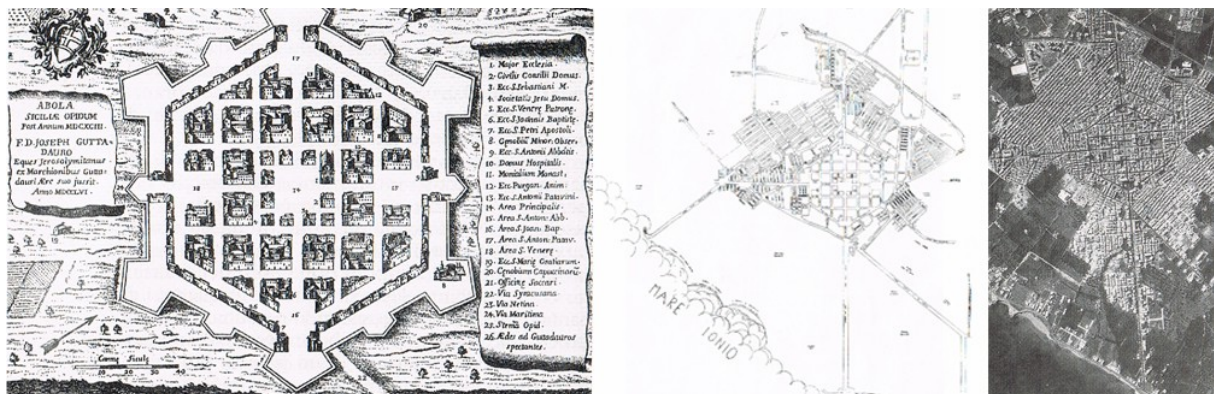

Fig. 2: The evolution of the city of Avola

After the disastrous earthquake, some of the cities destroyed were rebuilt on site, while others, among them Avola, were rebuilt in other safer areas for the protection of the inhabitants from future seismic risk. This choice derived from the complete destruction of the buildings, due to their placement on the slopes of a limestone soil unable to resist the violence of the earthquakes: so, the underlying coastal plain was certainly good for its greater elasticity.

So, Avola is not a city prone to seismic risk and this is, therefore, one of the reasons for exclusion from the centers of the city of Val di Noto, declared a World Heritage Site.

Another aspect that, for this purpose, is not good for the city of Avola is the fact that the Management Plan of the UNESCO World Heritage Site considered for this research, raises the need to clearly identify, for the possible inclusion of a center in the World Heritage, a late baroque architectural and artistic style: not coincidentally, the title of this UNESCO World Heritage Site Management Plan is *Late Baroque Towns of the Val di Noto*. In fact, while the reconstruction phase of the centers included in the list is configured through a decidedly and richly late Baroque style, manifested in sacred and profane buildings, both public and private, the same is not true of the avolese style, that in general is more sober and straightforward. The studies and observations allow to conclude that the origins and architectural presence of Avola are too modest compared to those present in other towns in the valley, and they are characterized, above all, by a simple peasant or craftsman architecture. Too bad, very

few are considered, among the public buildings, the important and representative examples of architecture made with a late Baroque style.

Among the examples worthy of mention, emerges the Church - Abbey of SS. Annunziata, declared a national monument: it is, in fact, a typical Baroque building, featuring a façade embellished with two semi-plastic orders. The church, with its magnificent façade concave - convex, built starting in 1753, is still considered one of the most beautiful and accomplished expressions of the Baroque in the Val di Noto. However, it may be interesting to note, as can be seen at the website www.patrimoniounesco.it, that the cities of Modica, Palazzolo and Militello, have only two churches built in late baroque style. But this observation does not detract, however, the town of Avola from the fact that it has been rebuilt in a safe condition from the point of view of seismic risk. This fact suggests, therefore, the need to draw a route describing, making justice, of this center's identity, and the need of a research focusing on the important points to observe and investigate, and therefore useful in order to declare the city in the UNESCO World Heritage Site. Today, the increase in Avola building is impressive, especially thanks to the tenacity, temperament and work of avolesi citizens, very determined to achieve this goal. Not surprisingly, the emblem of Avola depicts three bees flying at the foot of some hills to express the typical industriousness of its citizens.

Fig. 3: To the left, the Church of SS Mary Annunziata - to the right, the emblem of Avola

Among the selection criteria, in order for a site to be inscribed in the World Heritage List, there are several aspects that identify Avola as suitable site, including *to represent a masterpiece of human creative genius*, and the need to prove that *a site is a place of major interchanges of human values, over a span of time or within a 'cultural area of the world, on developments in architecture or technology, monumental arts, town-planning or landscape design*: it is enough to think about its unique urban hexagonal plan or about the important Nature Reserve of Cavagrande;

it is also necessary that a site is *an outstanding example of a traditional human settlement, the use of local resources or marine [...]*, and in this regard it is sufficient to look at the extraordinary production of typical local products, such as Avola's almond or Nero d'Avola wine, known throughout the world for its unique characteristics, that distinguishes them.

There are many features that seem important to emphasize urban planning and production, and also historical – artistic aspects, for the possible inclusion of Avola in the heritage of 'UNESCO.

To achieve this goal the citizens, including the President of the Proloco Giuseppe Corsico, show a lot of commitment, enthusiasm and interest.

Urbanistically, between the potentially cities UNESCO presenting geometrical characteristics very similar to those of Avola, and which may present some possible common points to be taken into account for the insertion site of the object of study within the World Heritage, are surely reported the cases of Palmanova and Grammichele.

The hexagonal pattern of a fortified city, which Avola has got, is considered, in the nineteenth century, able to defend the city from enemy attacks, and it was used in Europe since the sixteenth century.

So, in addition to Avola, the other existing cases with hexagonal plant are Palmanova, urbanistically resolved in 1593 with the radial system, and Grammichele, which in 1693, was designed at the same time of the town of Avola. Palmanova, Friuli city-fortress in the shape of a nine-pointed star built by the Venetians in the late sixteenth century, still preserves the original topographic system, with roads that

converge radially from the walls and the ramparts in the central Piazza Grande: its square, which has the form of a hexagon, is different from the avolese central square, which is quadrangular. Palmanova, declared National Monument, is part of the UNESCO World Heritage. Grammichele, as Avola, is a Sicilian town, and it is instead located in the south eastern side of the province of Catania. From these comparisons, it is important to emphasize the possibility to admire the city of Avola as unique and unified artistic product, thus able to compensate the absence of magnificent buildings like those that are in the other cities in the Val di Noto.

Fig. 4: The comparison between the plant of Avola, Palmanova and Grammichele

In this regard, some authors say that this choice has been determined by the expressed desire to give greater force to the layout system of the city, thus voluntarily placing overshadow the architectural singularity that would distract the viewer from the original plant.

Analyzing the plan through simple geometric and structural patterns, extrapolated from this carried out research, it is clear that the orientation responds to the dictates of the Vitruvian city.

The two primary roads and perpendicular, a Greek cross forming the *decumano* and the *cardo*, meet in the large square and define the epicenter of the town: along the *cardo* are placed the most representative buildings of the city.

It is possible to read and to report the presence of five large squares, covered by the orthogonality of the principal axes, and the system of the four smaller squares, placed on the vertices of the large quadrangular square.

Archeologically, in 1955, the important work of excavation begun, from which is derived the discovery of several archeological remains, including, very importantly and found on the beautiful Ionian avolese coast, a dolmen, whose name is *Ciancio Dolmen*, which is a Neolithic prehistoric monument, probably early built as necropolis, but later used as a dwelling containing ten small niches rituals. It is part of several discoveries distributed in the region and, in particular, relating for the most part to the province of Syracuse.

Fig. 5: On the left, Tombs of the X and IX century. B.C. – On the right, the Dolmen Ciancio

Scenically, as it emerged from a brief interview to the President Proloco of Avola, it seems important to point out the natural reserve Cavagrande of the river Cassibile.

This reserve is included in the municipalities of Avola, Noto and Syracuse.

It is a deep valley formed by the continual erosion of the river water, which over millennia has created a series of deep canyon in the limestone soil of the Iblei mountains.

Fig. 6: The Nature Reserve of Cavagrande

In the valley, there is a complex system of small waterfalls and natural reservoirs often bathing: it's possible admire numerous lakes, with fresh and clear waters, among which stand out for their beauty small lakes near Avola Antica. In addition, on the north side it's possible to see a small cluster of cave dwellings, while in the south, there is a complex system of houses dug into the rock. At the edge of the reserve, in the north-east, there are various ancient necropolis. The reserve was created precisely in order to preserve the different riches of its territory, from a natural, landscape, archaeological and anthropological point of view. Among these, it is sufficient to think that Castelluccio village of Noto, gave birth to a prehistoric settlement that gives its name to an entire type, the so-called Culture of Castelluccio, remembering that we are in the World Heritage Site-UNESCO Pantalica. Very obvious are the natural beauty of Avola, which develop in continuity with the local landscapes and bucolic coastal Sicily, proceeding down to the south, and which represent the important and obvious things in common with some of the centers closest to it, and that are part of the Val di Noto. Along the highway Avola - Syracuse and the road Avola - Noto, you can enjoy the unique spectacle of long and wide expanses of almond trees. Its territory is, in fact, grown mainly in almond orchards, which produce a very fine variety of almond, whose shape, lanceolate and pointed, hence the name "*pizzuta*". The almond is a product that makes Avola famous all over the world. There are also olive groves, vineyards and citrus groves. More generally, the territories of the Val di Noto offer typical agricultural products of high quality, such as the red orange of Palagonia, the prickly pears of Militello, grapes of Mazzarrone, oil, wheat and oranges of Grammichele.

From an interview to the President of the Proloco of Avola, Giuseppe Corsico, which involved a major and active sources for the purposes of this research, it's argued that both sites of Cavagrande, partly included within the territory of Avola, and the oasis of Vindicari, which is included within the territory of Noto, and Cava dei Servi, included in the territory of Rosolini, and also the typical products of the southern part of the Province of Syracuse, who are the Avola's almond, "*femminello*" lemon and "*ciliegin*" tomato of Syracuse, on the initiative of the Pro Loco of Avola and of the Gal Eloro, a consortium based in Noto for the promotion of local development in the area and that consists of the municipalities of Avola, Noto, Pachino, Portopalo and Rosolini, have been included in the UNESCO project to be presented by June 15, 2014, to the Ministry of Agriculture of Rome.

Fig. 7: The typical almond, named "*pizzuta*" – the "*femminello*" lemon – the "*ciliegin*" tomato

2. A best practice: the cultural tourism of Alto Douro in Portugal ⁽²⁾

Avola's hexagonal shape plan denounces the derivation of the Renaissance type. Instead, the orthogonal urban grid is similar to the urban grids of the other towns inscribed into the UNESCO World Heritage list "Le città tardo Barocche della Val di Noto". So, even if area inscribed into the perfectly defined hexagonal perimeter, the matrix is open to a linear subsequent urban extension, revealing also a greater cultural sophistication in regard to the radial Renaissance patterns in which the hierarchy of spaces is due to the centrality of a square of buildings and places in a radiocentric sistem, as like for Grammichele and Palmanova. The flat area allows to have a grid almost perfectly oriented in the directions of five of the eight towns of the Val di Noto (Noto, Modica, Ragusa, Catania, Scicli) and tilted about 45° with respect to the other three (Caltagirone, Militello, Palazzolo). So Avola is situated in the same mutual reference and within the network of urban bodies defined by the new cities founded after the earthquake. As previously revealed, the historic hexagonal urban center is not the only peculiarity of Avola. The city, known as the "Pearl of the Ionian Sea" and "Ground almonds in bloom", it's also characterized by vineyards that produce one of the finest Sicilian wines. Really interesting are also archaeological sites such as the Dolmen, the Roman villas, the tuna and Old Navy and the nature reserve Cava Grande with remarkable landscape and archaeological emergencies.

Fig. 8: Geometric interpretative schemes of Avola

In this opinion Avola could be count between those areas setting in the background of the original landscape and environmental excellence, as well as an exceptional offer of Cultural Heritage, witnessed a continuous evolution and merging of peoples civilization which is expressed through unique artifacts and wise use of land.

While not integrated in the list of Late Baroque Towns of the Val di Noto, Avola could be fully included among the UNESCO World Heritage sites of mixed type, as it responds to the dictates of a cultural and natural site, for the management of which is possible to provide differentiated tourism products, relying on the complexity of the spatial features. The aim is to develop a strategic mission of Local Tourist System that transforms the geographical location in a completely usable product, managing the network infrastructure, reception services, access for tourists, consultation between Local Institutions and between public and private. The city might as well take a strategic position in the cultural landscape as rural and cultural tourism destination, the protagonist of an evolutionary process

that the preservation of traditions can go to the enhancement, promotion, up to the definition of a cultural offer wide and varied.

Cultural tourism is in fact a catalyst for new travelers who aspire to explore the places and the cultural and social contexts in order to grasp the essence given by the lifestyle, traditions, art, iconic symbols, from the rural landscape and emergencies and by the flavors of local products. At the base can be proposed a kind of emotional and experiential tourism that poses as legitimate bond between people and places, creating a sort of eternal present and creating a meeting point between the economic and cultural sectors in order to define a sustainable use of the heritage. It creates also valuable capital that increases capital firm to invest in the protection and conservation of natural, cultural and artistic areas of UNESCO Heritage. The emotional tourism brings with itself the logic of the multi-sensory experience, whereby each city or valley become places where you can enjoy an experience of well-being that founds in landscape the ideal scenario because the viewer could play the role of both actor and spectator. Expanding the range of tourist offers, we no longer talk about only visual landscapes, but also about auditory, olfactory, gustatory and tactile evoked by nature trails guided by the sound of the wind, the water, the scents of crops or wild plants, from taste of local products.

Among the UNESCO sites that are already operating according to the logic of multi-sensory experience for the promotion of its territory, for the purposes of this research, the Portuguese region of Alto Douro has been identified as best practice of development and management of the territory, because of its similitudes with the urban area of Avola.

Fig. 9: Alto-Douro Vinhateiro area and Logo

The inclusion of Alto Douro in the list of UNESCO World Heritage Site in 2001 is justified by the criterias iii, iv, v indicate the Region as a producer of wine and historical landscape that has been shaped by human activities and that reflects an evolutionary constant. Even estates, complex wine farm, as well as villages, roads and chapels are the result of this union between man and nature.

The Douro is a river that rises in Spain and flows into the Atlantic Ocean by describing a furrow of 987 km and taking in Portugal on an irregular shape with gradients that reach 400 m. The meeting of the river with the granitic terrain of Paleozoic Era have arisen deep valleys that wise anthropomorphic measures have translated into shale terraces planted with vines. Without sacrificing its original charm, the fragrance and colours, the landscape has undergone a number of changes related to the needs and human intervention, including through the introduction of new farming techniques and modern wine production processes. Over the centuries, the terraces were built with different techniques: datable to the end of the nineteenth century are *socalcos*, narrow and irregular terraces made of slate on which are planted one or two rows of vines; in the immediately following period where built regular shaped terraces with continuous rows of vines.

The new terraces altered the landscape as wider and slightly angled for better sun exposure for screws, small villages, chapels, churches and dirt roads linking the fields. In order to facilitate the mechanization of the vineyard, from 1970, testing techniques of terracing contribute to further modifications of the built landscape. Other typical crops are olive, almond, and orange groves site almond the banks of the Douro. The UNESCO recognition is mainly due to the cultural landscape of

this valley and to its agricultural unchanged over time and specialized knowledge handed down for over 200 years by the inhabitants of this land: it seems that the majority of the grapes was introduced by the Phoenicians. Thanks to the shape of the landscape, characterized by the presence of valleys and uneven ground, along with the abundant water of the river Douro and the fertility of the soil, the cultivation of the vines can perpetuate ancient times. The Atlantic winds are hampered by the mountains *Marão* and *Montemuro* that mitigating climate mainly torrid Portugal, allow the production of Porto, the famous wine.

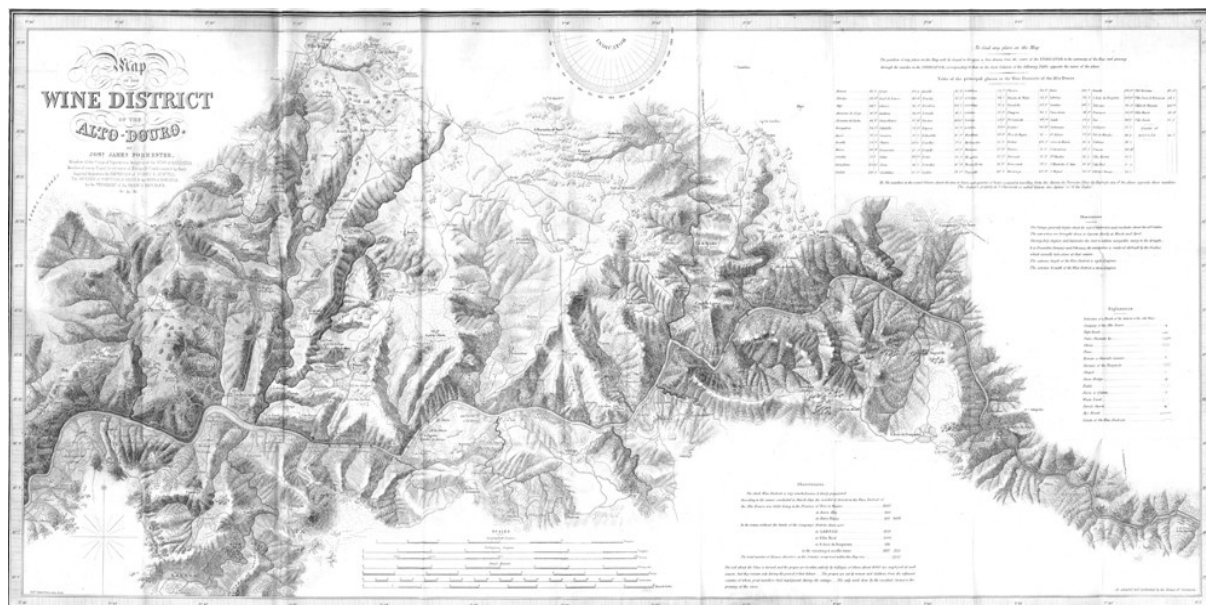

Fig. 10: Historical map of the wine district of the Alto-Douro (J. J. Forrester XIX century)

Beyond the exceptional intrinsic characteristics and anthropomorphic landscape, we want to highlight the practices of tourism development that allow tourists to enjoy the place not as passive spectators, but in an interactive manner, through a multi-sensory and cultural tourism that relies on routes and offers local differentiated products for the revival of historical traditions and cultural values.

Cultural tourism affect first the *quintas* that preserve the history of the country and the secrets of wine making. *Quintas*, major landmarks of the Douro, are readily recognizable as identified by a group of farm buildings around a main house. At some of the oldest of them it's possible to practice *allenoturismo*, thanks to which stay, stroll through the vineyards, visit the sites of production, purchase or taste wines, participate in themed dinners or watch the harvest. Experience, the latter one, which makes the system senses of smell, thanks to the aroma of the vines, hearing and touch, sharing the joy of folk songs, and taste with a glass of wine from the Douro at a glance whole new loaded by the other senses. Tourists can cover different routes of usability that allow to experience the essence of the place through the rediscovery of the commercial, agricultural, historical and artistic traditions.

Fig. 11: Landscape views from *Linha do Douro*

A first route runs along the old trade routes of Port wine with locomotives and carriages to steam and diesel of the twentieth century. It travels to the historic 30 km/h along the *Linha do Douro*, a great feat of engineering, embedded in the natural obstacles with bridges and tunnels.

A second route allows to navigate instead of the Douro by *Rabelo*, typical local boat, or on a boat-hotel, to reach the farms producing Porto Wine and in the meanwhile enjoy the view of one of the most impressive landscapes formed by anthropomorphic rural expanse of vineyards by Barqueiros to Barca d'Alva lining the rocky shores of the river valley.

Fig. 12: Traditional Rabelo on the left and view on Douro River on the right.

A third route is finally dedicated to Medieval and Baroque artefacts and cultural sites, from the Monastery of Tarouca, the Sanctuary of *Nossa Senhora dos Remedios* in Lamego, at the *Palacio de Mateus*, Portuguese Baroque masterpiece surrounded by gardens in a large estate and seat of Mateus Rosé wine. Notable examples of vernacular architecture are present along a network of narrow, winding streets.

In this scenario, full of timeless traditions, an important role is played from crafts. Constantly present in any shop they are wooden shoes, metal objects, stone and pottery, baskets and wicker and straw hats, blankets, linen and lace to show off itself during the medieval fairs of crafts and typical food. The popular festivals of the harvest, the cherry blossom, apple, almond, chestnut follow the biological rhythms of crops and the changing of the seasons.

The choice of the development of the area, resulting from the cultural value of the land itself, finds its premises in increasing demand for culture and for the desire to use a place closely linked to the pleasure of immersing in the local way of life and in all that constitutes identity and character. The culture is, in fact, an industry which has a multiplier effect on the economy and monetary social community, as it has significant impact on employment aspects, collective identity and education. In this sense, the tourist offer consists not only in terms of leisure, but in terms of promotion of tourism as a strategic axis of development that is implemented by making multiple system resources, aimed at integrated and unified management of assets.

Register Avola in the UNESCO list would convert it in an attractive cultural and economic magnet founding the exploitation of its territory on the rediscovery of complex vocations of cultural, environmental, and typical handicrafts and agriculture emergencies, as is the Alto Douro .

Thanks to territorial development policies, Avola would come from a fast track within the circuit of the UNESCO towns of the Val di Noto, characterized by its specificity and fitting into integrated development plans. The involvement of neighboring countries through network projects aimed at guiding synergistically international tourism would bring added value to the city and led to the Sicilian territory. Steps in this direction have already been taken by Emilia Romagna and Lombardia with the presentation of the "Quadrilateral Unesco", and Arco Latino sites that focus on common strategies and areas of cooperation between the local communities in order to foster a wider scale local cultural and tourist areas. System through the development of territories from the peculiarities and cultural landscape recognized by UNESCO as World Heritage Sites in a collaborative territorial systems based on shared values.

Pompeii: urban regeneration for cultural heritage.

Agrippino GRANIERO

Department of Architecture and Industrial Design "Luigi Vanvitelli", Second University of Naples,
Aversa, Italy
architettograniero@gmail.com

Abstract

The subject matter is urban regeneration in support of archeology and cultural heritage in general. Starting from the identification of local resources in the Pompeian area, it's possible develop lines of action for the enhancement of existing heritage, capable of promoting and driving development of the city and the region. If the archaeological excavations World Heritage Site, the Sanctuary of Beata Vergine del Rosario, the favorable geographical position and the horticultural industry represent important cultural and economic resources for the territory, thanks to the interventions of modification and upgrading of some areas that can be create that perfect seam between cultural heritage and the city. Urban regeneration, realized through interventions of urbanistic restructuring and building renovation, also thanks to equalization and densification strategies, on the one hand allows recovery of more or less large parts of territory, degraded or abandoned, on the other the promotion of cultural heritage in the city. It is proposed as an example an intervention located in an area near to the archaeological excavations and along a main road connection between the highway and the sanctuary. The project consists of the replacement of an industrial shed of poor architectural quality, with contemporary formal language, in support of the principal poles of the city and in the design of outdoor spaces with green areas and pedestrian walkways.

Keywords: City, regeneration, development, improvement, modification.

1. Introduction

In the context of the promotion of cultural heritage, improving the use of cultural places and the increase in the supply certainly constitute the fundamental objectives. Operate on a regional scale in order to act on a single archaeological site, such as Pompeii, it becomes necessary to improve the use of the same and make the tourist experience more meaningful and complete. Particularly interesting is the possibility to intervene through the redevelopment and re-use of areas adjacent to archaeological sites, large or small, public or private, now in a state of decay or used badly, in which insert functions, equipment, services, create cognitive and educational paths, directly or indirectly related to the existing cultural heritage. Through the design of the modification of urban regeneration you can create a perfect seam between cultural heritage and cities, so as to develop the local economy, improve the cultural offer, promote and support interventions for heritage conservation and enhancement of the image of Italy at international level.

2. Resources

In order to develop lines of action aimed to the cultural valorization of city it is necessary to know the area, identify existing resources, its problems, recognize the potentials and understand how to best use the opportunities.

In order to develop lines of action aimed at enhancing you need to know the area , identify existing resources, its problems, recognize the potential and understand howto best use the opportunities present.

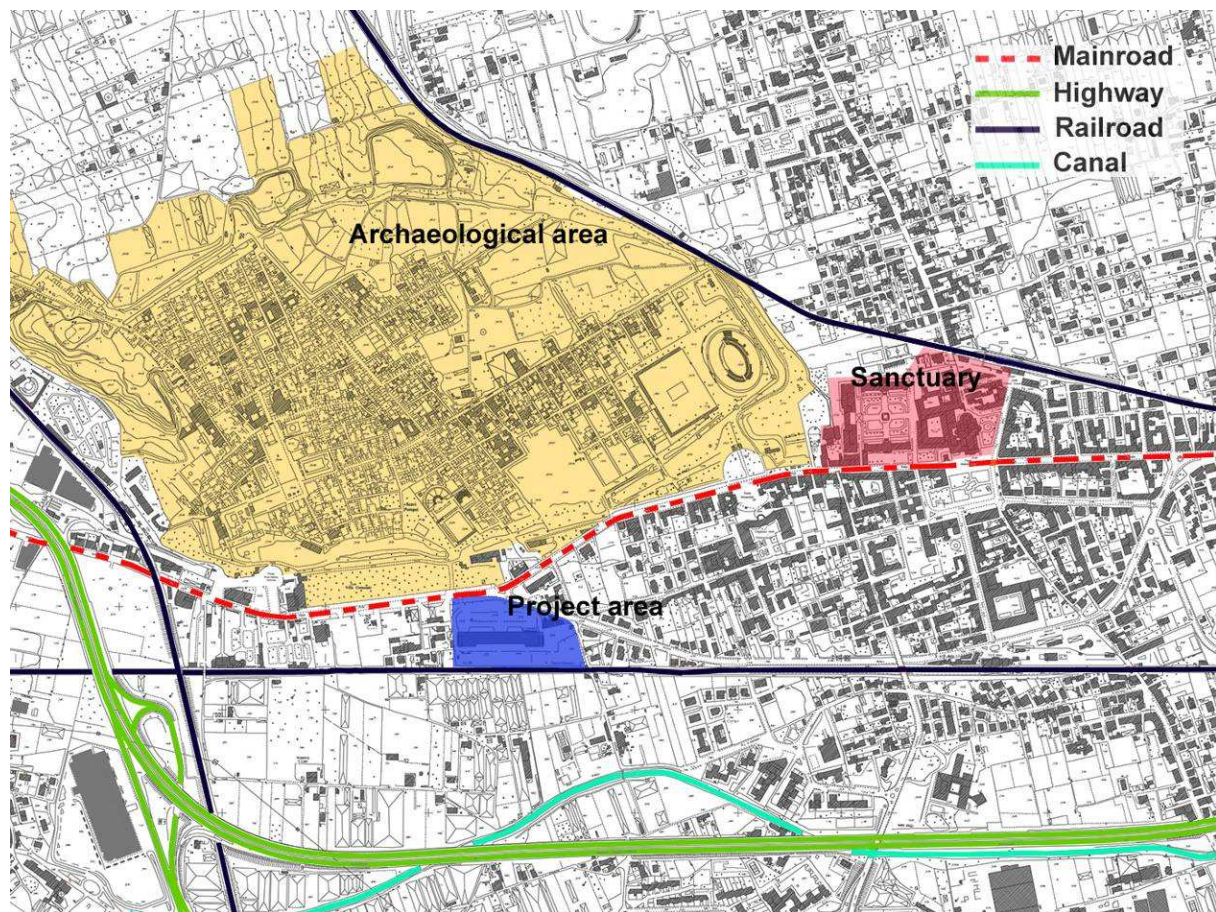

Fig. 1: The territory of Pompeii with identification of main elements.

Study the territory of Pompeii means to analyze an area rich in resources, certainly capable of promoting and driving the development of the entire piece of land. The two principal attractors of the city are certainly the archaeological excavations of the ancient Roman citadel, a UNESCO World Heritage Site since 1997, one of the most visited sites in the world, with almost two and a half million visitors in 2013 and the Sanctuary of Beata Vergine del Rosario, which welcomes in a year about two million pilgrims. These two poles are certainly two resources of immense value to the city and the region, given the number of visitors, users to whom could be sent further cultural or religious offers. Another interesting and important resource is the cultivation of flowers, that characterizes the entire vesuvian coastline, and particularly the southern part of the territory of Pompeii. The identification by the satellite of this type of agricultural production is easy due to the massive presence of greenhouses on the territory, constructed in various materials and sizes.

The floriculture industry, if in Italy represents the 5% of national agricultural production, in Pompeii, mainly characterized by the production of cut flowers, it is certainly an important economic resource capable of giving employment to hundreds of people. In addition to the resource listed, it's possible to identify equally important potentialities, starting with the geographical position of the city, particularly favorable due to its proximity to Naples on one side and the Sorrento peninsula on the other hand, they also major destinations for tourists. The looming presence of Vesuvius behind, is also an extraordinary landscape, unique in the world, which alone can be considered an exceptional attractiveness. Another great potential is to be identified in the possibility of intervention in urban areas of the city, a city that has undergone significant changes over the years, the modern Pompeii in fact, born as a result of the construction of the Sanctuary, has expanded in recent decades throughout the surrounding area, also in the areas near to the ruins, coming to occupy the area south of Sarno, an area that, before the repeated interventions in the course of the river appeared to be marshy and unhealthy, and yet now subject to flooding. The presence of archaeological excavations and the Temple, the favorable geographical position, the particular vocation of agricultural areas, with the possibilities offered by the interventions of regeneration and reconfiguration of certain areas, degraded or abandoned, are important elements on which to base the regeneration of the area Pompeii.

Fig. 2: Degraded area near the archaeological site.

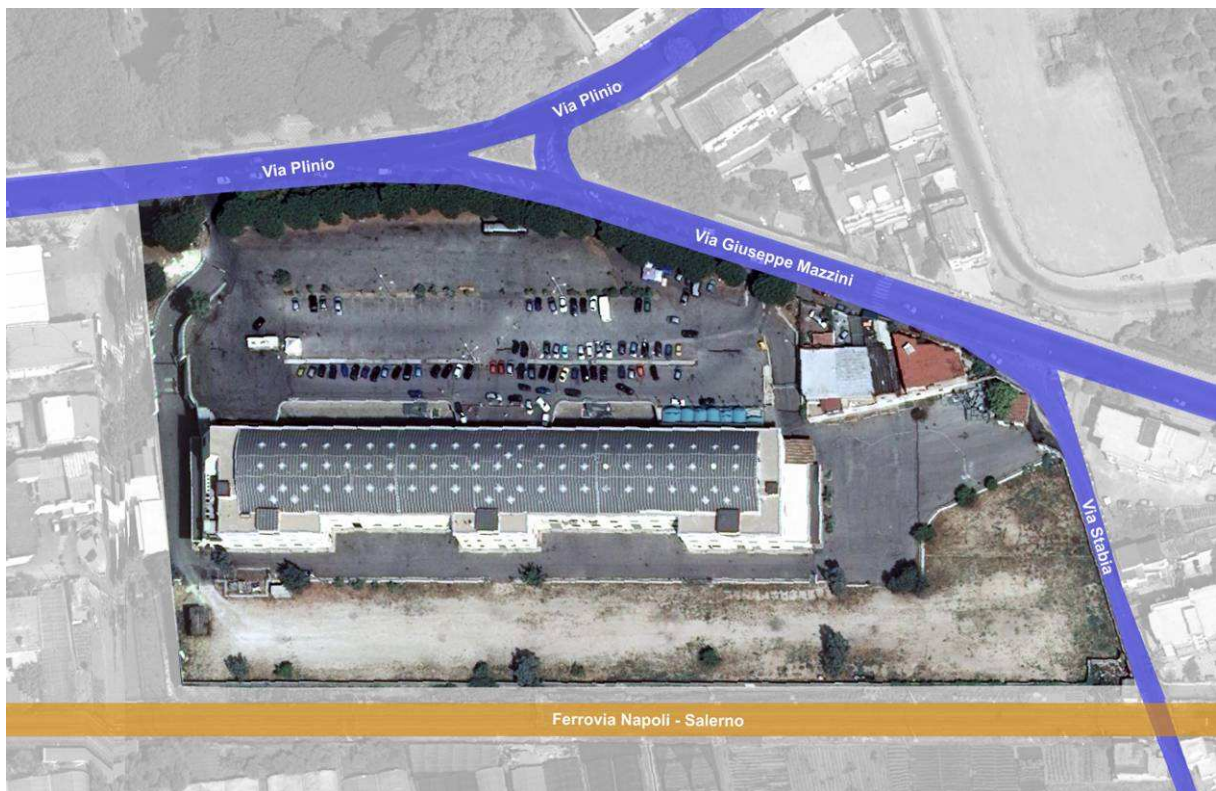

Fig. 3: Project area.

3. Regeneration

If then, until today, the city of Pompeii was extended and fragmented so often random and spontaneous, it's necessary now to tend to the model of the city characterized by two words: mixité and compactness. The compact city is made up neighborhoods, able to accommodate functions and different social classes, which grows and develops according to specific lines of action, through projects of architectural and urban recycling that transform and enhance the most degraded areas, regenerating and making them more beautiful and more useful.

The urban equalization, combined with the strategic inclusion of special use destination and with use of specific building types, would, there where possible, to curb the phenomenon of urban sprawl, arresting the process of fragmentation through the rationalization and optimization of use of the available space internal to the already urbanized areas, giving them a new identity and a new value.

Fig. 4: General plan of intervention.

Fig. 5: View from via Plinio.

The restructuring of urban territory if one side is the main way forward for sustainable development of the city, the other is an important form of valorization of existing cultural heritage, because it can create the conditions necessary for the improvement of the use of places of culture and the increase in cultural supply, through the inclusion of specific functions to support of tourist and cultural activities.

4. The project

The regeneration of the Pompeian territory can certainly start from the areas near to archaeological site, in fact, the recent urban expansion has not spared this zone, especially the strip between the ruins and the railway line, which starts from Villa Mystery comes down to the pinewood on Via Plinio, where, in addition to spaces and structures in the direct service of tourist flows , such as car parks, restaurants and hotels were built industrial buildings and small interstitial residential areas , many abusive , invisible from the road because at a lower level.

This area has already been studied in the past in a workshop at the Faculty of Architecture of the Second University of Naples, which was followed by interesting design proposals, subject of thesis with prof. Efisio Pitzalis, such as the design of a multipurpose building with conference and exhibition halls, located in the area between Via Plinio, Via Mazzini, Via di Stabia and rail Naples-Pompei-Salerno.

Fig. 6: View of project from north.

Fig. 7: View from internal park.

The lot that contains the proposed intervention measures about 30.000 square meters, has a fairly regular shape, presents various inclinations, but never excessively steep, sloping down towards the railway.

The planimetric location is strategic, near the entrances to the archaeological site and along a main road connection between the highway and the Sanctuary, due to this placement, the flows, pedestrian and vehicular, are determinant for the insert of particular functions.

From the point of view of landscape it is interesting to note that from the area in question is possible to see from one side the Vesuvius and the archaeological ruins, places a few meters but at a higher quota, on the other the plain that reaches up from the volcano to the mountains of the Sorrentine Peninsula and then to the sea.

The proposed project consists of the replacement of an industrial shed of poor architectural quality, completely decontextualized, now partly used as a supermarket and partially abandoned, with a multifunctional building with contemporary formal language and arrangement of all outdoor spaces with green areas and facilities for public use.

The building has three internal auditoria for respectively 900, 300 and 250 people for a total of 1450 spectators who may assist simultaneously. The two smaller auditoriums can also open up and share a central space, so as to form a single conference room, but are independent from each other, having their own entrances and foyers. The largest auditorium instead is divided into two levels and unlike the other two has an opening that allows the natural lighting. The lower part reaches up to an altitude where it is located the underground stage. Since its foyer you can access the other functional areas of the center or the exhibition hall, bar and restaurant. Also, the bar is divided into two levels, so as to serve the different areas present.

Fig. 8: Plan of ground floor.

Fig. 9: Section AA'.

The building has three internal auditoria for respectively 900, 300 and 250 people for a total of 1450 spectators who may be present simultaneously. The two smaller auditoriums can also open up and share a central space, so as to form a single conference room, but are independent of each other, each having their own entrances and foyers. The largest auditorium instead is divided over two levels and unlike the other two has an opening that allows the natural lighting. From its foyer it's possible to access to the other functional areas of the center, the exhibition hall, the restaurant and the bar that is split over two levels, so as to serve the different areas present.

The exhibition space is located on the second level and can accommodate different activities because it is an open space, and it's also the end point of an exhibition path that starts from the main entrance of the building and passes through an interior walkway. Interesting is the possibility of using such spaces for exhibitions of cultural, archaeological, religious or commercial nature.

The restaurant, also on two levels, can accommodate up to 650 people and is open on outdoor spaces and courtyards that burrow the building allowing natural light diffused at several points due to the use of translucent panels. Also this dining function can be at the direct service of the archaeological site and the Sanctuary, because it could accommodate the visitors going to or coming from the different poles of the city.

From the main foyer, through a sort of tunnel that connects two different levels you reach the area entrance, where is located the lobby, cloakroom and office area, destined to activities related to the administration and management of events.

Another important function in support of tourist flows is the parking, completely underground under the pedestrian area in front of the building. It can accommodate up to 140 cars and 13 buses, has within it an area of arrival for visitors who can receive an initial welcome and go directly to the structure or go up and come in pedestrian area leading to the entrance of the excavations. From the car park you can also go directly to the roof of the building on which there is a panoramic promenade and outdoor tiers in which to organize various activities and events.

The spaces surrounding the multipurpose building are all pedestrian areas or green spaces. The area in front of the railway is characterized by a series of level curves, modeled after the form of the building that create a barrier of protection, visual and acoustic, against the passage of trains. However, these curves at a point decline further allowing to see the railroad. The creation of an urban park is a response to a real need of the city that has no enough public green spaces, and creates occasion for stop and recreation for the numerous tourists in the area.

5. Conclusions

Therefore, through interventions of urban regeneration, even small, it's really possible to change the face of the city, adding value to cultural heritage, implement strategies that integrate the archaeological site with other resources and the socio-economic structure of the area.

Abstract

The survey techniques based on photo acquisition have nowadays regained importance thanks to three main aspects related to technological innovations: the cheapness of production of digital images; the evolution of capacity to compute, memorize and share data; the consequent development of recursive algorithms on massive data. In the last years many experimentations have been conducted on the acquisition of this data, but the way to display and communicate them - both for scientific and simply informative aims - is still uncertain and not sufficiently investigated.

The experimentation we want to illustrate here concern the opportunity to realize an interactive and multimedia informative system of an architectural or archeological space, based on a progressive fruition of several multi-thematic spherical panoramas. The activities of study, experimentation and test have involved both technological aspects and communication problems, at the different levels of representation, fruition, interaction and characterization. The quality of the realized model and its structuration in an easily shareable format allow to investigate the properties in order to increase the knowledge of it, also in a remote way.

The case study of our experimentation concern the paintings by Andrea Pozzo at St. Ignatius in Rome.

Keywords: Spherical panorama, Survey, Andrea Pozzo

1. Introduction

The instruments and techniques of architectural survey have been deeply transformed by the advent of digital technology.

Within this transformation, we can see clearly a change of orientation in the definition of three-dimensional models, which is focusing on discrete models, rather than on continuous geometric models.

If in the past we tended to catch a few significant points on the object to be detected and with them we built a synthetic geometric model, today we prefer to collect, massively, dense clouds of points on the object and derive from them, only when necessary, few selected geometric information.

Of course, this comes from an exceptional evolution of computational power and data storage currently available.

Today, the laser scanner can easily produce three-dimensional point cloud which describes with very high resolution models captured.

The three-dimensional coordinates of the points can be associated with other qualities, which are sampled simultaneously from other sensors, aligned with those of measurement, such as color, reflectance, etc..

While in the past the final three-dimensional model of a survey operation was constituted by a mesh constructed by interpolation of points clouds poorly defined, it is now usual to provide exclusively the

clouds that, for definition quality, can be directly navigate in 3D and processed for derive, for example, some significant sections.

We tend, therefore, to operate directly on a discrete model, a set of distinct points, rather than on a continuous model, an approximation and geometric abstraction of the same cloud.

This is not surprising if we consider that the real world is discrete.

In the field of discrete models digital images, which are structured sets of sampled points in the quality of color, play a predominant role.

In recent years, due to the increased resolution of the images acquired by digital, several techniques have been developed in the survey

These can be considered supplementary and, in some cases, replacement of the laser scanning. Among these, the spherical panorama giga-pixel takes on a role gradually increasing.

The technique involves capturing spherical panoramas in high resolution, these are taken from different points, chosen appropriately. The images thus generated are virtually navigable and searchable on your computer in various ways.

Using two spherical panoramas, properly oriented, we can define a system of stereoscopic vision and measure with it the space represented. On the market there are different software, both proprietary and open-source, allowing you to navigate this kind of images.

However, if the systems for displaying spherical panoramas have been extensively tested, are still largely unexplored modes of representation, navigation and characterization of multiple panorama aimed at the architectural survey.

Therefore the aim of this study was to investigate the methodology of the survey phase of spherical panoramas, with the critical eye aimed at the subsequent integration and use of the acquired data.

2. Subject of experimentation

The experimentation presented here is suitable for application in many fields: from reconstruction and navigation of partially or totally changed spaces compared with the current configuration, to visualization of in-progress projects; from description of archaeological sites, constantly changing, to interactive and interdisciplinary fruition of environmental, artistic and cultural heritage.

Particularly interesting in this regard, is the representation of two-dimensional or three-dimensional Architectural Perspectives, pictorial or sculptural apparatus making use of perspective representation - on the plane or in space - to offer to the viewer a misleading impression of reality. The two-dimensional Architectural Perspectives are painted on one or more surfaces of different kind (walls, ceilings, vaults, domes, etc.) and allow in most cases a panoramic vision from one or more points of view, depending on the real space conformation and on the author's expressive intentions.

The work that we have chosen is one of the most emblematic of the Architectural Perspective tradition: the corridor frescoed by Andrea Pozzo at the Rooms of St. Ignatius in Rome. In a trapezoidal long and narrow space¹, covered by a barrel vault with elliptical profile (fig. 1), the artist realized a single, wide, 360° perspective, painted on the four walls and the ceiling, which, if observed by the unique center of projection, completely subvert the perception of real space (fig. 2). In place of the longitudinal flat walls, it appears a regular sequence of niches and pilasters. The oblique wall at the end of the corridor is neutralized by an arch supported by two groups of columns that leads to a bright room covered by a large dome, which appears well over the surface of the painted wall. The real vault is replaced by a flat ceiling, consisting of a series of beams supported by large shelves, which rest on the side walls pilasters. Furthermore, the viewer is surrounded by many figures of angels and cherubs, whose physicality is made even more plausible by the strong illusory power of Perspective Architecture.

Even assuming only one privileged center of observation, the work of Pozzo is particularly suitable to a sequential vision. Manifest and declared intent of the author is in fact lead the visitor (the faithful, in the author's conception) through a path that, between wonder and mystery², leads to the only point from which suddenly appears so clear the "divine truth", the point from which the strange shapes of the painting are recomposed in the perspective of an illusory space (fig. 3). The observation of the subject through consecutive panoramas favours in this case, as in many other cases, this double reading of space: one in which the perception of the room's real shape prevails; the other one in which the viewer is totally and intensely immersed in the illusory space, thanks to the painter's scientific and technical abilities.

3. Survey through spherical panoramas

¹ The lateral walls are respectively about 15 and 18 meters long; the corridor is about 4 meters wide and, at the top of the vault, is about 4.5 meters high.

² The architectural subjects painted on the different surfaces, if viewed from a point of view far from the center of the corridor, appear strongly distorted and destabilize the viewer.

To represent the chosen subject, we have first conducted a photographic campaign, in order to make some 360° panoramas in Ultra-High Resolution.

A panoramic image derives from the combination of several pictures taken from a single center of projection. In fact, it represents the subject viewed from a particular point of view and the individual shots are combined identifying many pairs of homologous points in contiguous photos. Therefore, to make a spherical panorama is necessary to take a series of photos at regular intervals covering horizontally and vertically an angle of 360°, providing an appropriate overlap of the individual shots for the recognition of homologous points. The quality of the panoramic image depends on two main factors: sharpness and metric reliability. The overall sharpness of the image is conditioned by the sharpness of the camera's sensor (in terms of resolution and micro-contrast), the type of used lens³, the distance from the subject and the overall quality of the shot (focus, noise, vibration reduction, etc.). The metric reliability of the panorama depends by other factors, such as the quality of the used optic and the correction of the distortions due to the lenses, the identification of the lens's nodal point – around which the camera must rotate during the shooting in order to eliminate parallax errors – and the quality of individual shots union.

In the case considered, we decided to realize three spherical panoramas acquired from three points of view aligned along the longitudinal axis of the corridor, according to a logical fruition of the work that put in evidence the main features previously mentioned. We made first a panoramic shooting from the perspective center of projection and two other from areas close to the entrance and the oblique wall at the end of the corridor.

The used camera (a full frame digital SLR Nikon D800E) was combined with a 50mm lens, sufficiently short to limit the number of shots required to make the entire panorama but not so excessively to reduce the image resolution.

As regards illumination, we decided to use natural light of the room, because it was the same light source the author has considered painting the *chiaroscuro* of his perspective. Because of the strong variations of exposure of the different surfaces, we decided to take HDR images, capturing three photos at different exposures (0, -1, +1) for each position of the camera.

As we said, the camera settings related to exposure and focus are of fundamental importance for the panorama quality. In a panoramic view, especially if it is spherical, it is necessary that each framed area appears clearly focused. The lack of lighting in some portions of the corridor has made difficult to use camera's autofocus and it was therefore necessary to lock the focus at an average distance between the minimum and maximum distances measured from the subject. Therefore, to ensure the depth of field – in relation to the focus distance – that is essential for a clear representation of the different areas of the subject, it was necessary to find an appropriate aperture value⁴, not too high in order not to compromise the image sharpness⁵. The exposure time was then calculated – according to the aperture – at the portion of the wall most exposed to the light.

For panoramic shooting we used a motorized head⁶ in order to maintain the position of the camera's center of rotation, which coincides with the nodal point of the lens. The identification of this point is the most delicate phase of panoramic shooting because it influences the geometric reliability of the panorama. Each lens has a nodal point located along its optical axis, which varies depending on the focal distance: set the parameters of the camera, we have identified this point thanks to the parallax method. Once correctly positioned the camera on the motorized head, we have programmed the panoramic shooting: according to the panorama field of view, the lens's focal length and the percentage of overlap between contiguous frames (in this case 25%), the motorized head's software has automatically calculated the quantity and the disposition of the required shots⁷. For spherical panoramas, there is finally a specific problem to solve, concerning the shooting of the floor portion below the used equipment, which partially obstructs the vision of it. After removing the equipment, we photographed the portion of the floor previously inaccessible to the camera and then we manually integrated this shot in the composed panorama.

Afterwards, in order to represent specific frescoes details at a higher resolution, we took many photos by the same point of view of the panoramas using a 200mm telephoto lens.

³ Maintaining the same position of the camera, the use of a telephoto lens allow to make a higher resolution panoramic image: in fact, reducing the field of view of the lens, we should increase the number of photographs to compose the entire panorama.

⁴ To calculate the value of the aperture in relation to the average distance from the subject and the necessary depth of field we have used an application available at the site www.dofmaster.com.

⁵ When the diaphragm is too close the sharpness of the image is lower. Each lens reaches maximum sharpness at a given value of the aperture.

⁶ Gigapan Epic Pro.

⁷ The photos needed to cover the entire panorama were acquired in a matrix, calculated by the software installed in the motorized head, of thirteen column and eight row. Each panorama is a composition of 312 photos taken by 104 positions at three different exposure values. The photos were taken in RAW format, which allows to control the images parameters in post-production.

In addition to the panoramic shooting we did a metric instrumental survey⁸. First we detected spatial coordinates of the remarkable points that determine the geometry of the corridor, also performing selective scans that allow to identify the main sections of the room (an horizontal and two vertical sections, one transversal and one longitudinal). After we took a series of significant points belonging to the frescoes, evenly distributed on the different five surfaces. Later, overlapping the detected points to the panoramic image, properly scaled, we have verified the correctness of the merge of the individual shots during the stitching phase.

4. Normalization of data

The union of the individual photos, for the three different panoramas, was performed using the software Autopano Giga. This software, using the camera's data, has made a correction of the photos deformations due to the specific lens used and then has identified – comparing pairs of images – the homologous points needed to reconstruct the location of the shots in the space relative to the center of projection. The software, recognizing sets of shots at the three different exposure values, also calculated the fusion of exposures in order to obtain a final image equally exposed. To get planar representations of the different panoramas, they were projected in equirectangular Gigapixel images (about 66.560 x 33.280 pixels), on which it was possible to intervene later to control white balance and exposure (fig. 4).

The equirectangular image created for this research activity is easily viewable in stand-alone mode as a single user operating on a local computer.

However speak today about use of data outside of the Internet is an activity anachronistic, but to make available the panoramic image on the network it is necessary to further processing, which facilitates the transfer.

To solve this problem we use pyramidal images.

This type of image is organized in several levels, each with a copy at half resolution of previous level. The image in each level is also divided into many small pieces (256x256 pixel).

When the user requests a view of the whole, the system responds with a low-resolution image, however, suitable for displaying on the screen.

However, when the user requests a detail view, the system responds with a high resolution single piece image, which is related only to the small portion of observed image.

To display an image equirectangular within a web browser, we can use the WebGL technology, which provides software tools for the representation of three-dimensional spaces.

A multi-faceted sphere - whose faces are sized on the amount of blocks in the maximum level of detail - is initially mapped using the equirectangular image as a texture, then it is rendered within the browser window through a special shader.

The ability to enjoy the panoramic model, by geographically distributed users has prompted the reflections which led to this trial.

The question that we wanted to answer is whether the giga-panorama could be used as a model to integrate and view easily the various kinds of information that can characterize a survey campaign.

As an example, the display system has been developed to integrate and visualize, in three dimensional space, the panoramic image in conjunction with other information, so to increase the accessible content.

In particular, for purely experimental, the panorama model has been expanded, associating to it some other information as study documents, already present in the laboratory and collected over time in the corridor frescoed by Andrea Pozzo:

- the three-dimensional model of the control points measured in the survey with a Leica 3D Disto;
- the three-dimensional vector model, designed to highlight some peculiarities of the apparatus perspective of the illusory architectural space that characterizes the wall painting;
- the panoramic image of the virtual model, reconstruction of real space, stripped of its painting and materials that characterizes it;
- images related to a recent restoration operation (fig. 5);
- a selection of textual and iconographic information of the parietal opera .

The set of aggregated information in this specific application, do not want to configure a documentation organic, much less describe the object identified for testing - an operation that would have required a specific project selection, acquisition, study and integration of the data - but only evaluate the possibility to integrate and make use of data of a different nature within a spherical panorama.

The control points were included in the model after they have been normalized. This operation has served to correct the orientation problems of the panoramas acquired.

⁸ To detect the points we used a Leica 3D Disto laser. The data were automatically and progressively stored in a handheld computer connected to the 3D Disto and saved in a DXF file.

The same type of normalization was required for the insertion the vector model used for the study of the apparatus prospective.

The overlap between the vector model and the panorama model can be performed easily in the three-dimensional environment by setting a coincidence between the projective points of the two models.

The analysis of images, which result from the restoration, have been carefully assembled into a single panoramic image. Representation of this image can be shown in overlay with the panorama of the surveyed space.

The panoramic image of the virtual model, conceived as reconstruction "naked" of the real space, was displayed in a secondary window, in which the representation is synchronized with the first.

The reasons for this choice are derived from specific considerations about the surveyed object.

We wanted to create a representation that highlighted the distribution of illusory architectural form over the real architectural space.

The other textual and iconographic information, that experimentally we associated with the panoramas, are accessible by selecting "tag" that become visible during navigation, when the user aims them.

The simultaneous representation of the captured panoramas, realized in a single window or multiple windows, has provided several aids to the study of the data surveyed.

For example, we created a visualization in which two windows were displayed panoramas of the architectonic space, observed from two different points of view.

In this way, if the views are properly oriented, we have available a pair of virtual theodolite with which we can aim and measure, with good accuracy, the three-dimensional coordinates of points in space.

This is particularly evident in the sample space used in the experiment. Here the illusory architecture is revealed and understood, in his wonderful occurrence, thanks to the possibility to observe the same part from two centers of view.

A final deepening was directed to the study of how navigate within the virtual model, passing from one center of projection to another of multiple spherical panoramas.

Developing some considerations of perceptive character, about central perspective, we have developed an algorithm that allows the user to move through space, moving from one panorama to another, reducing the perception of discontinuity.

5. Conclusions

The experiment has produced several results both in terms of gathering information in the survey phase, and on the next phase of sharing and dissemination the information.

As regards the phase of survey, we have identified several precautions methodological, that are necessary to acquire spherical panoramas, operating within confined spaces and with adverse illumination.

The information collected will help to improve this detection technique.

The union of information with spherical panoramas and the relative techniques designed to show them in integrated mode, shown that it is possible to make tools, both for sharing scientific data acquired (aimed at further investigation) and for the dissemination of the cultural heritage surveyed.

Under these aspects, research has also shown considerable potential for further exploration, for which we hope to cooperate with transversal competences.

Environmental degradation and urban design: nature as starting point for regeneration

Gaspare OLIVA

Department of Architecture and Industrial Design "L. Vanvitelli", Second University of Naples, Aversa, Italy
gaspareoliva@tiscali.it

Abstract

In the scenario of territorial rarefied systems constituting city in extension, urban regeneration projects often work in areas characterized, not only by compromised spatial configurations and social decay, but also by strong environmental degradation.

This contribution, referring to applied research experiences conducted on PIP areas in Sarno river valley (Salerno) and on Patria Lake (Napoli), tries to develop a reasoning about a possible role for nature in urban projects aimed at regeneration of problematic areas through environmental requalification interventions. They should have the capability of converting natural compromised situations into value elements that can be assumed as structure of new spatial configurations and can be thought as territorial polarities. These areas can host collective facilities, they can become energy infrastructures or places for sustainable productions. This design possibility starts from the idea that natural spaces of urban sprawl, that are unbuilt areas and abandoned agricultural fields standing as fragments in urbanized continuum, need to find a new role in territorial dynamics and a new identity in a general idea about nature intended as a complex entity. In this perspective open space can be thought both as a contemplative place and as productive area. The theme of production must be intended from the point of view of sustainability and it can guarantee the survival of open areas during the years.

Keywords: Urban regeneration, environmental regeneration, urban design, nature, agriculture

1. Urban development and environmental degradation

The urban design, conceived as a tool for territorial re-balancing, must confront itself with environmental and ecological issues. Indeed, there is a strong correlation between problems related to urban super-development and environmental problems generated by pollution.

The context in which urban design works is characterized by a widespread deregulated urbanization that has transformed the entity we used to call periphery in a sort of *weak urban entity* characterized by an unrecognisable urban structure connected with a clear idea of the city and by the absence of strong polarities and places for people meetings. The countryside has turned into a rather ambivalent context in which the low-density urbanization is gradually devouring portions of agricultural land.

The unprecedented soil consumption which has affected Italy during the last thirty years has produced also serious and often irreversible changes in ecosystems. The undergrounding of water channels in situations of hydrogeological risk, the indiscriminate construction on coasts or in protected natural areas, the phenomenon of illegal construction, the spread of quarries for the extraction of building materials, the construction of infrastructure with high environmental impact (often with a dubious value), are just some of collateral phenomena connected with the recent uncontrolled growth of urbanization. These circumstances have determined and they are continuing to determine some significant changes in the landscape of the Peninsula, altering irrevocably the ecosystem's balances in numerous local contexts and putting at risk the safety of inhabitants. The serious events associated

with floods of Messina in 2009, in Genoa in 2012, define a focus on fragility of Italian territory and insecure living conditions of many people in the Country.

In different geographical areas of the Country the health conditions of the environment are aggravated by heavy pollution determined by diffusion of polluting productions and by development of eco-mafia's illegal activities. We can mention as an example the destruction perpetrated for years in *Ager Campanus*, the plain situated between the provinces of Naples and Caserta, which has been the object of illegal waste spills and waste landfills, determining the infamous name of *Terra dei Fuochi*, or high mortality levels associated with noxious emissions produced by ILVA steel plant in Taranto.

2. Nature and urban design

In the territorial scenario, as we described in the last paragraph, nature often takes a side role and its function in urban and territorial dynamics appears absolutely irrelevant.

We want to clarify that, in this paper, when we use the term "nature" we are referring contemporaneously to entities strictly definable as natural (situations in which the human presence is marginal) and to entities defined as "second nature" in which, the human presence is important and contributes to the maintenance of spatial conditions as in the case of agricultural fields and protected natural areas or urban parks.

Urban design, that seriously wants to operate in the context of contemporary polycentric city, must necessarily examine the role of natural areas in development of a new idea of city-region. The opportunity to give a new sense to natural spaces, putting them in the middle of reasoning about urban development, passes through the possibility of considering nature as an useful, productive and necessary entity.

The concept of environmental sustainability clearly expresses the idea of nature as a resource and reflects on the need of preservation and growth. To bring nature to a new centrality, however, contemporary culture must overcome the idea of tout court conservation opening a dynamic perspective in which the resource can be implemented through the possibility of intervening respectfully on it. The de-marginalization of production activities related to natural resources, such as agriculture, forestry, farming or fishing, in association with the possibility of conceiving natural resources as energy resources to be used in a sustainable way, could allow to contemporary culture to look again at the nature as a productive reality. In fact, the energy crisis, the end, at least in the West, of big industrial production and food problems connected with the exponential growth of the world population, put agricultural production and renewable energy at the center of the debate about life of tomorrow man.

Fig. 1: Two shots for Agronica project for Philips Strijp in Eindhoven by Andrea Branzi.

Agronica project, developed in 1999 by Andrea Branzi and Domus Academy for the urban regeneration of Philips Strijp in Eindhoven, acted exactly within the conceptual framework just described, trying to postulate a possible new re-signification of green spaces within a concept of post-industrial economy. The gradual conversion of the areas formerly occupied by Philips factories provided for the realization of large agricultural areas, in which traditional agricultural activities were associated with renewable energy productions. Through a model of weak urbanization, conceived as "an experiment introducing the concept of reversibility of uses, of inexpressiveness of artefacts, of absence of urban form global meaning; of total integration between environment designed and the natural environment; of separation between type and function", the designers proposed a possible new central role for nature. This research also experimented the use of mobile, temporary, removable and adjustable building components scattered in a large semi-urbanized park with very low density of

built masses. The energy distribution and internal mobility were ensured by an infrastructural network homogeneously distributed on territory that in the project is named urban tartan.

The project proposed by Branzi in 1999 can be placed in a modern research line directed to overcoming the opposition of city and countryside, aiming at an idea of urbanized nature in which the two terms can be composed. Quoting Branzi we could say that the aim is the building of a "city without architecture and architecture without city" in a disurbanist point of view that, starting from Garden City by Ebenezer Howard and Broadacre City by Frank L. Wright, passes through the proposal for Green Moscow by Moisej Ginzburg and projects for new city of Magnitogorsk by Ivan Leonidov and Ernst May, and arrives in our days. This research line postulates the end of the city as defined during several millennia of urban history, to propose a new unity between architecture and land without the mediation of urban scale.

In this paper we want to propose a different idea of urban design. It could reconcile, respecting each other's otherness, the dialectical terms of nature and city, pursuing a coexistence able to define a new identity for the two entities, in the framework of polycentric city's dynamics.

The huge natural spaces that are actually abandoned or with no role, can be conceived as territorial polarities, entities referred to a wide scale. If we rethink them in terms of sustainable production they can constitute contrast structures against increasing urbanization.

3. Integrated urban design: environmental reclamation and "urban reclamation"

This paper wants to propose an idea of urban project intended as intervention simultaneously aimed to urban regeneration and environmental regeneration. It assumes as principle of intervention the possibility of changing the environmental and urban detractors into valuable elements, using and organizing in a system the existing resources. So we can use the expression *integrated design* that must be intended as an interactive place for collaboration of environmental engineering, urban planning and architecture. Urban design, as we defined, provides for the establishment of a strategic framework in which environmental remediation must be associated with architectural solutions.

This strategy considers environmental remediation not as an emergency measure but as a stable structure for control and maintenance of ecosystems' balance within the broader framework of urban regeneration.

The environmental remediation operations, which run parallel to operations concerning spatial modification, become visible elements taking part in new urban compositions.

Heavily polluted places and difficult situations from the environmental point of view can be rehabilitated to play a focal role for territories looking for a new identity.

4. Integrated urban design: the experiences of Patria Lake and Scafati PIP area

The area of Patria Lake and the PIP area of Scafati town have in common the strong conditions of environmental degradation and the incoherent spatial asset. In both cases, there are aquatic environments in which the conditions of water pollution determine great emergencies.

Patria Lake is located in one of the most polluted geographical areas in the Peninsula, at the western edge of the Campanian Plain, just a few steps away from the big garbage dump named Taverna del Re, while the Scafati PIP area is crossed by several canals connected to the basin of the river Sarno, that is considered the most polluted river in Europe because it is interested by influx of waste water produced by near factories.

The projects are aimed, therefore, for definition of environmental and urban regeneration interventions at same time. For Patria Lake we propose the realization of a equipped territorial park and for Scafati PIP area PIP we imagine a gradual reconfiguration of industrial area in which non-polluting factories are preserved such as logistics and other light activities linked to agricultural production.

Intervention strategies for environmental regeneration require the use of phytoremediation technology for the disposal of water pollutants, and the creation of large areas for sustainable production represented by biomass.

5. Patria Lake: from abandoned place to new generation park

The project for Patria Lake regeneration has been developed by myself with Arch. Paolo De Michele and Arch. Nicola Pietrantonio between 2012 and 2013 and was presented in the call named EcoLuoghi promoted by association Maecenate 90 with the support of Ministry of Environment.

5.1 Actual situation

Patria Lake is located on the Litorale Domitio, in the northern part of the province of Naples. This coastal area, from naturalistic point of view, was once affected by the presence of a lush mediterranean vegetation and a wide beach of fine sand. The lake and its surrounding areas are also part of the nature reserve named Foce Volturno - Costa Licola, area characterized by international importance because of the transit of migratory birds (Convention of Ramsar).

Today, the widespread phenomenon of illegal construction, which has devoured miles of pine forest, coastal dune and beach, the carelessness and criminal activities related to illegal disposal of waste, have made this part of the coast particularly polluted and degraded. Near the compromised environmental arrangement there is, for disastrous coincidences, situations of high marginalization of vulnerable social groups, particularly African migrants, resulting in a situation of widespread urban and social decay.

The Patria Lake, salty coastal basin of probable alluvial or volcanic formation, extends about 2.76 square kilometers and has an average mass of about 2,500,000 cubic meters of water. It reaches a maximum length of 2 km and the maximum width of 1.5 km and the depth does not exceed 1.5 m. It also has two soft water tributary channels (Vena and Amore) and it is connected to the sea through an artificial outfall built during reclamation works of the Thirties by deviating the original estuary channel.

In Roman Age, on the shores of Patria Lake there was the city named Liternum. It has been abandoned in the Middle Age and only in the Nineteenth Century archeologists began digging to bring to light the remains. In the city there was the tomb of General Scipio the African who was exiled there and the name of the lake comes from the inscription on his tomb *Ingrata patria ne ossa quidem mea habes* (Ungrateful country, you will not have my mortal coil), of which the oldest and unsuspecting explorers viewed only the word *patria*. Currently only the remains of *foro* are visible, while the archeological area, in which the experts think there are other buried remains, is used as a public park.

The eastern shore of the lake is affected by a strong urbanization. The settlement, grew up in a spontaneously, is characterized by an incoherent road system, by poor spatial quality, by total absence of public spaces and public facilities and by insufficient underground utilities.

The lake waters are highly polluted and this situation should be managed with a specific intervention strategy. Among the causes of this situation, according to various studies conducted over the last twenty years, there are: direct disposal of domestic waste water due to the lack of a sewage system; the pollutants resulting from agricultural activities of surrounding areas that arrive into the lake through tributary canals; the illegal waste disposal by criminal organizations.

Fig. 2: Photos of actual situation of Patria Lake. From left: wooden piers on lake, the pollutants on lakeshore, ruins of ancient town of Liternum, birds on lake, a spontaneous *Arundo Donax* bush, spontaneous plant species on lakeshore

5.2 Design criteria

The project actions are addressed to environmental restoration of the lake and its surrounding areas as a unique complex ecosystem and to urban regeneration of the settlement developed on the eastern shore.

The project uses phytoremediation technology because it is the best possibility of intervention for an ecosystem already compromised. Phytoremediation allows the disposal of pollutants present in water and soil, through the action of specific plant species. The planting of local plants or species compatible with the wetland ecosystem of the lake, becomes an opportunity to identify specific points where it is possible to concentrate not only purification systems but also the main facilities serving the park. The environmental reclamation is a visible fact, an architectural episode, and it is inserted in spatial systems forming polarities of the park.

Specific design actions-interventions are defined as follows:

1. WOODED STRIP to absorb fine dust and noise produced by vehicular traffic of near suburban freeway
2. PHYTOREMEDIATION SYSTEM to stop pollutant flow from tributary canals Vena and Amore. Sub-surface vertical flow phytoremediation systems are organized along the final parts of the canals; while systems with hydrophyte plants are located at the mouths of canals creating nymphs.
3. RIPARIAN PHYTOREMEDIATION SYSTEM. The spontaneous growth of particular plant species such as *Phragmites Australis* and *Typha Latifolia* along the shores of the basin is encouraged to induce natural phytoremediation processes.
4. FOREST consisting of trees for aquatic environments such as holm oak, pine and mastic, capable of lowering the moisture level.

Fig. 3: Plan of Patria Lake with urban regeneration and environmental regeneration interventions.

5. PEDESTRIAN AND CYCLE PATH along the lake to connect to future cycling routes of Domitian way. It crosses the Biomass Park, the urban area interested by urban regeneration located along the eastern shore of the basin.
6. HORSE PATH running through the biomass park and the oak forest and finishing in two circuits connected with two equestrian activities facilities.
7. ACCOMMODATION. The buildings situated on lakeshores, outside of town (that in part host hotels and restaurants) are regenerated and used for tourist activities.
8. PHYTOREMEDIATION SYSTEM FOR DOMESTIC WASTEWATER that actually, because of there is no sewage system, go directly into the lake. The project proposes a system of horizontal sub-surface flow phytoremediation basins with IMHOFF pre-treatment. This system is organized in special tanks that qualifies new eastern lakefront.
9. Regeneration and expansion of ROWING CLUBS through the construction of new parking areas and facilities for athletes and visitors.
10. REGULAR COMPETITION FIELD FOR ROWING ACTIVITIES.
11. BIOMASS PARK. The western and northern lakeshores are converted into a park consisting of *Arundo donax*, which is a particularly suitable species for bio-fuels production.
12. ARCHAEOLOGICAL PARK. Ancient Litternum archaeological site is used as an urban park where the system of internal routes is connected with new pedestrian and cycle path around the lake.

5.3 Phytoremediation

Considering the high pollution level of the lake the project uses a local resource to purify the waters of the lake. The *Phragmites Australis* is a plant species used in phytoremediation systems and it is widely present on the lakeshores.

The project proposes a system of vertical sub-surface flow systems arranged in series, with rooted macrophytes (*Phragmites Australis* and *Typha Latifolia*), along the final parts of tributary canals. At tributaries' mouths, the project involves the construction of basins with floating hydrophytes, such as water lilies, which complete the purification of canals water. These basins, designed as nymphs, are an integral part of spatial systems hosting the service facilities for the park.

Along the shores, the presence of *Phragmites Australis* is implemented to induce natural phytoremediation processes, contributing to the purification of lake water.

Domestic wastewater coming from adjacent settlement is treated through horizontal sub-surface flow phytoremediation basins with IMHOFF pre-treatment. The tanks are designed like real flower beds becoming an integral part of the new spatial configuration of the eastern lakefront.

Fig. 4: Functional scheme for a horizontal sub-superficial flow phytoremediation basin.

5.4 Biomass Park

Within the global debate about energy resources, production of ecological timber and dry biomass is gaining an increasing importance. Patria Lake area is rich in *Arundo Donax* plant. In fact, they grow on soils rich in water in riparian environments, forming dense bushes along the banks, on the edges of fields and sand dunes.

The species *Arundo Donax* is an excellent candidate for the production of high quality biomass and biofuels, because it grows very quickly. *Arundo Donax* is a large size perennial plant producing more biomass than any other grass species. It reaches maturity in about 1 year and, depending on the climate, can be cut and collected from one to three times a year. A field of *Arundo Donax* can be used for 20-25 years without the insertion of new individuals and without using pollutant fertilizers and herbicides.

For these reasons, the project proposes to increase the *Arundo Donax* presence on the western and northern shores in order to establish a park producing biomass. The features of a sustainable Biomass Park are the rational exploitation of plants and ecological processes. The cut takes place twice a year, cutting every time 25% of individuals in order to complete a cutting cycle in two years. The cuts can also be made following to specific shapes (parallel strips, concentric circles, etc ...) in order to change the aspect of the park continuously.

Fig. 5: A view of pedestrian and cycle path in Biomass Park.

5.5 Facilities

The project framework identifies a series of significant points to place small facilities serving the park. These buildings can be built *ex-novo* or they can be obtained rehabilitating existing volumes.

At the main entrance to the lake from the Domiziana, we realize, integrating existing rowing club and restaurant, a small horse riding field with stables and offices, a porch for trade fairs, new piers for rowing activities and a small building for bike sharing.

At the two mouths of tributary channels there are two small facility buildings, one for sports (multipurpose outdoor playgrounds and spaces for indoor fitness activities) and the sale of goods produced in the park, and the other for didactical activities for children.

Near the access from Via Lago Patria, in the lot occupied by an abandoned rowing club, the project localizes buildings for rowing activities, horse riding stables and a bike sharing.

The buildings (or the building systems) are always perpendicular to lakeshore and they stand for large wooden piers resting partially on the shore and partially on the water. The buildings situated at the mouth of Amore Canal and Vena Canal integrate square nymphs basins. They are designed according to the concept of minimal environmental impact: they have wooden structures and coatings constituted by ecological materials. The wooden technology allows an easy and fast construction and ensures the reversibility of the building process.

5.6 Urban regeneration for settlement situated on eastern lakeshore

Urban regeneration acts primarily on the existing incoherent road network formed by a system of neighborhood streets (sometimes private) with perpendicular direction respect to the axis of Via Lago Patria. They almost always end in cul de sac and from them it is often impossible to see the water

basin. The project proposes the transversal connection of these roads with two driveways parallel to the lakeshore. The whole system of phytoremediation basins for domestic wastewater, to be realized close to the shore, reconfigures the riparian line setting up a green system and so a new lakefront. The pedestrian and cycle path closes the new waterfront on the west side providing a new opportunity for fruition of eastern shore. The lakefront is also connected to the archaeological site, which is currently hosting an urban park.

Excluding expensive and complicated demolitions of existing buildings, it was decided to act on landlocked free lots and on residual agricultural lands to build transversal green strips connecting functionally, spatially and visually Via Lago Patria, the main access road to the settlement of Patria Lake, with the lake itself. In these green wedges there are, in the form of isolated buildings, collective facilities and small retail spaces with associated parking areas.

Fig. 6: Areal view of eastern lakeshore with urban regeneration interventions.

6. Scafati PIP area: from inefficient productive site to model in sustainable productions

The project for the reconfiguration of the Scafati PIP area has been developed for research PRIN 2009 named From urbanized countryside to "city in extension": the composition rules of architecture, of territory, of small towns (national scientific coordinator: prof. L. Ramazzotti) and in particular by Prof. F. Costanzo, with whom I collaborated, Research Unit of the Second University of Naples (unit coordinator Prof. C.A. Manzo).

6.1 Actual situation

The Scafati PIP area is cut diagonally by A3 Napoli-Salerno highway, which represents a real physical barrier, and by a water system consisting of three canals of Sarno basin, built for water supply of agricultural fields and for flooding containment. Close to this area is located one of the many water treatment plants built in the last 10 years for the reclamation of Sarno river.

The settlement's urban structure is incoherent and there are a lot of problems about accessibility. The production lots are organized along a main axis in North-South direction. It should be noted that within the boundaries of the PIP area there are many residential volumes.

The plan for PIP settlement was drafted in 2010. It follows, in lots distribution, the boundaries of existing lots and implements the infrastructural facilities but does not realize a clear and recognizable urban structure.

6.2 Design criteria

The project aims to optimize the PIP area providing a new planimetric organization of industrial lots and improving the infrastructural network. In this organization, canals, regenerated and placed in larger strips used as a park, assume a new role in urban dynamics and become structural elements of the system.

The project strategically acts through phases determining a gradual spatial reform of the settlement, pushing out residential units and re-configuring lots and roads.

The main axis is maintained in its existing split shape and it is flanked by a road system with a parallel direction to suburban road linking the town of Scafati and the town of Sant' Antonio Abate; the free strip identified by these two roads is defined as a green esplanade hosting facilities for agricultural cooperatives.

Between the two internal axes arranged in North-South direction, the project organizes new production lots served by a secondary distribution roads network.

Because of its adjacency to Scafati's historical core, the area lying at north of the A3 is transformed into an urban park and can be used as a relational space for the entire city. The new park is in continuity with the great territorial park of Sarno river. The existing factories adjacent to the new park (some of which are now abandoned), are changed into leisure buildings serving the entire city.

The improvement of PIP area also depends on the definition of a modular building-type that can increase using structural steps of 5m. It is designed as an alternation of built and unbuilt bends that host productive spaces, administration and services. This type reinterprets the conventional industrial artifact through the assumption of typical constructive-technological solutions (modularity, prefabrication, expandability, etc ...).

Fig. 7: Actual situation (left) and project plan (right) of Scafati PIP Area. Areas in grey represent park and green spaces.

6.3 Canals as energy infrastructures

Canals, as axes cutting the settlement transversally, are included in park bands 100m wide that represent the boundaries of flood area, as defined by the Basin Authority of Sarno River.

The project uses phytoremediation technology (paragraph 5, subparagraph 5.3) in order to contribute to the purification of Sarno water. It proposes a series of vertical sub-superficial flow tanks along the canals, forming a group of thematic flowerbeds. The surrounding park, set at a lower level than street's level, works as big lamination basin in which, in case of flooding, the water can flow without generating damages for factories. The park is also completely planted with *Arundo Donax* in order to form fields for biomass production (paragraph 5, subparagraph 5.4) that can be used by people as a sort of productive garden.

Canals, because of polluted water, are currently configured as dangerous environmental detractors, the project, providing for their rehabilitation, aims to build a new urban scheme in which they stand as structuring elements of spatial configuration.

How to manage a urban color plan which takes in account the supporting materials and the conservation state of the buildings

Maria Paola BORGARINO¹, Stefania BOSSI², Anna PIANAZZA³

Abstract

The contribution deals with conservation of the external surfaces and analyses two case studies in which this issue has been addressed through a “proactive” approach, leading to an advanced management tool. While the traditional “piano del colore” regards plasters as a “skin” to be replaced and provide a selection of approved colours and patterns without taking into account the actual state of conservation, in both these examples, preservation is the first choice: the need for a complete replacement has to be justified and a thorough analysis is required to design any intervention (which means choosing the colour, but also the materials and application techniques).

Coccaglio has set up a “conservation plan” to manage the renovation of the facades of the historical center and promote best practices. A web-based platform dedicated to conservation and management of historic buildings has been tested, to manage both private and public interventions and solve critical issues at building and urban level.

Crespi D’Adda was inscribed in the UNESCO List as an exceptionally well-preserved ‘company town’. Uniformity should be one of the characters of the site but actually there is a range of different situations: the original plasters are well preserved but over half of the buildings has been compromised with either modern plasters or painting. A “soft rule”, that is currently being tested, has been proposed as part of the management plan (currently being drawn), consisting in a set of tools and guidelines.

Keywords: planned conservation, guidelines, management, historic centre, company town

1. Introduction

As is common knowledge, interventions carried out on building exteriors are those most capable of determining the image of a place, leaving a mark in the memory of the community and providing an identity to which it relates, and until recently, exterior surfaces has often been regarded as a matter of “urban quality”, without any real attention to the preservation of the existing layers of plasters and finishes [14].

Nevertheless, that idea has been widely revised over the years and today there are many who consider that to be a subject of the field of architectural restoration [8] [11] and a greater attention is paid to existing surfaces in the latest urban planning tools (on this subject, see Regione Liguria, L.R. 26/2003 [1] [13], the experiences carried out in the historic centre of Chiavenna [12] and the so-called “second- generation” urban colour plan, who have given more attention to the material of the technical elements, including coatings [5]).

However, managing conservation in an historical urban context is still a challenge, because of the presence of different situations and different degrees of damage and authenticity. Besides, it is difficult to combine the case-by-case approach established in the field of architectural preservation and currently applied on listed building with the need to find generally applicable rules, that can work in a

complex system, characterized by a myriad of owners who act in different times and often without any awareness or statutory obligation.

The paper presents two different case studies in which a very similar approach has been tested, in order to demonstrate the feasibility (and cost effectiveness) of conservation, even in a broader and more complex context.

Coccaglio is a typical town of the Lombardy plain: a settlement of ancient origins that underwent huge changes as an accidental and uncontrolled urban sprawl and a large amount of rebuilding and renewals. However the inner city conserves several historical evidences, including some listed building.

Crespi d'Adda is a company-town and is as such characterized by the substantial standardization of the workers' houses: none of these was supposed to be more visible or different from the others as well as no worker had to differ too much from the others. None of the residential buildings is listed (despite the UNESCO label achieved in 1995) but there have been no demolitions, new construction or replacements. At first glance, uniformity is the main feature of the site but, in fact, each building is different, due to the renovation work conducted over the past 40 years.

In both cases a "proactive" perspective is assumed since the goal is not to realize a detailed conservation project or offer some ready-made solutions, but rather to encourage good practice, through a guideline to be followed during the planning process. The guideline acts as a "operational guide" for the Building Regulations in force; it suggests a procedure to be adopted and fosters an investment in knowledge, also through the use of cutting-edge tools for data storage and organization. A thorough analysis on different scales is required since all the interventions need to be evaluated on the entire urban system, taking into account the proximity between the buildings and the character of the whole milieu.

In both cases, we are facing a bet. It is necessary a long process and it is obviously very difficult to change widespread ways of thinking to acquire a different viewpoint and approach, not only in technical-executive terms, but first of all in terms of decision-making, evaluation, management and shared awareness.

2. Coccaglio: guidelines for the facades of the historic centre

Coccaglio is a town that has very ancient origins (castrum, pagus ...), located in the Brescia province between the plain and the Franciacorta area, at the foot of the Montorfano mountain. It was built in a strategic area for communications and trades [7]. Nevertheless, starting from the 50's, Coccaglio has undertaken the same transformations that involved many small and medium town in northern Italy, where, under pretexts as progress, industrial development and the progressive urbanization of agricultural land, has often given way to the processes of decay and neglect on the one hand and destructive processes of speculation on the other. The city experienced a great expansion and nowadays a few traces remain of its ancient past, also because of the urban planning tools, that have systematically disregarded conservation, leading to a progressive loss of the architectural heritage.

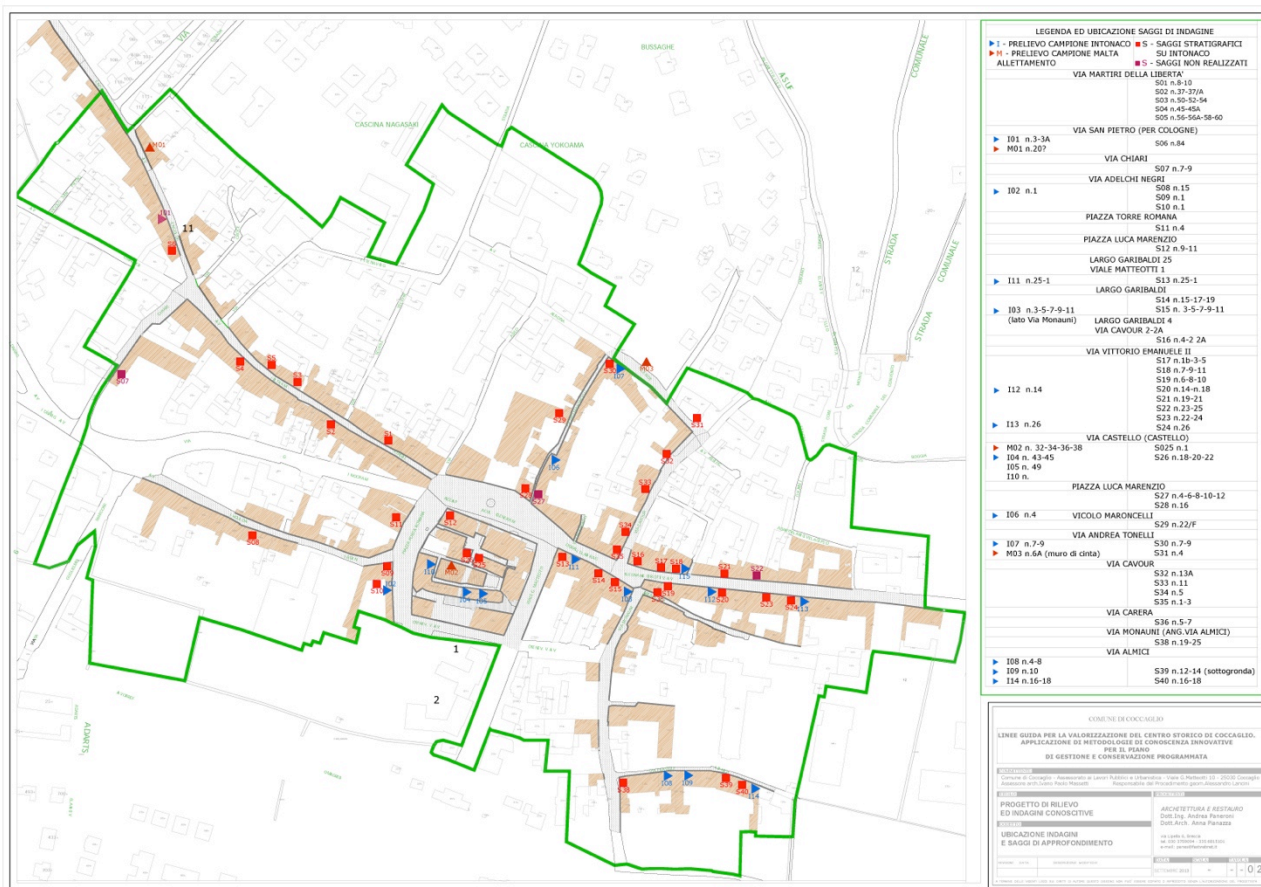

There are a few buildings protected through listing but the historical centre of the city, developed over the centuries around the castle and the parish church, has always been considered as a "sum" highlighted by some outstanding monumental buildings, rather than an integrated system, to be kept as such.

In 2011, as a result of an important turn over, the Municipality, granted by Cariplo Foundation in the call "Promoting Innovative Methodologies for Planned Conservation" decided to entrust a working group, composed by municipal technicians and qualified professionals, to set up a guideline for the whole city centre.

A first step in this direction had already been made, by integrating in the municipal Building Regulations with some requirements that the guideline integrates and explains [4].

The starting point was an accurate and analytical phase of knowledge and documentation, based on diagnostic analysis and survey activities of a significant number of buildings of the old town identified as the most representative.

First a laser scanner survey has been performed on a selection of facades, and plasters have been studied in depth in order to assess the characteristics of the layers (stratigraphic investigations, colorimetric measurements and chemical and physical surveys).

The data collection, including both historical information about each building and the results of the investigations carried out, has been completed through an advanced information system, which can be consulted and updated by different users. A web-based platform dedicated to conservation and management of historic buildings, subject of a recent research carried out by Politecnico di Milano-ABC Department, has been tested, to manage both private and public interventions and solve critical issues at the urban level; amongst others, the problem of defining all technical elements on the facades as well as urban furniture has been tackled.

That sample may be implemented in the future but it is important to notice that techniques and tools typically used for monumental buildings were in this case applied on a complex urban environment, allowing the Municipality to implement comprehensive “conservation plans” to manage both private and public facades.

Investigations and surveys were used as the basis for the guideline that provides strategies and intervention policy for the exterior surfaces of the whole city centre, including historic and modern buildings, with different degrees of “sensitivity”, that corresponds to different levels of care.

Four major categories of intervention are identified on the basis of three key indicators: characteristics of the facade, state of preservation and position of the building in the urban context.

Figg. 3 e 4: The fragment of fresco paintings dating from the 15th-century discovered through the stratigraphic analysis

The characters of the buildings of the historic centre can be summarized under the following points:

A. position / perception:

1. single building, in a marginal position, with limited exposure;
2. single building, part of and consistent with the continuous curtain of buildings;
3. building located on a corner, very representative, near to public and important open space.

B. level of conservation and coherence with the historical context:

1. completely replaced or heavily compromised building;
2. heavily renovated building; some elements of the original character of the building are still evident or perceivable (e.g. plaster, frames, stone slabs ...);
3. simple historic buildings with authentic materials and architectural elements, already known or studied with diagnostic analysis;
4. complex historic buildings with authentic materials and architectural elements, already known or studied with these diagnostic analysis;
5. Building with very important details, listed or similar to a listed building.

Regular maintenance must be assured for all buildings and specific preventive and conservation measures are recommended for historic buildings, that require a more accurate level of design and diagnostic, while for the new constructions a greater degree of transformation is allowed although the intervention must be consistent with the urban context and the surrounding buildings. In addition, for each building the most significant elements are identified, for which the guideline sets out mandatory requirements and instructions (e.g. specific instructions are provided for the fragments of fresco paintings dating from the 15th-century, found in the stratigraphic analysis under recent layers of plaster and stone portals). Besides, some general instructions are provided, as a support for the local commission ("Commissione per il paesaggio") in charge of evaluating the projects.

To encourage the adoption of these, an extensive analytical phase is required to be included in the project, starting from the information from the first phase of the project provided in the database, that includes the survey of the facades in a digital format, stratigraphies and samples of the historical plasters and a historical iconographic documentation. Besides, the provision of subsidies and grants is under evaluation.

At the time, the Municipality of Coccaglio is about to approve the guidelines. Nevertheless, the positive outcome of some pilot cases, that have shown the advantages, even in economic terms, of a more conservative approach, allow us some optimism about the impact of the project.

3. Crespi d'Adda, a management tool for the WHS.

Built in late 19th century by the Crespi family of cotton manufacturers to house their workers near the Adda river, Crespi d'Adda is an exceptionally well-preserved example of a 'company town'. The village is inspired by the most advanced experiences of Saltaire and Mulhouse and combines the philanthropic ideals of utopian socialism with the need to ensure the rational management of a state-of-the-art industry.

In the '20s the huge factory employed over 3600 workers, but just over one thousand of them could live in the village, where the various typologies of buildings reflected the roles and the hierarchies within the factory. The various types of house reflected of the hierarchy within the factory (bourgeois-type houses, labourers' houses, detached houses for managers and clerks...) and were built by using

low-cost or recovered building materials. Besides, numerous social and recreational facilities were provided to the workers and their families (a church, a school, a doctor's surgery, sports activities...).

Fig. 5 Crespi d'Adda. General view.

In 1930, the Crespi family was forced to sell the village following the worldwide economic depression; the subsequent proprietors provided housing and services to the workers until 1972, when houses were sold to private owners.

Thus, for almost one hundred years the factory owner was in charge of maintenance, and changes were few and done in a coherent way. Between 1939 and 1943 facilities were added to the workers' houses (toilets and storages), the terracotta frames were removed and the houses were repainted, replacing the original straw-yellow colour with brighter colours (red and green).

Fig. 6: Residential building; where it has been conserved, the original plasterwork is well attached to the masonry support and the original faded finishing show signs of “noble” deterioration, or rather, a progressive fading of the material that gradually brings out its transparency

Many houses are still intact but, after privatisation, building works became progressively more frequent and invasive. Refurbishments were driven by functional and aesthetics needs and a large amount of plasters were replaced with modern materials, without even considering the possibility of keeping the original surfaces and materials. Moreover, numerous houses were recolored by owners who were perhaps keen to intervene on the appearance of their house so as to distance themselves from the recurring style of workers' houses and, in addition, the modernization of the houses resulted in a number of changes, as the placement of several pipelines and plants on the facades.

Fig. 7 Recent changes; the exterior of over half of the buildings in the village has been irreversibly compromised with either the plaster being removed or new finishing being applied. These works, even in cases that have maintained colours or materials in keeping with the context, have in any case eliminated important information and have greatly altered the site's appearance.

In 2003, after a long period of hardship, the production ceased and only in 2013 an entrepreneur willing to restore and re-use it acquired the factory. Today about 400 persons still live in the village, mostly former workers and their families.

In 1995, the site was inscribed in the World Heritage List, on account of the perfect balance between landscape, industry and architectural heritage.

The Committee decided to inscribe Crespi d'Adda on the World Heritage List on the basis of criteria (iv) and (v), considering that

"it is an exceptional example of a working village of Europe and North America, dating back to the 19th and 20th centuries, and reflecting the predominant philosophy of enlightened industrialists with respect to their employees. Although the evolution of economic and social conditions constituted an inevitable threat to the survival of Crespi d'Adda, its integrity is remarkable and it has partly conserved its industrial activity".

The management plan, currently underway, is necessary to maintain label and has to be consistent with the justification for inscription on the World Heritage List [9].

In the past few years there has been a growing interest on the subject of the colors and there are many who call for a strict regulation, so as to reinforce the stereotyped and 'picturesque' image of the "ideal" village. What colour must the houses be? Is it better to reproduce (on the basis of historical documentation) the original straw-yellow or should the greens and reds introduced in the 1930s be kept?

As seen above, it would be therefore simplistic to assume that "visual integrity" is the main value to be preserved in the site and "even copying an existing colour is a design activity, just as all past colours were: so replacing the appearance is a minor problem compared to conserving historical quality" [6]; nevertheless, this is a central issue when dealing with the inhabitants, and a "Guideline" about the facades (both public and privately-owned) has been the first outcome of the management plan's preparatory activities, as part of a more complex tool that deals with other urgent issues as refurbishment of homes, energy efficiency and garages [10] [2] [3].

Contrary to people's expectations, the guideline does not indicate the "right" colour or a selection of suitable colour schemes, but propose a "methodological procedure" that helps in choosing the most appropriate materials and application techniques, taking into account the actual state of conservation of the plaster.

There are indeed many recurrent situations in the village, that have been identified through a careful and thorough survey, which covered all the buildings of the village: the original plasters (still existing in about half of the buildings) are well preserved although the rain has almost completely washed colourings away. The remaining half of the buildings has been irreversibly compromised with either the plaster being removed or new finishing being applied. Those changes had a strong impact on the site, since the colour perception depends on the different layers which constitutes the plaster, material and application technique and modern colourings tend to give a uniform and “flat” appearance to the surface and leads to a rapid decay.

Fig. 8: Saturated colour shades made possible by modern colouring tend to give a uniform and shallow appearance and also because the deterioration process, caused primarily by modern plasters, has entirely different dynamics to that of traditional materials.

The Guideline comprises two parts: in the first intervention criteria are provided, establishing both colour and technical principles, along with the practical information needed to draft and present the projects.

The second part contains scenarios, which provides a “project outline” for the most common situations:

- 1st case scenario: original / traditional plaster in good or fair condition, with fading and detached colour.
- 2nd case scenario: original / traditional plaster in good or fair condition, with colour that has been replaced recently with polymeric paintwork, RPAC or similar plastic exterior cladding.
- 3rd case scenario: original/ traditional plaster in poor condition, with faded and detached colour.
- 4th case scenario: recently replaced plaster, with polymeric paintwork, RPAC or similar plastic exterior cladding.

Each scenario have a validity time period (5 years) and can be redefined on the basis of further information found through investigations and surveys; nevertheless, as a general rule, existing plasters should be preserved and unnecessary and questionable substitutions has to be avoided.

Original plasters in good or fair condition affected by widespread leaching (1st case scenario) can be treated using traditional lime-based paintings and the guidelines suggest regrouping and colour restoration of the faded surfaces by overlaying a semi-transparent layer. By resorting to this technique, it is possible to maintain all characteristic traces of the building, in particular avoiding eliminating signs of alterations made in the 1930s that can still be seen today.

The guideline allows corrective works to be carried out on surfaces that have already been compromised by the application of synthetic materials (2nd and 4th case scenario). In those scenarios, special attention must be paid to technological compatibility, to be verified on the basis of the support conditions and of the context. Polymer paint can be removed and the new finishes (both on conserved and new plaster), should be designed according to the characteristics of the support, avoiding polymeric colouring, unless this is not reasonably practicable.

In the event of conservation not being possible due to previous interventions, loss of support or irreversible disrepair to the support (to be demonstrated through careful analysis), corrective works or the design of new colouring will be required and plasters can be replaced with compatible materials. That situation does not occur today in any of the buildings.

Technological choices must be justified by a careful analysis of the type of support and the context and the colour chosen must meet various criteria, both aesthetic and technical.

Colours are chosen on the basis of indirect documental assessments (past documents and archived evidence of the building) and direct contextual assessment (analysis of the support characteristics, the building and the context). The Guidelines guarantee compatibility of new interventions, since alterations and technically incorrect works are prevented by the initial checks of the design choices (eg, limiting the choice to natural materials too bright colours are avoided).

The analysis of the layers, required in the analysis phase, serves as an indicative reference although the colours found do not necessarily have to be repeated. On the contrary, the chosen colours must be in keeping with the surroundings.

Furthermore, the choice of colour is somewhat influenced by the technical choices. New plaster must consist of a preliminary layer of natural hydraulic lime mortar followed by a top layer of non-hydraulic lime; the non-hydraulic lime layer can be totally coloured, with earthy colours or ground stone. Where there are existing finishes, it is suggested that the existing layers of colour be regrouped and the gaps be integrated in a "film-like" manner, adapting the faded colours with traditional semi-transparent materials. The requirement of using traditional colours prevents excessively dark, saturated or bright colours.

Each design proposal will be assessed by an "advisory committee", which evaluates the project, and decides whether the analyses are complete and that the choices made are congruent. It will also assess the samples produced on-site (each project must be equipped with samples of at least 70x100cm with the proposed colour).

Finally, the assessment procedure extends to all façade elements, to which the same criteria concerning conservation of the building materials used and compatibility of the decisions made applies.

Restoration of outer wainscoting, decorative and raised elements that are no longer present is not permitted, even if these elements are documented. A database, that can be consulted and updated, that assigns a file to each of the buildings in the village and that can be used to collect information and progressively monitor changes, inspection results, maintenance activities and alteration requests.

At the time the guidelines are being tested on a few pilot cases waiting for the final adoption.

SURVEY OF 'LIBERTY' IN MILAN, 3D PRINTING FOR THE RESTORATION OF DECORATIONS

Maria PIGNATARO¹

⁽¹⁾ ABC Department, Milan Polytechnic School of Construction and Architectural Engineering, Milan, Italy

maria.pignataro@polimi.it

Abstract

The survey of villa Faccanoni-Romeo, important example of Liberty architecture in Milan, designed by Giuseppe Sommaruga and built in 1912, was undertaken on the occasion of the centenary of its construction. The work was done at the request of the current users (Columbus Hospital) to create a useful digital parametric model, for long-term maintenance of the façades and decorations.

Carried out using direct and topographic measurement techniques, the survey was modelled using Revit parametric software, integrated, as far as possible, with Rhinoceros and related applications. Thus, a database useful for the management of future construction projects was also created.

Following the survey of the façade materials and the 'typing' of the construction elements, these data were transferred to the digital model for quantitative computation, where a study of the shadows during actual sunlight conditions was developed using georeferenced climatic data.

Particularly interesting was the digital modelling of the floral decorations and the transformation of the column bases into physical models.

Here we document the development of the physical model from the photographic relief. This procedure is interesting for its possible applications to restoration. The reconstruction of damaged or destroyed decorations using 3D printing is possible.

Keywords: survey, digital parametric model, 3D printing

1. Preface

This project was developed on the occasion of the centenary of the construction of villa Faccanoni-Romeo, designed by architect Giuseppe Sommaruga in 1912. This is one of the most important examples of the Liberty style in the city and one of the few works in Milan by the architect, who worked mostly in other cities in Lombardy. The building was designed by commission of the engineer Faccanoni, as a country home for his family just outside the city.

Following the latest post war urban development, the villa, being adjacent to the former Fiera di Milano convention centre (now relocated to the new Rho Fiera exhibition area, designed by Massimiliano Fuksas) has been recently involved in the City Life urban requalification project, in its completion stages of the residential and office buildings and skyscrapers designed by the architects Liebskin, Zaha Hadid, Isozaki.

Shortly after its construction, the villa was sold to the Romeo family, which had just then initiated the manufacture of Alfa Romeo automobiles on an industrial scale. In the 1950s, the family devolved the villa to a female religious congregation, the Cabrinian Missionary Sisters, who had cared for a severely ill member of the family for a long time, in order to let them continue their mission in a suitable facility. Over the years, the villa has remained with the congregation. It is today known in Milan as the 'Columbus Nursing Home'.

The different uses of the villa over the last century has caused only a few changes to its interior layout and has left its façade unchanged, as a precise reflection of the project drawings (Fig. 1).

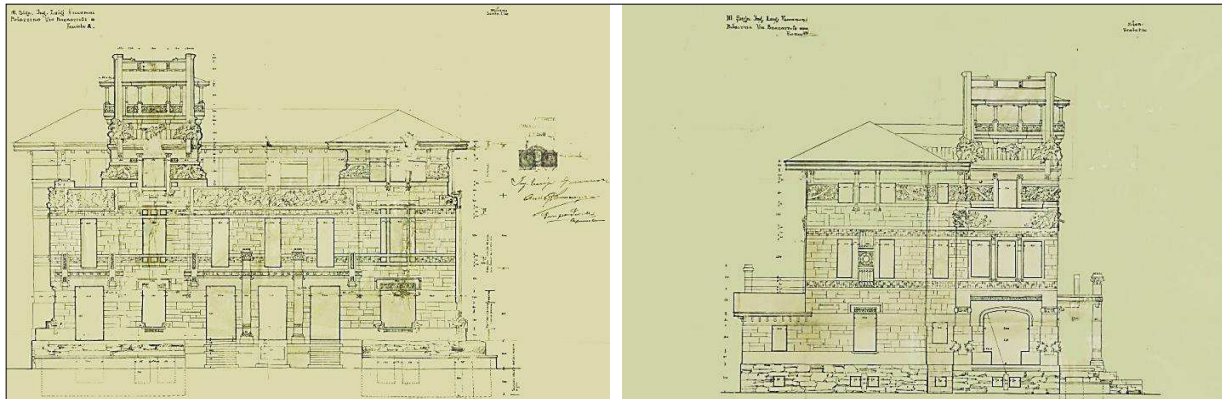

Fig. 1: The drawings in scale 1:100 of the Sommaruga design project of the main façade, (Civic Historical Archives of the Municipality of Milan, Castello Sforzesco, Milan)

The archive search, undertaken at the start of the survey, acquired Sommaruga's original project drawings, from which it was possible to check their correspondence to what was built, even in the choice of the materials and the decorations.

Indeed, the subsequent requirement for a real healthcare facility was met by the Cabrini Congregation, by building a new hospital building behind the villa in the large surrounding garden and leaving the Liberty structure for use as the sisters' residence and administration offices.

The design project for the hospital building, not included in this survey presentation, was assigned to Gio Ponti. Therefore, the complex is a unique example for the city as it is a direct record of the evolution of Milan architecture from the Liberty period to the Modern Movement.

2. Purpose

The purpose of the survey of villa Faccanoni Romeo arose from the concomitance of two factors. In the first place, the Columbus Hospital wanted to obtain graphic documentation of the building that was as complete and accurate as possible, in anticipation of maintenance operations that were gradually becoming necessary for this hundred-year-old structure. Its cultural value, protected by environmental restrictions, the peculiarity of the historic materials used and, last but not least, its public function, imposed a careful control of the works and expense planning. Hence, a survey became necessary. However, not just a 'static' survey based on traditional measurements but one that could be used to easily plan and manage restoration work on the façades over the time.

The Columbus Hospital's intentions were consistent with the educational objectives found in the Milan Polytechnic Construction Engineering Department's '3D Modelling' degree programme, which provided for the application of modelling software to the survey of historical buildings. This Liberty style building, with its complex forms and distinguished by its 'exuberant' decorative scheme (Fig. 3), not only become the subject of a particularly interesting research project but was turning out to be also quite challenging. In this context, the students, in their last year of study for the first level degree, discovered a suitably complex laboratory where they could apply and verify their learning.

The main objective was the development of parametric drawing files that would enable the setting up of a database to be used as a tool by which scheduled maintenance of the building could be planned over the time.

Given the façade's decorative complexity, there was a secondary purpose as an offshoot of the primary objectives: the verification of the possibility of the integration of the different software programs required for the survey into one parametric model.

The possibility of the use of a digital model to create a physical model of the decorative scheme was also to be explored, trying out the most appropriate techniques and tools to reproduce the decorative features quickly [1].

3. The Sommaruga project drawings

In Lombardy there are two villas designed by Sommaruga commissioned by Faccanoni. The first had been built just a few years earlier, in 1907, at Sarnico, while the second was built in 1912 in Milan and is the subject of this survey report.

Sommaruga's original project drawings for the Milan villa are preserved at the Milan Civic Historical Archives at the Castello Sforzesco of Milan.

They include plans, elevations and sections in scale 1:100 and 1:200, in addition to construction details of the wrought iron fencing, made by Mazzuccotelli, a well-known artist and smith of that era in Milan, who also contributed to the work on other decorations on Sommaruga's buildings (Fig. 2).

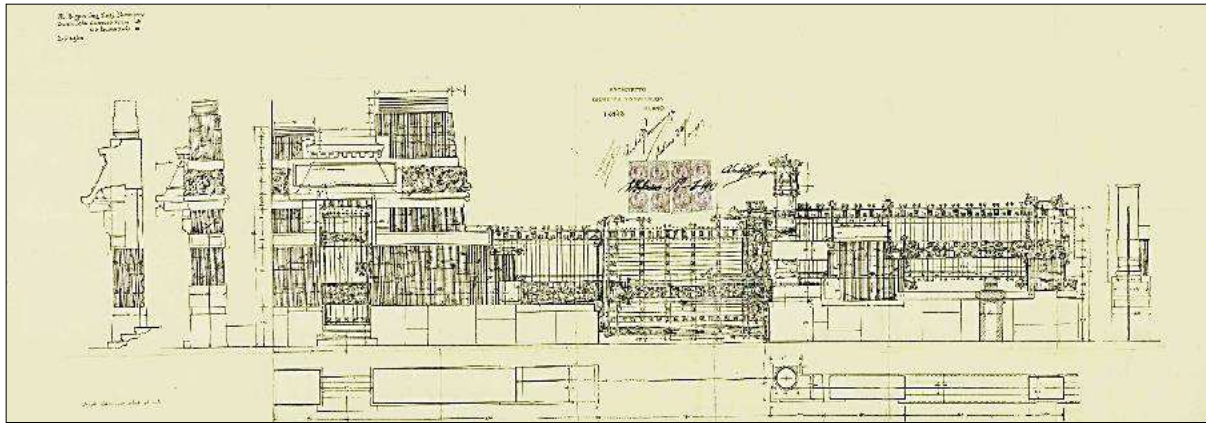

Fig. 2: Detail of the wrought iron fencing, by Mazzuccotelli in scale 1:50 (Civic Historical Archives of the Municipality of Milan, Castello Sforzesco, Milan)

The plan of the top floor, which exists only in scale 1:200, is poorly defined. Perhaps this was expecting additional instructions from the principal, and it was probably completed midway.

The cladding on the façades used stone in different colour tones coming from Lombardy quarries, combining different sized elements with different surface treatments from split to bush hammered.

Different materials were also used for the decorative scheme: bas-relief cement for the columns and balconies, horizontal strips of coloured ceramic with wrought iron used for the fencing, balustrades and parapets. One of the side elevations was subsequently adorned with two statues, previously located on the facade of another building designed by Sommaruga, Palazzo Castiglioni, Corso Venezia, Milan.

The two large figures, by Ernesto Bizzarro, symbolising peace and industry, were subject of discussion among citizens, both because of their large size (more than two metres high) not justified by any function (for example, as supports such as caryatids for a portal or a balcony) and because they were partially nude and considered too provocative. For this reason, Palazzo Castiglioni was ironically nicknamed, in dialect, *'la Ca' di ciapp'* [the House of cheeks].

Therefore, it was decided to relocate the statues to the site of another of Sommaruga's works. They were placed on one of the less visible façades of villa Faccanoni-Romeo, turned toward the inner garden (Fig. 3).

All of the drawings include dimensions, which for the most part correspond to what was built.

Fig. 3: The statues, initially located at Palazzo Castiglioni in Milan, and now placed on the villa's side façade. A detail of the decoration on the main façade

4. The survey parametric model

The parametric model of the building was developed on the basis of instrumental and direct measurements. BIM modelling software was used for the graphic rendering of the entire building. 3D CAD modelling was then added, for the rapid prototyping of the decorations in cement, using image treatments, for the colour studies in addition to the rendering of the building [2].

4.1 Survey of the measurements and the façade elements

The instrumental survey of the measurements was performed by combining topographic and photographic techniques. Only certain verification measurements and those in areas not accessible to the instrumentation were taken directly.

The instrumental survey, not being within the subject matter studied in the '3D Modelling' course, was undertaken by a study group coordinated by Prof. Carlo Monti [3]: "During the initial on-site survey phase, 7 laser scans were made so that all of the surfaces of the villa's two combined elevations could be covered. Those points so acquired were then imported into the dedicated software one by one and subsequently memorised, in order to obtain one single high-density point cloud (about 700 million points). The joining of the data surveyed from different angles enabled any shadow areas in the individual scans to be filled in." [4]

This way, the discreet 3D point surface could be navigated and measured: "...some orthographic projections were developed (Fig. 4) for the digitalisation of the elevation (the colour was given by the surface reflectance of the laser) of the façade. The resolution of approximately 5 mm enabled the features of the wall texture to be read" [5].

Direct survey measurements (as in all of the subsequent 3D modelling) were made by the students. In addition to the standard utility measurements, the different types of construction and decorative elements featured in the façade were surveyed and classified.

A schedule was constructed, in order to create an initial database, which included, for each type: measurement specifications, materials used, surface treatment, the colour and the location on the façade (Fig. 5)

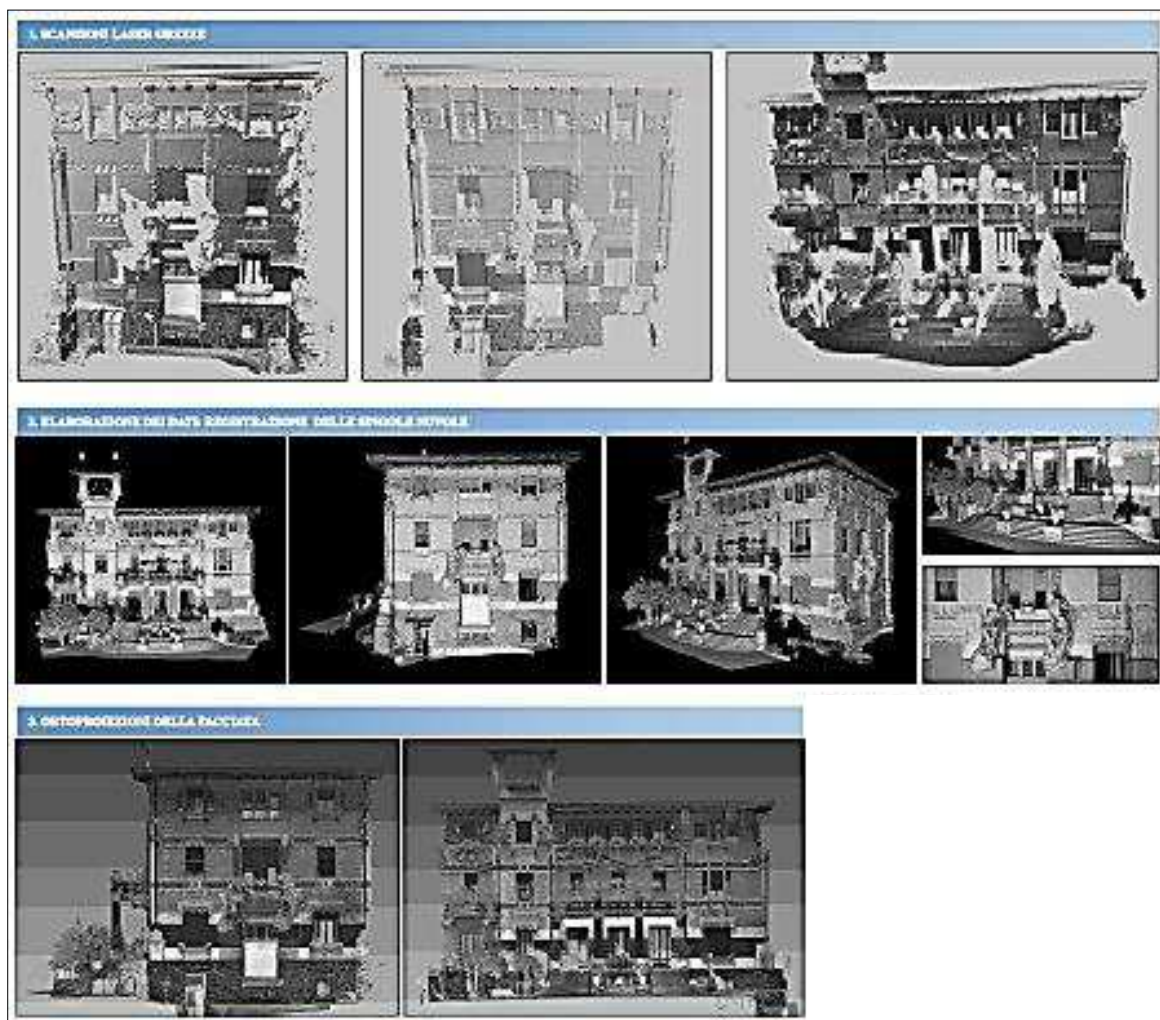

Fig. 4: Topographic survey images

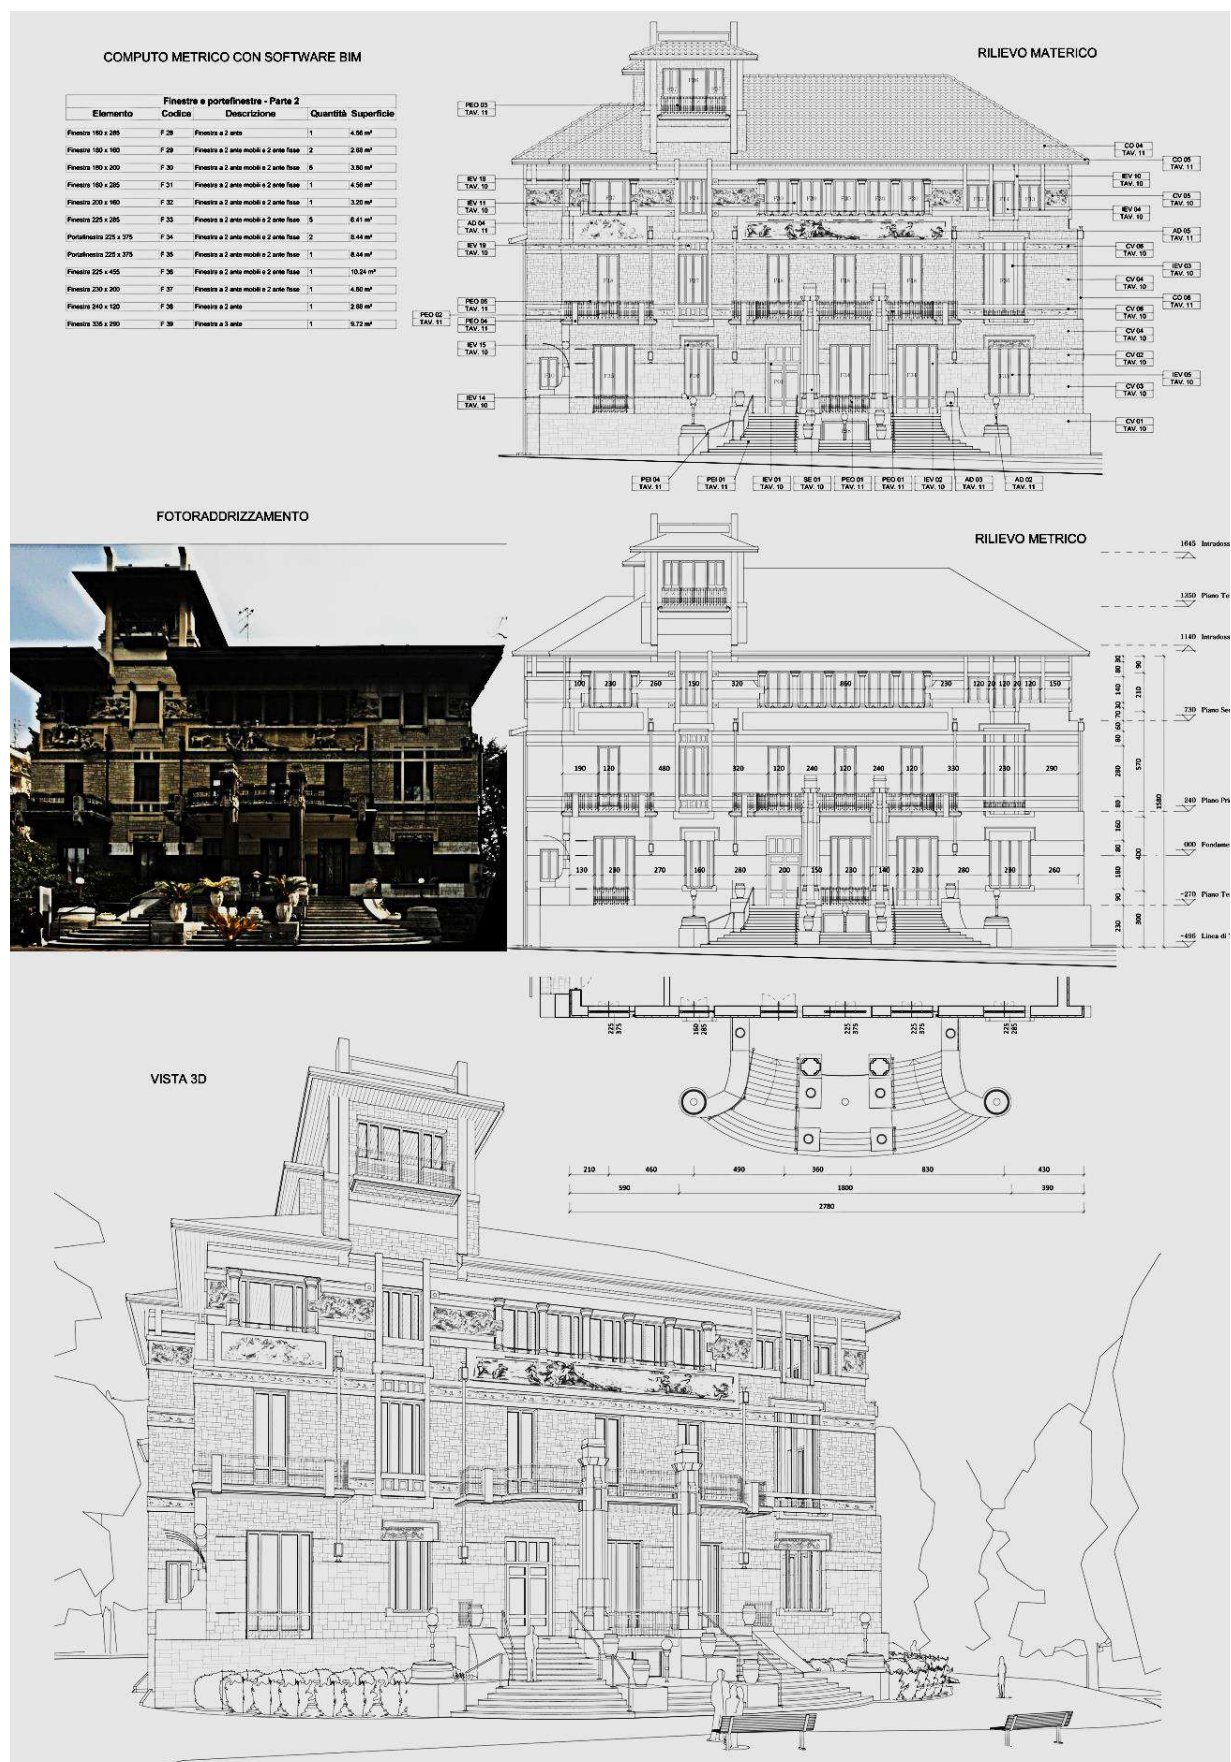

Fig. 6: Images of the digital model: in the centre, the image rectification and the simplified elevation, without the sculptural decorations, for the creation of the database. Above, the codification of each element and the computation table. Below, the 3D visualisation

5. Application of the parametric model

The aim was to check how the digital models generated in BIM might be used for different purposes and by way of suitable processing, in order to obtain results useful for scheduled maintenance of the building to be planned over the time. In addition to the transformation of the physical digital model described below, some of the more common applications were developed, in order to verify its practicability in an historical building with such a complex façade.

5.1 Bill of Quantities

The bill of quantities for the accounting of the works and the activities connected thereto was easily obtained by consulting the database previously implemented. Each material of the façade was assigned a code as an expression of the calculation parameters. As is clear in Figure 6, the codes assigned to each element were indicated in the elevation. On the left, there are the tables generated by the query, where the different parameters used and quantified can be found. In this way the total of all of the elements and the specific location of each on the façade are easily legible.

5.2 Sunlight study

The sunlight study was performed assuming the actual conditions of the context in which the building is located. By way of an automatic geo-referencing connected to the Internet, it was possible to locate the building in this context and import all of the parameters required to transfer the actual position of the sun to the database. Actually this in reality is a quite simple operation that enables the automatic display of the sun's route and the shadows of the building for each day of the year, at any time. Figure 7 shows some 'views' of the building at different times on Saturday 23 June 2012.

Fig. 7: villa sunlight study on 23 June 2012.

5.3 Rendering, colour and walk through

The creation of databases integrated with the digital model, processed in this manner, made the graphic rendering of the many decorations, which characterise the façade, problematic, even those in high relief, including the two large statues moved from Palazzo Castiglioni and located on one of the sides.

In terms of setting up a digital model that can also represent the Liberty style of the building, it was however necessary to be able to view all of the decorations that are featured on all the façades of the villa. Acquisition of the topographic survey required the use of expensive procedures and instrumentation, (which now, just two years later, are much more easily obtained), which were not appropriate for the course of study. A simpler solution was therefore chosen. This comprised the adoption of commonly used software, dedicated to the digital processing of photographic images. The results obtained were still much more limited and related to two-dimensional images, as the two files generated in different environments could not be integrated. To complete the rendering it was necessary to acquire the colour of the different materials making up the façade, by direct survey (Fig. 8).

The rendering thus processed was also used to create a virtual visit around the outside of the villa following a route that runs through the large garden surrounding it.

Fig. 8: Rendering of the building with a view of three façades

6. The physical model for restoration of the decorative cement

In terms of future scheduled maintenance façades of the villa, the idea to create a physical model from the digital model arose.

However a reduced scale model of the entire building was not the aim. Rather, attention was to be given to the façade decorations. In fact, their deterioration caused by environmental agents or any damage incurred over the time often requires either their partial reconstruction or total replacement. In this case, the physical model, elaborated from the digital model created from the survey of the still intact object, would be of great assistance for any future restoration work.

It is not by chance that buildings with a certain historical significance are beginning to develop their own digital model archives, generated using topographic surveys, in anticipation of maintenance and restoration works, so that the original form of the building may be brought back (see, for example, the surveys of the spires on the Duomo of Milan, performed by the work group coordinated by Prof. Carlo Monti, Politecnico di Milano, ABC Department).

Therefore, it was decided to undertake a simulated digital survey to create the physical models of the villa's decorative elements, taking as a reference point the base of a column in decorative cement used as a support for the main entrance portico. The work was developed in successive survey, modelling and rapid prototyping steps.

During the instrumental survey phase, "... 160 photographs were taken. Appropriate target points were applied, in order to improve the identification of uniform points on the images and to enable metric scaling of the model." [7] Processing of the images "... was undertaken using orientation and image-matching operations performed automatically by specific photogrammetric software.

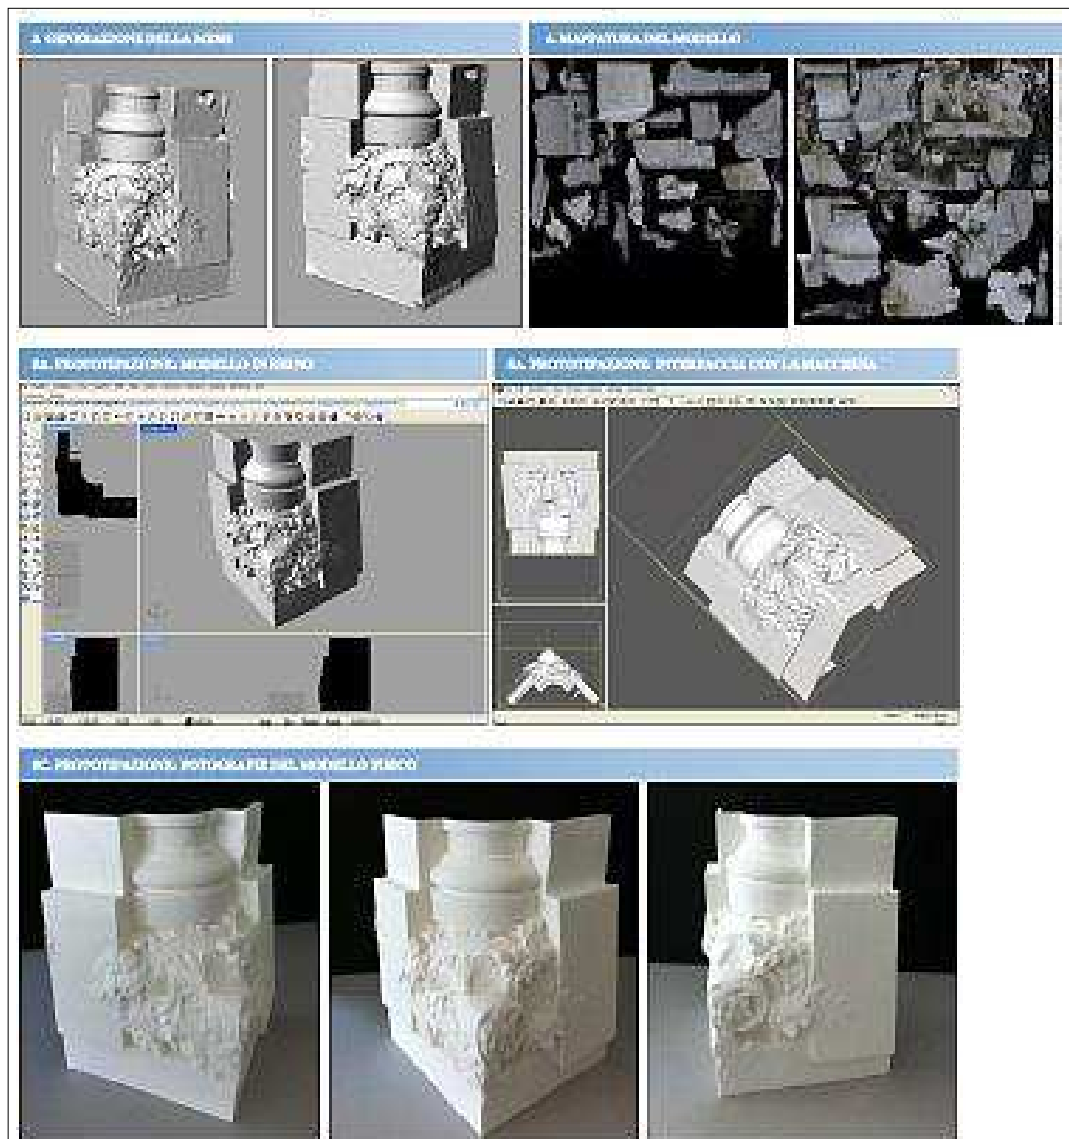

Fig. 8: The main phases of the 3D printing of the base of a column from the villa Faccononi Romeo designed by Giuseppe Sommaruga

A 300,000-point cloud was extracted and the results obtained generated a mesh (of about 600,000 triangles), which is manageable using three-dimensional modelling programs. In addition, in order to obtain the display of realistic photographs of the model, a texture was added to the processed mesh.” [8]

During the digital modelling phase, the meshes prepared were acquired by the free-form modelling software, which generated the surface of the column base chosen for 3D printing [9]. This was subsequently changed and then transformed into a solid model. For this purpose, an appropriate thickness was assigned to the 3D print out of the model. The print interface conditions required by the rapid prototyping machine were also considered.

In the final 3D printing phase, the model was sent to the rapid prototyping machine [10] for the creation of the physical model, which was created in just a few hours and was extracted ready to use.

7. Conclusions

The survey of the villa Faccanoni Romeo was undertaken, in order to verify the rendering of a digital model of an historical building. The choice of Liberty architecture turned out to be a very useful test field, because of the variety of the materials used and, above all, because of the morphological complexity of the decorations. Attention was given to the nodal points in the graphic processing and to the interoperability of the software, which was necessary to use for the representation of all of the features of that specific building. It was found that BIM environment modelling offers, even for existing structures, the possibility to create or update databases over the time: certainly useful for future scheduled maintenance procedures.

Nevertheless, at the time of the development of the work, the integration of the files generated in other environments created problems linked for the most part to the transfer of the data from the decorations surveyed instrumentally into the BIM environment, mainly due to the complexity of the methods and the equipment to be used.

The hoped solution of being able to use simpler procedures and equipment has been pursued over the last two years, achieving the objective through encouraging innovations, which can be further developed. In this, the rapid prototyping of the building or parts of it (as in the case of the base of the column) may substantially contribute to the precision and the simplification of the files, because of the simplicity of the language required by 3D printing machines, still and regardless of the manufacturing flexibility achieved by mechanical production [11].

Armenian experiences in consolidation of ancient buildings: the study cases of Anberd, Tatev, Arudj and Ani

Lorenzo JURINA,¹ Edoardo O. RADAELLI

⁽¹⁾ A.B.C. Department, Politecnico of Milan, Milan, Italy
lorenzo.jurina@polimi.it

Abstract

The ancient Armenian culture offers a wide number of historical buildings, that show interesting technologies and materials adopted during the construction phases.

In the least decades, some of these ancient heritages have suffered an evident structural deterioration, especially due to seismic events. In some cases, the structure has even reached local or global collapse.

Herein, four study cases are shown, analyzing some consolidation interventions proposed by the author.

The first case deals with the ruins of Anberd Castle. The ancient stone walls were subjected to a strong degradation phenomenon of washout, especially for the joints of mortar. Furthermore, some local overturns of the walls occurred due to out of plumbs and lack of material in the foundations. To prevent collapse mechanisms of the structure, among the consolidation interventions, the use of steel cable stays has been proposed.

The second case deals with Tatev Monastery. In 2002, the new use of the buildings, as well as the seismic vulnerability of the area, forced to reconsider the structural qualities of the buildings in order to assess the needed strengthening works. Some geotechnical interventions and consolidating solutions for the masonry structures have been proposed.

The third case has to do with Arudj church. Local kinematics have been detected during the survey, so that a global intervention of chaining to restore an overall "box-like behavior" has been proposed. Furthermore, the re-construction of the collapsed lantern and dome by a new steel and glass structure has been suggested.

The fourth and last case concerns the ruins of Ani, where several innovative applications of the RAM "Reinforced Arch Method" have been proposed.

Keywords: Seismic vulnerability, collapse mechanism, consolidation intervention, confinement

1. Introduction

In the last decade a *re-discovering* of the construction techniques and materials belonging to ancient buildings and heritage has grown up.

Professionals and researchers have made a strong effort to understand resisting mechanisms in masonry buildings, trying to evaluate the safety factor in presence of vertical and horizontal seismic loads. As a consequence, innovative techniques and materials have been introduced to prevent local and global collapse mechanism, increasing the safety of the overall structure.

The same interest in the historical matter has occurred in Armenia, where ancient buildings have been studied, trying to give them a new life, or simply to maintain and preserve them as they are.

Before analyzing the four study cases proposed in the present paper, it's worth to mention some relevant principles concerning the meaning of "restoration"..

Various "restoration charters" offer a useful, but not exhaustive though. In fact, the principles they set out demand reasoned adoptions. Anyway, there is one aspect that may be considered common to all restoration projects: in-depth analysis of the constituent materials and the structural condition of the monument under discussion.

The crucial value of reference in a consolidation intervention consists in safeguarding the ancient memory as the best foundation for the future, providing the necessary resistance to the structure. It follows that the conservation of heritages must be planned and executed on the basis of an accurate analysis of the buildings, using materials and techniques that are mainly compatible with the existing ones and adopting the well known criterion of “minimum intervention”. Each intervention must be specific and well calibrated, remembering that each monument is irreplaceable, unique and witness of the historic memory.

2. The Armenian Architecture

The Architectural Heritage of Armenia is characterized by an astonishing homogeneity of styles, especially of materials and construction techniques. This homogeneity is mainly due to the fact that Armenians, victims of frequent invasions and wars, not being able to recognize in a politically stable Nation, identify their cultural foundations in Church and traditions, even in the artistic ones.

This strong identity is recognized in the "signs" of their culture: the spoken and written language, religion and artistic expressions. Armenians were the protagonists and creators of a wonderful season of art and architecture, which lasted through many centuries.

In the field of religious architecture, results were achieved at the highest level since the first realizations, that date back to the conversion of Armenia to Christianity in 301.

The previous architectural knowledge and the geographical position of Armenia have allowed a development of original and precocious synthesis, asserting (between the IV and VII cent.) almost all the construction schemes that have characterized Armenian ecclesiastical architecture until modern times, often anticipating the solutions adopted few centuries later in Europe.

Fig. 1: The monastery of Haghpats and the church of Marmashen in Armenia

Ancient fortifications represent another architectural manifestation of the Armenian culture. The greatest period of development of military architecture in Armenia is placed between the VII and IX century a.C., when more than four hundred fortifications were built. Today, although only a part of that huge patrimony is preserved, it has been possible to conduct researches on the building techniques of this singular type of structures.

In particular, walls were made with the traditional technique called “midis”; it consisted in a double layer of stone, filled with a mortar of lime and aggregates of various sizes, often connected by horizontal wooden beams. The corners were usually refined with high accuracy: in some cases the curtain walls were adorned with the use of stones of various colors, with geometric decorations.

The interior of the towers and gates were usually barrel-vaulted or had a stone dome set on a square plan, recalling some geometrical aspects of the Armenian churches.

The large diffusion in all the Armenian areas of churches, monasteries, bridges, aqueducts and caravanserais was strictly related to trades. Dvin, Ani and many other famous cities of ancient Armenia were, in the fifth century, a great economic, political, cultural and spiritual power in international trade, retaining their status for many centuries. Greeks, Assyrians, Persians, Jews, Georgians and many other peoples from the far East traded with the Armenians, contributing to the most flourishing artistic and architectural period.

Fig. 2: The ancient “Silk Road” that linked East and West passing through Armenia

3. Study cases

3.1 Consolidation interventions of ruins: some proposals for Anberd Castle

Anberd Castle represents an important example of ruined structure, especially interesting from an architectural and structural point of view.

Many events, both natural and anthropogenic, have brought the Castle to be as it appears today, so that any attempt to "erase" the signs of aging and to restore part of the former would be conflicting with the principles of a conservative restoration. For this reason, the structural intervention has opted for a specific series of operations to be performed only where strictly necessary, respecting the authenticity of the monument and its peculiarities both aesthetic and structural.

The main problems regarding the ruins of the Castle were associated to the washout of the mortar in masonry and to the lack of mortar joints. Such problems were localized in few areas and clearly identified.

In particular, two were the portions of intervention: the south-east façade and one internal wall.

Regarding the south-east façade, the stone wall was a high diaphragm, not sufficiently thick and poorly connected with the rest of masonry structures. The slenderness was not sufficient to prevent the rotation of the façade, especially of the upper portion of the wall.

Something similar happened to the portion of the inner wall, where a remarkable out of plumb was recorded. Luckily, in this case, the collapse was prevented thanks to the presence of deposit, at the foot of the wall, that acted as "struts".

Fig. 3: The complex of Anberd castle

Looking at the structural problems, one of the first task consisted the integration and injection with mortar of the existing masonry. These interventions has been proposed only at those points where the static consolidation was absolutely necessary, so that the perception of 'ruin' couldn't be compromised.

Furthermore, from a static point of view, each wall has been schematically represented as a cantilever, clamped to the ground. On the element, subjected to its own weight and horizontal loads such as earthquake and wind, axial force, shear and bending moment acted. Being the masonry a material not resistant to traction, a dangerous partialization of the resistant section has occurred due to bending.

A consolidation intervention, adopting post-tensioned bars, placed internally to the wall, has been proposed. The aim was to increase the axial load, acting on the masonry, so that the majority of the section could work in compression, limiting the tensile stresses as much as possible. In this way, the masonry could resist to higher horizontal loads.

Fig. 4: The consolidation intervention proposed for Anberd castle by adopting steel post-tensioned bars

A numerical FE analysis has been recently conducted by the author to a similar case in Italy, related to the Forte of Fuentes in Colico. In this case, the effects of post-tensioned external cables have been evaluated, confirming the beneficial effects of the system.

In the following the main results of the FE Analysis of Forte Fuentes are reported.

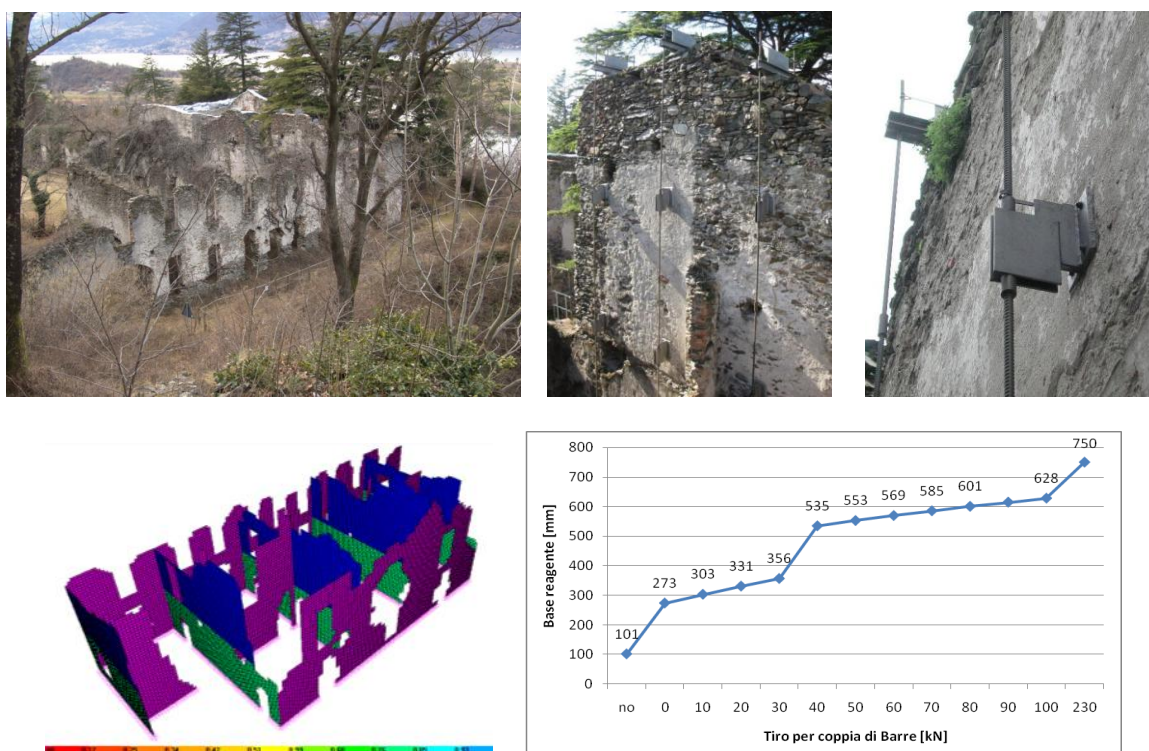

Fig. 5: The complex of Forte Fuentes in Colico (Italy). A consolidation system of steel post-tensioned bar (called EHT – Edera Hi-Tech) has been adopted. Results obtained by the FE Model show the increase of the reacting compressed section and the consequent reduction of tensile stresses, adding more tension applied in the bars.

3.2 A new life for Tatev Monastic Complex

From its construction to the disastrous earthquake that in 1931 destroyed most of the buildings, Tatev monastery has been a very important center, and for twelve centuries its cultural skills have been widely appreciated.

Fig. 6: Plant of the complex of Tatev, the monastery after the earthquake occurred in 1931, and the monastery during the restoration works in 2002

In 2002 His Holiness Karekin II, Catholicos of All Armenians, decided to bring the complex back to its importance. The project foresaw the reuse of the existing buildings in order to lodge 50 students, the classrooms, the library and all the functions and sets that a modern institution of higher education required.

In addition, the monastery would be also able to welcome pilgrims and tourists.

The new use of the structures, the increasing tourism and the seismic vulnerability of the area forced to reconsider the structural qualities of the buildings in order to assess the needed strengthening works.

Several surveys conducted in site highlighted the areas of intervention, mainly focused on the foundations of the monument resting on cracked rock, on the damaged buildings that hosted the library and on the principal church.

From a geological point of view, the area was quite interesting, since the southern monastery buildings rested directly on a basaltic crown, that showed the tendency to slide down. The rock mass, in fact, was characterized by discontinuities that caused the relative movement of the stone blades, especially in case of earthquake. At the same time, some other buildings rested on soft soil.

Another relevant fact influenced the structural performance of the buildings; in particular, edifices were built in different periods and the complex developed by subsequent additions. Thus, the connection between the bearing walls was not always well realized, and the reestablishment of the missed links was necessary, in order to assure the three dimensional monolithic behavior and to limit the seismic damages.

Two types of structural interventions has been proposed: the first one concerned the ground level, while the second one interested the upper parts of the buildings, especially arches and vaults.

As regards the intervention on the ground, grouted rock bolts has been foreseen to stabilize and strengthen the rock mass. To locate the bolts, some boreholes has to be drilled in the rock, and steel anchor bars provided to connect two or more rock blades in order to prevent them from any slippage.

Fig. 7: The reinforcing scheme of the connection bars in the ground and a detail of the fractures rock

In the upper part, the structural consolidation of ancient arches and vaults represented a difficult task. The solution named RAM “Reinforced Arch Method” has been suggested to consolidate and strengthen the Tatev monastery’s vaults.

The main purpose of the “RAM” is to modify the distribution of loads acting on the arch so that the combination of the old loads plus the new loads can be the “right one” for the given and known geometry of the arch.

Steel post-tensioned cables can be applied either on the extrados or on the intrados (working as an “active” system), and a radial distribution of forces is immediately applied to the arch. This new load distribution induces an axial compression between the blocks and, as a consequence, the thrust line is re-centered. As shown by more than 500 experiments and calculations, the proposed technique achieves results that are equivalent, in many cases even better, than the ones obtained with the more traditional (but much more invading) method that consists in a “passive” concrete layer, poured over the arch, at the extrados. Using the RAM method, the additional reinforcing elements (i.e. the cables) do not interfere with the in situ masonry material and respect the original structural behavior of the vault.

Another interesting reinforcing intervention has been planned on the church. Although this building had been restored few years before, structural problems persisted. The simplest thing to do was to provide a sort of bandage in the upper part of the walls in order to recreate a three dimensional monolithic behavior, by means of tie rods.

A last consolidation proposal has to be mentioned: the two masonry towers were completely filled by detritus that had to be removed. To consolidate the structure, an interior bandage made by 10 thread bars, located in the tower masonry and fixed using a special anchoring mixture of hydraulic binders and fines has been designed. At the end of each bar, an “eye” trough which a stainless steel rope passes was fixed. The link between the two ends of the rope was obtained by using a turnbuckle so the structure can be tensioned.

Fig. 8: The confining system for the consolidation of the two masonry towers

3.3 Arudj temple

Arudj temple is the biggest among medieval domed churches in Armenia. During centuries it had stood numerous earthquakes and invasions, which seriously affected it. An earthquake in 1139 ruined the huge dome of the temple, and caused the opening of significant cracks on the façade. Although the temple has been repaired more than once, starting from the first rehabilitation initiated in 1973, a new consolidation intervention has been recently proposed. The aim was to prevent local or global mechanisms of the walls, in case of seismic events.

Fig. 9: Arudj temple: the huge dome collapsed due to an earthquake

An accurate diagnosis has been carried-out, applying both in-situ tests (sonic tests, thermography, crack opening monitoring) and laboratory tests, in order to analyze the chemical and mechanical properties of constituent materials. The diagnosis has been developed by Politecnico di Milano, inside the II° Level Master for Architects and Archaeologists called “Progettazione al restauro, formazione al restauro in Armenia, sostegno alle istituzioni locali per la tutela e la conservazione del patrimonio culturale”, based on the agreement between the Italian Ministry for the Foreign Affairs and the Armenian Ministry of Culture.

The analysis of the crack pattern and of the mechanisms of collapse is an essential prerequisite for a careful assessment and effective interventions.

The safety evaluation, with respect to static and seismic actions, required a conscious reading of both the damage that the church has historically manifested, and details of the response to vertical and horizontal loads.

Fig. 10: The thermography applied to the walls has provided significant information about the masonry

The behavior (especially seismic) of churches with a longitudinal development plan, like Arudj, has been interpreted through the decomposition into portions, called macro-elements, characterized by a structural response that is substantially independent from the church, considered as a whole. Among the main macro elements, the facade, the apse, the dome, the arches and the vaults have been identified.

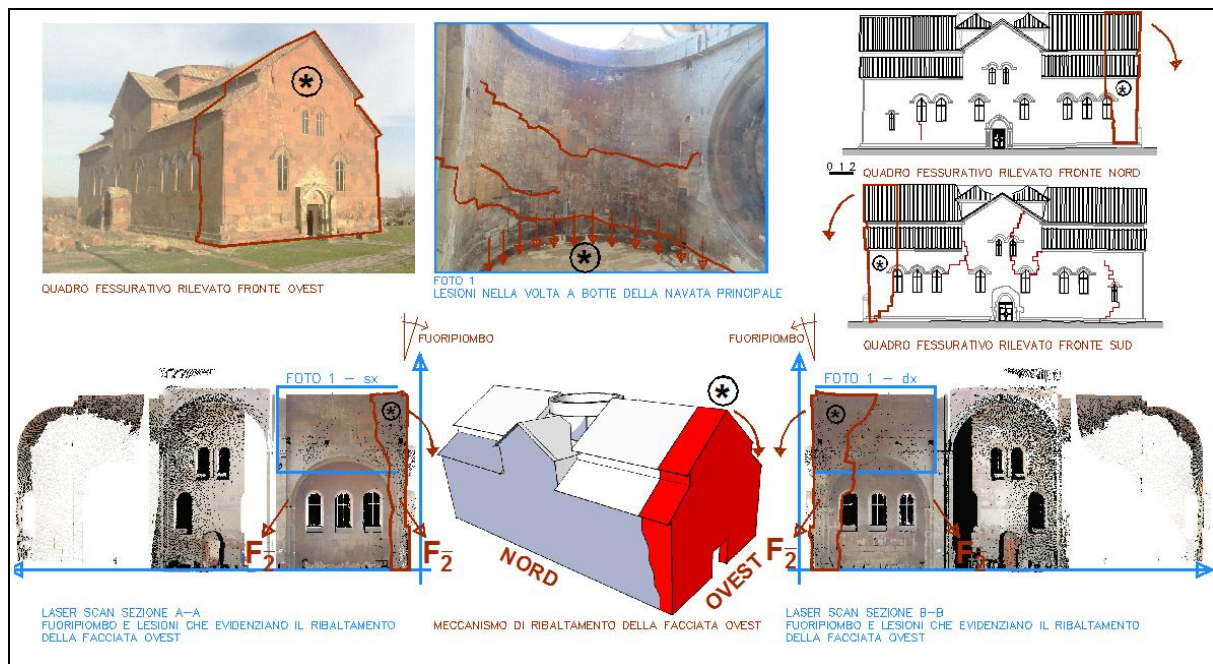

Fig. 11: Among the possible kinematic, the overturning of the façade has been detected

Based on the information obtained, several consolidation intervention were proposed.

The first solution aimed to prevent local collapse mechanisms with ejection of the stone blocks, returning a monolithic behavior of masonry.

The mutual connection of the large blocks of tufo was obtained by thin bars arranged in a "pyramid" shape and grouted inside the walls, alternately in both internal and external layer.

Compared to traditional systems, "pyramids" are three-dimensional systems that limit the visual impact, because placed in the joints of mortar.

Another type of intervention has involved the insertion of chains of containment, formed by steel bars able to connect the masonry walls in the longitudinal and transverse direction at different levels.

The main objective of the project was to ensure a "box-like behavior" of the entire building, in respect of seismic actions, increasing the resistance to horizontal loads, but at the same time maintaining a certain ductility of the structure.

To obtain such results, three different tie-orders has been proposed:

- The first order, the main and indispensable, allowed the structure to increase its overall resistance to horizontal loads, achieving a good level of seismic improvement;
- The second order led to a further improvement of the seismic structure, preventing possible failure mechanisms of local portions of masonry;
- The third order led to the achievement of a seismic retrofit of the structure, so that the structure was able to fully satisfy the maximum stresses provided by the project, in accordance with the current regulations.

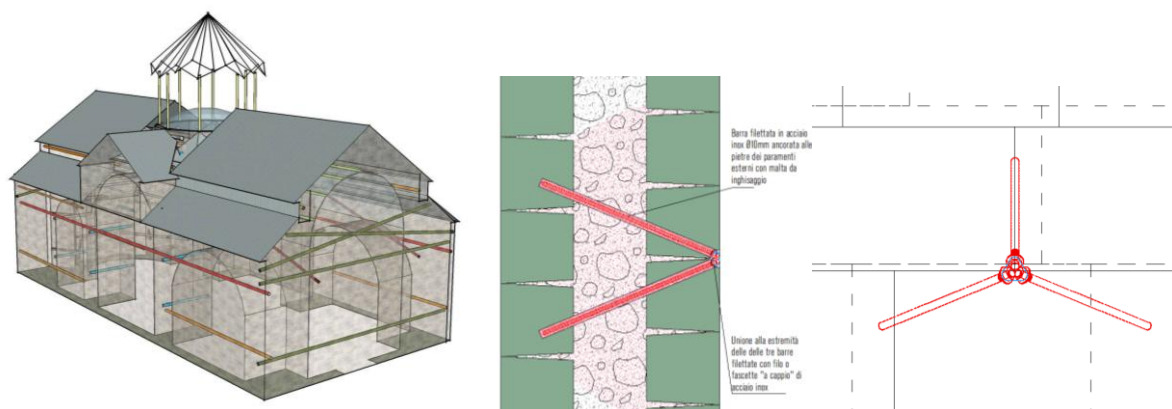

Fig. 12: The insertion of new chains and steel connections (pyramids) guarantees the box-like behavior

Furthermore, an interesting proposal has been advanced for the collapsed dome and lantern. A new octagonal lantern in steel has been proposed, providing only the "skeleton" steel perimeter, without closures or coverage. The purpose of this solution was to perceive, in a discreet manner, the presence of a structure common to other churches of Armenia, now missing. Concerning the dome, a new steel and glass covered has been proposed to close the actual hole, but at the same time without erasing any evidence of the past history of the church.

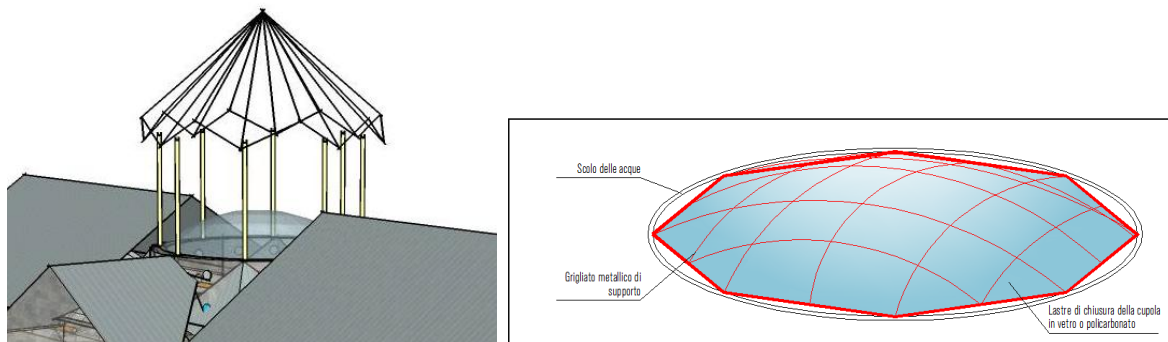

Fig. 13: A “light solution” for the reconstruction of the lantern and dome of Arudj temple

3.4 The “Reinforced Arch Method”: an alternative solution for Ani

The ancient church of S. Amenaprgitch in Ani (Turkey), represents another interesting case of “ruined” structure. The only part that is still conserved corresponds to the apse. The remaining portion of the building collapsed for a strong earthquake years before.

In order to guarantee the necessary strength to the dome and the walls, an alternative solution of the “RAM” was proposed.

The general principle of the Reinforced Arch Method fulfilled even in this case, where two different possible configuration of cables has been proposed.

In the first configuration, several steel post-tensioned cables were positioned in the horizontal direction, along the parallel. In the second case, steel cables were placed vertically, connecting the top of the dome to the ground.

In the following some sketches of the two solution are reported.

Fig. 14: The “RAM” applied to Ani apse and some small scale models of the intrados and extrados cables

A numerical FE analysis has been recently conducted by the author to evaluate the seismic response of a masonry dome of Santa Caterina Church in Lucca (Italy), where the RAM method has been applied.

Three different models have been developed: in the first one cables are placed along the parallels, in the second one cables are placed along the meridians, while the third one is the combination of the previous two models. The dome is subjected to horizontal seismic forces.

Numerical results obtained in the consolidated situations, if compared with the non – consolidated one, provide a significant reduction in terms of tensioned areas and displacements.

For example, the maximum tensile area at the extrados of the dome in the non-consolidated situation corresponds to 75% of the total area. Thanks to the RAM, the tensile area is reduced to 55%, 42% and 33% in the three different configurations analyzed.

The table below summarizes the main values obtained with FEM calculations

	Maximum tensile stress	Tensile Area INTRADOX	Tensile Area EXTRADOS
Non consolidate	 0,18 MPa	 66%	 75%
Cables along parallels	 0,10 MPa	 42%	 55%
Cables along meridians	 0,06 MPa	 38%	 42%
Cables along meridians and parallels	 0,05 MPa	 34%	 33%

Fig. 15: Results obtained by a numerical analysis on the dome of Santa Caterina Church in Lucca (Italy)

4. Conclusions

The city of Ani, as many other Armenian cities, were partially destroyed after II° World War, causing a huge loss of ancient heritages. Among them, the ancient bridge upon the Akhurian River, that separates Armenia and Turkey.

The author has the hope of re-building the ancient bridge, by creating an essential and light new steel structure, to re-connect Armenia and Turkey.

Dynamic identities for the Cultural Heritage

Francesco E. Guida

Department of Design, School of Design, Politecnico di Milano, Milan, Italy
francesco.guida@polimi.it

Abstract

Today the rigid hierarchy of visual identity, which has been consolidated over time, has been placed into question. Various factors have contributed to this remix: the technological factor above all, but also others associated with the critique, aesthetics and ethics of communicating.

The world of cultural heritage has certainly not remained immune to all of this, and may even be considered fertile testing ground. In this regard, Nick Bell [1] questions the efficiency of an identity based on its branding which maintains that cultural heritage graphics must be determined by their content, and therefore suggests that we should accept the differences and incoherence that this approach may generate.

Sergio Escobar [2], attributes a fundamental role to communication in the process of legitimising and enhancing the value of cultural heritage places, however in order for this to occur it is necessary to resolve the problem associated with the impoverished language of communication. On one hand, that means that new forms of relations and communication are therefore necessary as well as new ways of establishing relationships with their public, on the other hand there are new ways of thinking and new approaches to design which similarly lean towards innovation.

This paper, starting from the observation of a series of case histories, wants to reveal those new approaches and directions in the field of visual and communication design, which we can name as post-logo, in the own area of cultural heritage.

Keywords: Visual Identity, Communication Design, Corporate Identity

(1) Identity as a multitude

The distinctive and peculiar trait of new forms of visual identity applied in particular within the context of cultural heritage places and assets, is that these seek to interpret a system of values and contents in a variable, dynamic, manifold manner, in order to communicate with a diverse range of publics, assuming different tones of communication.

The traditional logic of visual identity can be referred to the philosophical definition of identity, attributable to Aristotle, according to which this represents a unit of one or more things, provided the definition of their substance is identical, therefore making the logo the distinctive element; if this is true, this new form can therefore be referred to the definition by Waismann, which states that when speaking of identity, the important thing is to "declare the criteria adopted or to which reference is made" [3 p. 445], and therefore a base code or a method of managing a process. However, at the base of an identity there is always, in any case, one unit, a common factor amongst different elements belonging to the same group, to the same context.

The identity of a subject, its own unit, is reinforced by the differences in its attributes and methods of expression: a multitude of visual elements, their expressions, and therefore a richer visual language, is more likely to better express the diversity of contents and values which cultural heritage places now need to transmit. Although expected to be firm and confident, the overall institutional voice must be ready to modulate in pitch and volume, that means having at disposal a wide range of choices in terms of communication [4 p. 6].

2. Identity, image and communication design

Within the realm of the discipline of visual communication design, the term identity refers to the notion of image, or rather the representation of an organisation, or better still, a subject (defined as a personality), based on a certain code. According to Henrion & Parkin [5] and Anceschi [6] The system of reference is that of corporate identity, therefore the representation of a subject through a series of primary and subsidiary elements, whose normative expression is found in the corporate manual.

For cultural assets, in reality this means effecting a transfer, at least historically, from one world, predominantly consisting in goods, to another. About that Klanten, Sinofzik & Schulze wrote [4 p. 6]: “cultural institutions and organizations rarely focus on selling goods. Above all, they produce ephemeral constellations, intersubjective structures of experience and information (cultural approaches and exhibitions, directorships, ensembles and programs, heritage, site). Institutional identity, or cultural branding, in a more generous sense of the term, evolves from these structures”.

The identity of a cultural place, or a cultural asset, is no doubt constituted by the extent to which that asset represents something in a given context, as well as by its intrinsic and recognised value, and that which is attributed to it; or, reasoning from the point of view of communication, by that which the observer, (therefore the user or beneficiary), gains in terms of experience, memory, emotion, or in other words, in terms of image. But image is constituted by a variable number of elements: by a network of communicative artefacts, all coordinated with each other in the best of cases, and by numerous tangible and intangible elements. Image is also the user's impression and their experience with the efficiency of the channels or instruments which are the carriers of knowledge. In this sense, we once again find ourselves in the disciplinary context of visual communication design, which deals in particular with designing those artefacts and relative interfaces (traditional more so than digital), which will allow the suitable fruition of the asset itself. It is clear that when reasoning in terms of the asset's fruition, we are reasoning in terms of its identity.

Translating visually this identity is the role of visual communication design. That means – according to Baur [7] – constructing a unitary system (that of the visual identity, therefore reasoning in terms of language), which, through the linkage of the contents and their container, generates a cohesive image of the asset. Contents imply both recognised values, attributed in terms of relation and exchange [8 p. 42], and those intended by the strict sense of the word: objects, findings, signs – according to the definition provided by Eco [9 p. 22] –. These must be capable of transmitting the emotion and knowledge sought by the user, just like all those superstructures of an informative nature (and here the term is used in its most noble form as a carrier of knowledge, and not as a trivialisation or exemplification) and interpretive nature, without which the asset would not be understood.

It is therefore possible to identify various specific categories within the broad realm of communication in cultural place contexts. These include communication with the public (editorial products, services or events), object-user communication, communication as a form of orientation, educational communication and that transmitted via the new media. This system of elements, which can be defined as points of contact, is nothing more than a coordinated communication system where these points in fact contribute to defining the asset's identity, and subsequently from the point of view of the user, its image. It is not the asset itself, but rather the superstructure, the second skin, which allows, or in any case facilitates, knowledge and fruition.

The system must be consistent with the asset, or rather must reflect the true values carried by the asset, but also the expectations set by those responsible for its protection and management. Such expectations should be the same as those of the public which enters into relation with the asset (or perhaps it would be better to say the types of publics, from expert to generic types). That confirm the need of a dynamic form of communication, able to change tone and voice referring and appealing to different types of target [10 p. 222].

3. From static-logo to post-logo

In the corporate identity system the central element is traditionally the logo. At the beginning of the 1990s, this may have been the case for the identity of the renewed Louvre, for which the label-logo, superbly conceived by Pierre Bernard, is still invariably used today with a few dimensional modifications, in its various applications.

It is necessary to say that through time – since the 1960s, when the corporate design culture established – designers have affirmed the difficulty of manifesting an institutional identity for a cultural place through a singular logotype or graphic system. This was the case of Chermayeff & Geismar who were charged to design the Museum of Modern Art of New York logo. They had to admit that for such kind of institution was in no position to establish a symbol that was meaningful or not [4 p. 5].

Nowadays the traditional rigid hierarchy of visual identity – that we can name as static-logo attitude –, which has been consolidated over time, has been placed into question. Various factors have contributed to this remix: the technological factor above all, but also others associated with the critique, aesthetics and ethics of communicating.

The world of cultural places and heritage assets has certainly not remained immune to all of this, and may even be considered fertile testing ground [10 p. 218]. In this regard, Nick Bell [1 p. 16] questions the efficiency of an identity based on its branding, observing in particular the panorama of identities of various art galleries and museums in London. He in fact maintains that cultural places graphics must be determined by their content, and therefore suggests that the differences and incoherence that this approach may generate should be accepted. A tempting idea which presumes a higher level of public intelligence than that needed for the application of more homogenous systems. Clearly, as Bell himself admits, this idea about the post-logo does not belong exclusively to the cultural heritage sphere but is rather undoubtedly congenial.

Felsing [10 pp. 217-218] declares that one of the main reasons that dynamic or flexible visual identities appear predominantly in the cultural or public sectors undoubtedly lies in the transfer of basic content to the form of visual identity. And it is possible to add that the adoption of flexible visual languages is considered consistent to the contents and the activities of some kinds of organizations particularly devoted to contemporary arts, although not uniquely.

In an interview with Sergio Escobar [2 pp. 417-425], he attributes a fundamental role to communication in the process of legitimising and enhancing the value of cultural heritage places, however in order for this to occur it is necessary to resolve the problem associated with the impoverished language of communication. Escobar strongly highlights the different interpretations of the definition of public interest, previously attributed to cultural heritage places in an entirely spontaneous manner. During the last fifty years the meaning and sense of such kind of institutions and organizations has changed, and new forms of relations and communication are therefore necessary [4 p. 5].

Whilst on one hand institutions, in particular cultural heritage ones, need to find a new way of establishing relationships with their public, on the other hand there are new ways of thinking and new approaches to design which similarly lean towards innovation. About that Shaughnessy [11] affirmed “a brand is no longer simply a nice, clean logo that is attached in the same place every time. A brand is a platform, a brand is flexible, a brand is a place for exchange, it is not fixed, and therefore there is no such thing as a single brand. Methods exist which allow a shape to form, which allow communication and recognisable behaviour, but this is no longer about something inflexible and permanent”. In some spheres of visual communication design, the idea of imposing strict rules has been renounced in favour of more fluid and expressive languages, characterised by “variability, reference to context, process, performance, non-linearity, coherence and variety” [10 p. 13] that we can name with the term post-logo.

New technologies offer wider ranging possibilities for the design's control, structure and development with respect to the past. These offer the designer the possibility to programme not only the second and third dimensions, but also the fourth, the dimension of time, which modifies the manifestation of an image, no longer in a simply controlled, but rather programmed manner. All this according to paradigms which are not necessarily new, but rather extremely current (cases of flexible visual identity can already be found in the second half of the 1960s [12 pp. 96-109]), which are more likened to diverging methods “focusing on the production of a multitude, of variety” and more removed from a converging, operational and pragmatic way of thinking. More likened to the Behrens house-style soft approach, where the designer often becomes jointly responsible, or at least the manager's right arm, and more removed from the manual, intended as a technical and bureaucratic tool [13 p. 174].

4. Looking to the practice

Observing the panorama of international production, it is possible to identify two groups of cases where logo or visual system designs better interpret the idea of the multi-dimensional nature of cultural places and cultural heritage branding.

One group in which the logo, or rather the central element of the visual system, changes over time and in the various situations in which it is applied, according to established parameters of control (shape, colour, font...) and in any case according to a logic of controlled variations, with predefined limits of expansion, as may be the case for the British Tate Galleries, the Brooklyn Museum, the New Museum and the Museum of Arts and Design (MAD) in New York or the Historiska Museet of Stockholm.

The other group in which the design is aimed not only at defining a group of variations, but essentially at managing the process which manages such variations, and therefore the formalisation of a visual code, which when used becomes a genuine language, as may be the case for the Casa da Musica in Oporto, the Walker Art Center in Minneapolis or the new brand for the city of Bologna. Those cases

use a specific and personalized software to manage and generate the visual code. Can be part to this second group the visual identity for the Musée d'archéologie et d'histoire de Le Mans in France too.

4.1 Logo variations

In the first group we therefore encounter those cases where modifications are made to a basic sign, the intention of which is to communicate the new idea of a museum or cultural heritage place, transmitting the sense of the diversity of contents, initiatives, and tones, aimed towards specific targets of publics. In this regard, the director of the Brooklyn Museum, Arnold L. Lehman, in the press release issued during the presentation of the new visual identity programme, declared to be convinced that a flexible graphic identity and logo “best reflect the objectives of the Museum focused on the visitor” and “emblematically represent the diversity of our collections and our public” in a new way.

The new logo is composed of a fixed capital ‘B’, behind which eight different seals or sketches in a brilliant blue colour (defined as electric cyan) continuously change. These eight seals are randomly used in order to emphasise the uniqueness of the Museum. The visual identity designed by studio 2x4 is used in all print material and is adapted to all promotional and web applications. Michael Rock, the creative director of the design, presented the logo in this way: “the new logo has been designed to reflect flexibility, change, surprise and accessibility.

The dynamic seal has been designed to represent a museum willing to scrape off the mould from a familiar and existing concept, in a process of continuous experimentation, open-mindedness, and most importantly of all, reinvention”. The continuous mutation of the seal depicts various forms each time: a stamp, a flower, something strong, a bubble, a spurt of water, leaving the possibility open to broaden the repertoire.

This is therefore a design based on a strong, shared objective, between the client and the designer, aimed towards renewal. Though not spectacular renewal, also because here we are dealing with an institution strongly tied to a specific context, rather than a process of reeling in a target public. In fact, the Brooklyn Museum is not a traditional tourist attraction, but is rather family-oriented and facilitates processes whereby visitors can easily form their own interpretation of all the history and art on display through a series of different, yet simple paradigms. A combination of intellectual authority and an alternative approach, insofar as it is intelligent and people can relate to it. When defining the image of the institution, Rock speaks of solidity destabilised, in the sense of a non-monolithic institution, open to change and comparison, therefore continuously placing itself into question.

Fig. 1: Brooklyn Museum (New York), logo variations, design by 2x4, 2004.

This approach influenced during the last years a certain number of designs alike the one for the swedish Historiska Museet, one of Sweden's largest museums with collections that include more than 10 million individual objects from a history spanning thousands of years. The museum is also a venue for lectures, concerts and activities for all ages. The new visual identity is based on a new

communication strategy that aim to make the museum Sweden's number one storyteller, arousing curiosity and interest in Swedish history and revitalise the museum. The Stockholm based design studio Bold created a dynamic and playful identity inspired by the museum's mission: to create curiosity and interest in history and to get the visitor to reflect on the link between past and present. The logo is a combination of a classic serif font (the past) and a modern sans-serif font (the present). The interesting aspect is that the serif part can be replaced with historical artifacts giving the museum an opportunity to be playful in their visual expressions and display the museum's breadth of exhibitions and activities. The result is a basic so far as an open system that allows for endless communication possibilities [14].

Fig. 2: Historiska Museet (Stockholm), logo variations, design by Bold, 2012.

4.2 Multitude based and flexible visual codes

The visual identity of the Casa da Musica conceived by Stefan Sagmeister allows us to introduce the second group. This design is in fact based on a software (Logo Generator) which allows the management of the logo, clearly inspired by the shape of the building designed by Rem Koolhaas, from different perspectives (six in total). The logo is transformed in its various applications, changing from media to media, and similarly its colours can change. As this is an institution whose objective is to host different initiatives tied to the world of music (from jazz to classical music and more contemporary expressions) which are each aimed at different types of audiences, its visual identity cannot be static. The system in fact allows a palette of personalised colours to be selected from thematic images, for each specific event or initiative. Various institutional applications are similarly managed: for internal staff for example, business cards are personalised with a logo whose colours are taken from a photograph of the individual person. The system therefore offers a variety of solutions for both those responsible for managing identity on a daily basis, and those who benefit from it.

A similar approach we can find in the visual identity design for Walker Art Center, a true container of initiatives and events open to a range of different publics, a generation utility of visual identity was designed. This is represented by a type of font or typographical character which makes it possible to compose a string of keywords relative to the Center's activities and its contents, accompanied by decorative graphical elements, making it recognisable. These "words" define the matrix of intonation with which the institution communicates with its public, tones selected on a case by case basis as the most appropriate for dialogue on one level as opposed to another, or for channelling one type of initiative as opposed to another.

The same concept of variations has been developed for the city brand Bologna. It is possible to include this case as visual identity for cultural place looking to it in a wider perspective considering a city like a complex systems of values, concepts, heritage, activities that through their interconnection are perceived like a unique cultural image. The context of visual identities for places or territories and the one of culture assets are both experimenting and experiencing flexible and dynamic visual languages. For Bologna the Italian designers Matteo Bartoli and Michele Pastore designed a software that generates the basic code inspired to signs and attractive elements taken from the city's material culture. This code allows to construct a visual narration that has the aim of narrating the multiple aspects of Bologna's personality.

Those are therefore examples of cases where the visual code is centred around a dynamic logo, whose variations are managed according to a markedly meta-design approach. The design of the

process is given priority in order to guarantee control of the overall identity and those “control knobs” which generate variety and guarantee the identity’s constants [15 p. 12]. Finally, in the case of the Musée d'archéologie et d'histoire de Le Mans, the visual language explores and shows the variety of the collection to present the Museum in a new and fresh manner developed on the idea of multitude. Contents inspired the signs, that allow to identify the different sections, the evidences, the different objects. At the same time this family of signs defines a unique visual language together with typography and colors. The visual code is the applied all over the information plan, from orientation signage to punctual identification, defining a continuous disposal that facilitate access to knowledge.

Fig. 4: Bologna City Branding, visual code, design by Matteo Bartoli and Michele Pastore, 2013.

Fig. 5: Musée Archéologique e d'Histoire de Le Mans, visual code, design by Voiture 14, 2009.

5. Conclusions

What both groups have in common is this strong sense of arranging a style, and therefore pre-organising a language according to controlled morphologies. When applied to communication or branding design, this approach in fact acquires information about the brand linked to its complexity and the fact that it has been generated through relations and interactions with the public (with interfaces intended as communicative artefacts or points of contact), and with the context. The invariable is nonetheless a common feature, even in stylistic variations, the idea of an open system which can be amplified, having clearly defined the constant elements which assume the role of ensuring the organisation, the personality, is always recognisable. When visions and concepts are formulated with genuinely and significant content of the cultural assets, places or organizations rather than attributes, general values, or clichés ideas, a differentiated visual identity emerges.

According to Felsing [10 pp. 220-225] what appear evident is that static visual identities have less potential to reference changing contexts because they run the risk of losing the coherency of the visual identity; the prevailing singular logo cannot refer to changing contexts but remains identical. With flexible visual identities, coherence is maintained as the constant aspects provide stability and only the variable aspects generate dynamics.

The Arab-Norman influence in the architecture of Campania in the 11th and 12th centuries

Lamia HADDA

Department of Architecture and Industrial Design "L. Vanvitelli" - Second University of Naples, Aversa (CE), Italy

E-mail: lamia.hadda@laposte.net

Abstract

In general, the theme of the architectural relationships between the two coasts of the Mediterranean has received little attention from historians. The research on the Arab-Norman tradition concerning the historical and architectural heritage in Campania between the 11th and 12th centuries tends to analyse monuments with common architectural and stylistic features. By using a suitable typological analysis of the decorative elements, the research aims to identify the artistic models between Campania and the Islamic Mediterranean. The identification of a common thread that binds the transformation of the diverse types of construction has defined, on this topic, a global overview of the state of the studies on the architecture in Campania, with the specific purpose of identifying the cultural elements of continuity and innovation.

Keywords: *tarsia*, interlaced arches, Norman architecture, Islamic architecture, Campania.

The decision to perform a detailed analysis of the Arab-Norman presence in Campania and its relationship to Islamic architecture came about from research performed by previous academics. In fact, there is a historiographic thread that started at the beginning of the 19th century that identified aghlabide art in Ifriqiya and Fatimid before and after ziride. That Islamic culture is still clearly visible in the architecture and decorative aspects of religious and cultural monuments in Southern Italy today^[1]. Moreover, recently, important strides have been made to bring to light, through appropriate scientific analysis and exploration *in situ*, the remains of the rich monumental heritage left as a legacy by the Arab civilization in Campania^[2].

In this study, which deals in particular with the origins of the Islamic influence in the architecture of Campania in the 11th and 12th centuries, there are many historical elements that the Arab, Berber and Andalusian populations across the Mediterranean have spread, thus giving life to an artistic syncretism of great beauty.

From the 7th century, a new Middle Ages developed along the coast of Italy. It was a Middle Ages that was culturally different from the western Christian and Byzantine one that, thanks to Rome and Greece, had imposed itself throughout the Mediterranean basin and the eastern reaches of the known world. Southern Italy, with its undefended coastline, was a place in which new peoples migrated. Unmistakable architectural traces of these migrations can be found in Sicily, Sardinia, Abruzzo, Southern Lazio, Campania, Puglia, Basilicata and Calabria. The merging and clashing of these diverse cultures generated integration as well as repulsion. Nonetheless, all over the territory, the fragments of this cultural reciprocity are to be found and it is only recently that they have been given due value. Therefore, in many parts of Southern Italy there exists a sentiment for a distant past that has never gone away. It can be seen in the alleyways of the feverish neighbourhoods in some cities, in the frenzy of the street markets, the colours, the faces, in the lexicon and, above all, in the artistic

and architectural knowledge of Medieval monuments found in southern Italy. Of the many points of contact still visible today, this research concentrates on the cultural material of the architecture - perhaps as it brings out the accents of North Africa and Andalusia - which are the objectives of this work.

Furthermore, this argument was considered relevant in that it characterises the similarities and dependencies, and the ties and inflections that sparked these two worlds, even if our knowledge of Arab monuments - those that still have to be compared with their counterparts in Campania - is not yet sufficiently informed. For this reason, this research assumes even greater importance as it sheds light on an evocative and fascinating period in the Medieval architecture of the Mediterranean in the 11th and 12th centuries.

The numerous monuments from the Norman period still present in Campania evoke a sober understanding of space expressed in the stereotomy of the decorative external hanging walls, occasionally interspersed with inlays of tuff and volcanic stone, according to diverse planes. The ornamental motifs, of Islamic origin, are characterised by a series of arches in doubled and tripled recesses, inlaid in decorative shapes and strings woven with two-toned blocks. These architectural styles attest to the skilled artistic craftsmanship espoused, in particular, by the craftsmen of the city of Salerno and the Amalfi Coast – a politically powerful and rich territory for trade that frequently took place throughout the Mediterranean. Numerous remains of *tarsia* have been found in this territory, a technique much in use in the Arab world, though it has not been found elsewhere in Italy. In Salerno, for example, some of the best known examples have been found. These include: the fragment preserved in the Nona chapel of the Archbishop's residence; the rose window of the apse of the Church of San Felice in Fellingine; the large mullioned windows of the Pinto Palace and the arches of the portico that once enclosed the atrium of the Church of St. Benedict; the decorations of the only existing tower of Castel Terracena; the atrium of the eleventh century cathedral of Salerno and later on the hanging walls of the Pernigotti Palaces; and finally the Fruscione and Veniero Palaces in Sorrento and Villa Rufolo in Ravello (13th century).

Tarsia is a decorative technique that consists of cutting different materials of various colours. These coloured pieces are then cemented on the walls of a building with the purpose of creating a continuous pattern of pure and simple fantasy. The resulting effect is created, not by the changing surface of the wall, but through the contrasting chromatic divergence of the various stones. The stone pieces are worked, with the aid of wooden panels or tin drawn to scale, in a rectangular or curved design so as to replicate the motifs and decorative designs. The creative procedures of *tarsia* are different and oftentimes difficult, though offer numerous decorative possibilities. Generally, geometric *tarsia* are characterised by rectangular motifs with the compositions creating geometric effects in the shape of squares, diamonds, rhombuses, cubes, or checkerboards. Typically, the direction is in symmetrical agreement with the axis of the splice, made with little sand and almost entirely of lime in a bright white colouring, thus accentuating the desired decorative effect.

Tarsia was a technique much in vogue in antiquity and was well known as far as Greece where it was referred to as *plákosis* while in ancient Rome the term *incrustatione* was used – from which the Italian word “incrostazione” comes from. In the classical world, *tarsia* was utilized to decorate walls as well as pavements. Pliny the Elder proclaimed that the technique of encrustation was invented in Caria as the walls of the governor's palace, the Mausoleum of Halicarnassus, were decorated in *proconnesium* marble^[3]. The Romans used mainly marble from which the term *incrustatio* derived, being almost a synonym for the expression *incrustatio marmorea*^[4]. This was greatly diffused in Roman architecture and was widely used in the decoration of many buildings in the Imperial period. The buildings in Pompeii would attest to this. The Pompeian examples are clearly attributable to the period before 79 AD, the year of the devastating eruption of Vesuvius. Other examples of architectural decorations done, using the encrustation technique, in antiquity can be found in Campania. For example, in Quarto Flegreo (NA), in the phlegrean fields, there is the ruin of a mausoleum from the second century A.D. where the technique was used on the outer facing wall^[5]; at Santa Maria Capua Vetere (CE), in the north of Campania, stands another mausoleum that is considered to be the antique model of the bell tower in Amalfi^[6].

According to Pliny the Elder, starting from the Julio-Claudian dynasty, another technique was developed: *l'opus interrassile da interrado*. This technique consisted of either making grooves and leaving the pattern or by cutting out the pattern so that the openings form the design and then filling these bottom plates with a warm mixture of marble dust, or thinner sheet of metal in a different material or by using a different quality of marble^[7]. This particular ancient decorative technique was only used on walls given that for the floors the *crustae* (slices), inserted into the recesses and necessarily much thinner, were regarded as being prone to wear.

One of the most obvious differences between *tarsie* in the classical period and that of the medieval period consisted in the fact that it was used sparingly in the classical period. Conversely, in the medieval period it is possible to observe a veritable “cycle” of decorations. Another substantial difference consists in the choice of building in which the inlaid motifs are found in Pompeii; they are

not present on religious buildings. Meanwhile, in the medieval period, they are found mainly on bells and in churches. In some churches, the medieval *tarsia* is used in the centre of a ceramic bowl whose function was to "shine" when the sun shone, thus creating a pleasant chromatic effect. Such decorative details are still visible on the façade of the Veniero Palace in Sorrento (end of the 12th, beginning of the 13th century) – where the circular medallions are closed at the centre with tiled basins, commonly known as Hispanic-Arab, and are characterized by their particular bowled shape. Likewise, similar bowl shapes have been found in Villa Rufolo in Ravello^[8].

There is much research related to the origins of the *tarsia* technique in the medieval period. Some academics think that it has Arabic origins and that it was brought from Sicily to Campania, or that it occurred simultaneously, while others state that the influences that underlie the origins of the use of *tarsia* are of the Campanian-Sicilian type^[9].

The academic Luigi Kalby hypothesized, in his research, that the decorative motif of *tarsia* is of Arabic origin and that this design arrived in Campania from Sicily, particularly at the end of 12th century. He believes that Arab craftsmen were forced to abandon the island after the sudden and rapid collapse of the monarchy, which had been restored by the Normans^[10].

We must note that, in Sicily, many Arab monuments were defunct of multicoloured *tarsia* and that the oldest *tarsia* present in Sicily are those found in the cathedral and cloisters of Monreale, where in 1176 the monastery, attached to the cathedral, became associated with Cava dei Tirreni and the sculptures of the famous cloister bells where master bell craftsmen worked^[11]. In fact, King William sent a letter to the Abbot of Cava in 1176 mentioning the presence of 100 monks from Cava in Monreale.

Certainly, master Arab *tarsia* craftsmen existed in Sicily and skilled carvers are also mentioned as being amongst the Arabs deported to Lucera; though that is not to exclude that in Sicily the taste for such works is linked, indirectly, to Montecassino, which obviously had its inspiration from Salerno. Moreover, we know that in 1081 Duke Ruggero I, in the surroundings of Messina, allocated large sums of money in order to draw skilled bricklayers and craftsmen "*undecumque terrarum artificiosis caementariis conductis*" ^[12]. In Sicily, in addition to the known examples of the Cathedral of Cefalù and Monreale where *tarsia* walls are found, we are also able to cite the Church of St. Peter and Paul in Agrò, the Church of St. Mary in Mili San Pietro and the Church of St. Peter in Itàla (11th–12th centuries).

The importance of the city of Salerno, as the place in which *tarsia* gained particular importance, is documented by the fact that territory of Salerno has the major number of edifices decorated with this technique. In fact, the portico of the Cathedral of Salerno is one of the most notable examples^[13]. The Cathedral of Salerno was made possible thanks to the will of Alfano, the great archbishop who ran the diocese of Salerno, at the time of the arrival of the triumphant Robert Guiscard in 1077. Alfano of Salerno was also profoundly linked to Abbot Desiderius of Montecassino^[14]. The two clerics, despite the distance between their dioceses, continued to meet and, in particular, Alfano continued to be fascinated by the reconstruction that his friend undertook on the summit of Montecassino. Meanwhile, Desiderius, for his part, probably urged Alfano to undertake the same endeavor for his offices in Salerno. Therefore, Abbot Desiderius must have had a direct influence over the new cathedral which was built in the maritime city shortly afterwards; not only due to the influence that his action exerted on his friend the Archbishop, but also for the friendship that bound him with both Robert Guiscard, who's patrimony financed the new building, and his wife, Sikelgaita, who Desiderius happened to be related to.

Desiderius and Alfano were further linked by a predisposition and adherence to the ideals of an eclectic culture - universal, halfway between East and West - that was visualized through works of art, both architectural and figurative, and in terms of both antiquity and innovation^[15].

Numerous artists from all over the Mediterranean participated in the reconstruction of the Abbey of Montecassino. Desiderius devoted himself to the reconstruction, restoration and embellishment of all of those buildings which were in particularly bad condition^[16]. Specialized artisans came, more than likely, from Egypt. They also came from Byzantium, bringing all those technical secrets which recalled the Roman, Greek, Germanic and Arabic heritage, thus bringing the Cassino school of the 9th century to its splendor. This new cultural trend can be seen not only in painting and architecture but also mosaics, enamels and miniatures. Furthermore, the Arab and Byzantine artists who arrived in Montecassino found fertile terrain thanks to the splendid artistic season the abbey experienced in the 9th century. In particular, Abbot Gisulfo created an art form that was highly influenced by Roman antiquity. One must bear in mind that the monastic artists, who lived at the abbey at the time of Abbot Gisulfo, had the possibility to see, better than we can today, the remains of the Roman buildings in Cassino and of all the buildings in the vicinity of the abbey. Moreover, Desiderius had no reservations when it came to repairing the columns of the abbey by making purchases at a Roman antique shop.

The Cathedral of Salerno also plays an important role as it was responsible for influencing many of the Romanesque churches in the surrounding area. For example, the Cathedral of Ravello and Scala, the churches of St. Maria in Gradillo and St. Giovanni del Toro in Ravello, St. Eustachio in Pontone and The Annunciation in Scala, just to mention some of the notable examples whose walls were decorated using *tarsia*.

Only recently have academics agreed unanimously that in Campania, Romanesque builders were inspired by the decorative inlay systems of the Islamic world. Roberto Pane affirms that "it is conceivably possible to visualize a thirteenth-century Salerno; stunningly coloured by the East".

In the Arab-Islamic world such decorations were widely known in the Umayyad Caliphate and afterwards in Ayyubid architecture in Syria and Egypt. In the 8th and 9th centuries, with the arrival of the Umayyads in Iberia, the use of this technique, when applied to decorations with multicoloured segments, became prevalent. There are numerous examples of Arabic buildings, using *tarsia*, above all, in Andalucia: The Great Mosque of Cordoba (789-988). Only from the 10th and 11th centuries do we see North African monuments decorated with multicoloured segments or stone motifs in *tarsia*: the dome of the narthex gallery of the Al-Zaytuna mosque in Tunis (10th-11th centuries).

Furthermore interlaced arches, many of whom were also decorated with *tarsia* motifs, had a strong Arab influence. The idea of reinforcing the arch system through interweaving is most definitely of pre-Islamic origin, while in the West interwoven arches appear frequently in Roman mosaic designs. In Syria, they were already present in the early Christian period and were used to decorate facades, like on the lintel of the church of Behyo (6th century) such as the slab of stone of the church of Qasr al-Hayr al-Gharbi (728-29), where it is possible to see a multi-level architectural structure in which the ground floor consists of a small open archlet formed by intertwined arches.

The creation of the ornamented arches was realised by southern Italian craftsmen using stone material; dark slate; yellowish limestone; terracotta; travertine, sometimes perforated; bricks and, above all, grey and yellow tuff that allowed for various chromatic interplays^[17]. The use of intertwined arches characterised many of the buildings during the Norman period. Such decorations, achieved using fascinating fantasy shapes and geometries, conferred a certain Orientale style on the walls. The decorative elements were usually inserted in the upper parts of the churchly buildings and in the apses area; on the upper crowning of bells and, in general, on the external walls of noble buildings - articulated in complex and lively twists that would incorporate creative effects of light and shade.

The intertwined arches, even if used in the pre-Islamic period, can be placed in North Africa as belonging to the Fatimid culture. There is no doubt that there are many artistic links that have various origins, as decorated intertwined arches are present on many Romanesque monuments in Normandy, England and Norman Sicily; but also in Andalusia and in Islamic North Africa. And, in particular, in the Arab world, there is an accentuated regression of the functional form towards the supremacy of an ever more decorative one.

The flat treatment of the outer surface of the intertwined arches of the drum of the Salernitan bell tower recalls examples in the Algerian Islamic buildings, such as the palace of Ziride in Ashir; the minarets of the mosque of Sid Okba in Biskra (7th century); the mosque of Al Qal'a of Beni Hammad (11th century); the mosque of El-Mechouar in Tlemcen, built at the beginning of the 13th century in the Hammadite and Almohad style; and the Moroccan buildings, such as the Kutubiyya Mosque (1160-1195) and the *Qubba* al Barudiyyin (12th century) in Marrakesh. The use of intertwined arches is quite diffuse, above all, in Andalusia, where it is still present in the mosque of Bab al-Mardum in Toledo (999-1000), The Aljafería Palace in Zaragoza (1049) and finally, the Giralda in Seville (1184-1198).

The intertwined arches of the transept and apse of the Cathedral of Cefalù (1145), most clearly Islamic, are the first examples built in Sicily – following those of the bell tower of Salerno (1140), by only a few years. The intertwined arches, with chromatic valences, of the churches of Monreale in

Sicily, St. Eustachio in Pontone of Scala and the Cathedral of Casertavecchia in Campania are all very similar.

It is possible to state that the Campanian models draw their inspiration from Umayyad Spain, this may be postulated from the Andalusian origin of the motifs, intertwined arches and the use of multicoloured *tarsia* - almost certainly reaching Campania through the role played by the city of Amalfi in the Mediterranean. It is no coincidence that the Arab traveller Ibn Hawqal (972) considered Amalfi as being more important than Napoli: its boats were the fastest in the Mediterranean and its territory the most fertile - enjoying the best conditions and being characterised by its richness and opulence^[18].

To summarize, we can state that the routes that intertwined arches and *tarsia* took to penetrate the architecture of Southern Italy were numerous and varied. Primarily, they highlighted the differences that distinguished Arab architecture, with its Sicilian and Andalusian elements, assigning only to the later the artistic components that legitimise the Arabic morphological origin of many architectural elements. Conversely, as for the intertwined arches, they had a simultaneous emergence, at the expense of any temporal clue in Southern Italy, similarly to what happened in England, with the presence of the Normans.

Art and nature in a lost garden: the Park of the Caracciolo Prices in Avellino

Francesco ZECCHINO

Università degli Studi Suor Orsola Benincasa, Naples, Italy
francesco.zecchino@unisob.na.it

Abstract

In the years between the 16th and 17th centuries, Prince Camillo Caracciolo, through a series of purchases of private lands, significantly expanded the already extended landholdings of his family in the area adjacent to the castle of Avellino. Right in this extensive green area developed in large part on the slope of a hill emblematically called Belvedere, the aforementioned Prince made a magnificent and grandiose useful Park for hunting and leisure.

The different heights determined the division of the Park into two distinct parts; the bottom one, closest to the castle, was embellished with a decorative wise use of water. In addition to some fishponds, an artificial lake and artistic fountains, stood out, above all, a very special element: a cave housing a nymphaeum decorated with stuccoes, sponges and sculptures. Several sources describe this garden as a marvel known throughout the kingdom both for its refinement and for its botanical variety and there are numerous testimonies of famous visitors who stayed in town just to see in person the much-vaunted and today disappeared Princes Caracciolo's Park.

Keywords: Italian Renaissance garden; water artifices; nymphaeum; Giovanni Antonio Nigrone.

1.

For almost all of the 14th century the county of Avellino was governed by a very particular figure who, together with the Caracciolo princes some time later, would prove to be fundamental for the history of this city: the Countess Maria de Cardona.

Descendant of a noble family of Catalan origins, the Countess de Cardona was prematurely orphaned of both parents, thereby becoming, in 1513, at the tender age of 4, heiress of the marquisate of Padula and of the county of Avellino. Her lineage allowed her to be raised in the best aristocratic Neapolitan milieu of that era, and this contributed in making of her a perfect Renaissance noblewoman. Inclined to sophistication, and a lover of culture and the Arts, once she entered into full possession of her fief, she became friends with the most illustrious personalities of the Reign. These scholarly friendships gave life to vivacious meetings of intellectuals in the Countess's Avellino residence, the old Norman castle, which the Countess de Cardona had restored to Noble Palace after two tragic events; the plundering of the city by Alfonso of Aragon in 1440, and the terrible earthquake of 1446, had substantially destroyed it. The indispensable renovations were particularly aimed at the creation of a sumptuous new noble floor with rooms that would guarantee a befitting reception not only to its owners, but also to its numerous guests. A turning point for the modernization of the Avellino dwelling was then offered by her second marriage, propitiated by Charles V in 1539, with Francesco d'Este. The union with the young member of one of the most illustrious families of Italy, in fact, certainly had to make the Countess of Cardona consider it appropriate to adapt her palace as much as possible to the rank of the Este court. This assumption applies in particular to the work carried out in the years after the wedding if you consider that immediately after the wedding, which took place in 1539 by proxy but officiated in fact only the following year in Naples, the Countess de Cardona had the opportunity of visiting the famous Duchy of Ferrara and of appreciating the luxury and the

architectural refinement personally. His military career led Francesco to be away from Maria and his Avellino fief very often, and, when particular contingencies in the struggle between France and Spain forced him to side with the French (1555-1557), there was also in fact a definitive separation from his Spanish wife. With no heirs, the countess continued to brilliantly administer the county alone, an activity which at the time was rarely entrusted to a woman alone. In 1561 a new violent earthquake devastated the city and her palace, but this time the countess was not able to see the completion of the reconstruction. Maria de Cardona in fact passed away in 1563 and after her demise the estate passed to the *Demanio Regio*. Precisely an estimate of the Royal Chamber referred to the income of the county in 1566, making it clear that the Countess's Palace, despite the damage suffered as a result of the earthquake and the partial neglect of the last few years, looked rather dilapidated but a good part of it was still habitable [13]. The same document, listing each baronial income, speaks of 50 ducats obtained from *the castle garden*. The data in itself is not very enlightening as to the nature of this entry, it is, though, very useful in ascertaining that already at the time of the Countess de Cardona there was a garden with the building, and allows us to legitimately assume that the green area may have been a sort of anticipation of what would have later become the vast and magnificent Park created a few years later by the future rulers of Avellino, the Caracciolo family.

In 1581, in fact, after about eighteen years of royal exploitation, the fief was finally bought by Marino Caracciolo I, first prince of Avellino - the city was elevated to the status of principality in 1589 - Marino marked the beginning of the very long dominion over the fief of the noble Neapolitan Caracciolo family that would last continuously for nearly two and a half centuries. The new dynasty, definitely destined to leave its mark on the fate of the city, from the beginning aligned itself with the process of renewal already begun by the enlightened Countess de Cardona, hugely amplifying the project by far. The first real initiator of this renaissance was the second prince of Avellino, Camillo, who succeeded his father in 1591. Marino's firstborn, also heir to the huge economic wealth of the family, was both a man of arms and a man of culture, and to heroic military exploits - in Piedmont, France, and Germany, but especially in Flanders - he associated interest in the arts and literature. He did his utmost in many works of urban improvement of his fiefdom, such as the significant redevelopment of the ecclesiastical architectural heritage of the city, and expanded its boundaries through the acquisition of new properties. One of Caracciolo's great merits was to understand the administration of estates through a more modern business perspective. In Avellino, thanks also to the clever exploitation of the many albeit small watercourses on the territory of the city, a productive milling activity flourished and the old wool processing activity was intensified with the construction of new factories. As for the castle, the substantial changes gave back a building that had lost much of its appearance of fortified architecture, gaining instead the features of an elegant, stately palace with a rich system of stables and other outbuildings dedicated to horse breeding. In fact, the equestrian activities, aimed both at war and hunting, were enjoyed by Camillo so much, that for this very reason, he decided to equip his Avellino residence also with an adequate space for the exercise of hunt. To do this, the prince arranged to expand, through divestitures and new acquisitions of adjacent land, the feudal hunting reserve of which the castle had been able to avail itself of since the medieval period. It was the north area of the castle which from the valley of the Rio Cupo - the river which encircled the ancient Norman fortress to the north and the east - stretched uphill along the ridge of a green and panoramic hill emblematically called Belvedere. Camillo greatly expanded the boundaries bringing them up to the limits of the existing Picarelli and Pianodardine hamlets, areas respectively distant about three miles north and four miles northeast from the castle. This sumptuous Park was characterized in its lower section, that is in the area that is closest to the castle, by a section that is more decorated, and therefore rightly defined as a garden. It is very likely that the eastern part of this section included that unspecified green area which has been mentioned previously, attributing it to the period of the Countess de Cardona, and identified in the document of 1566 as *the castle garden*. The game reserve and the garden were therefore two different entities but closely connected and together they formed a single magnificent park. A description of the city of Avellino dating back to 1629 offers an interesting testimony of both structures [2]. The precious passage only briefly indicates the type of game in this park, while giving a more comprehensive picture of the elegant garden. In fact, it is clear that, thanks to a ramified system of water pipes, the system could rely on a substantial amount of water, and this factor was expertly used for decorative purposes.

A considerable contribution on the implementation of some of these decorations in the Camillo Caracciolo Park was undoubtedly made by Giovanni Antonio Nigrone, known *fontanaro* and water engineer of the time. Florentine, but with probable Saracen origins, Nigrone was, in his field, a real celebrity. Active, among other places, in Rome, Florence, Matera, Sermoneta and Viterbo, he worked with special continuity and fortune in the Kingdom of Naples, where, between 1603 and 1604, he appears to have been the creator of at least three of the six fountains built along the road which from Naples led to the fifteenth century Villa of Poggioreale in the attempt, commonly attributed to the then viceroy Count of Benavente, to transform that part of the city into a public promenade [17]. Nigrone himself provides us with a more comprehensive review of his works, with the implementation, between

the end of the 16th and the beginning of the 17th centuries, of a manuscript containing detailed descriptions of several hydraulic mechanisms, fountains, water games and rich scenographic apparatuses which he devised. Among the many documented works, the author lists some that, without a shadow of doubt, confirm his great professional competence; these are works created in some of the most important gardens of the time, such as Villa Medici in Rome, Pratolino near Florence and Villa d'Este in Tivoli. This necessary clarification explains the importance of the figure of Nigrone in the context of landscape gardening and renders his presence in Avellino very significant in the early years of the seventeenth century: a presence that has been ascertained precisely from the aforementioned Florentine artist's treatise. Among the 313 drawings present in the 531 pages of the manuscript divided into two volumes, in fact, there are two watercolor plates depicting a fountain with artistic hydraulic automatisms that a handwritten annotation states had been created specifically for Prince Camillo's garden. Nigrone gave full proof of his abilities with a very structured work, by staging an artificial representation of the Avellino landscape which proved to be characterized by abundant waterways and in which the city's main architectural emergences, idealized, stood out. The park itself was symbolically depicted in the foreground through the reproduction of a classic decorative fountain surrounded by a few trees proposed with geometrically shaped tops. The entire system was driven by well-hidden hydraulic mechanisms that allowed the movement of certain elements of the picturesque scenery like the blades of the windmills or the small terracotta figures engaged in many different activities that populated the faux landscape. The two drawings mentioned and the brief description with which the author himself described them, are today the only evidence left of the fountain [1]. Despite the paucity of further information about this work of art, such as its precise location in the garden, there is no doubt that the rich decorative apparatus with which the Park was equipped, did not take long to increase his reputation among his contemporaries. So it was that, from the beginning of the seventeenth century, many visitors, more or less famous, vied to admire it. The testimonials of these visits which have reached the present day are the only tool available to attempt a more detailed reconstruction of the Park. Particularly with regard to the botanical aspect, one of the most interesting is the one proposed by Gian Vincenzo Imperiale, Genoese nobleman and man of letters who, between May of 1632 and the same month of the following year, crossed the whole of Italy to fetch possession of his fief in Sant'Angelo dei Lombardi. In the detailed guide of his long journey, Gian Vincenzo Imperiale also describes his fleeting visit to the Park on the day of Wednesday, March 30th, 1663, providing new insights and some confirmation [9]. Firstly, it certifies the great notoriety of the Park in those years, which, however, he judges to be deserved. He then implicitly clarifies the particular use which the owners made of it. In fact, with all evidence, the Caracciolo's intended this property of theirs as an elegant portion of constructed landscape, in which nature and art vied with each other in order to offer the most wonderful of shows, and they generously shared that beauty with all those who manifested the desire to do so. These noble intentions were indeed fully declared by the epigraph that stood out on the great gateway to the Park *To appease Mars with the delights of Peace, and to carry forward Peace in the midst of the games of Mars, Camillo Caracciolo, prince of Avellino, delight of Mars and defense of Peace, prepared, in this most splendid theater in the garden, for himself and his own, for the citizens and for the foreigners, in order to delight, the competitions of nature and art* [2]. Once again, Gian Vincenzo Imperiale helps to better understand how and which different botanical types were arranged inside the garden, of which the morphology of the system is specified - organized on different levels - the immediate proximity to the residence and, above all, the unfortunate exposure to the weather. Precisely in this latter feature, normally extremely detrimental to a green architecture, Gian Vincenzo Imperiale was surprised to detect the paradoxical strength of the Park. The forced use of plants, more commonly known for their strength than for their pleasant appearance, for decorative purposes, determines for the narrator the great originality of this garden, constituting proof of how it, in spite of everything, and indeed perhaps even more evidently, proves a masterly example of the art of the gardens of the time. Even though these plants were in fact a little too ungenerously denigrated even by the author himself - that which is called *fetid boxwood* for example, even though it really does have unpleasant smelling inflorescences, is actually an evergreen shrub greatly appreciated since ancient times for its excellent cutting resistance which makes it very suitable for topiary artistic pruning - Gian Vincenzo Imperiale himself extolled the skillful arrangement in the garden that gave rise to valuable intersections of paths marked by live borders, to shady pergolas covered with green, artistic plant espaliers. The reason why only Flemish tulips, daffodils, peonies and anemones found space in the garden flowerbeds is easily explained by the time that Prince Camillo spent in Flanders.

If the latter may in fact certainly be referred to as the main ideator of the creation of the Park, the overt ability of the various members of the Caracciolo family to ensure the continuity of their dynasty is to be considered, and is also reflected in the management and care of their beautiful garden. The third prince of Avellino in particular, Marino II, son of Camillo and his immediate successor (1617), distinguished himself as a passionate promoter of culture and of the arts, and therefore, in perfect harmony with his father's work, continued the enhancement and beautification of the Park. In this

respect, it is essential to stress here that the travel records of Gian Vincenzo Imperiale widely discussed above, which go back to 1633 and are therefore three years after the death of Marino II, while also referring irremediably to the original work of Camillo, are mostly based on the state of the sites found after the government of the third prince of Avellino. The same is true with regard to the brief mention of the Park proposed by the Avellinese historian Scipione Bona Bella in 1656 but with referral to 1632. The episode is the visit to the court of the Caracciolo family by he who is referred to as the *King of Ethiopia, welcomed into the city with all honours, he was amazed by the Park and called it a delightful garden [...] of every delight in nature, wonderfully filled with art* [3;6]. Subsequent authors have identified the person in question as Zaga Christos, not agreeing, however, on exactly who he was, if the rightful heir to the throne of Abyssinia or a clever imposter [13;31].

Even more certainly, the state of the Park in December 1630, proved to be the result of the management of Marino II, when the Spanish Infanta, Maria Anna of Habsburg, was a guest of the Caracciolos for a few days, at the time travelling to Vienna where she was to marry the future emperor Ferdinand III. Marino II had died only the previous month, leaving his wife Francesca d'Avalos a widow and about to give birth to his only son. Pietro Veronesi, trusted secretary of the newly deceased prince and evidently still in service at his palace, in a detailed account of the episode, as well as confirming the decorative richness of the Park and emphasising the perfect function of the hunting lodge, denounced the presence in the garden of a further delectable distraction: a fishpond where to catch the trout that populated it [31]. Although the Infanta of Spain could not effectively fully enjoy the leisure activities offered by the Park due to bad weather, the wonderful welcome she received convinced her to offer herself as exceptional godmother to Marino's unborn successor. This happened punctually, by proxy, in January of the following year. In fact, during her stay in Avellino, the future fourth prince Francesco Marino I not being yet born, his uncle Marzio Caracciolo, brother of Marino II, and later archbishop of Taranto, who went by the name of Tommaso, did the honours, and acted as an attentive guardian throughout his nephew's childhood. The management of the fief of Avellino was thus firmly in the hands of Tommaso until 1646 and, curiously, the moment in which the young Francesco Marino took over the government more fully, coincided with one of the darkest periods in the city, which also irreparably marked the fate of the Park. At the end of 1647, the violent antispanish riots that had erupted in Naples a few months earlier, also extended to the province, and the city of Avellino was the object of looting and devastation that obviously did not spare the palace of the Caracciolos and its extensive garden. The damage to both structures was enormous, and even when things calmed down, and the Caracciolo's re-took possession of it, in 1648, they were never as they had been in the past. The castle was gradually abandoned, firstly in favour of the renovated ducal palace that the family owned in Atripalda, and then of a brand new structure built not far from the old medieval castle. As a result of the princes' increasingly frequent stays in other locations, the Park itself ended up losing the appearance of an important element of representation, and its lands began to be exploited instead as mere sources of income. In effect, a good deal of its vast surface was from the beginning intended for productive purposes, and it is known that inside there were areas for various structures, equipped for various activities such as beekeeping or grape pressing. After the progressive transfer of the court, however, this kind of activity definitely took over and radically transformed the past appearance of place of delight and elegant hunting lodge of the Park. Of course the ancient glories could not be so quickly forgotten, and during the second half of the seventeenth century to the early eighteenth century, there was no lack of evidence that they continued to celebrate the glorious past. This is the case of Abbot Michele Giustiniani who, in 1656, remembers the Prince's garden as one of the most delightful in the Kingdom [4], of a tax document kept in the State Archives of Naples which in 1676 still speaks of the Park as of a garden enriched with ornamental espaliers, and with cypresses, laurel, myrtle and boxwood in it [31], but especially in the case of the description offered by Giovan Battista Pacichelli in 1703 [5]. Probably mostly referred to, nostalgically, to the ancient splendor of the Park, the passage in question offers new insights regarding the analysis of its structure. The part already called *garden* by other authors, to differentiate it from the area used as a hunting reserve, is here further divided into a smaller area, referred to as the flower garden, and a larger one, characterized by the well-known water games, by paths, by the fishpond but also by a small artificial lake and by an unspecified number of statues. If of the small lake, there are no further significant references elsewhere, in the middle of the 1600s Bella Bona might have indicated the source of the statues. In his *Raguagli*, later taken over almost literally by others, the author, narrating the ancient Roman Abellinum which stood near Atripalda, whilst browsing the archaeological remains which could still be seen at the time, writes about the amphitheater: *From the Amphitheatre [...] in our, and in past times, many marbles have been gouged out, and beautiful statues, some of which have been transported to the small garden of our Lord Prince* [3;6].

However, despite these belated celebrations, during the eighteenth century, the Park became progressively more and more degrading and reduced in extension by the continued sales of its land to private persons. As mentioned, what determined such a state of decline was primarily the definitive transfer of the Caracciolo family to their new palace. This building, which today is the seat of the

Provincial Administration in Piazza della Libertà, was built in the early 1700s in what was then the extensive *Largo* in the western part of the city and that in those years, thanks to its orientation towards Naples, began to become the new administrative center of Avellino. The remains of the now abandoned castle were used for its construction, and its features as the family's representation palace are well testified by Carlo di Borbone's visit to Avellino in 1735. A report published in 1742 recounts the episode in which the king, welcomed into the city with the highest honours on January 4, was hosted in the Caracciolo's new palace, which was appropriately adorned for the occasion. In particular, a hall was prepared to look like a *faux ornamental garden*, which the Spanish king proved to appreciate, calling it *muy lindo*. Shortly after, the guests went into *the real great garden of the palace, (which had been prepared in advance by the Prince, master of the handsome, richly executed study, in order to provide an abundance of every kind of animals and beasts, and birds) in which His Majesty amused himself with great pleasure, hunting throughout the remainder of the day* [7].

It appears evident that the magnificent Park built by Camillus, though probably not surpassed in beauty, in fact, had been replaced at least in all its main functions. It is no wonder, therefore, that in 1779 the vast majority of its surface area had been converted to farmland by the new owners and the only remaining part of the old structure still owned by the Caracciolos resulted, according to what we learn from a document preserved in the Notarial Archives of Naples, a very small area near the castle ruins, where there had already been for a few years, a building used as an inn. After only a few years even that last strip of land was sold, and what was left of the Park started to slowly disappear. Already in 1810 the traces of the glorious plant were only vaguely readable: *even today you can still see a place called the Park, which was used for hunting, another area called the wall, where a rivulet formed a lake, and other vestiges of gardens, and hydraulic couplings that demonstrate its ancient magnificence* [24].

The history of Caracciolo Park would seem, therefore, to end this way, and in fact until a few years ago nothing of the old structure appeared to have survived, the only proof of its presence being entrusted only to the name that identifies the inhabited area which subsequently arose in the same area, the Park District in fact. Surprisingly, however, during some restoration work of the eighteenth-century Casino del Principe that became necessary after the 1980 earthquake, and which ended only in 2008, some underground rooms have come to light, undoubtedly attributable to the ancient garden. The so-called Casino del Principe, owned by the city since 1987, is a building constructed on an existing architecture around 1760 by Antonia Maria Carafa, wife of the seventh prince of Avellino, Marino Francesco Caracciolo. The princess wanted the Casino to make it into a hotel and, as such, the structure can be traced back to the inn which has already been mentioned above, and which stood in the last small area of the Park still belonging to the Caracciolo's before its total alienation from the family property. In the year in which the inn entered into business (1763), the Princes had in fact already begun the gradual sale of land in the Park, now marked by farms, and the construction of a room equipped to accommodate the many travellers, turned out to be a smart solution to reap additional profits from the residual properties of the time. In this sense, however, the hunting lodge lent itself particularly well to the purpose because its location, just a few meters east of the castle and along the busy Strada Regia di Porta Puglia (now Via Umberto I), ensured an intense daily flow of potential customers. Leaving aside the classic eighteenth-century structure of the edifice constructed by Carafa, the most important interest here concerns the aforementioned pre-existence on which it was built and from which the recently discovered underground rooms decorated with nymphs, constitute clear remains which have unexpectedly survived. Unfortunately, with respect to the old building, it was not possible to derive any useful information, neither from the restoration at the end of the last century, nor from any other relevant documentation. Even today, therefore, it is not quite clear what the original conformation of this architecture was, the period of its creation or the purpose for which it was conceived. In the absence of certain evidence, in fact, a univocal understanding about its precise temporal positioning wasn't found, and the doubt remains about whether its implementation can be traced back to the Countess de Cardona or the Princes Camillo and Marino II. On the other hand, full agreement seems to register about the suggestion that that structure constituted a pertinence of the large garden now disappeared, so much so, that it is commonly identified as the place where the gateway to the Park, accompanied by a previously mentioned epigraph, was to have been built. To further accord this already condivisible thesis, the analysis of the two splendid, recently rediscovered underground rooms that are actually proposed, to say the least, unequivocally as classical decorative structures of the late Renaissance, concurs fully, in line with the dictates of sixteenth and seventeenth century garden art. Both rooms present themselves today with the walkway flooded by about a foot of water, the level of which, in order to prevent it from rising excessively during periods of rain, is kept under constant control and if necessary, is suitably drained. The first, a barrel vault, is the most spacious but has no decoration. Far more interesting is the second room whose vault is centrally enriched with stucco decorations, which, although missing in many parts, maintain a reasonable state of preservation. The design, composed of these white stucco decorations, is that of a central ellipse mounted by several orders of rectangular frames variously

made up of floral patterns or laborious embroideries. In the short side, which looks towards the back of the room, a large white shell and a large frowning mask, stand out among the frames. This second element is colored red, and is depicted while irreverently showing a long white tongue which, bifurcating, acquires a further decorative value. The aforementioned mask thus appears to dominate from the ceiling, the main element of this environment, which is represented by an artistic wall fountain located on the apsidal bottom of the room. Here the various friezes appear significantly worse preserved, and the idea of what the decorative apparatus should have been in its entirety, is mostly offered by the remains of two statues, depicting a male figure and a female figure, respectively located to the right and left of the central compartment from which presumably water was supposed to gush. Both the anthropomorphic figures are flanked by the remains of two tuff stone columns with Ionic capital, ideal pediment supports which probably surmounted the fountain, while other more damaged parts of the latter still allow only a glimpse of a few hints of the typical sponge and shell decorations which enriched the drawing. Ultimately, the structure here described, is fully in the category of caves and nymphs, typical of 16th century Italian gardens, widely replicated even in the following century. Distinctive elements of these imagined and natural-looking specific spaces, in order to offer a refreshing and delicious break in the Renaissance garden, are mainly rock gardens, corals, marbles, sponges, shells and more generally all those decorative elements that recall the suggestions of the myth of the cave in which the presence of water is clearly guaranteed in the form of the various effects and games. The most famous gardens of the time did not fail to enrich their plants with similar architectural events, and the cave fashion was affirmed to such an extent as to be often integrated in the compositions of prior periods also. Emblematic in this regard is the case of the fifteenth-century Villa Medici at Careggi in which only in the second decade of the seventeenth century, that which was originally a cellar, hosting casks and flasks of wine for the famous Florentine family, was transformed into a beautiful underground cave - from the conformation, however, very similar to that found in the Casino del Principe - with a barrel vault decorated with frescoes and a wall fountain embellished with sponges placed centrally at the back of the room [20].

Based on these considerations, the reasons which have led to imagine the subterranean structures of Avellino traceable to the time of de Cardona or the Caracciolo's, seem both equally condivable.

The first hypothesis could be fully justified by the experienced influence which the knowledge of the Este court exercised on the Countess. In fact, apart from the beauty of the gardens probably directly admired in Ferrara, of course you cannot ignore the fact here that the brother of Francesco d'Este, and therefore the brother-in-law of de Cardona, was the famous Cardinal Ippolito, or rather, one of the largest Renaissance buyers of magnificent garden plants, the best known of which is probably that of Tivoli; indisputably one of the most significant models of all the literature on the art of gardens, exactly for all that which concerns water games, and all that which acts as its accompaniment. It is also known that Francesco d'Este himself was not at all insensitive to the garden fashion. When, in the second half of the 14th century, he went away from de Cardona for reasons already mentioned, returning to Ferrara, he built that which today is known as Palazzina Marfisa, from the name of one of the two daughters he had had, out of wedlock. Here, in fact, he created a garden, now lost, which was exalted by scholars who tried to ideally reconstruct the structure as a typical example of an Italian garden. Within this green space, even though clear evidence of those elements related to the tradition of grottos and nymphs, has not surfaced, it should be emphasized that various rooms of the building feature ceilings decorated with grotesques, that is, those particular pictorial subjects very popular in the sixteenth century, generally depicting naturalistic backgrounds, which were often associated with more traditional decorations in different materials, precisely in the faux caves recreated within a garden. On the basis of these considerations, therefore, it would at least seem possible that among the works of adaptation of the ancient castle from fortress to noble palace, undertaken during the Countess de Cardona's period of government, the creation of these underground rooms with nymphs could have been started.

On the other hand, the theory that takes their creation back to the Caracciolo's is not less plausible, when you consider the constant references to the various fountains or to the many water artifices never minutely described but regularly and systematically mentioned by numerous eyewitnesses, who were guests at the Park during the seventeenth century. Finally, the ascertained involvement in the creation of Camillo's garden, of a master *fontanaro* such as Nigrone, trained at the most famous courts of the period, and connoisseur of Renaissance gardens, certainly does not help to shed light on the possible paternity of the recent findings.

What is certainly clear, is that the underground nymphaeum found in the Casino del Principe, seems to be the last precious testimony still existing today, in that articulated garden complex, and those green spaces, which constituted the historic Caracciolo Park in Avellino, and which, because of its intrinsic historical and artistic importance represents a heritage that undoubtedly deserves to be concerned by a far more prudent work of conservation and enhancement.

Abstract

The so-called “baraccata house” – the first theorised building answer to earthquake-resistant behaviour improvement of the traditional masonry fabrics, as well as the first organic practical outfit of a legal post-seismic reconstruction standards (1784) – is attracting the increasing interest of a wide turnout of experts and scholars, because of its good performances in this field, as observed in well-conserved historic so-made examples and, more lately, in the laboratory-testing on proper specimens too (CNR-IVALSA). Focusing on the Ischia's historic tuff-masonry heritage, built in association with timber or metal frames after the massive 1883 earthquake, this paper examines islander last existing episodes, having fortunately survived replacements with reinforced concrete elements spreading during the 20th century. Thus, their constitutions, assets and arrangements have been surveyed and assessed at the light of on-site stratigraphic and “as-found” state of condition analyses of current fabrics, also helped by relating to the proper original unreleased philological *corpus*. Therefore, so-made dwellings and architectures detailed account has been obtained, relevant to designing compatible building conservation treatments, as well as up-dating the specific frame solutions.

Keywords: partition timber-framed wall; tuff-masonry walls; restoration; “as-found” survey; trusses.

1. The Ischia's “baraccata house” building system

On July 28th 1883 a strong earthquake had stricken the Ischia's island - a well-known, thermal holiday resort, particularly loved abroad - damaging and crushing most historic masonry heritage. Being in compliance with the Borbone's code of 1784, which had disposed the timber frames adoption, the so-called “baraccata house”, for re-building the Calabrian and Sicilian cities and villages heavily beaten for the 1783's seismic events, the late XIX's reconstruction management of Ischia's dwellings widely used the cited frameworks, too. Missing an effective understanding of the traditional local-tuff masonry structures performance, seismic behaviour-related, because of their so-many falls and decays the technicians all had been called for the reconstruction planning, preferred a whole renewal of the isle building heritage, trough introducing timber or, in case of bigger sizes, iron frameworks in association with local tuff and pumice walls. Therefore, the initial huts design – later transformed into durable lodgings (“improved huts”) – as well as the refurbishment intervention works and the public edifices renewals all were carried out on the basis of a short variety of typological solutions, using masonry-timber frameworks, since the first emergency program (1883). Though the late XIX's Ischia urban reconstruction policy and strategy together with its technical solutions were already studied on a historical point of view [1], what actually was built in that occasion as well as its past and current effective building transformations have never been directly surveyed, unless paying attention to the relevant constructive aspects. With the aim of understanding and assessing features and frameworks

Fig. 1-2: Mileto (VV), the ex-Episcopal Palace. Re-built after the 1783's Calabrian earthquake the fabric adopted a chestnut timber framework with inner coating of rendered "wattle and daub" technique.

of this urban re-building program, so to valuating its compliance with the proper code and safety grading, few Ischia's buildings have been surveyed, also relating to unpublished archival documents. The chosen samples of course are those fortunately survived the late XX's reinforced-concrete wide dissemination. Thus, while so many studies begin valuate the interesting earthquake-resistant performing of the historic timber frames in the Mediterranean area, this paper puts light on the Ischia's post-seismic re-building program. It was the newly-born Royal Italian Government first text bench for forming and applying a common seismic-resistant building best-practice, though with relevant contradictions and operational limits. More lately, some laboratory tests and procedures have been carried out on similar artefacts. Among these, it's important pointing out the laboratory tests on the scale specimen of the former Episcopal Palace of Mileto (VV), re-built after the 1783's Calabrian earthquake (Fig. 1-2). Conducted by CNR-Ivalsa in S. Michele all'Adige with the partnership of the Department of Earth Science of the University of Calabria, the alternated increasing motions cycles highlighted the timber framework good performance, even after the masonry damage with material expulsions.

2. Origin and developing of the "baraccata house" building typology

Timber frames, even often in association with other constructive systems, used as earthquake-resistant structures date back to the Babylonian time. Being formerly made up of basic woven reeds matting and brick masonry (Aqar Quf's ziggurat), with the Romans this building solution evolved into the *opus craticium*. As Vitruvius documented and the ancient Pompei and Ercolano's remains still spotlight, this structure entailed timber trellis walled up with rubbles (*opus incertum*). This was the so-called "baraccata house" ancestor [2]. Other relevant authorities are the so-known tabernacles, made up of boards and used as emergency shelters after seismic events since the fourteenth century in Rieti [3], and the late XVII's dwellings reconstructed in Sicily using Calabrian woods after the famous Noto's earthquake [4]. Furthermore, it seems that this kind of structure were also used after the 1703's earthquake in L'Aquila [5], as well as in the urban reconstruction of the Calabrian and Sicilian historic centers damaged by the 1783's seism, for which, as it's known, the relevant Royal Instructions (1784) disposed the "baraccato" building system adoption, combining timber frames and masonry walls. Even though Giovanni Vivenzio was the first scholar to have underlined the "baraccata house" anti-seismic behaviour, certainly influenced by what had been planned and built in Lisbon after the famous quake

Fig. 3: Ischia, a gentry residential “baraccato” system solution with timber frames and tuff masonry walls.

Fig. 4: Ischia, Casamicciola, a “baraccata house” of “four compartments” building standard.

of 1755, it is particularly the late eighteenth century Calabrian and Sicilian reconstruction program the widespread of this building system is traditionally linked to. The cited code ordered two-storey regular sets made up of three different bodies, whose the central one larger, with no projections, high no more than 7.80 m, or 10.40 m because of a loft addition, but only where the fabrics were on the main streets. Moreover, improved timber joints were disposed as well, especially by using metal laces [6] while, as even Vivenzio suggested, the wall plugs were to be built with ashlar masonry or in *opus incertum*, made up of hard-stone rubbles.

It was possibly for the Royal Engineer F. La Vega, the technical committee director wanted by Borbone for studying the terrific 1783's seismic event damages, that the "baraccato" building system was chosen for the cited reconstruction planning. He had supervised the long-lasting excavation campaigns of the ancient Ercolano, Pompei and Stabia's ruins since 1780, indeed. Regardless of the codes, the Calabrian urban reconstruction practically went along with wide margins of autonomy for technicians and constructors, being only ordered the adoption of masonry structures reinforced with inner timber frames in chestnut or oak [7]. Still notwithstanding that regulation, i.e. in Reggio Calabria, the use of such timber structures was considerably reduced, often to a unique storey or even deleted [8]. Also the "baraccato" building system foundations presented different solutions; the most were continuous masonry walls or wooden pilings. The latter, particularly, were recommended by Vivenzio for using about 3.00 m tall timber posts, while for the continuous ones he advised to resort to stone beds, so did A. Gallo [9]. Moreover, this prescription was disposed for the same region after another big earthquake too, earlier in the 20th century, when Baratta suggested a reduced version of the "baraccato" building system, called "reduced", placing the timber frames on the second storey only [10]. As being codified by the Naples' Kingdom engineers after the cited 1783's earthquake, in the same regions the "baraccata house" building typology was newly adopted for urban reconstruction planning also in other occasions, as after the 1905 and 1908's seismic events [11], just due to its earthquake-resistant performance. Those shakes had only damaged the masonry portions [12].

3. Huts and "improved huts": the Ischia's "baraccato" building system

At night on the 28th of July a terrific earthquake, the most intense since 1228, heavily damaged Ischia with over 2300 victims. Most damages were on the northern side, especially at East [13]. Casamicciola, then the most populated island municipality with about 4300 inhabitants, got almost half of the total victims and most buildings destroyed or seriously ruined. There was the 1883's epicentre and the Ischia's economic development engine too, because of the thermal activities, since the 17th among the main reasons that had made up Ischia a famous holiday resort internationally known, above all in the nineteenth century. Hence, Casamicciola was firstly and more subjected to the urban renewal as well, testing solutions and procedures later adopted with minimal changes for the reconstruction planning of the other island districts. Even if referring to the cited bibliographical references for understanding the relevant historical context of these paper, some notes are however necessary to better picture the building solution features.

Since the first aids the reconstruction leading and management were assigned to the central administration, that took however advantage of the various stakeholders, as the Naples' Civil Corp technicians and the local professionals, with the decisive contribution of the Board of Architects and Engineers, as well as the building enterprises, that presented so many technical solutions and patents. But the Neapolitan Civil Corp engineers were the urban renewal planning actual supervisors, also for what concerned building aspects. Making blank slate of the local building tradition, basically upsetting the historic settlements of several mid and small villages scattered all over the island, the plan placed the new districts in the seismic safer zones – i.e. most along the shoreline – fixing up gentry lodgings and shack areas just where the first emergency huts had been settled up. Though it was the first time the seismic micro-zoning got in the codes, so revealing a decisive innovation, accordingly to the post-seismic urban renewal planning criteria just seen in Calabria and Sicily in the late 18th century, Casamicciola's and the other districts reconstruction corresponded to a fully desk-design, totally unrelated to the landscape and environmental relevant qualities, determining a draughtboard settlements link joined with the new coastal street, the core-element of the whole urban renewal. On a building point of view, all the intervention works must adopted the "baraccata house" system, preferably combining timber and masonry, leaving the usage with iron frames only for the biggest extent and public structures. Hence, the so-called "Calabrian system", as disposed by the cited Royal Instructions of 1784, was chosen as the building paradigm, only varying some features to allow the use of local resorts of best quality. For instance, for making up the stone-bed foundations were suggested the Arso's trachyte – a very lightweight and resistant lava – and for mortars the Perrone's and Casa Lauro's pozzolana, while to reducing the load-bearing timber frames costs the chestnut and fir were preferred to oak.

The "baraccata house" system was not through-and-through out of the Ischia's context, indeed. After another rather destructive earthquake on March 1881, some so-designed timber huts were raised as

Fig. 3: Ischia. This residential typology initially reserved to four families, though diversely modified, later was reduced to two.

Fig. 4: Ischia. The typical building solution known as “baraccato system” for huts. At the bottom a geo-radar prospections equipment used for timber frames surveying.

first-aid shelters. Still inhabited two years later, these fabrics stood up very well under the shakes, so that this constructive procedure was almost automatically considered the best solution, although not cheap. Thus, in order to saving even more, it failed to comply with that building tradition had ordered brick side-walls, to preferring the local tuff-stone, provided that it were reduced in ashlar and set up in regular pattern, with good quality lime-mortars. Although various and repeated dissents regarded the cited frameworks above all for costs, many speculative shares connoted the nineteenth century Ischia's enterprise, also impeding, for instance, the adoption of large common dormitory timber rooms instead of the less reasonable solution of single timber fabrics for two or four families each.

4. Earthquake-resistant historic building best practice: patterns and procedures

The Casamicciola's building code (1884) fixed the "baraccata house" constructive system adoption for both new production and refurbishment, on the basis of a limited variety of typological and morphological solutions. No attention was reserved to the heritage, going on with its demolitions even more than ten years later the seismic event. Hence, whether intervention works must were carried out to areas included in the master city plan or out of there, the timber-framed building technology with external tuff-masonry walls constituted the reconstruction program core-factor, almost automatically applied, and invariably unrelated to the environment and landscape features and to the relevant building damages, as well.

The basis module was a square room of 3.80-3.90 m in side – the so-called "compartment", module itself of the timber framework [14]. Thus, the urban parcel pattern could comprehend a couple or, better, a single residential unit on each short side. Always in accordance with the Naples' Civil Corp of Engineers, the main building typologies consisted in the following three standards: "the ordinary type of four compartments", or "of four" and of two of them (Fig. 6-9). Once accomplished the emergency stage, a lot of "four compartments standard" fabrics were transformed into durable dwellings, by bundling adjacent units enlarged through the privatization of the next street portions and also improved with new small rooms for kitchen and utilities. A new storey and lofts often were added to these so-called "improved huts", while tuff-masonry sidewalls were raised up for insulating them. Only by the mid-twentieth century balconies and wider openings were settled on, too (Fig. 3-4).

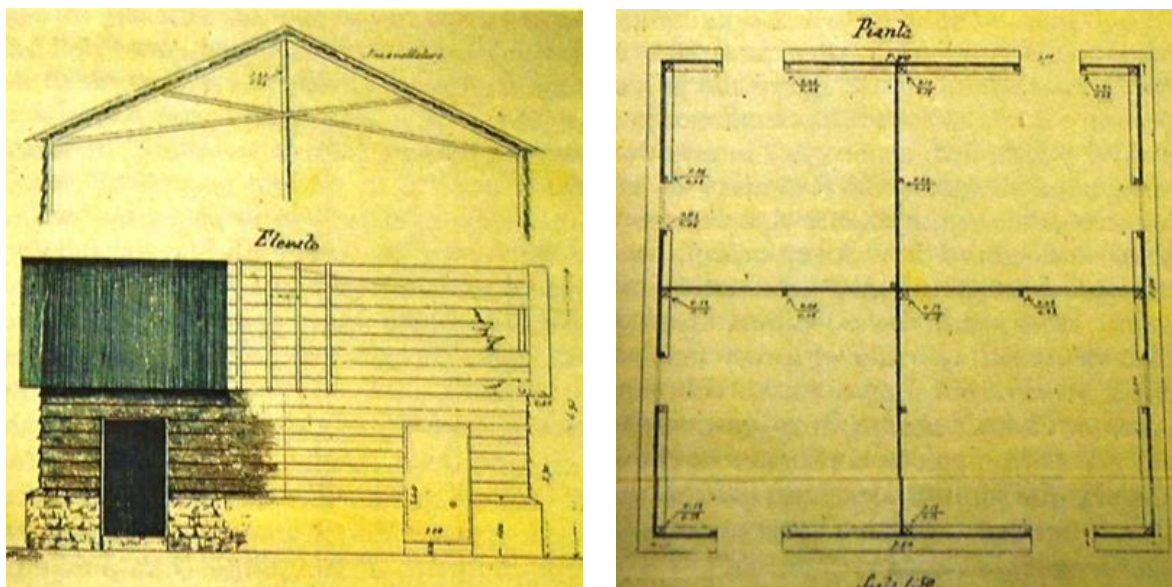

Fig. 6-7: Naples' Civil Corp of Engineers, the Ischia's four compartments ordinary building standard (1883). (Casamicciola Municipality Historical Archive – CMHA)

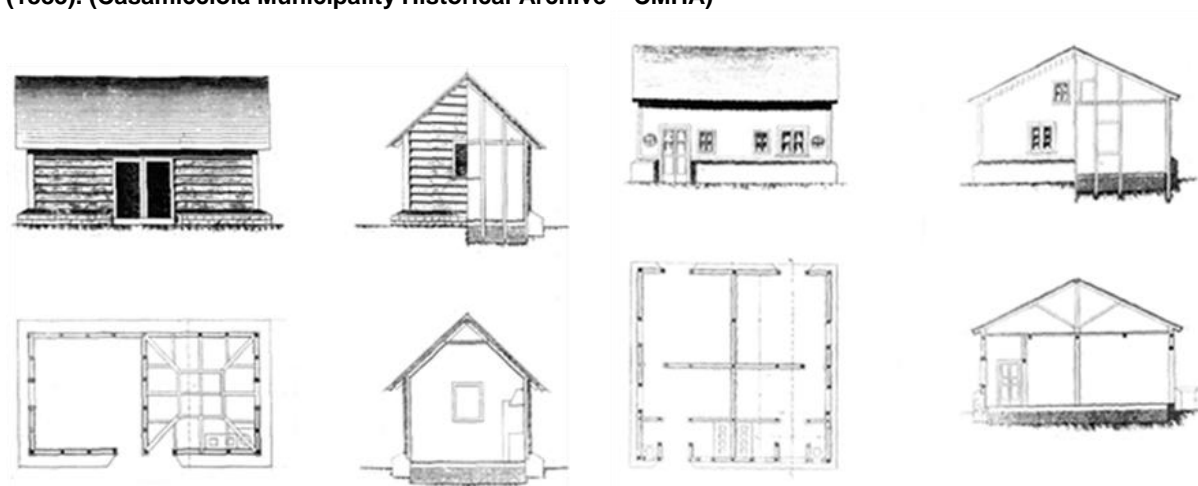

Fig. 8-9: Naples' Civil Corp of Engineers, Ischia's timber-framed building standards (1883) on two (left) and four compartments (right). (CMHA).

Between 1884 and about 1888 the plenty of these building licenses for improving huts into durable lodgings is documented in the Naples' Civil Corp cadastral maps of the new urban sections [15] (Fig. 5). The relevant archival documentation, most unpublished, also consists of many building permission requests, from which taking effective constructive requirements and operational methods [16]. The instructions invariably indicated almost square layouts of 7.90 x 7.50-7.90 m built up with timber frames of fir, formed by vertical and horizontal members (12x12 cm) with cross-inclined posts (trestles) in the voids. Inner siding, rendered nailed boards and tuff-masonry side-walls, plastered as well, completed this structure. Also partitioning were timber-framed, coating by a mortar layer of 10 cm and then rendered too. Instead of the common timber trussis, the smaller roofs could also presented "post and beam" frameworks, covered by boards and corrugated iron, nailed to fir joists ("longherini"). Moreover, all the boards were overlapping each other for at least 3 cm.

Chestnut seemed to have been preferred for existing masonry structure refurbishments and for improving the new post-seismic dwellings with storeys and enlargements. Basing on size, these skeletons were composed by main and secondary piers (respectively, 12x12 and 15x12 cm) with cross-beams (18x15 cm) and 45° cross-inclined posts (10x10 cm). Generally, the "tenon and mortice" joints and the lap links of timbers, as well as the half-lap connections of the roof rafters were reinforced with nails and even iron squares. The tuff-masonry walls were plastered on both side. Roof frameworks didn't provide for any effective differences with the cited ones, being also still in fir. Oral statements of some of the older local building contractors talked about plastered jute tissue inner coating, nailed to timber-frames, rarely substituted by the "wattle and daub" workmanship.

Also the restoration and refurbishment intervention works were leaded by these building criteria. Where the masonry box could be survived, vaults, except the ground ones, raised storeys and thrusting elements were demolished, for erecting timber frames and floors, finished with plastered

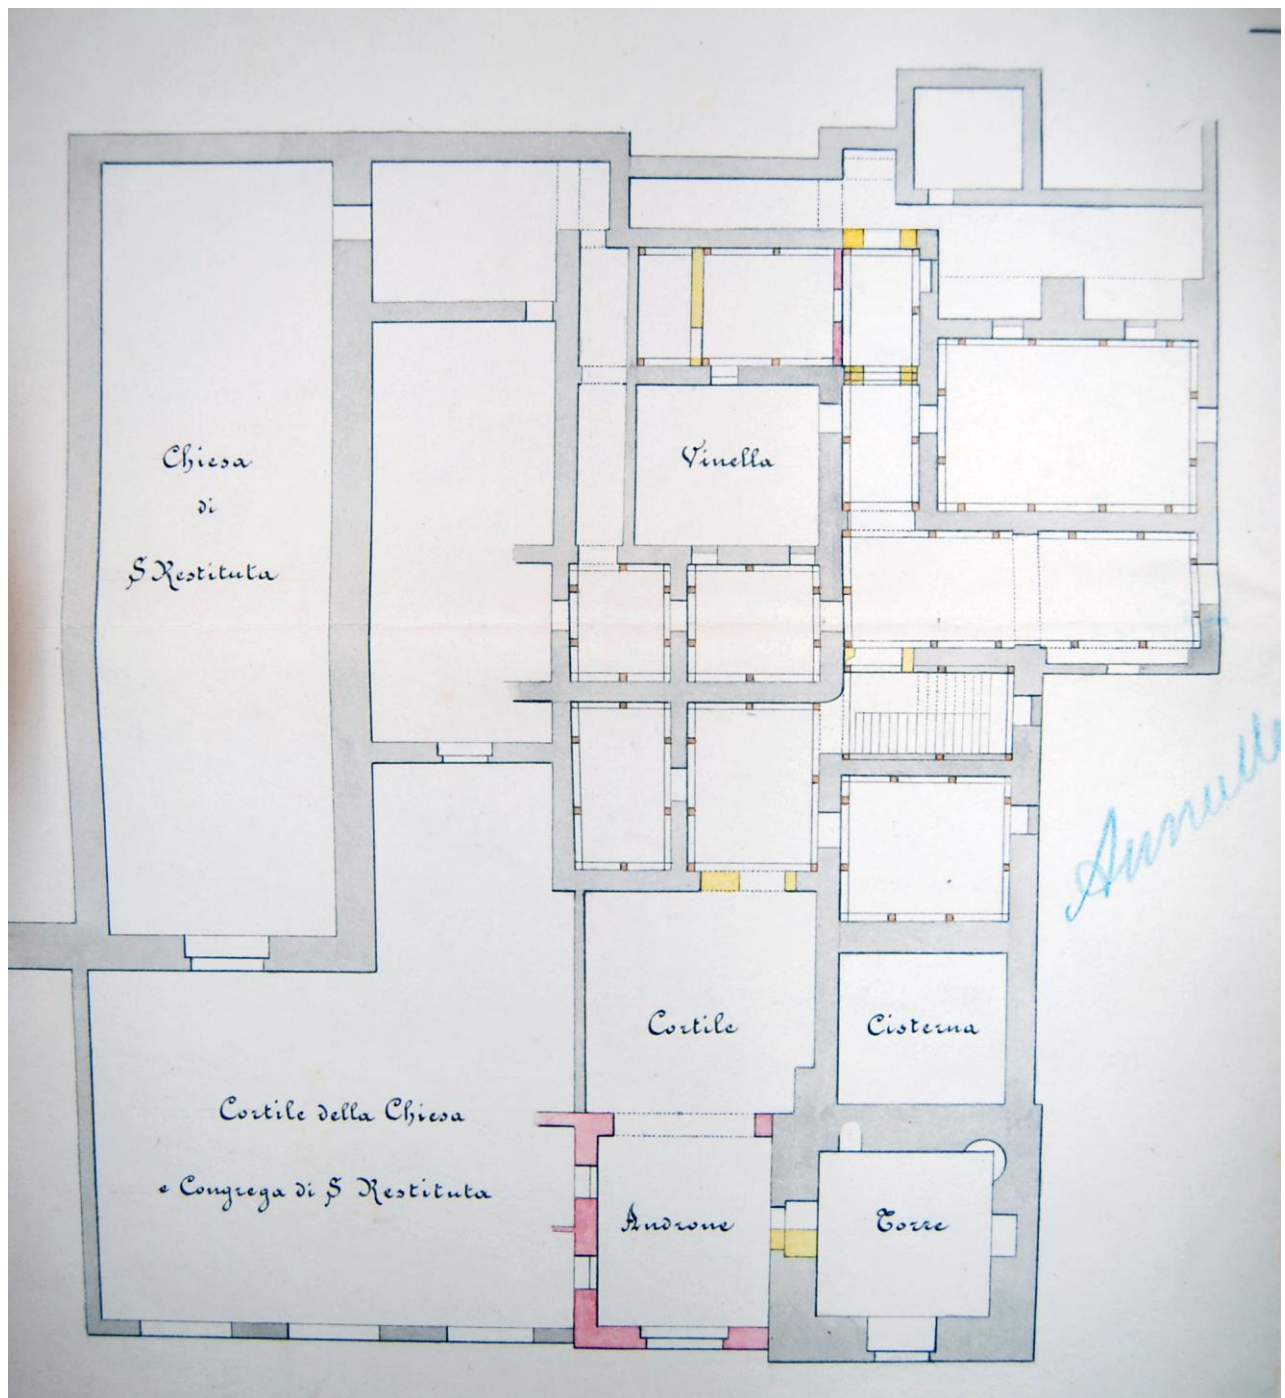

Fig. 10: Ischia, Lacco Ameno, the new town hall design in the former St. Restituta's monastery (1885), ground floor (NaSA).

boards. In Lacco Ameno the reconstruction plan of the St. Restituta church (1885), by the Naples' Civil Corp engineer F. Botta, and the so-called "restoration" program, a refurbishment one indeed, of the city hall in the adjacent former monastery (1888-90) well outlined the cited operational procedures, unconditionally using timber-framed solutions (Figg. 10-11). Since the bigger extent of the church they also laid on iron pointed oak piles, deeply driven into the ground [17].

5. Conclusions

By visual and measured surveying the building, material and measurement features of the Ischia's "baraccato" frameworks still in force, for some samples even observed with the geo-radar prospections, the relevant archival data have been compared and contrasted, highlighting interesting clarifications of the initial operational methods, as well as further fabric modifications undergone [18]. As it can be observed in other historic post-seismic re-built contexts using the timber-framed system – the Calabrian and Sicilian ones of the late 18th century, for instance – some working qualities of the

Fig. 11: Ischia, Lacco Ameno, St. Restituta Church's refurbishment design (1885). The new front.

timber-framed structures are out of line with the pertinent building code, revealing decisive approximations in joints and fixings workmanship, above all [19]. These artefacts earthquake-resistant performance strictly depends on their junctures holding, of course. Thus, inadequate timber joints forcedly entails house-builders and contractors improper acknowledgement of the “baraccato” framework requirements of an effective anti-seismic behaviour. In Casamicciola, Lacco Ameno as well as the other Ischia's districts, even most battered by the 1883's event, the “baraccato” timber frames often display similar improper workmanships of wooden members and joints alike. Posts, cross-beams and 45° inclined cross-bracing of the timber-framed tuff-wall dwellings have been only drawn from chestnut debarked logs indeed, rather than sawn in accordance with the relevant rules. Their size cross-section vary basing on dwelling extent, of course. Some of these timber elements, now taken apart, can be directly survey today, constantly revealing 12 cm in diameter and about 2.30 m in length. As referred above, generally the timber joints are of the “tenon and mortice” kind, also nailed and stiffen with iron squares.

Another common vulnerability of these timber-frameworks concerns their inadequate proofing. At that time for timber-insulating the traditional building culture entailed two or three pitch coats, not easily verifiable in the current fabrics as well as in the archival data [20]. Also about the local tuff-walling some notes must be underlined, due to its improper cross-wise concatenation. As well, the side-walls often lack the ashlar, rather substituted with rough-hewn stones of the local varieties of pumice and tuff - the Ischia's green one. At the end, some archival data also show the timber-framed masonry side-walls could also be fortified by applying on iron cross-beams, fastened with clamps to the timber skeleton. No samples of these, indeed, have been founded by now.

The ideological approach to the study of Italian rural architecture in first half of XX century

Emanuele ZAMPERINI¹, Valentina CINIERI²

Department of Civil Engineering and Architecture, University of Pavia, Italy

⁽¹⁾ emanzamp@yahoo.com

⁽²⁾ valentina.cinieri@gmail.com

Abstract

In Italy between 19th and 20th centuries, the gradual shift from traditional to industrialized agriculture has led to a progressive detachment from secular forms of rural architecture.

Thus a critical study of these architectures started in order to understand the defects and to propose interventions of functional improvement or hygienic renewal; however, the growing interest for this type of architecture meant that researchers began to better understand and appreciate them.

The paper proposes a historical analysis of the phases of initial detachment and of subsequent critical re-evaluation, stressing that they have been deeply influenced by the ideological factors that characterized the 19th and 20th century both at the socio-political and at the architectural levels.

The rural rationalization typical of 19th century positivism was followed at the end of the century by a negative judgment related to the emergence of industry. In the fascist era a first critical re-evaluation was connected to the exaltation of rural life promoted to counteract urbanization and was characterized by the appreciation of essential volumes seen as forerunners of modern architecture. In the postwar, the whole of the anti-fascist parties praised the social values of rural life by promoting architectural neo-realism.

Keywords: Rural buildings, Vernacular architecture, XX century, Italy, ideological approach.

1. Preface

Although starting from the ideal purpose of the representation of an existing reality, any act of study starts from the reality itself to generate a critical discourse that – if properly read – is able to provide a large amount of information about the author of the study, as well as on its object [1].

In architecture, even the simple research based on an indiscriminate and uncritical accumulation of documents related to existing buildings (e.g. by surveying and describing a series of buildings considered as examples independent from each other) tells much of the method and operational tools of its author, through the ways of collecting data. A fortiori a historical research that has as its purpose the search for a system of relationships between these “documents” and between them and their context (geographical, historical, economic, social, ...) is based on the concepts of causality and correlation. Thus it requires the use of the tools of selection and interpretation, both of which involve subjectivity, that is dependence on the personality and intentions of the researcher [2].

The article aims to explain how, in Italy, the ideological currents that developed between the second half of the nineteenth and first of the twentieth centuries have significantly affected the study of rural buildings.

2. “Spontaneous” and “codified” rural architecture

Before getting to the heart of the discourse, it is important to define of the study the object at least in a synthetic manner. Rural architecture is in fact made up of a vast built heritage which includes buildings with different origins and characteristics; the term “rural architecture” is therefore not sufficient to

uniquely identify a homogeneous series of building objects and therefore requires further specifications [3].

The prerequisite to be able to classify a building artefact within the category of rural architecture is that its origin is closely linked to agricultural production or primary processing of agricultural products: thus without doubt the buildings intended for housing farm implements, but also mills, dairy farms, and buildings for providing housing of farm workers and livestock belong to rural architecture. Often, however, in the same building complex or in the same building there are both spaces for agriculture, livestock and housing. Within this class of buildings, a first distinction can be drawn between the rural buildings scattered over the territory and made up of isolated buildings and the one agglomerated in more or less small urban centres [3].

Regarding the ways of the original realization, we instead distinguish between two possible origins, often intertwined and not clearly, nor easily distinguishable, to which the two types of architecture correspond: "spontaneous" architecture and "codified" architecture.

"Spontaneous" architecture arises from the initiative of people in response to their own housing or productive needs; this architecture is built, therefore, by unskilled workers, that are often the same end-user [4]. As a result, the employed construction techniques are linked to a local technological tradition that has developed slowly over centuries, closely related to the nature of the place (material resources, morphological and hydro-geological characteristic, climate) and transmitted from father to son from generation to generation [5]. Through a process of abstraction – due to the simplicity and schematic nature of their shapes – these buildings represented the archetypal idea of home consolidated through the centuries in the common imagination of local people [6] and they have established a solid foundation of empirical knowledge spontaneously revived in new buildings making only minor modifications from time to time [7]. Technologies and building types were born and evolved in adherence to the nature of the place, acquiring a strong local nature; for its strong connection with territory, social structure and local culture, spontaneous buildings are therefore also called "vernacular" [5] and assimilated to dialects [8].

Instead "codified" architecture originates from the ideational action of a specialized individual (master builder, architect, engineer, ...) which conceives the work and other specialized individuals who realize it (craftsmen). "Codified" rural architecture is typical of a proto-capitalist or capitalist economic organization of agriculture, in which the buildings were commissioned by the landowner (e.g. a noble or a religious organization) that granted them in use to those who ran the farm land [4]. Since they do not coincide with the end user, these specialists were not necessarily linked to the place of execution, and could more easily move from one place to another or come into contact with other cultures and architectural techniques, giving life to a more rapid evolution of architectural traditions through learning and interaction, factors that led over time to a higher degree of experimentation. In this category of rural architecture are also some examples of "major" architecture (e.g. Venetian villas designed by Palladio).

3. Ideological approach to rural architecture

3.1 Interest in rural architecture in the second half of 19th century

In Italy, the gradual emergence of capitalistic agriculture has fostered over time many investments for the rationalization of the use of built spaces according to the new techniques of cultivation and for the gradual introduction of improvements in the standards of accommodation for men and livestock.

This rationalization process became more pronounced since the end of the 18th century, when the spread of the spirit of the Enlightenment led to the re-evaluation of technical/practical knowledge applied to productive activities and there was an increase in attention to the topic of rural constructions by skilled technicians.

During this period, the development of hydraulic and the growth of capital investment promoted the reclamation of wetlands and the improvement of irrigation of drylands in order to bring water where the needs of (agricultural, but also manufacturing) production were greater; moreover the growth of mechanical engineering favoured the increase of the efficiency of milling plants.

After the mid nineteenth century, the gradual spread of the positivist spirit and the emergence of hygienist theories [9] led people to take a negative critical attitude towards rural architecture seen as backward and hygienically inadequate [10]; new types of model agricultural complexes were also designed and tested according to the most modern standards of hygiene and technology.

At the same time, the national unification (1861) gave rise to a different cultural debate focused on the formal aspects of architecture rather than on the technical and typological ones.

In the Middle Ages – from the common Roman root from the persistence of pre-Roman roots – under different socio-economic and cultural impulses many local architectural traditions developed; Renaissance led to the gradual recovery of classical architecture and the gradual emergence of an architectural culture that – even in the various local variations – had a common national character.

Through successive stages of diffusion, the classical language – considered an example of order and rationality – finally consolidated in the neoclassical style that reached international diffusion.

Democratic ideals that were born in the cultural context of late 18th century and gradually spread throughout Europe, gave rise to the modern idea of nation and to the principle of self-determination of peoples. This phenomenon was – along with many other cultural factors – the basis for the revival of interest in medieval architecture in its multiple local and national manifestations and for the birth of neo-Romanesque and neo-Gothic revival. In particular, in Italy neo-medieval revival retrieved the different local architectural variety, both in monumental and in popular and vernacular elements.

When the formation of the unified state gave rise to the debate on the national architectural style, the upholders of neo-medieval architecture – among which is essential to remember Camillo Boito [11] – proposed a style that could promote national identity through its local diversities, however, the cultural neo-classical and neo-renaissance trend gradually prevailed and – in accordance with national centralist policies – it tended to cancel local differences in favour of a common and homogeneous identity [12].

In the last decades of the century, large numbers of people moved away from countryside to urban centres of many regions (in which the first big industrial companies were growing) and to foreign countries (mainly North and South America, but also France and Germany), with a significant increase of emigration (about 300'000 people/year in the last years of the century and a total of over 5'000'000 people between 1876 and 1900) [13, 14]. This phenomenon was partly caused by population growth and partly by a crisis of Italian agriculture due to the spread of certain pests of cultivated plants (e.g. grape downy mildew and phylloxera) or of silkworms (pébrine), and to the lowering of prices of agricultural products due to the growth of imports from the new continent [15].

The stagnation of agricultural economy increased the feeling of eternal immobility of large areas of the countryside, this was associated to the corresponding progressive growth of major cities according to modern town planning criteria (e.g. need for railway routes, location of industrial settlements, hygienic and sanitary criteria, real estate speculation). In this context, the gap perceived between the two worlds grew enormously, resulting in a progressive cessation of architects' interest in the vitality of vernacular buildings, now deemed incapable of providing useful lessons to modern architecture.

The indifference of architects began gradually to be joined by a new kind of interest in the exotic and picturesque character of rural life and – consequently – of rural architecture.

Since the mid 19th century, explorations had arisen knowledge interest of the "primitive" cultures of Asia and Africa, giving birth to ethnology, a new science whose birth is «linked to the formation of colonial empires, with the interests of joint control of peoples subjugated by the colonizing nations» [16]. In Italy – more than in other European countries – the large cultural gap between urban and rural society of some part of the country favoured the application of ethnographic studies to the local reality. Ethnographic studies pointed their own attention mainly on folkloristic and cultural aspects of agricultural life and only by reflex of architecture, giving rise to a systematic collection of data and materials which were gathered in museum collections and temporary exhibitions.

These studies took shape in isolated attempts of reconstructing vernacular buildings or urban environments, however, limited to demonstrative contexts and almost never applied to contexts of contemporary life. For example, the castle and the village of Valentino in Turin (1882-1884) [17], the Neo-Gothic village of Grazzano Visconti (begun in 1906) [18], and examples of vernacular buildings from each Italian region constructed for Exhibition of Italian ethnography (realized in 1911 for the 50th anniversary Italian national unification) [12] belong to this category of interventions.

3.2 The ruralist policy of the fascist period and the rediscovery of vernacular

The First World War was, in some ways, a turning point with regard to the attention given to rural culture and architecture: the enormous social and economic damage caused by the war put a strain to the values of the *Belle époque* and undermined the foundations of the positivistic trust in progress and modern technique [19]. Therefore, a revival of interest in vernacular culture and art took place.

In architecture, this resurgence of interest is demonstrated by La Garbatella and Aniene districts in Rome, designed under the direction of Gustavo Giovannoni and whose urban organization was inspired by the English garden cities; in these districts buildings are characterized by forms and decorative details taken from rustic architecture. Marcello Piacentini himself (who in the 1930s would become the standard-bearer of monumentalism architecture) between the late 1910s and early 1920s designed several residential buildings inspired by the shapes and materials of architecture minor [12].

The main contribution of this renewed interest, however, is due to the first systematic applications of geographical research to the study of rural architecture. Unlike the aforementioned ethnological inquiries, geographical studies on rural house tended to further integrate the analysis of formal and cultural factors with economic factors related to agricultural production and with environmental conditions and topographical context, extending, finally, also to the study of historical evolution [20]. These geographical studies – for several decades already active in many central and northern Europe

countries – were promoted in Italy by Renato Biasutti starting from 1924, before the affirmation of the «mythical ruralism which affected the nation» since the late years of the decade [21].

Another key aspect of this period was the rise of the Fascist regime, into whose origins some of the reasons for the Italian agricultural policy between the two world wars can be traced. The years following the First World War were characterized by a deep economic and social crisis – linked to the depletion of war orders, to the unavailability of raw materials, and to the outstanding public debt – which caused the failure of many minor industries [22].

This moment of crisis gave start to union protests both in industrial cities and in rural areas of northern Italy, characterized by capitalistic farms. These protests aroused among industrialists and landowners the fear of a communist revolution. To this period of social instability – which was named red biennium – the petty and middle bourgeoisie reacted by supporting the fascist squads that helped put an end to union demands with violence [19, 23].

The credit acquired by the fascist movement in this situation favoured its rise to power in 1922 following the March on Rome. The slogans promoted by the regime in this period were marked by a spirit of renewal and modernity; between 1922 and 1925, fascist policies were aimed at promoting economic recovery through the reduction of taxes on industries and higher social classes and at the moderation of wages, in order to reduce production costs and promote export at the expense of domestic working classes well-being [22].

Following this phase of economic recovery, the Fascist regime began to promote agriculture and to strongly foster the social class of landowners, who was among the supporters of its rise to power. In 1925 Mussolini gave start to the so-called "battle of the grain" – a plan to increase the production of wheat and «to liberate Italian people from the bondage of stranger bread Italian» [24] – and to plans for reclamation of swampy areas of the national territory [23] in order to gain new lands for agriculture and to prevent malaria [25].

In the following years a anti-urban and ruralist campaign was also promoted: its motivations were manifold and manifold its relapses. In addition to the aforementioned independence from food imports (considered to be essential in time of war), another openly declared reason was demographic: in fact, it was believed that the urban population had lower fertility rates than rural one. Therefore, the reduction of migration from countryside to cities would have to ensure the stability of demographic growth and allow for a population growth; the aim was to make national inhabitants approach or exceed in number the population of other large European countries [26]. In the ideas of the regime the containment of migration towards cities would have allowed also to reduce the need for investments in the construction sector [27] therefore they could be concentrated in agricultural and industrial production – vital to the war effort – encouraging productivity improvements [28].

However another motivation – never explicitly mentioned in official speeches – was the need to reduce the risks associated with the presence of large amounts of unemployed in the cities, which could have encouraged strikes and uprisings, and instead of keeping the population in rural areas where it was most easy to regiment it in the ranks of the regime through the corporatist unionism [19].

Fig. 1: From left to right: poster of the "Battle for Grain" (1925), cover of an issue of the journal *La conquista della terra* (The conquest of land), showing Mussolini in the act of harvesting wheat (Duilio Cambellotti, 1938) and poster of the land improvement of Pontine Marshes (Duilio Cambellotti, 1936).

Fig. 2: Farm "Bainsizza" in the municipality of Latina (formerly Littoria), founded in 1932 in Pontine Marches.

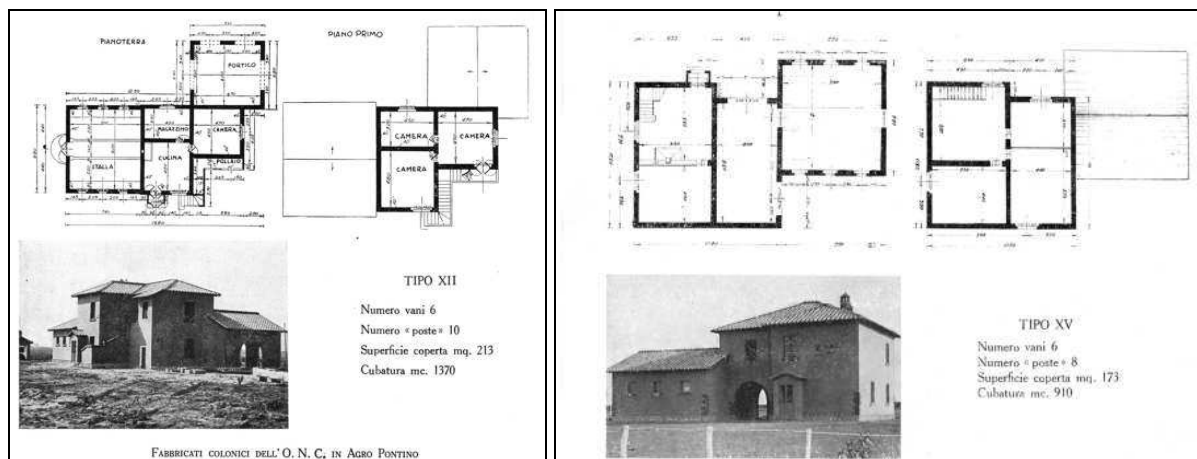

Fig. 3: Standard plan for small farmhouses in the municipality of Latina (formerly Littoria), in Pontine Marches.

In this context begins - and continues until the beginning of World War II - the policy of colonization of reclaimed campaigns and of establishment of new settlements in the service of agricultural production. The main example of this policy is the reclamation of the Pontine marshes: at the end of the first district land reclamation, officials of the National Opera Fighters (body responsible for the reclamation) had to face the problem of the organization of the agricultural system; they opted for the fragmentation of the territory in small size farms entrusting the management to sharecroppers, each of which corresponded to a farmhouse [29]. The choice of small family-run units was also aimed at maintaining the social unit formed by the patriarchal family, which – with its system of rules and discipline – was a greater guarantee of social stability compared to larger farms, in which many farm labourers were present and therefore a greater number of family units not related by blood had to cohabit [23].

The promoters of the reclamation believed that colonization would have failed without the reference of urban entities therefore, the territorial system of Pontine reclamation areas was organized on various hierarchical levels: the scattered settlements – constituting the basic unit of the system – were hierarchically subject to the villages, which they referred from the administrative point of view and for key services and these, in turn, were subjected to a city [29].

The materials used in the construction of farm houses and rural buildings were the traditional ones (local stone, brick, wood, plastered mats of reeds, etc.) and the buildings were constructed following some models developed depending on the location and size of the household. With a historicist approach, the architecture of these houses resumed, by stylizing and trivializing them, many morphological elements considered archetypal (arc, external staircase, chimney) [30] in order to elicit a traditional image of simplicity and modesty and to encourage immediate recognition by the settlers [29]. Even in the development of the newly founded cities, formal references were almost always rural, thanks to the use of «a traditional rural village image» [31].

At the same time, since the first post-war period abroad a new architectural trend was establishing itself. Its demands were summarized in five points by Le Corbusier (pilotis, roof garden, free design of ground plan, free design of façade, horizontal window) [32]. Proponents of modern architecture refused the reference to history as a tool for the project, but at the same time many of them drew from

the history of architecture essential cues for their architectural poetics; in fact, many architects were inspired by Mediterranean vernacular architecture, but they operated in an ahistorical way, i.e. taking their references as formal models that could be decontextualized and exported to any place and, therefore, used without a connection neither with local characters, nor with climate, nor with building traditions.

In Italy, the link with history was more alive and declared in all the architectural trends. The unequivocal historicism of the monumentalist and ruralist architects is accompanied by the explicit Mediterraneanism of many rationalist architects (e.g. Adalberto Libera, BBPR, Figini and Pollini) [12]. Since the mid-1920s, these architects emphasized the Mediterranean origin of many of the formal components of modern architecture (flat roof, volumetric simplicity, white surfaces, absence of ornamentation) for the purpose of exalting the Italian character of their own architecture, which the promoters of an enduring classicism charged with xenophilia [33], however they confirmed the substance of the unhistorical and decontextualizing design method of modern international architecture.

However, in the 1930s a new approach to the study of vernacular architecture started as a reference for modern architectural design. The leader of this new approach was Giuseppe Pagano, an active member of the fascist party – but later a socialist partisan during the Second World War – and the director of *Casabella* magazine (1933-43). From the pages of the magazine he edited, Pagano strongly opposed to the rhetoric monumentalist drift of the "official" architecture of the fascist regime, but also to the personal formal studies of most of the other modern architects, considered as a form of mannerist drift from rationalism [34].

A key moment in Pagano's research was the exhibition *Architettura rurale italiana* – staged together with Werner Daniel in the *Triennale di Milano* in 1936 – in which they exposed photos of many rural buildings from all over Italy, divided by region and by functional and constructive type, but without reference to the construction dates.

Pagano saw vernacular architecture as the emblem of essentiality and rational design; the absence of reference to the historicity of the proposed buildings was suitable for enhancing their nature of examples of «collective and anonymous» [35] design synthesis between context, form and function and to shield them from the stylistic and historicist approach to architecture.

In addition, the study of vernacular architecture in its many local expressions became for Pagano the research for «a more concrete and less abstract national style» (far both from the monumentality and from the picturesque) [12], but also for the principles of «respect of money, abolition of superfluous, morality» summarized in the concept of "modesty" [36].

However, as a whole the period of the fascist regime showed a strong discrepancy between the rhetoric ruralist proclamations and the reality of a progressive and constant urban growth [37].

Between the end of the 1920s and 1930s, the effects of fluctuating domestic economic conditions and of the great international crisis of 1929 caused the fall in the prices of agricultural products [22], resulting in underemployment and in a decline in domestic consumption. This aspect and the awareness that the development of a modern industrial sector was essential to implement the projects of imperial expansion, urged the regime to invest in industrial development plans [23].

Although the manufacturing sector with the highest number of employees continued to be agriculture, on average, in the 1930s the living conditions of rural population worsened and the phenomena of depopulation of countryside and industrial urbanization (i.e. those that the ruralist policy was intended to counteract) were strengthened. The size of the cities grew significantly, but the lack of funding (focused on agriculture and on war related industry) to public housing determined a severe lodging shortage and therefore precarious housing conditions.

In addition, as a result of the progressive rise of colonial policy and after the founding of the empire (1936), over the years also the architectural image of the regime show a gradual marginalization of modernist and ruralist trends and linked itself to the monumentalist architecture with classical inspiration [36].

3.3 The critical recovery of rural architecture in the postwar

At the end of the Second World War, Italy was still an essentially agricultural country with a low level of industrialization, aggravated by war damages [38]. The high rate of unemployment among veterans drove the new republican state to entrust the task of absorb unskilled labour to building, thus discouraging the technological progress of the construction industry and encouraging immigration from rural areas [39].

Building activity in this period involved primarily the major urban centres, both in order to remedy the damage of the war, and due to the critical condition – that we have already described – in which social housing was because of the policies of the previous two decades [40].

However, interventions on historic centres were not limited only to areas damaged by bombardments, but they were extended to many neighbourhoods that were considered hygienically unhealthy, with the declared purposes of building renewal and the latent goal of property speculation. This situation led to

the gentrification of the redeveloped areas with the systematic expulsion of humbler social classes towards newly built suburban neighbourhoods [41], generating a devastating impact on the social fabric of the historic city.

In the general climate of the building and moral reconstruction of the country the cultural current of neo-realism developed. It was characterized by «a sort of celebration of the dignity of deprivation» [31] and it involved various forms of artistic production, including architecture. The recourse to neo-realism was a polemic act against the arrogance of fascist rhetorical excesses [36] and was promoted by both of the major political and cultural currents emerged victorious from the Civil War: the Christian Democratic and the Communist.

In architecture, neo-realism was certainly the outcome of the rejection of the monumentalist rhetoric dominant in architecture during the fascist regime, but it was also reconnected to the movement for organic architecture, sponsored by Bruno Zevi in the years after World War II in the wake of the North American and Scandinavian experiences [39].

Many suburbs – built to accommodate the displaced from the historic centres bombed or "redeveloped" as well as the first groups of immigrants from the countryside – were designed by resorting to the realization of low rise building volumes, organized according to organic and informal planimetric schemes in an attempt to recreate housing and environmental conditions similar to those of traditional rural villages [39]. The morphological and stylistic reference to rural architecture was not a simple formal research, but it was connected to a re-evaluation of psychological and social aspects of the population, in order to protect individuals from the alienation that would have resulted from the total distortion of their ways of living, in the conviction of the close connection between the physical environment and the human environment [42].

Therefore the formal and morphological research that starts from the study of rural architecture is aimed at bringing attention to the individuals, no longer seen as impersonal components of a mass regimented in totalitarian assemblies, but as vital reality studied in its socio-cultural aspects.

One of the key moments in the birth of architectural neo-realism and in the new attitude towards rural architecture was the study of the architectural and social reality of the Sassi of Matera. This complex of cave dwellings of great historical interest – declared UNESCO World Heritage Site in 1993 – became a symbol of urban decay in southern Italy after some research brought to light the poor hygienic and housing conditions due to the lack of modern sanitation, to overcrowding and to cohabitation between humans and animals [43].

The research undertaken had led to the understanding of the social structure of the population of the Sassi, that was discovered to be strictly related with the morphology of the settlement. Characteristic element of this reality was the "neighbourhood unit", that is the social relationship between the group of families whose homes faced the same public space, in which a large part of their social life took place. [8]

The knowledge of the social reality became a design tool when the rehabilitation requirements led to the need for evacuation of the inhabitants and for their transfer in newly founded neighbourhoods and villages built closer to the land cultivated by the population: in the construction of the *La Martella* village between 1951 and '54, the designers (Ludovico Quaroni, Federico Gorio, Michele Valori, Piero Maria Lugli, and Luigi Agati) organized the buildings according to the contour lines of the land as to enter in an organic relation with it and attempted to produce an architectural environment capable of perpetuating the system of social relations that characterized the life in the Sassi [44, 45].

In the second half of the 1950s the so-called "economic miracle" took place: a radical process of economic, social and housing transformation. This phenomenon was combined with a rapid development of the industrial sector favoured by the influx of cheap manpower in urban areas as a result of decline in employment in agriculture. The economic miracle caused and at the same time was powered by a mass migration from the countryside to cities and from the poorest South, to the more industrialized North, which resulted in a construction boom that doubled the urban fabric of the major cities during only twenty-five years (1946-1971) [46].

Large transfers from one region to another, the extension of compulsory schooling to eight years, the spread of television have contributed to a sharp decline of traditional culture, which had markedly different character from region to region and from place to place, and which was directly handed down from generation to generation. These phenomena have produced a progressive cultural homogenization that has configured as a real anthropological break [5].

In this context, there has been a profound change in housing needs and, consequently, in building standards, which, combined with the desire to move away from a past of poverty seen as something to be ashamed of, led to a rejection of the vernacular building and in particular of the rural ones [5].

In the following years this refusal meant that the studies on rural architecture, returned to being relegated to historical-geographical research, moving them away from the relationship – that had developed over the previous decades – with modern architectural design.

Fig. 4: View of popular housing INA-Casa *Tiburtino* in Rome (project coordinators: Ludovico Quaroni and Mario Ridolfi, 1949-1954), published in the journal *Casabella-Continuità* n.215, 1957

4. Conclusions

The article pointed out that the evolution of the ways of approaching the study of rural architecture has always been closely linked to the cultural and political ideologies that have occurred over time. Indeed during the analysed period, the focus on rural architecture has changed repeatedly over time involving different researchers (engineers, ethnologists, geographers, architects, ...) and passing from an initial negative opinion and desire to reform, to a superficial interest for its folkloristic and picturesque character, to achieve progressively a wider interest for fundamental aspects of its nature (essentiality and functional rationality, relationship with the environment and correspondence between built environment and social forms) in order to revive them in the design of contemporary architecture. Today, heritage rural architectural has undergone a process of decay and de-contextualization as a result of the extinction of the traditional agricultural world. The one who had to begin the study of these architectures would be in need of basing a significant part of his knowledge on secondary sources created in the period analyzed in the paper; the research summarized in the paper can then help them gain a critical look at these sources openly denouncing their historicity, that is the connection with ideologies and research methods of the different periods.

Design Tools and methods for the enhancement of cultural itineraries and thematic cross-border pathways

Roberto de PAOLIS¹

⁽¹⁾ Department of Design, School of Design, Politecnico di Milano, Milano, Italy

E-mail: roberto.depaolis@polimi.it

Abstract

The aim of this research project is to reinforce the shared identity of Northern Lombardy (Italy) and Southern Ticino (Switzerland) by preserving and enhancing the shared cultural heritage present in the historical network of footpaths that connect the regions concerned. By synergizing experts in cultural itineraries, municipalities, landscape designers, geomatics engineers, architects and designers, the project seeks to pursue this aim through the protection and enhancement of the local heritage of areas crossed by the paths, integrating promotional activities to raise awareness among the public and encouraging people to get to know and use the trails. This historical trail network, categorized according to the different functions of the anthropogenic structures (transit routes and population migration, devotional trails (art and faith), connections between villages in the valley and high altitude pastures, forestry and rural micro-economies (local food and wine production), is investigated participatively with extensive use of ICT and the computerized management of spatial and environmental information.

Keywords: Design, Heritage, Landscape, Routes, Tourism

1. Background and overall scenario

This research is part of a wider cross-border program, the aim of which is to implement measures to protect, enhance and promote the landscape and the historical and cultural heritage of the area.

In addition to the Politecnico di Milano in the role of leader, the partners in the program are: the Fondazione Politecnico di Milano, Iubilantes Association, Mountain Community Lario Intelvese, University of Applied Sciences of Italian Switzerland, Office of Cultural Heritage of Cantone Ticino, Mountain Community Lake Como and Lugano valleys, Museum of Via Spluga, Town of Cernobbio, University of Pavia.

The “Via Regina Lariana”, from Como to Sorico, is one of the oldest routes of historic and cultural exchange between Italy and Switzerland. The beautiful Swiss-Italian footpath along the Via Francisca and Via Spluga, with which it forms a continuum, is a fundamental “system” of transalpine soft mobility, the potential of which for European development has so far not been adequately grasped. It possesses all the characteristics required to be identified as part of a Major European Cultural Route [1]: a trail and a territory, therefore, to know and to protect, and to maintain intact for those who travel on foot.

The specific objective of this project, called “I CAMMINI DELLA REGINA”, ID 33829732, Misura 3.1, P.O. Cooperazione Transfrontaliera – INTERREG IT-CH 2007-2013”, born from the synergy between cultural experts, local museums, government departments, landscape designers, architects, designers and geomatics engineers, is to create an adequate tool for the full development of this important route and the surrounding area.

Fig. 2: From “Tabula Peutingeriana”. The route from Bergomum to Comum.

2 . Historical Background

The name *Via Regina* is commonly used to refer to the road which starts at Como and keeping to the west of the city continues along the lakeside to the top of the lake itself, at the Ponte del Passo. Here begins the valley road, opened in 1837, to Chiavenna, which from here climbs the mountainous foothills up to the Spluga and beyond, to Chur. However, the road from Dongo on Lake Como that climbs up to the pass of San Jorio and continues through Switzerland to Bellinzona is also called *Via Regina*.

Known since the Middle Ages, the name of this road appears in documents in various forms: sometimes *Via Regia* (1256), at times *Strada Regina* or *Via Regale* (1352). Whatever form it takes, the name simply indicates that this is the main route, with minor ramifications. It is however understandable that the name *Regina* has often brought to mind Queen Theodolinda, to whom we owe the development of the region after the Lombard occupation, and who is credited with rebuilding many stretches of this road.

The road is also documented in the *tabulae geographicae*, Roman military maps that have come down to us under the name of “Tabula Peutingeriana”. The Romans marched towards the Alps and their crossing points by this route, starting from *Novum Comum*, the new city built on the shores of the lake by Julius Caesar between the years 89 and 59 BC, inhabited by 5,000 settlers including 500 Greek nobles.

There is considerable documentation of inhabited places along the Via Regina in Roman times. This mainly consists of inscriptions, but there are also archaeological remains, including some fine mosaics and traces of fortifications erected during the decline of the Roman Empire, when the increasing pressure from barbarians called for greater defense of the territory. These findings are still visible in the area, or preserved at the Archaeological Civic Museum of Como. In the twelfth century Barbarossa marched both to and from Milan along the Via Regina.

Maintenance obligations for the road, and also the eastern shore of the lake and its hinterland in Ticino, were settled by the *Statuti Comensi* (1335), to which the various municipalities located along the Via Regina had to submit, testifying to the importance of the road for the entire region of Lake Como.

Paolo Giovio refers to the *Strada Regia* in his book *Larius*, written in 1537.

3 . Objectives of the project

The aim of this research project is to reinforce the shared identity of Northern Lombardy (Italy) and Southern Ticino (Switzerland) by preserving and enhancing the shared cultural heritage present in the historical network of footpaths that connect the regions concerned. By synergizing experts in cultural itineraries, municipalities, landscape designers, geomatics engineers, architects and designers, the project seeks to pursue this aim through the protection and enhancement of the local heritage of areas crossed by the paths, integrating promotional activities to raise awareness among the public and encouraging people to get to know and use the trails. This historical trail network, categorized according to the different functions of the anthropogenic structures (transit routes and population migration, devotional trails (art and faith), connections between villages in the valley and high altitude pastures, forestry and rural micro-economies (local food and wine production), is investigated participatively with extensive use of ICT and the computerized management of spatial and environmental information.

In this context, design plays a strategic role in guiding surveying activities and the recovery, protection, enhancement and reuse of the architectural heritage and landscape of cultural interest (buildings, arts, historical documents), with particular regard to the thematic itinerary of the "Via Regina", which runs from Como to the Splügen Pass, and therefore between Italy and Switzerland. This is a fundamental system of transalpine pathways characterized by slow mobility, of which the potential for European development has not yet been adequately grasped.

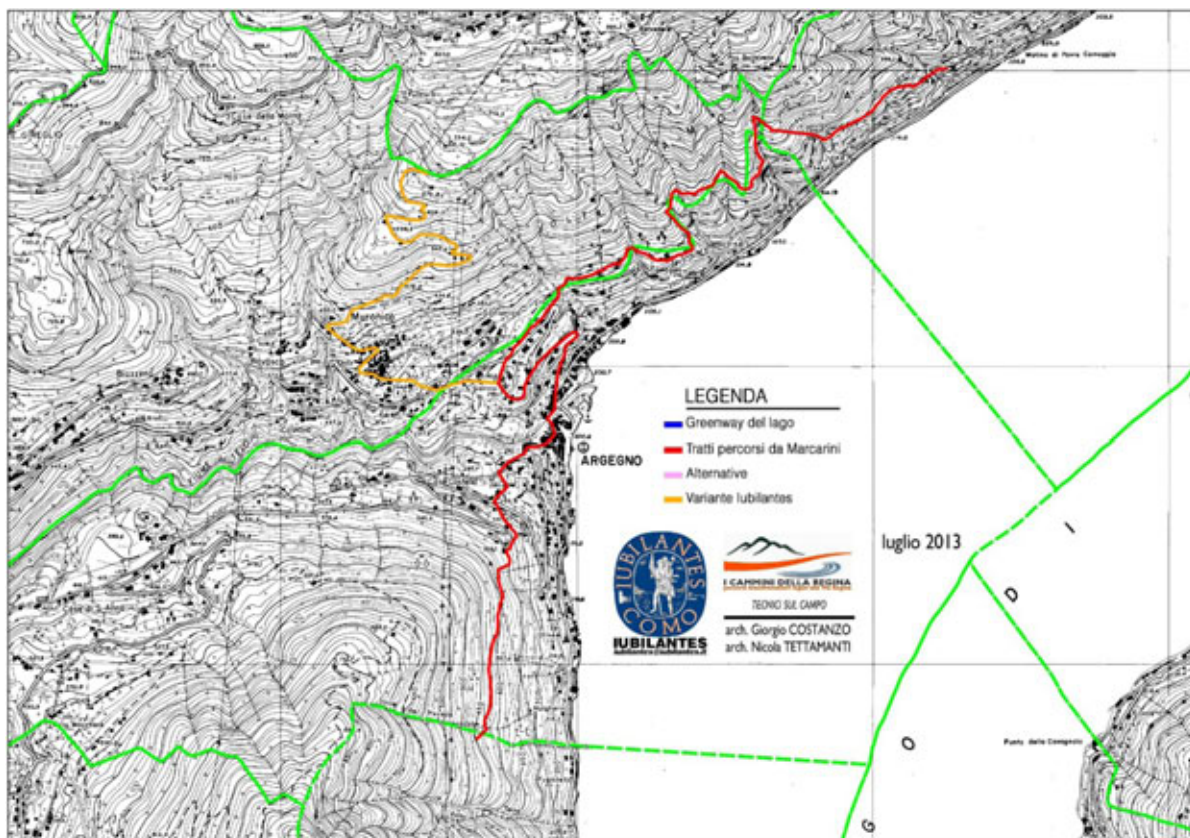

Fig. 3: Map of the area used to carry out survey operations, indicating the pathway (or its alternatives), which was. In particular, it highlights the stretch that runs through the town of Argegno.

Fig. 4: The board used to collect information in the survey divided into three categories: historical and cultural elements, morphological elements, tourism elements. Each category is split up into detailed sub-categories. All information has been transferred to digital data base. On the right are some pictures of the photographic survey of the Ossuccio area.

4 . Recipients and expected impact.

The main beneficiaries of the project are the local communities who are invited to rediscover and enhance the potential of their territories through integrated methods of acquiring new knowledge and experience. These combine historical traditions with the innovations and devices of information technology and communication, which enable collaborative participation.

A further aim of the project is to reconnect the system of footpaths with wider thoroughfares in the great tradition of European cultural routes (Via Francigena, etc.). This will benefit walkers, whether locals or visitors, who will be able to enjoy accessible, safe, scenic routes immersed in nature and spectacular landscape.

Re-opening these pathways will help local and cross-border communities rediscover past values and build new hopes for the future in the traditions and cultures that unite people who are today separated by a land border but are aware of belonging to a broader, shared heritage.

Tour operators will be able to use the new and more flexible tools for information and promotion provided by new technologies.

Young people will be attracted by the new technologies that provide them with more immediate sources of knowledge and access to new job opportunities.

The future establishment of information points along the route or the re-use of toll booths , stations , religious structures , customs facilities and farm buildings, as places of information and refreshment may also impact on the job sector, by training professional figures dedicated to the care and maintenance of paths, assistance to walkers / pilgrims; the management and organization of visits, accompanying guided tours, etc.

In short, the project has the following specific objectives:

- to compare methodologies and experiences of safeguarding assets, heritage and cultural landscape, particularly the axes of pedestrian border crossings, and artifacts found along these pathways;
- the physical regeneration, restoration and maintenance of sections of footpaths, bridleways, pavements and buildings present on the ancient roads (toll plazas, fountains, gravel stream beds, fords, old roadhouses, customs facilities, hospitality and reception sites in general) and religious buildings (churches, shrines, canonical pathways votive chapels) can be valued as such or reutilised as in the case of canonical functional structures, such as paths and / or reception facilities;
- to support collaboration, exchange and mobility between operators and between cultural institutions, strengthening links and exchange of experiences in research and the identification of best practices carried out by the various parties in the specific context ;

- to promote the recovery and enhancement of the peculiarities of local cultures and the use of innovative tools for communication and promotion of cultural heritage and historical memory of the border.

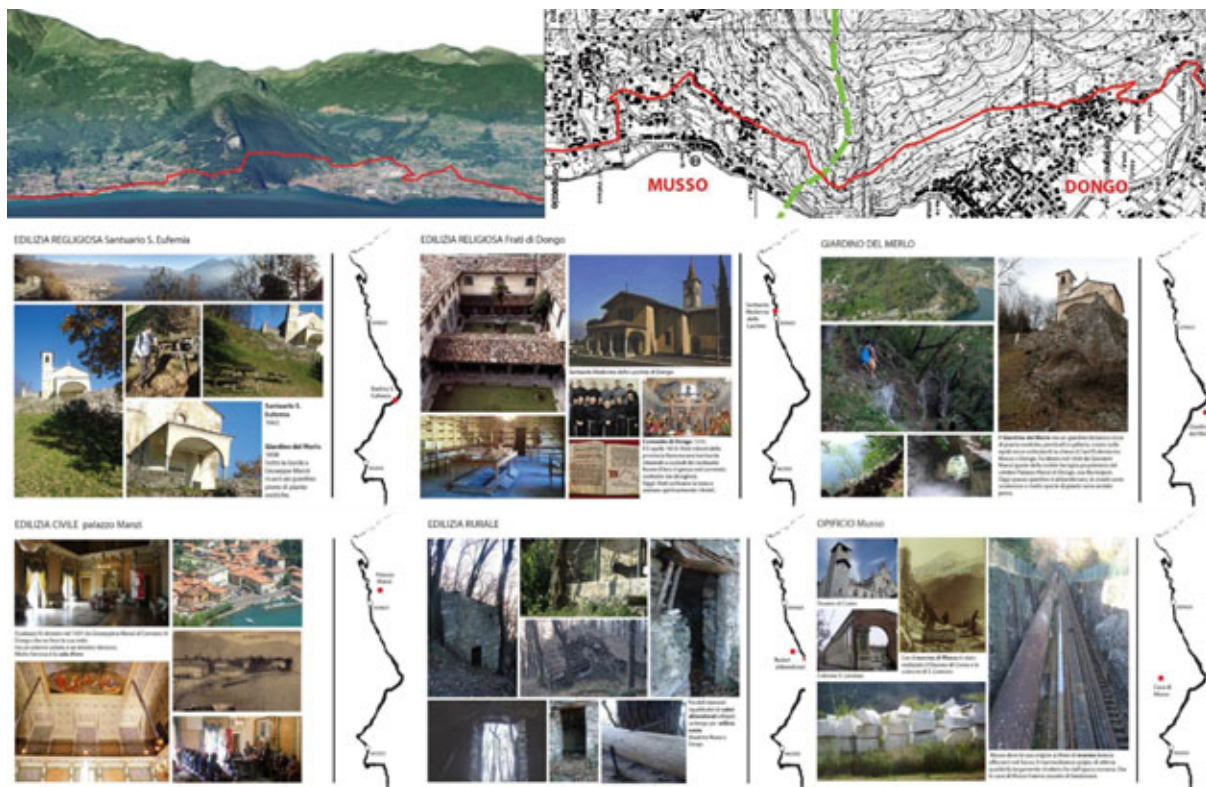

Fig. 5: Summary of significant survey operations between the towns of Dongo and Musso returned with summary tables showing the characteristic points and highlights of the area. These include pre-existing buildings and religious convents, and important material or work related findings (e.g. the marble quarries of Musso), and fine gardens which are characterized by a unique lake climate which fosters the growth of tropical plants. Analysis gathered by Fabio Ferrara, Luca Carbone, Diego D'Angelo.

5 . Description of the project: the contribution of design

This document describes the objectives, the methodology used and the first results obtained by the design research team at the Politecnico di Milano.

The research team, which operated in coordination and interaction with the other two units of the Politecnico di Milano, respectively devoted to geomatics and cultural heritage conservation, has offered a contribution on two different, interrelated levels.

In terms of analysis, a methodology for detecting and reading the connotative elements of the area was defined (divided into three categories: historical and cultural elements , morphological elements, tourist elements). A benchmarking exercise was carried out in relation to similar experiences in communication design, analyzing: best practices, target audiences, user samples, user needs and ease of access to the trails, and the detection of user needs by the system. All of this resulted in a meta-design and the definition of reference design scenarios .

In terms of the project, a first contribution was made in the strategic design of products and services in its widest commodity-related applications, which range from product to furnishings, temporary installations, visual communication and media, and in communicative artifact design, with particular reference to the role that design plays in appraising promoting and developing cultural and environmental heritage .

The research team dealt with issues relating to the reading of morphological elements that characterize the environment (materials, types of structure found in areas of human activity and along the pathways), identifying taxonomies and meta-planning scenarios for the concept designing process.

Mapping and spatial analysis of best practices was undertaken in relation to the network of historical "trails" "corridors" and eco museums, and their possible implications for the Italian and Swiss territory .

In addition, it was decided to collect and systemize initiatives already undertaken, or in progress, by different actors and institutions, including those in other INTERREG programs.

The research group has been involved in drafting the integrated visual communication (brand identity) that will identify the values expressed by evidence of visual and material culture in the area. They have designed products and services and communication artifacts (creating logos and trademarks, signage, information points, manuals, visual identity, objects, interfaces, and digital publishing products), taking into account the regulations on signs to slow traffic widespread in Switzerland.

Fig. 6: Designs by Alessandro Grasso, Dania Barbin, Sara Flamigni for the recovery of the pathways that from Cernobbio, climb Mount Bisbino reach Carate Urio. They are proposed enhancements for the Museum of World War I, the reuse of the stone quarries of Moltrasio and shelter for the famous "Bisbino horses" a breed that lives in absolute freedom.

Fig. 7: Between the towns of Ossuccio, Lenno and Mezzegra, where the particular climatic conditions have historically permitted a flourishing production of olive oil, Sara Gabbioni, Alice Conti, Sara Biasini, Chiara Berbenni devised a pathway equipped for folk events based on olive oil tasting and buying local products.

The phase currently being drafted includes, *inter alia* :

- definition of the territorial brand identity;
- identification of integrated tourist routes;
- creation of a network for the re-development of the former barracks of the Guardia di Finanza, located along the Swiss-Italian border, as "stations" in an ecomuseum (dedicated to travel related services and information, insights and 'portable' cultural museum experiences of local production and cultural excellence, mobility services and hospitality, local food and wine, etc.) and as a dining and reception area for visitors;
- graphic design of vertical and horizontal tourist signs and the media through which to apply them;
- creation of an informative totem / a first aid kit distributor;
- graphic design, promotional paper (brochure / guide, pocket maps, flyers, postcards) and digital (Apps depth on routes, dining areas, first aid);
- planning/teaching an International University project workshop (summer school) for the development of design scenarios for the dissemination of good practice, to be implemented in the context of academic degree courses and open to schools of architecture, design and landscape design. The theme of the workshop will be the development of a strategic plan for the enhancement of "cross-border trails" in view of Expo 2015.

6. Impact on university teaching: experimentation of educational models

The theme of the project was also proposed in the teaching program for undergraduate students at the Politecnico di Milano who were attending the Degree Program in Product Design, Furniture orientation, Como Campus [2]. On the basis of information generated in the initial phase of field research and analysis, together with autonomous research on the area carried out by students (using surveys, photographic documentation, interviews, literature research, dialogues with institutions, libraries, on-site visits, inspections, and user-safety tests on the route itself), groups of undergraduate students were assigned the development of design proposals along the entire route of the Via Regina, which runs from the town of Cernobbio to the town of Sorico.

10 areas have so far been studied, assigned to as many student groups. These are administrative areas in 24 municipalities, which are crossed by the Via Regina, between Cernobbio and Sorico (Ponte del Passo), at the end of Lake Como where the Valtellina (from the East) joins the Val Chiavenna (from the North).

Fig. 8: He Yingying, Gao Jie, Chen Guangkai designed a number of service buildings for visitors, in front of the famous Comacina Island, such as a watch tower on the lake shore, toilets cabins with a sky view, and a pavilion on the banks of a stream, in order to hear the sound of the rushing water. All projects are designed to transfer a sense of calm and peace to the visitor.

Students have designed systems, services and products to enhance experience of the historical, environmental, scenic, geomorphologic and gastronomic qualities of each area, as well as the evidence of material culture and the memories of work and the local economy still alive there.

In this perspective, designing environments and local areas by redefining and reshaping the way the local area and landscape can be seen and enjoyed, by developing cultural walking trails in alternative to the routes commonly used by other forms of transport, has become a way of strengthening and enhancing awareness and diffusion of the culture rooted in places. Design tools and methods (tools of innovation for creating new scenarios to be perceived and enjoyed) were used to produce new visions of historical traditions and by inspiring people to outdoor action, to walking and hiking, foster local development.

Focusing on the needs expressed by walkers and trekkers (the typical user of historical trails) students were also asked to design a "traveler's kit": a set of items useful to the rambler along the Via Regina (walking from Spluga in Switzerland, or vice versa, walking from Como). These might be: a walking stick, route map, sketch book and water-colors, backpack, bandana, association membership card or badge and so on.

Abstract

Up to last century, waterfronts were principally used for industrial and commercial purposes due to their strategic position. However, in recent decades these urban places have been undergoing renewal interventions aimed at valorizing their cultural and recreational potentialities for both tourists and citizens.

In fact, ever more architectural, urban and environmental studies are focusing on this issue with it representing one of the elements that contributes to improving the quality of life of the people experiencing the city.

The way in which people come into contact with the cities waterfronts is influenced by an ensemble of perceptual and environmental features that allows to identify the representative parts of the cities and their cultural and natural richness, in spite of their dynamic nature.

In current literature, there are not many studies on the way in which people perceive the waterfront environmental quality nor the influence of specific aspects, such as visual and auditory, on their overall perception.

This paper is aimed at carrying out an overview of these emblematic open spaces based on their restorative and recreational features. With the objective of assessing how the sonic environment can influence the perception of the overall environment, full spatial acoustical references are registered by means of in situ binaural and ambisonic recordings.

Keywords: Waterfront, sustainability, soundscape, perception

1. Introduction

The complex relationship between the urban renewals and hydrographical elements with their whimsical behavior has left traces that can be appreciated from the foundations up to the current configurations of our cities. River rises or floodings on the one hand, and the construction of commercial ports or river basins, on the other, are examples of transformations suffered by the frontier between the urban developments and the geomorphological configuration processes that have contributed to the current shape of waterfronts.

The renewals suffered in the coastal boundaries at the beginning of the last century led to radical changes at urban and social scales with the attraction of the population and commercial activities. The privileged condition of being nerve centers of trade between cities led not only to the construction of port structures with a large presence in the urban fabric but also to the parallel development of a culture of wellness and welfare. Along with the transformation linked to their inherent activities, interventions aimed at making the most of the cultural and historical values of the coastal boundaries were also added. In recent decades, the rapid development of the tourism sector has encouraged the transformation of the land uses and the leisure activities traditionally linked to the waterfronts. The need to show an image of an attractive multicultural destination focusses the attention of authorities

and stakeholders on these areas, that are intended to convert them through major interventions on the business cards of their cities.

The approach to the characterization of the waterfronts can be carried out from different points of view based, for example, on the kind of hydrographical element, the complexity of the topography or the extent of the human intervention in the coastline boundaries. On this occasion, we have preferred to focus on the complex relationship between the urban limits and the coastal line from the point of view of the needs of the residents and tourist.

The aim of this paper is to offer an overview of the waterfront features that contribute to enhancing the lively conditions of these areas and the wellness of their users, with the ultimate goal of improving the quality of life of the citizens. The waterfront of Naples has been chosen as a case study in order to undertake an approach to the complex process of how these places are perceived by their users. With the view of assessing the influence of the sonic environment on the perception of the overall environment, full spatial acoustical references are registered by means of in situ binaural and ambisonic recordings.

2. Sustainable developments of the waterfronts

Waterfronts play an important role in urban areas, being together with other open spaces as parks and squares enjoyment reference points in citizen's life. The need to obtain better environmental standards as well as the rapid development of the touristic sector in the last decades has prompted renewal projects to promote their leisure and recreational potentialities.

The coastal boundaries are an assembly of parts that needs a balanced coexistence and integration with the human intervention. Its inner reality is a result of the articulation of morphologic, cultural, historical, economic, politic, environmental and social issues that converge in a complex system in a state of unstable balance [1]. Nowadays the touristic sector as the driving force of the coastal cities' economy is the trigger for changes in social, urban, environmental and infrastructural planning and development. As a favorite tourist destination, especially in regions with warm weather, the environmental quality and amenity of these areas needs to be carefully managed.

The approach to the intervention projects on the waterfronts should be made from a perspective of sustainability and environmental respect, understanding sustainability as the difficult work to strike a balance between nature and individual interests [2]. It is very important to tackle the renewal project of urban spaces from a holistic approach, that includes multiple disciplines into the design process. [3]. Evaluating the environment together with people's behavior should be such an important stage of the project as the design itself.

3. Outline of the waterfront problems from the point of view of the perceptual characterization

As in the rest of the city, there is a large quantity of variables of different types and from diverse origins that can affect the complex process of the perception of the waterfronts. A positive or negative evaluation of one element may be decisive in the overall satisfaction of the quality of the area, so the attention and care of the details are essential in getting full enjoyment of the waterfront users. Purely functional aspects such as the accessibility or availability of areas for the rest, and issues beyond the urban design such as maintenance or cleanliness should be taken into account by the authorities in order to offer a quality product capable of attracting potential users as well as to compete with other tourist cities.

Road traffic constitutes one of the biggest and hardly solved environmental problems of developed cities. On waterfronts, the characteristic layout of a road beside the coastal line, constitutes in itself a not constructed barrier difficult to overcome between the natural and the anthropogenic environment at different levels: displacement, perceptual (visual-auditory-smells interaction), pollution. While vehicles passing are an obstacle to the flows of persons and also for the visual perception of the natural and built environment, traffic noise acts as an excellent masking of natural sounds like the one of the wind or the waves.

Urban waterfront soundscapes are not normally characterized by the predominance of natural sounds, but rather by a meshing of artificial and mechanicals ones, that contribute to the homogenization and loss of identity of the sonic environment. Though the soundscapes are dynamic entities, resulting as the evolution of the sound sources acting, it is important to rescue and valorise the natural elements that result favourable for the restorative and liveliness features of the urban spaces, to allow users a comfortable relation with the environment.

4. Overview of the urban waterfronts

As a result of different independent and disarticulated strategies of improvement, many of the urban waterfronts are characterized as being constituted by a cluster of residential, commercial and industrial areas somehow connected to the urban fabric. This and other problems of a diverse nature

(environmental, dismantling of port areas, deterioration and degradation of unused areas ...) are the origin of many interventions undertaken by the authorities, aimed at making the most of the underused waterfront.

Compared with other sort of interventions, the ones intended to promote the restorative properties of a waterfront do not constitute by themselves a high economical inversion and contribute to the improvement of the liveliness and quality of life of the citizens.

The pedestrianisation of a road that runs parallel to the coast line is an alternative adopted by some municipalities to tackle environmental problems. However, the border configuration of this roads and its role of traffic receiver and channelers makes it difficult to do without them.

A brief description, not exemplifying, of some European waterfronts with a promenade is reported below in order to explain different dispositions and solutions that are offered to the costal boundaries. To target the understanding of the wide variety of realities that can be found in the study of the waterfronts, we have elaborated a non-exhaustive classification based on the kind of environment and the proximity of a road. A first classification has been established into two main groups based to the level of human intervention: waterfront in natural areas and waterfront in urban areas. For both groups a second distinction has been made according to the existence of road traffic adjacent to the waterfront promenade: waterfronts with road traffic and waterfronts without road traffic. In turn, the waterfronts with road traffic have been classified in those with restricted road traffic or with non-limited road traffic.

Venice (natural lagoon-waterfront without perceived road traffic). This waterfront intervention in the area of Soto Pezzegalo Barena of the Venice Lagoon can be classified such as those that, with a subtle transformation of the environment enable walking on the path in a complete integration with the nature. This promenade away from the urban development is intended to allow eventually the visit to the fragile area that surrounds it subject to environmental regeneration [4].

Benidorm (Fig. 1) (urban seafront promenade with road traffic). Benidorm city bases its economy mainly on tourism and entertainment, and it is together with the islands, one of the favourite national and foreign tourist destinations in Spain. The project of the waterfront “Playa de Levante” in Benidorm, inaugurated in the year 2009, is already considered an emblematic example of intervention undertaken in the waterfronts. The design of the seaside promenade presents a layered topography that allows a transition adapted to the two levels of reality coexisting in the urban coastal boundaries. The higher level, with concrete and ceramic finish shows a sinuous topography and contains landscape gardens and areas for rest in contact with the road and the built strip area. The lower level instead is made with natural materials and proceeds along the retaining wall in direct contact with the sand [5]. These two levels enable the user two different ways of experiencing the waterfront, one linked to the constructed area, that allows also the contemplation of the sea from a privileged position, and another one linked to the natura that facilitates to walk all along the coastline. On the bottom level due the height difference, the harmful noise perception of traffic is reduced by the shielding effect of the retaining wall structure.

Fig. 1: Waterfront promenade of Benidorm. Ortophoto (Source: Bing maps.)

Oporto (Fig. 2) (urban seafront promenade with road traffic and urban park). The “Passeio Atlântico” is only a part of the ambitious set of interventions that have been carried out in the coastal boundaries located between Matosinhos and Oporto. The part of the promenade placed in Oporto, inaugurated in 2002, is constituted by two promenades, separated by a green area. The upper promenade runs parallel to the road, and serves as a link between two green areas of the city [6]. The lower promenade instead adapts this trace to the irregular topography placing itself only a few metres above the sea level[6], and acting like a transition element between the urban and the wildlife nature with secondary paths that leads directly to the shore. As in the example of Benidorm, the disposition of the bottom promenade reduces the negative effects of the traffic because of the difference of level. The green area contributes to improving the environmental quality and enables citizens to approach the experience of a natural place through an urban park.

Fig. 2: Waterfront promenade of Oporto. Ortophoto. (Source: Google maps.)

Pozzuoli (Fig. 3) and Salerno (urban seafront promenade with road traffic). The Lungomare Yalta of Pozzuoli runs parallel to Giacomo Matteotti street and it corresponds to a model of promenade at the same level as the road. It is provided by landscaped gardens arranged sinuously along its route to improve the environmental quality of the area. Within the same group, we can include the Lungomare Trieste of Salerno, which is composed of green stripes of vegetation organized between the two directions of the road and between the road and pedestrian promenade.

Fig. 3: Waterfront promenade of Pozzuoli. Ortophoto. (Source: Google maps.)

Ligurian coast (urban seafront promenade; the promenade lays on the trace of the former railway trucks, and it shows a great variety of solutions along its route: with and without road traffic and with- without landscape gardens). One of the most difficult problems that some Italian coastal areas face is the disposition of the railway line parallel to the shoreline. To the usual breakdown of the urban fabric assumed by the existence of the train tracks, the difficulties to interrelate the narrow strip that remains between the railway and the coastal line with the rest of the city must be added. The connections are usually inhospitable places located far away from each other, more intended to channel the flows of road traffic than the pedestrian ones, which do not favour the access and enjoyment of the citizens to the coastal areas. The solution of covering the railway or the removal of it leaves traces of the neglect, decay and abandonment that these areas have been suffering during decades. This situation which can only be resolved through an unitary intervention of improvement and integration of this forgotten areas with the rest of the city/ies. On the Ligurian coast, the railway line was moved inland, and 25km were transformed in a promenade designed for bicycle and pedestrian traffic [7]. Due to the long route of the promenade, the waterfront presents different solutions as a result of the articulation of the existing items before the translation of the tracks with new ones. The renewal works finished in 2007 have contributed to the improvement of the accessibility to the sea, with the promenade acting like a connector between the landscape gardens and the leisure areas. Though the footprint left by the railway line has only allowed the area to be an outline of what could have been, the intervention implies a huge improvement to the environmental quality of the waterfront, and puts the coastal strip to the service of citizens.

Malmö (Fig. 4) (urban seafront promenade without road traffic in a stretch of the route, and with restricted road traffic in another). The route located between Ribersborgstrand and Östra Varvsgatan is an example of urban seafront promenade integrated into the citizens' life. Its route runs in parallel to a restricted road traffic area, or alongside a large urban park, and is composed of a combination of sandy stretches and finished wood surfaces that ceate a perfect blend with the environment. In the area of the Sunspromenaden, wooden steps lead to concrete platform to have a closer relationship with the water surface [8]. The urban park is used by the citizens as a resting area in which to enjoy the positive effects of the contact with nature.

Genoa (urban seafront promenade without adjacent road traffic) The current waterfront Voltri of Genoa has been created to improve the image that the city offers to the sea. Running separately to the road, it is an intervention in which the promenade acts like a distribution element along which recreational and public services are arranged to improve the offer of leisure activities of the area.

Fig. 4: Waterfront promenade of Malmö. Ortophoto. (Source: Google maps.)

Lisbon (Fig. 5) (urban riverfront promenade without adjacent road traffic but nearby the bridge Vasco de Gama). This waterfront promenade has its route linked to an urban park designed for its integration in the social life of the city. The beautiful main promenade runs from the Passeio dos Heróis do Mar through the urban park and rises on the river bank allowing for a beautiful relationship with the shore [9]. Two perpendicular paths connect the road adjacent to the park with the main promenade and enter the river. Despite the strong negative influence on the overall environment of the road traffic noise coming from the bridge, the intervention gives a satisfactory improvement and recuperation of the area at the service of the citizens.

5. Case study: Waterfront of Naples

The waterfront of Naples is currently undergoing the implementation of pedestrian areas and road traffic restrictions in various locations, which makes it of particular interest to compare different environmental qualities perceived by users along its route.

5.1. Definition of the area of study

The study area includes the stretch of the waterfront promenade between the intersection of via Mergelina and via Francesco Caracciolo and the curve where Via Ammiraglio Ferdinando Acton and Via Francesco Caracciolo converge.

Ten zones have been established along the study area attending to the different visual, auditory and olfactory features that can affect the perception and characterization of the places (Fig. 6).

Fig. 6: Photos of the locations in which the measurements have been made. In order from left to right: intersection via Acton - via Nazario Sauro, intersection via Nazario Sauro - via Cuma, fontana dell'Immacolata, Castel dell'Ovo, via Partenope 1, via Partenope 2, via Caracciolo 1 (in front of Villa Comunale), via Caracciolo 2 (entrance to the sea), via Francesco Caracciolo 3 (in front of Ali Lauro), intersection of via Francesco Caracciolo – via Mergelina

5.2 Methodology

The approach to the citizens's perception of these urban spaces was carried out through a set of 128 surveys done on the waterfront promenade of Naples between January 15th and February 25th of 2014. The questionnaire was organized in three categories of questions: demographics questions, questions about global perception, and questions about a specific group of sense stimuli (visual, sound and smells) and the weather conditions. The survey included, inter alia, questions related to the environmental quality, and the subjective perception of the landscape, the soundscape and the smells of the area. The questionnaire is composed by single and multiple choice questions. The answer to the questions about assessment, were rated in a seven points Likert's scale from positive (1), to negative (7).

As a preliminary study, soundwalks and measurements in fixed positions were carried out along the waterfront promenade in the months of September and October of 2013. The interviews were conducted in the proximities of the points of study and combined with binaural registrations in order to correlate subjective and objective parameters. The binaural audio signals (16 bits/44.1 kHz) were recorded after or before the surveys with the use of a portable device "M-Audio Microtrack 24/96" and headphones "Sennheiser HDC 451". With view to further studies, several recordings were performed in different points along the seafront in Naples with the ambisonics technique. By means of this method, it is possible to register full spatial information of the sonic environment. With the adequate post-processing, acoustic immersion into the recorded soundfield becomes possible. The equipment utilized includes a Soundfield microphone SPS200, digital recorder Zoom H6, and wind shield Røde Blimp.

5.3 Analysis and results

The main characteristics of the sample of people interviewed are given in Table I. As expected, most of the visitors of the area are local people (77%) and the the rest of them are divided into tourists and inhabitants of a nearby city (23%).

	Provenance(%)	Gender		Age (%)						
		Male (%)	Female (%)	15-19	20-24	25-29	30-39	40-49	50-59	>=60
Tourist	12.50	4.69	7.81	0.00	1.56	2.34	4.69	1.56	1.56	0.78
Local	77.34	36.72	40.63	18.75	12.50	9.38	14.06	6.25	10.94	5.47
Inhabitants of a nearby city	10.16	6.25	3.91	3.13	2.34	0.78	1.56	0.00	1.56	0.78

Table 1 - Characteristics of the sample of people interviewed

The sound sources recognized during the preliminary works in the area are mainly the following ones: traffic – with engine (cars, motorbikes, trucks, buses, touristic trains, car toys), traffic - without engine (bicycles, skates, pedal cars, scooters), planes overflying, boats with and without engine, horns (from cruise ships, buses, cars, bicycles, and pedal cars) voices (children crying, children playing, people talking, persons shouting, laughs), steps, music, sounds from restaurant-food activities (movements of chairs and tables, cutlery and plates, movement of awnings, engines, fans, generator), baby carriages, wheelchair, wheel luggage, construction sounds (hammer hitting, noise of tools) . In figures 7 and 8

Fig. 7: Example of SPL time history of soundwalk recorded along the waterfront of Naples in a road without restrictions to the traffic circulation (13th October 2013 -17.30 till 17:43- Stretch of via Caracciolo between Ciro Merigina and Ferdinando Galiani)

Fig. 8: Example of SPL time history of soundwalk recorded along the waterfront of Naples in a stretch with two main traffic conditions: a pedestrian area (till aprox. 400000ms) and an open to traffic area (from aprox 400000ms till the end of the registration). (13th October 2013 -18:08 till 17:20 - Stretch of via Caracciolo between the entrance to the sea and piazza Vittoria)

two representative time histories in which are written the predominant sound sources acting recognized by the operator are displayed.

The sound pressure levels along the waterfront promenade vary from 55.40 dBA in the zone 5 (pedestrian area) to 78.1 dBA in zone 9 (table 2). The partial results are that for similar sound pressure levels, some soundscapes are considered more pleasant than others according to the kind of sound sources acting.

Location		Kinds of traffic	Mean LAeq (dBA)	Max LAeq (dBA)	Min LAeq (dBA)
Via Acton - Via Nazario Sauro	1	WR	69,86	72,40	68,70
Via Nazario Sauro - Via Cuma	2	RT	67,14	73,70	64,80
Fontana dell'Immacolata	3	RT	59,80	61,90	58,40
Castel dell'Ovo	4	P	67,92	71,80	67,50
Via Partenope (near Antonio & Antonio)	5	P	60,74	68,90	54,90
Via Partenope (in front of Vainilla Caffé)	6	P	58,96	69,00	55,40
Via Francesco Caracciolo (in front of Villa Comunale)	7	WR	69,06	74,20	55,40
Via Francesco Caracciolo (entrance to the beach)	8	P	66,09	71,60	59,90
Via Francesco Caracciolo (in front of Ali Lauro)	9	WR	70,64	78,10	62,50
Via Francesco Caracciolo - Via Mergelina	10	WR	70,86	75,60	65,80

Table 2 – Mean, maximum and minimum LAeq of all the registrations made in each position. Kinds of traffic restrictions; WR = without restrictions to road vehicles circulation. RT = restricted to one sense of circulation. P=pedestrian area

The percentage of subjects that have evaluated positively (5, 6, or 7 points in a 7 points Likert's scale) the environmental quality and several sense stimuli (landscape, soundscape or smells) was obtained. For example, more than the fifty percent of the subjects interviewed have expressed a positive judgment of both the environmental quality and the landscape. Forty percent of the interviewees gave positive judgments to the environmental quality and the soundscape, and a slightly lower percentage of the subjects gave a positive judgment to the environmental quality and the smells. Obviously, the higher number of different sense stimuli considered, the less number of subjects that express a positive rating to all of them (Fig. 9). These outcomes indicate that the visual parameters have a significant influence on the overall assessment of the places confirming previous research results [10][11][12]. Slight differences have been found between the number of women and men that gave a positive judgment to the questions considered, especially to the last group of questions (environmental quality – landscape - soundscape - smells).

Fig. 9: Percentage of subjects that have given a positive judgment to several issues.

We have referred first to the percentage of subjects that have expressed positive judgments to the aspects previously cited (fig. 9). If the same evaluation is made with the negative ones (less than 4 points in a 7 points Likert's scale), the highest percentages correspond to the group of subjects that have judge negatively both the environmental quality and the soundscape (13%), and the environmental quality and the smells (11%). This seems to indicate that for positive judgments visual has an important role in the perception of the waterfront, but for the negative ones sounds and smells have a very remarkable influence. Significant differences have been found between the number of women and men that have given negative valuation in the different aspects assessed, except for the judgment of both the environmental quality and the landscape. In these cluster of questions, women have shown a trend to give stronger judgment than men. Further research is needed in order to compare these outcomes in other places with more generally accepted negative features.

6. Conclusions

The way in which people come into contact with the cities' waterfronts is influenced by an ensemble of perceptual and environmental features that allows to identify the representative parts of the cities and their cultural and natural richness, in spite of their dynamic nature.

The visual stimuli play an important role in the perception of the overall environment, but the influence of the other senses together with other psychological and physical parameters cannot be underestimated.

In current literature, there are not many studies on the way in which people perceive the waterfront environmental quality nor the influence of specific aspects, such as visual and auditory, on their overall perception. There is a need for more detailed research on the perception of the waterfronts in order to understand the multidimensional characteristics of people's environmental experience.

The Acoustics of Underground Places in Campania

Francesco SORRENTINO, Amelia TREMATERRA, Gino IANNACE

Department of Architecture and Industrial Design "Luigi Vanvitelli", Second University of Naples, Aversa, Italy

francesco.sorrentino@unina2.it; amelia.trematerra@unina2.it; gino.iannace@unina2.it.

Abstract

The interest for the acoustics of underground places is increasing in recent years. The charm of the place and properly equipped shows generate success and appreciation from the audience. In Campania there are several caverns used for shows. The caverns are: Pertosa and Castelcivita, in South of Salerno. The show in the cavern of Pertosa is the "Inferno di Dante" while the show in the cavern of Castelcivita is the "Myth of Orpheus and Eurydice". During the shows the tourists are accompanied along the path by an actor that explains the scene view in that place. The caverns are karst origin, and the touristic paths have length of 1.0 km inside the earth with stalactites and stalagmites.

This paper describes the characteristics karsts and acoustics of the places in which the shows are organized.

Keywords: Underground places, caverns, shows, acoustics

1. Introduction

The caves, with their wide halls, endless depths, stalactites and stalagmites that form natural surreal sculptures, suggest an unknown world where, according to fables and legends, fairies, witches, elves and goblins lived in. On the other hand, for the primitive man, that he lived them millions of years ago, they represented the entry of mysterious underground worlds.

Today some of these caves are used for public shows, in particular: since the second half of XVIII century in France, the royal Superintendent of province organized a party, with banquet, music and dance in the caves of Osselle (France) lighted with hundreds of torches; around the 1778 choral groups climbed close to the Peak Cavern (England) in order to offer their songs to famous and wealthy travelers. In 1822 the caves of Postojna in Slovenia were opened to the public for dancing parties with popular music. Later the idea of using caves for public shows, particularly in the summer season, it is consolidated in several parts of the world. In France, concerts of popular music and jazz take place in the Cave of Aven Armand, while in the large Cave of Lombrives there are many forms of entertainment and services for ceremonies. In the Caves of St. Michael, in Gibraltar, dating about 40,000 years ago, a large room of the cave is fitted out as an auditorium for prose, ballet and symphonic music, and it is open all the year.

In Italy, despite the presence of many karst caves, their use for public shows involving real aspects of representation is not widespread. In Campania, the Caves of the Angel in Pertosa and the Caves of Castelcivita, both in the province of Salerno, host for several years entertainments that owe their success to the particular acoustics and the mystery that they evoke.

2. The Caves of Angel

The Caves of Pertosa, called also "Caves of Angel", are located in the heart of National Park of "Cilento e Vallo di Diano". They date back to 35 millions of years ago and they are the only caves to be crossed by an underground river, the Tanagro, whose course was deviated at the beginning of '900, for the purpose of energetic uses [4]. In this way the entry of the caves is been flooded, so as to allow the access to the interior only by suggestive boats carefully led by expert guides who, standing on the bow of the raft, moved them with the help of their hands and an iron rope stretched horizontally on the middle of the water course. (Figure 1).

The cave of Pertosa looks like a large gallery, 15m wide and 20m high, which opens, at about 70 m above sea level, at the foot of the "Intagliata" Mountain. The enormous entry seems like a great mouth of the mountain, hidden among ferns, ivy and moss (Figure 2).

The geo-morphological characteristics of the Caves of Pertosa inspired, several years ago, a natural setting for shows. In this place were also made some scenes of the movie "The Phantom of the Opera" directed by Dario Argento. Now the performance of the show "Dante's Inferno" takes regularly place. On a route of about 1 km, viewers are accompanied by groups at several stations, each of which takes place in a topic related to a circle of Dante's Inferno. The show takes advantage of the natural scenario of the caves. People, divided into groups of 30 units, "live" the caves along a route suited to the spectacular needs, and, interacting with the actors, become themselves the characters of the opera of the poet. The entire show-route is made even more emotional by a suggestive artistic lighting, particular special effects and attractive tridimensional reconstructions. Led by Dante himself, people come into the tunnels of the mountain and, cave by cave, they meet Paolo and Francesca, Ulysses, Minos, Count Ugolino and many other characters of the first canticle of the Divine Comedy (Figure 3). The audience moves within the scene and meets the characters. There are not papier-mâché scenes and backdrops, but a prehistoric scenario with 35 million years.

Moreover, for fifteen years, a summer festival of ethnic music, the "Negro Festival", takes place in the music antrum, at the entry of the caves (Figure 4). The name comes out of the river that flows into the inside of the caves, by which it is possible to access in order to enjoy the charming view of stalactites and stalagmites. The Negro river offers an appropriate title for this festival, which has become an important and expected time of celebration and multiracial exchange. Created in 1996, it welcomes and accommodates about eight thousand people immersed for three days in the uncontaminated nature dominating the entire complex. The square and the area of the Caves of Pertosa are transformed into a citadel of music and culture, where concerts, exhibitions of photography and contemporary art, music workshops and ethnic dance stages are organized. The program offers many different activities, all in the name of the interaction between music, art, culture and nature.

Fig. 4: "Negro Festival"_ Caves of Pertosa

3. The Caves of Castelcivita

Inhabited in prehistoric times and known since antiquity, the Caves of Castelcivita are one of the most important and extended underground karst complexes of Southern Apennines. Next to National Park of "Cilento e Vallo di Diano", at the foot of the mountains of Alburni, just elevated above the Calore river, these caves consist of 1700m of tourist routes, on a total of about 5000m. [5]

The underground was unknown until the end of the '800; in fact in the 1899 there was the first adventurous and tragic exploration of the caves by two brothers, Francesco and Giovanni Ferrara, who entered with the oil lamps in the early 300m of the cave and there they got lost in the tunnels and died. The entrance was different than what it is today, just more than a hole visible from the thick vegetation that covered it. The people believed that the entrance was the devil's mouth, from here the name "Devil's Cave", because often from the hole came out flows of fire and smoke due to the combustion of the gas contained inside.

The Caves of Castelcivita originated because of the erosive and corrosive action of the karst waters on the fractured cretaceous limestone mass and, from a morphological point of view, they consist of a main branch of large size, where are connected a series of secondary tunnels, in different ways and at different levels. The caves are a series of galleries, salons, narrows and wells, which chase each other, overlap, sink in leaps and abysses where the horrid and the fantastic alternate in a rainbow of colors. The entrance to the caves, at the foot of a limestone wall, opens up onto a large square, on the western slopes of the Alburni mountains, on the right side of the Calore River, about 94 m above sea level, and it is characterized by an opening, partially enlarged, enclosed by an iron gate, beyond which the ceiling rises up and a sense of dismay affects each one. Proceeding along a gentle slope for about 20 meters, there is the first cave, called "of Guano", 40 m long, 26 m wide and 12 m high, which until years 50-60' was the ideal retreat for bats. Just beyond there is the "Castle room", characterized by a group of stalagmites resembling an ancient medieval castle at the top of a hill. At the end of this tunnel, the route branches into two cavities, heading south there is the room known as the "Wells of Carbonic Acid", then sixty meters over that one called "Bertarelli Room", where the majesty of columns and stalagmites and the quantity of stalactites contribute to the creation of a wonderful

Fig. 5: Caves of Castelcivita _Planimetric portion with the route taken by the visitors (black line)

scenario. This room is more than 40 meters high and presents a multitude of concretions. Here another branch rejoins the walkway 70 m ahead.

In the extraordinary, unique and hypnotic scenario of the Caves of Castelcivita takes place the emotional mythological fable "Orpheus and Eurydice"; it comes out an exciting theatrical-literary adventure where, due to the magic background, a young Orpheus crosses the Hades searching his one and true love. At the entrance of the caves the audience was welcomed by the god Apollo, who offers to lead them in this journey. The people are divided in groups of about 40 units to start their journey into the realm of the afterlife. The public continues its journey until it meets Charon (Figure 6); then it comes to the dwelling of the famous "Erinnyes" who try to block the road to travelers with a simoniactal dance, but also them, deeply moved, let them pass. Apollo leads the travelers along the route, leading them to the presence of Pluto and Proserpina, whom Orpheus (Figure 7) asks, with a poignant song, to let him carry away the loved Eurydice, and he gets it on the condition that he should never looking back until he reaches to sunlight. Orpheus accepts and, followed by Hermes, he moves towards the exit with his beloved. Then the audience come back on the footsteps of Orpheus, Eurydice and Hermes in order to come out from the realm of the dead to regain the life, but before they hear the harrowing lament of Orpheus's head, detached from the neck by the Bacchae, wandering without rest, leaning on his lyre on the bed of the Ebro river.

This show is not simply a performance: in fact, it is a tool able to charm everyone, students, tourists and simple spectators through a well-established formula, which combines the mythological aspect of the story to the charm of the place, which wisely blends music and beautiful singing with a modern and understandable language, which joins special lighting effects with video and multimedia screenings, transferring unique and absolute emotions to the audience. Moreover, the show is sung, played, danced and mimed by the actors in a superlative way. The show is played along a route of approximately 1 km, characterized by the succession of large cavities adorned with huge stalactite-stalagmites groups and extraordinary morphologies of concretions that almost completely cover the ground.

4. The acoustics of the caves

The use of caves for public events has prompted acoustics experts to study these underground places, in order to discover the acoustic characteristics considering the parameters used for the characterization of auditoriums. Recently, in the caves, several surveys with modern instruments are been carried out [1] [2]. Indeed, to understand what are the properties of the sound field responsible for the sound perception in these environments, a model of analysis and description of the sound would required, but in literature there are not objective parameters for this type of situation because are replicated the acoustic descriptors born to define the behaviour of environments designed for musical performances. Therefore, to describe the acoustic behaviour of the two karst complexes studied, have been used precisely these parameters; in fact, the two caves of Pertosa and Castelcivita may be treated as large areas that, although not born to accommodate musical shows, must their notoriety, as well as the charm of the place, to the particular acoustics that can make these places fascinating and enveloping, but at the same time steeped of huge mystery.

5. Measurements methods

Because of the particularity of the places it was impossible to use the complete equipment, as recommended by ISO 3382 [3]; the responses to the explosion of balloons were recorded by means of an omni-directional microphone equipped with a preamplifier 01 dB PRE 12 H, connected to the interface of a sound analyzer, connected in turn to a portable notebook, all powered by a battery. Subsequent processing of the recorded impulses provided the acoustic parameters for the characterization of the environment. Because the audience, both during the show Dante's Inferno (Caves of Angel), and during the show Orpheus and Eurydice (Caves of Castelcivita) does not take up a fixed position to attend the performance, the relationship between stage and audience is different from that of a typical theater. For this it was necessary to place the source and the receiver randomly, but nevertheless at the height of the head of the viewers. In the study, only the places of greater size and permanence were monitored (Figure 7 and Figure 8).

Fig. 8: Caves of Castelcivita _Planimetric portion with the localization of measurement points (red points) and the route taken by the visitors (black line)

Fig. 9: Caves of Pertosa _Planimetric portion with the localization of measurement points (red points) and the route taken by the visitors (black line)

6. Conclusions

The measurement campaign has provided encouraging results in terms of descriptor indexes; almost all of the rooms showed, in fact, values in accordance with the optimal ones, except some of them where, although not reaching these good values, there is not however an excessive reverberation.

The caves are underground places, but they can be, likewise for theaters, auditoriums and concert halls, environments suitable for holding performances and shows; furthermore, compared to the latter, the underground places have the advantage of contributing to the achievement of extraordinary events due to the natural scenario as background to the representation. The audience lives a singular experience that induces special emotional effects and to transform the viewers from simple spectators in the real protagonists.

For both analyzed karst complexes, people become the key point of the representation. They are spectators and actors at the same time because, following the actors along a route, they become an integral part of the show itself.

Both caves are limestone, formed by porous material absorbing sound, while the stalactites and stalagmites being periodic surfaces in the environment allow the diffusion of sound in an optimal way. This explains why these places are characterized by a good sound diffusion. The diffusion, however, is relative because the sound generated in a room spreads only in its immediate proximity, without reaching the farthest rooms; this phenomenon could be used to optimize the performances, because at different points of the caves may be performed simultaneous shows.

Abstract

The redevelopment of open spaces contributes to the achievement of urban quality, especially in the presence of unfavorable microclimatic conditions or when the ecological balance is compromised. This plays a strategic role in the activation of architectural, environmental and social revitalization processes. In accordance with this premise, the authors propose a reflection eco-oriented transformation on strategies for the open spaces of the city of Juazeiro, in the Bahia region of Brazil, starting from the identification of the variables that affect the control of comfort in its various declinations. In fact, the natural areas in contemporary cities are ever smaller in their size and density, and insufficient to ensure benefits that come from nature for a physical and mental wellbeing of the urban population.

There is a need to integrate the issues that could be called "acquired", that is, related to the accessibility of the site in relation to its specific functions, issues related to security, lighting and cleaning, with further areas of reflections due mainly to environmental sustainability. In this sense, consider the creation of open spaces in the city of Juazeiro would mean reconsider, in a sustainable key, the social functions, the ecological contribution addition to aesthetic and economic enhancement which are resulting.

Keywords: quality of open spaces, comfort, green areas.

1. The case study of Juazeiro: the urban context (Rossella Franchino)

To intervene on the development of the urban territory in order to find an alternative to the model that has emerged in the twentieth century, all planning and redevelopment of open spaces needs to be addressed with particular attention to the control of a comfortable environment so that these places can be seen as important attractors of the urban context. In this perspective, the vision of urban territory changes, with it being conceived as a structure with a dynamic balance achieved through the technological control of complex functions. Such a framework should be set up, therefore, as a safe enjoyable environment with high standards of quality and special attention to the social dynamics and relationships that develop in the area. The urban territory must be conceived as a complex tissue in which the boundaries between the artificial and natural environment cannot be seen and in which each process is controlled so that its impact and consequently, the irreversible degradation induced, is the minimum possible in relation to the constraints of the process.

The urban territory, which creates an "urban ecosystem", with its complex of interrelated structures and relationships determines its own path in the surrounding environment which is primarily determined by the huge, interpersonal and informational energy flows that characterise such a system. Its is therefore very important to orient the transformation processes as controlled interventions of

these flows so that the irreversible impact is contained as much as possible. The qualitative and quantitative description of the flows, i.e., how people move, how information is exchanged, how they interact, how energy uses are sustained, how supplies and services are organized, is used to characterise the urban environment as well as to speculate interventions that have the goal of making these flows compatible with the sustainable transformations of environment in which they are located. Thus, the aspects that must be taken into consideration for the comfort control of urban open spaces are those of mobility and viability, of the greenery and furnishings, of plant networks, of social spaces in order to achieve the objectives of qualifying life, protect health, increase safety, promote the relationships of the population.

Starting from these considerations, we consider the eco-oriented transformation of open spaces in the city of Juazeiro in the northeast of Brazil, identifying the main strategies aimed at controlling comfort in its various forms. Juazeiro, in the State of Bahia, runs along the São Francisco river (fig. 1) in front of the city of Petrolina and constitutes an urban reality of particular importance from an ecological and natural perspective. The São Francisco river, which marks the state boundary, is approximately 830 km long with a reservoir of approximately 641,000 km² and plays a very important role in the urbanization of Juazeiro and Petrolina, which are situated on its banks.

Fig. 1: Urban canal that flows into the São Francisco river. Photograph by Matteo Nigro.

The town of Juazeiro, built just over a hundred years ago and thanks to the presence of the river is on a strip with a very high urbanization. It is surrounded by tropical forest and unspoilt Caatinga biome which is an exclusively Brazilian biome (characteristic of the region called Sertão), which means that much of its biological heritage cannot be found anywhere else on the planet. Caatinga means “grey forest” and can be explained by the vegetation that characterizes this forest, making it look dry for most of the year, with no leaves, while becoming green in the winter, in the rainy season. The Caatinga occupies an area of about 750,000 km² and is dominated by various types of dry vegetation, a rugged landscape with grasses, shrubs of about 3-7 m tall, deciduous, with many thorny plants, such as legumes, interspersed with other varieties such as cacti and bromeliads. [1]

The reference climatic context is semi-arid, typical of inland northeast Brazil and, therefore, characterised by high temperatures and a dry climate for most of the year. The open spaces currently present in the city of Juazeiro are characterised, in most cases, by the presence of vegetation almost

always spontaneous and water, in the form of small superficial channels that cross the city transversally.

2. The uses and potentialities of green areas in Juazeiro (Matteo Nigro)

One of the most existing worries when dealing with the issue of urban planning and architectural design in the contemporary city is the space allocated to urban green spaces.

Today, in the context of this reference case study - a city in the northeast region of Brazil, the urban population is more aware of the consequences caused by the accelerated growth of urban centers. This uncontrolled growth has resulted in, among other events, the lack of space for recreation in the open air and increasingly worst air quality in the medium and big Brazilian towns, such as the case of the city of Juazeiro-Bahia.

In this territory, the loss of the remaining areas with native vegetation, stimulated engineers and designers involved in the production of urban spaces, to act with more attention to the quality of the design of public green spaces, in the process of construction of municipal plans and programs.

The research that is being developed on the green areas of Juazeiro has as main objective to stimulate a critical view on the current state of the areas with vegetation found in the urban landscape and the lack of appropriate spaces for leisure, sport and contemplation of nature; these latter are only three of the many possible activities to do in contact with nature.

It is relevant that the green regardless of the geographical context where is located, it helps to maintain a healthy physical and psychological balance of man and offers moments of relax in contact with the elements of nature. In addition, there is a significant aesthetic function of the natural elements present in the city that elevate of much the quality of the urban landscape; in the considered case study (Juazeiro-BA), green as an element which constitutes the urban landscape, plays a role of connection with the principle of contextualization. To explain this principle which is directly associated with climatic and environmental conditions of Juazeiro, we use the example of native and endemic plants that are resistant over time to the type of semiarid climate.

The proper use of green areas suited to the context, it becomes the basis to fundament any attempt of action for cohabitation with the semiarid climate.

In addition to the uses and the social, aesthetic, economic and ecological functions of the green, Camponogara et al. [2] introduce the theme of human health related to nature: "of a general way, we can recognize the complexity that characterizes the environmental crisis and the nearness with the branch of health, starting with a visit to the many spaces and actors in the extended social structure."

In this sense, the importance of the connection health-nature becomes an increasingly cited theme, especially with a view to enhancing urban green spaces and to preserve the existing vegetation in the cities. Over the last few years, even in the context of the north-east of Brazil, where is located the city of Juazeiro, in addition to the destination of green spaces which are contemplated in the projects of architecture of the city, both the technical and civil society have developed a greater perception of the environment due to the benefits that these spaces reserve for the population.

According to Loboda and De Angelis [3], "the green areas have become the main icons for the defense of environmental degradation and the little space which is intended for the green in the urban centers." To exemplify this statement we can cite an example: thinking in terms of urban environment constraints or urban ecology, means in the common sense immediately make reference to the green, the native vegetation, the trees, the parks, all areas which have assumed a symbolic representation in defense of nature, especially in the city.

In the perspective of urban sprawl of the city of Juazeiro, the first results of this research show that the civil society is developing a greater awareness of environmental issues, and especially a recognition of the importance of green in the city, these factors make it possible the creation of sectoral public policies for the planning of squares, public gardens and parks in urban centers.

Currently in the city of study, there are several open public areas without a due use of destination but with a potential of urban green areas, dictated by the configuration of the spaces that are placed in strategic points of the city; the lack of space for the practice of open-air gym, jogging and other modality of sports and entertainment promotes the little contact with nature in the city and does not represent a form of action to establish a cohabitation with the intense heat in the region during most of the year.

Specifically, in Juazeiro does not exist a municipal public park; in the city center there are just a few squares fitted with trees which constitute a shady shelter to defense of strong end direct sunlight; the presence of trees in the urban road system is scarce and not contextualized, with exotic species not adapted to the type of climate and with a low standard of resistance. The figure 2 shows the typical structure of a city street not equipped with trees.

Given the conditions of the case study and the basics for understanding about the importance of green areas in the city, it can be summarized the main factors which would justify the actions directed to the realization of green areas: the first is the intent to make general improvements to the quality of life of the urban population; the second factor is the need for open spaces for recreation and leisure,

currently almost absent in the urban area; the third is the advantage of increasing the economic value of the properties next to green areas and the value of the city in general; the fourth is a legal obligation to environmental preservation of the remaining natural areas and areas of preservation of water resources (such as APP-Areas of Permanent Preservation), these last present in city of Juazeiro along the margins of the river São Francisco; the last factor identified is that of the practice of socialization that it needs to public, open and equipped spaces.

Fig. 2: Lack of trees in the district Quidé in Juazeiro-Bahia, Brazil. Photograph by Matteo Nigro.

3. Urban open spaces: environmental - technological issues (Caterina Frettoloso)

The planning of unbuilt spaces as well as the prospect of requalifying existing open spaces, often disused due to neglect or absence of a plan which clearly describes the forms of use, poses a number of questions about not only the formal and functional aspects of the project but also to the conceptual ones, i.e., “to some invariants - nature, art, memory, society - that from time to time, prevail and give value to the proposed interventions” [4]. Interpretive criteria related to the role that open spaces have traditionally held within the city system as nodal elements, not only in relation to the usability and comfort, but also to cultural identity, thus giving an added value to the urban fabric.

A value that is also expressed in terms of the capacity, of these open spaces, to play a significant role in the activation of the revitalization processes of the city, both within an architectural-environmental perspective as well as a social one, especially in contexts in which the environmental, social and economic balance is compromised. The open spaces of the city of Juazeiro are configured, in most cases, as urban spaces devoid of infrastructures, both natural and artificial, which support their use. They are mostly public areas even if, in the case of the abandoned ones, it is not always easy to identify the owners (public/private). Undoubtedly, the city of Juazeiro has been affected by very similar socio-spatial dynamics to those identified by Memoli for Salvador Bahia, “standardized policies, cultures trivialized by the tyranny of the demand for land, fragmented or overlapping functions at a territorial level” [5] that have not therefore allowed for a balanced urban development between solids and voids, between public and private, between the points of transition and meeting places.

The climate of this area of Brazil, semi- arid and characterized by high temperatures and low rainfall, is the main obstacle to the use of open spaces, not only as comfortable places in which to spend leisure time, but also, as a transition space to be used in a short space of time and safely. The almost total lack of vegetation which was discussed in the previous section is mainly due to the particular climatic characteristics of Juazeiro and is one of the factors with the greatest impact on the lack of suitably designed open spaces.

The role of vegetation in the context of requalification strategies aimed at the livability of those places which currently seem to be urban voids is a very delicate aspect. In fact, from the point of view of the micro- climate, if it is true that the presence of trees, properly selected and placed in reference to the

microclimate of the area, would contribute to the creation of shaded areas and paths channeling the flow of air and increasing humidity, on the other hand, the equally thorny question of the proper fluid intake to ensure their survival arises.

Fig. 3: Disused railway line. Photograph by Matteo Nigro.

The organizational patterns of requalified open urban spaces should meet specific functional requirements dictated by the collective way of life, more and more oriented towards increasing flexibility that does not mean, as often occurs, the lack of a design choice. It means working on the performance characteristics of spatial elements in an integrated approach to the project where the technical and functional aspects are interwoven with social and environmental issues. This will make it possible to integrate the issues that could be called “acquired”, i.e., related to the accessibility of the site in relation to its specific functions (also with respect to different types of flows that cross and overlap the open space), to the issues associated with security, lighting and cleaning, with further areas of consideration being mostly due to environmental sustainability.

In Europe, the comparison with the quality of life in its most all-encompassing meaning, has addressed the interests of local governments and planners, on the one hand, to qualify (and quantify) the contribution of the greenery in micro-climatic and ecological terms. While on the other, to work on the integration - systems engineering function of systems with high technological content (energy production systems, infrastructures for sustainable mobility, performing surfaces).

Proposing an approach that shares these strategic principles requires a careful analysis of the oriented status quo in order to highlight the potential of the urban environment trying to recover those elements that are critical points of the city. In this context, it is possible to consider, for example, disused areas or infrastructures that are often characterized by a strong degradation of the environment and that can be interpreted as strategic nodes for the redevelopment of open spaces. The city of Juazeiro is no exception in this sense, it is worth considering the disused Alagoinhas - Juazeiro railway line which crosses the city, in some sections parallel to the main traffic routes (fig. 3). Linear infrastructures offer, in fact, significant insights related to possibility to realise not only the new network of paths with a view of sustainable mobility (walking, cycling , ..), but also a type of “corridor” characterized by the inclusion of natural and artificial elements (technological systems to support the use). The concept of equipped corridor, recalling the main function of connecting, allows to introduce,

from a methodological point of view and design, the ability to put into the system and connect more open spaces and significant places of the city.

In fact, as part of a redevelopment strategy aimed mainly at improving the urban quality of Juazeiro, the reuse in an eco-technological context of these disused linear infrastructures could provide significant input oriented to the appropriate use of open spaces understood in the widest sense of shared sites.

4. Urban open spaces: ecological issues (Raffaela De Martino)

"In anthropised landscapes, the urbanization and infrastructuring of the territory has determined, together with the activities of agricultural mechanization and control of flowing waters, a tendency towards the simplification and homologation of the landscape" [6].

The phenomena of settlements, infrastructures and manufacturing, have therefore produced profound alterations to the ecological structure of the territory causing fragmentation of natural and/or semi-natural areas, which have lost with the passage of time the elements of contiguity and have been depleted of their environmental features. The phenomenon of fragmentation causes, from an ecosystemic point of view, a compromise of the "structure" and "function" of the elements of the anthropised landscape. The "structure" refers to the spatial characteristics, therefore, shape, size, number of habitats that make up the landscape pattern, while the "function" defines the relations (energy flows, transfers of material) that develop between the elements that make up the environmental system under consideration. A system capable of keeping a balance of structure and function is called stable. Stability, which is a property related to biodiversity, allows the system to react to any kind of natural and anthropogenic disturbances. Fragmentation is a strong threat to biodiversity: man-made areas and artificial linear structures (roads, highways, railways, power lines) in fact, represent low permeability barriers to the movement of many species that may be extinct either due to the reduction of the surface of the remaining habitats available, or because the increase of their isolation. The urban landscape is the place where this process has occurred more prominently.

"The city, from an ecological point of view, can be considered a complex artificial ecosystem that like any other ecosystem consists of habitats with different degrees of naturalness: artificial habitats (buildings, industries, infrastructures), semi-artificial habitats (gardens, trees, urban allotments), semi-natural habitats (urban forests, parks). The urban ecosystem degrades seamlessly from the city centre towards the peripheral area, blending in agro-ecosystems and natural ecosystems" [7].

Semi-artificial and semi-natural biotopes, in particular, can play a crucial role within the city in terms not only of usability and comfort, but also, from an ecological point of view.

"Green areas are, in fact, important habitats and valuable ecological niches for the protection of biodiversity in the city. The survival of many plant and animal species depends precisely on the presence of natural areas even small where they can find the ecological conditions necessary to carry out their vital biological functions" [8].

In this case, the open spaces of the city of Juazeiro, as well as those of many other cities in the same geographical region and climate, are public areas that are often without a precise intended use and sparse vegetation. Urban fragmentation is evidently clear: the open spaces are completely isolated in a hostile matrix formed by the settlements and infrastructure links which are slightly permeable barriers to the biological flows. The elements constituting the environmental system are therefore completely disconnected from each other and are characterized by poor ecological/ecosystemic quality due to the low levels of vegetation and faunal biodiversity. In this situation, there is also the poor "state of health" of the river system that should be the main ecological connection system of the territory. This drainage network consists of the São Francisco river that borders the city of Juazeiro and three canals that after cutting across the urban area territory converge into a single channel that flows into the river. Over the past 40 years, the São Francisco river has been the subject of a series of interventions that have fundamentally altered the ecosystemic and hydrogeological characteristics: the destruction of the forests that covered the banks, water pollution caused by urban and industrial waste, the monoculture of soy and sugar cane and the construction of seven hydroelectric power plants have contributed over time to its degradation.

The canals in the city (fig. 4) are partially covered by large slabs of stone, in the uncovered stretches, there are poor condition of the banks and the floodplains are often completely dry because of the very high evaporation rate that exceeds the water supply coming from the rain. In the design and/or requalification phase, in order to ensure the ecological functions of the urban green spaces, it is necessary that they are characterized by an adequate environmental quality and above all that they are connected to each other. This means ensuring a network of elements that can be useful to maintaining an appropriate level of biodiversity through the presence of connection and continuity elements between the physical and functional areas, both urban and peri-urban. It is obvious that these conditions, in the case of the open spaces of the city of Juazeiro, are not satisfied: this indicates the need to prepare a series of environmental measures to improve, on the one hand, the regeneration of the already compromised ecosystems, while the other, the reconstruction of the

connections between the natural habitats and remaining pockets of vegetation with a focus on protecting them from the São Francisco river and the existing channels. The environmental requalification of the area should also aim to restore the balance between the urban and hydrographic network. This will be possible if a sufficient level of quality is restored to the water and if the cemented stretches are re-natured, thus producing positive effects both from an ecological as well as perceptive and use points of view.

Abstract

The priceless landscape of this Iberian settlement consists in its unique site in an exceptional natural environment on a mountain ridge called "La Serra Grossa". Although the site's degree of conservation is very good, the basements of the buildings are the only structures conserved in situ and similar to what occurs with other deteriorated architectural artefacts, reading the volume of the buildings is difficult based solely on the conserved ruins. In addition, the itinerary conditions in this wild natural setting make it necessary to develop resources which provide an architectural interpretation and in an overall sense, define the meaning of the visit.

The main objective of this intervention has been to contribute in a progressive way to the conditioning and sustainability of this archaeological site to improve its visits, stimulate its appreciation and include new groups of visitors. The implemented actions have contributed to the progressive definition, conditioning and enjoyment of the route and the landscape by making use of a site boundary system and several tactile accessibility devices which did not exist until now. At the same time, they enhance the experience of the specific qualities of this natural setting, aromas, temperature, irregularity and variety of the environmental conditions among others, as stimuli which encourage a significant and unforgettable haptic perception for some visitors such as the case of persons with visual disabilities or children.

The tactile representation of this settlement in its natural context represents an innovative initiative and solution in its role as a means of useful communication for diverse audiences and particularly for the above mentioned groups.

The main value of this intervention consists in its contribution to improve the communication and accessibility to the cultural heritage, especially the rich archaeological heritage of the Iberian age (6th - 1st Centuries B.C.) which is little known among the general public.

Keywords: interpretation, accessibility, design, cultural landscapes, archaeological site

1. The Iberian Settlement of Bastida de les Alcusses: Value and Meaning

La Bastida de les Alcusses (Moixent, València) has been known since 1909. This site is an Iberian settlement occupied from the end of the 5th century BC to the mid of the 4th century BC. The Site. It is an upland site located on a ridge in the Serra Grossa mountains at 741 meters above the sea level. It is strategically located at the intersection of two natural routes of major historical significance from the interior to the coastland. The current environment of the site is a forest area with major ecological value with a pine wood and low Mediterranean scrubland. The current fruit tree cultivation in the plain have transformed many plots, but it is still possible to observe a landscape, essentially characterised by the traditional rhythm of agricultural labours with hardly any modern buildings.

La Bastida de les Alcusses is interpreted as an *oppidum* or fortified central place of a political territory. The *oppidum* is a crucial part of the settlement pattern throughout all the Iron Age in Iberia. Integrated

in their immediate environments and within the rural economy, they are the highest range of the hierarchy in the settlement pattern which, in this area, is formed by a number of *oppida* as centres of small regional territories. [1] [2] [3]. The site is a major reference for the study of Iberian culture and an exceptional case to learn about this type of settlements due to various reasons: first, it was occupied during a very short time period, not exceeding three or four generations, before it was abandoned. The conservation level of the structures is very good since there is no overlap with buildings from other time periods, and the wall itself has contained and sealed the artefacts of the occupancy in the interior. Secondly, the abandonment was triggered by a violent episode, which caused fires and pillage where the inhabitants left behind the majority of their daily life implements, tools in perfect condition and personal objects, which were discovered in situ in the excavations. And thirdly, a spacious zone of the site (approximately one third) was the object of an extensive excavation between 1928 and 1931 with a meticulous inspection method which was exemplary for that age.

Fig. 1: General Aerial View of the Site in its environment.

The settlement covered four hectares and was surrounded by a walled enclosure that followed the contours of the hilltop. This wall is some 4 metres wide and there are four gates: three located to the western area (South, West and North gates) and one to the eastern area (East gate). In its final phase of occupation there are three towers (two between the West and South gate and another larger one, by the East gate), probably because the site was under structuring before being definitely destroyed and abandoned. The gates provide access to the streets with variable widths, however they did permit road traffic, above all designed to channel the surplus crops and commercial goods. The organisation of the buildings has been structured along a central street which crosses the entire settlement and several perimeter roads next to the wall sections. Other nearby perpendicular streets organise lateral areas and spaces without buildings laid out as squares. There was a large granary where the excess agricultural goods were stored and houses of diverse size and complexity which were organised in neighbourhoods.

La Bastida was abandoned around the third quarter of the 4th century BC following a violent episode with other Iberian groups of the area. The extensive excavations carried out by the Museum of Prehistory in Valencia since 1928 and the fact that its inhabitants abandoned the settlement leaving a number of daily life implements in there make this site the best example for an understanding the internal organisation of an Iberian oppidum during the 5th and 4th centuries BC. The causes of its

destruction and abandonment are still subject to doubt and controversy, however they must be placed in the context of the activities and conflicts which arose between specific Iberian groups in their competition for resources.

The significance of the site is extraordinary. It was declared a Historical Monument in 1931 because of the size and outstanding quality of the upstanding remains and finds. The latter include Iberian inscriptions on lead tablets, bronze figurines, most notably the so-called Moixent Warrior, and a large number of iron tools and pottery. Today, the Museum of Prehistory of Valencia continues its research activities at the site with extensive excavation, restoration and educational projects around the Valencian archaeological heritage. It is open to the public all year round and there are guided visits. The objects recovered in the excavations are on display in the Museum of Prehistory in Valencia, although the archaeological museum in Moixent also exhibits a selection of findings.

1.2 Context of the intervention: conservation and use status

The site is located in a relevant landscape context, in a mountain area with a high ecological value surrounded by an agricultural environment devoted to grape cultivation. The plots are the property of the Town Council of Moixent which has ceded their management and the implementation of the research projects -archaeological excavations and laboratory to the Museum of Prehistory. The museum develops educational and experimental archaeological projects - simultaneously with the consolidation and the restoration of the structures for their enhanced experience and their inclusion in order to revitalize the local tourism industry.

Although the site's degree of conservation is very good, the basements of the buildings are the only structures conserved in situ. Similar to what occurs with other architectural ruin artefacts, reading the volume of the buildings is difficult solely based on the observation of the conserved ruins. Accordingly the Technical Team from the Museum of Prehistory has implemented resources to facilitate this architectural interpretation to visitors in various work phases since 1990. The main criteria has been a deep respect for the valuable landscape of the settlement in its particular site and the protection of the heritage of these ruins with minimal invasive interventions.

Since the sole conserved structures are the basements of the walls (both in the houses, walls and gates), always made of stone masonry, the consolidation works have been focused on their protection in various phases, by means of their partial reinforcement with masonry screens, taking into account the reversible nature of the actions. In this way, they aim to facilitate the spatial interpretation and prevent its progressive theft with the replacement of the floors at the original level. These actions were implemented in several phases between 1990 and 2010, in the entire West front of the wall, including the three gates (North, South and West) and in five house complexes.

In the preliminary studies conducted to carry out this project such as the analysis and overall action, we highlight the following issues:

- To improve the horizontal accessibility and the walking obstacles in the entire complex and especially in the zones of interest which help to define the route
- The safety in several traffic zones or premises which proved to be especially conflictive since they involve exceptional sites.
- To enhance the potential scenic value of its interior and exterior landscape.
- The identification of the built and/or consolidated complexes as well as the outstanding milestones.

2. Objective and relevant elements of the intervention process

The primary objective of this intervention has been to make a progressive contribution by means of design [3], to the development of the refurbishment and the sustainability of this archaeological environment and the improvement of its visit, by promoting its appreciation and the inclusion of visitor groups, such as the case of persons with a visual disability. The developed project implemented the concept of creative heritage management [4], in the framework of strategic planning in which the sustainability of the cultural site is linked to the quality of the visitor's experience, the diversification of the financing sources, the reinvestment to improve the heritage as well as contribution to the local development and job creation.

The criteria of the research team in charge of this archaeological complex have shown a major sensitivity towards the priceless landscape of the settlement in its particular site and the protection of the existing artefacts with minimal invasive interventions. This fact combined with the limited economic resources available made it necessary to establish several priorities and in the end, the scope of the original project had to be cut back.

Guided by these parameters, the decision was made to develop and implement simple resources which permit the enhancement of knowledge, the identification of the complex's perimeter area, the safety conditions and in turn, create a comfortable context to enjoy the magnificent scenic views. For this purpose, several site boundary elements were designed which limit access to the site zones, specifying the transit areas and the excavation sites and they also serve as the temporary support for the visitors. Three tactile scale-models were executed which provide new resources for the accessibility, the perception and the interpretation of the site. In both cases, the aim was to make an impact on the design options by means of forms and materials [5], in order to act as a mediator in the appreciation of this archaeological setting, the quality of this landscape, and visitor's exploration of the itinerary with greater autonomy.

As a relevant aspect, it is worth mentioning the difficulty of implementing this intervention in the work site, derived from the geographical location of this site in the ridge of the "Serra Grossa", without electrical lines, precarious conditions for vehicle access and works execution, the ground variations in order to perform the multiple drilling tasks as well as assuring the care of the original ruins. The soil removed in this process was used to fill in the gaps in several points of the visitor route, thus improving the ground conditions.

We highlight as an essential methodological aspect, the crucial involvement of the specialists, in this case, the archaeology team responsible for this site, in the selection of the contents for the tactile scale-models and in the assessment and the suitability of the solutions implemented by means of the simulated display images.

2.1 Description of the elements implemented in the archaeological settlement

Site boundary elements at two levels permit a different type of tracking, zoning and definition of the space which facilitated its configuration as well as the dynamic *wayfinding* in the site [6]:

- Safety and Support rails to be installed in the three zones of the settlement with steep slope changes, which required protection to hinder accidental falls: two rail sections in conflictive points of the visit perimeter (behind the panel called *Barri del Sector Sud* and *L'entorn i l'explotació agrària*) and a third rail section on an existing summit in the settlement's interior. The first sections were longitudinally dimensioned according to the minimum required space and also adjusted to the available budget.

Fig. 2: Site Boundary elements in different applications.

Several of the design considerations that were raised and solved in this site boundary include: simplicity and formal austerity, economy, resistance, low maintenance, surfaces and materials without shiny finish which contribute to their integration in the environment. The element is characterized by the oblique angle of the fastener struts which discourage climbing, the horizontal level of its front view and the height difference of the gaps which invite informal support for people of different heights.

- Continuous demarcation boundary of the work zones and/or archaeological remains in order to protect them from transit as well as frame or define the boundary of the wayfinding and the artefacts of interest. This element can be detected and followed by the white cane of blind persons and can also be used as a temporary rest for young people and children.

Accessible tactile representation supports which extend the resources allocated to the communication and experience of the site focused on the active perception and construction of the space. These scale-models contribute features of overall and partial representation of the site and the outstanding milestones along a specific route.

Three tactile scale-models have been defined and implemented as resources, available for people with visual disability and other potential users such as children in particular and the general public. They have been installed in strategic locations in the current visit conditions, which include the planimetry location data and descriptive texts in relief and Braille.

We highlight that the design feature of these scale-models has been executed based on the analysis and preliminary research for this type of 3-dimensional resource. This study has revealed the non-existence of equivalent examples of these specific accessibility resources: tactile scale-models in landscape environments and tactile scale-models for buildings and archaeological ruins. This has required monitoring the experimental and participative research process focused on users with visual disability, with the aim to determine their formal volumetric features and textures.

The three implemented tactile scale-models were manufactured in cast bronze on display tables and accessible supports. All of them include the overall representation in the same layout of the settlement comprised in the wall's perimeter, the position of each one in the complex and a compass for spatial orientation.

Each one displays different aspects and levels of information about the settlement as explained below.

Fig. 3: Tactile Scale-model of the entire Archaeological Settlement.

- Representation of the whole settlement in its environment, maintaining the shape and proportions of the Mountain ridge on which they are located. The dimensions of this overall scale-model and the selected scale were determined by the comfortable and accessible width by extending the arms and touching it with the hands. This scale-model displayed the perimeter wall in the consolidated section and in the ruined section with their entry doors, their main traffic roads, the wooded area in which it was built, the general layout of the settlement, differentiating the consolidated areas, the archaeological remains areas and the unexcavated zones of the settlement. These elements are reproduced with different texture and reliefs which are accordingly depicted in a legend which permits blind persons to previously identify them for their subsequent discrimination. In some cases such as the wooded area, geometric symbols in volume were used which facilitated their discrimination and memorization. Location: in the exterior of the wall entrance.

- Representation of House 1 reproduced in the exterior area as the interpretation centre. The scale-model comprises its relief in a ground plan in order to observe the interior layout and identify it in

relation to the consolidated section which it represents and its volumetry with the sectioned roof in a corner, displaying the construction system, its form and finishes. It is located in the central route aligned with the view of the consolidated house 1 which it represents.

- Representation of the North entry gate. The scale-model comprises its relief in a ground plan in order to observe the interior layout of this tower with the lateral surveillance benches of the entry and its volumetry in the original form. It is located in the lateral service/secondary route or the carts entrance laid out in the wall interior next to this entrance.

We especially highlight that compared with other types of representations such as drawings or photographs, the 3-Dimensional nature of the scale-model provides certain advantages: it permits the observation from different perspectives and at different levels of detail, at the same time that it facilitates a panoramic view of the whole and how the different elements that integrate it are related to each other. In addition, in the case of blind persons or with severe visual limitations, they are essential for the communication and learning of the concepts of the different scale or magnitude [7] [8] [9].

3. Living Landscape in the Bastida de les Alcusses

The project's main contribution is the enhancement of the experience and accessibility to this cultural archaeological heritage and specifically to the heritage of the Iberian Age (5th-1st Centuries B.C.) which is hardly known by the general public. The implemented resources undoubtedly improve the conditions and quality of the visits to the site and increase the socialization and integration of people with disabilities in this unknown heritage. This action is framed within the Iberian Route of Valencia called *Ruta dels Ibers de València*, in which work is currently in progress, whose aim is to increase the knowledge and improvement of the tourist use of the archaeological sites from the Iberian Age in nine inland municipalities of the Valencia province.

One of the aspects which contribute innovation to this project has been that for the first time, an intervention has been executed in this cultural asset in the framework of a subsidy in which social, cultural and economic agents from the area co-participated in the decision-making process.

On the other hand, we highlight the maximum respect for the values of natural landscape by combining its projection as a cultural landscape by means of history and the current uses of the environment. Accordingly, the implemented actions have deepened the relation of this setting with the appreciation, knowledge and enjoyment of this local scenic landscape. The project has especially considered the environmental and landscape values of the specific promontory setting on which it is located and the rural scenery of "Les Alcusses" comprised by isolated buildings on mild mountain slopes and stream beds (farm estates called "masías" from the 18th and 19th centuries) and the traditional farmlands with grape vines and cereal crops.

The intervention was focused on enhancing the experience of both heritages: the definition of the itineraries which make it possible to free the woods and the excavation itself from the random routes which tend to deteriorate them; and the presentation of landscape elements linked to this settlement as a historical site. The relevance and essential preservation of this complex adds associated environmental values to the landscape's own value, such as the outstanding presence of wildlife species, whose protection is directly linked to the active maintenance of the current existing mosaic of land uses, air quality, aromas etc. This relation is established from diverse perceptive scopes that reinforce the valuation and respect for the landscape.

Accordingly, the landscape is identified as the surrounding key and meaningful environment in this settlement, which acquires relevance with the creation of scenic viewpoints which promote leisurely halts and contemplation. The specific qualities of the natural landscape are enhanced, such as the aromas, temperature, irregular terrain and variety of the environment, thermal sensations, etc. which represent stimuli that encourage the meaningful and unforgettable haptic perception for some visitors, especially for people with a visual disability or children.

On the other hand, the representation of the landscape as a natural context of the setting in terms of the tactile perception constitute an initiative and innovative solution as a means of useful communication for diverse audiences and very specifically, for blind people. The settlement's overall scale-model has been designed with a composition which includes different scales and forms of symbolic and figurative presentation of the multiple elements which comprise this landscape at the present time; nature, paths, buildings, ruins, etc. This facilitates its interpretation and comprehension as a specific space at a specific scale in relation to its environment.

3.1 Conclusions. New Uses, Management and Maintenance.

The positive impacts of the intervention are directly focused on the improvement of the qualitative aspects of the tourist visit, the interpretation of the site [10] and consequently, the assessment of the cultural heritage of this settlement from the Iberian age.

In varying degrees, the performed actions have contributed to the progressive definition, conditioning, safety and enjoyment of the itinerary at the same time that tactile accessibility devices were installed which had not existed until that time. Specifically, the installation of the handrail has contributed to the enhanced experience of the zone's landscape by creating two scenic viewpoints which today represent two small visitor rest and observation areas.

Another positive impact has been achieved by installing the tactile accessibility devices since they significantly improve the understanding of the conserved archaeological remains (observation from different perspectives and at different detail levels and in turn, facilitate a panoramic view of the complex and the way in which the different elements which integrate it are related to each other) and to facilitate the communication of concepts and information to sectors of the population which have been traditionally excluded, such as persons with visual disabilities.

Fig. 4: The elements installed in this environment demonstrate the potential of objects as the mediators of the visitors' experience of the site

In relation to the accessibility devices, it is fitting to highlight that the 3-dimensional nature of the scale-models provide specific advantages over the existing drawings in the panels: observation from different perspectives and at different detail levels and in turn, facilitate a panoramic view of the complex and the way in which the different elements which integrate it are related to each other. In addition, in the case of the blind or people with serious visual disabilities, they facilitate the communication and learning of concepts, which is a central feature in the consideration of the management of public heritage asset according to an inclusive design [11]. As a whole, these equipment facilities extend the resources allocated to the communication and the experience of the site focused on the perception or the active construction of a space for the general public, and hence its immense interest for the public presentation of the heritage.

We wish to highlight that the design of the accessibility devices have been executed based on the exhaustive analysis and preliminary research of this type of 3-dimensional resource. This study has revealed the absence of tactile scale-models in reference to landscape environments with archaeological remains, which has required following an experimental and participative process involving users with a visual disability, with the aim to determine their formal, volumetric features and textures, especially the scale-model of the entire settlement in its environment. The result has been the development and implementation of an innovative and pioneer resource in the scope which concerns us.

The entire intervention has been guaranteed by the continuous works executed by the Prehistoric Research Service team of the Museum of Prehistory of the Provincial Council of Valencia [12] and the results of their educational and communication project for the use and enjoyment of this setting. Based on the tracking data which has been recorded, an average of 14000 annual visitors has been estimated in recent years, which have been enhanced by regular and original educational activities such as the aforementioned visit workdays which were attended by 1500 persons in a single weekend. In addition to the already loyal visitor groups, this action has now included groups of visitors with visual disabilities. In fact, ONCE, the Spanish Organisation for the Blind at the Valencian Community has already promoted organised visits to Bastida de les Alcusses in their annual activities schedule, which has been successfully used by the project's technical heads in order to evaluate and test the implemented scale-models and the verification of their usefulness.

Simultaneously, the presented intervention has become an essential support resource for the Communication and Educational Project of the Bastida de les Alcusses included as an educational program in the Secondary Education centres; the scale-models are milestones in the route which reinforce the oral lectures and the possibility to touch represents a sensory stimulus for the students. In addition, the scenic viewpoints are recovered spaces to transmit knowledge about the landscape; these spaces are invitations for discussion and debate, encouraging the participation and interaction with the teacher, regardless whether this involves visits in the framework of training cycles or general visitors.

The link with the research has another exponent in this intervention based on the novelty of the implemented resources and the type of context, where the framework of the experiences were implemented in the Ph.D. thesis of J. Gual Ortí [13] with tactile resources for blind people in natural open environments.

Finally, this intervention contributes to improve the tourism options in the framework of the Iberian Route of Valencia (*Ruta dels Ibers de València*). This project has been specifically promoted by the Museum of Prehistory of Valencia and covers the enhanced experience and tourist use of the archaeological sites from the Iberian Age in the inland municipals of the Valencia province in which the Bastida de les Alcusses forms a part. This intervention contributes to the work to guarantee the free access and enjoyment for all the people in this heritage site, as well as the creation of new resources for the economic and cultural development in the local scope in a privileged environment, complementing the landscape, gastronomy and enology opportunities which the district offers.

Anima valens in corpore aegro: Paths of the Spirit in the Places of Health-Care

Anna MAROTTA

Department of Architecture and Design, Politecnico di Torino, Torino, Italy
anna.marotta@polito.it

Abstract

This paper aims to present recent experiences, conducted between research and application, concerning the so called "paths of the spirit", to deepen, update and articulate places of worships in hospitals.

The goal was not only to offer a private place for praying, but also to create a 'radiate spirituality' in the entire complex. This means that the thought and the soul dimension constitute powerful experiences, which are constant and shared, not being relegated to a few moments of the day or week. A dimension that helps us to accept the personal troubles of living people, not only to add material quality to our lives, but also to find common values in the mutual comparison, respecting the complex system of religious differences. The project has been embodied in the book 'Anima valens in corpore aegro', presented twice: on December 3rd, 2013 in Turin at the Molinette hospital; and on January 14th, in Vatican City, by invitation of Monsignor Zygmunt Zimowski, president of the Pontifical Council for the Pastoral Care of Health Care Workers.

Through the examination of case studies, critically and disciplinary selected and analyzed, the project aims to demonstrate that, in addition to therapeutic screened positive results, a "sustainability of the spirit" could exist, together with the well-known idea of "eco-technologic" sustainability.

Keywords: Multiculturalism, Dialogue among Faiths, Human-friendly Hospitals.

1. Introduction

The Italian Constitution (art. 4) acknowledges to all citizens "... the right to work, (...)", but also states "the duty to carry out (...) an activity or function, which may contribute to material or spiritual progress of Society". These words imply the effort towards a deeper, more aware and complex spirituality, both in the individual and in the collective dimension. The same need of interior meditation is decisively strengthened by the confrontation with the disease, even in its worst conditions.

The project – which is described here – has been characterized by a unique path: taking off from an experience in Turin, it has become a proposal of national and international relevance, with a high degree of attraction and participation.

2. Halls of Silence at the "Health Care and Science City" in Turin: the Origin of the Project.

The origin can be found inside other wider and more complex initiatives for the reorganization and restructuring of the Hospitals in Turin, with particular focus on the so-called "Health Care and Science City". On February 4th, 2013, the contract of research related to the "Halls of Silence" project was signed by the *Agenzia Regionale per i Servizi Sanitari – AreSS* – and the Department of Architecture and Design – DAD, Polytechnic of Turin. The Scientific Responsible of this project is Anna Marotta (DAD), the author of this paper.

The "Halls of Silence" project is a part of the ARESS strategic initiatives, and can be considered as a thematic development of the general design and planning criteria established in the Health Care and

Science City master plan. The main themes it faces regard the relation and interaction among “function and Health Care places” and “function and Sites of Worship”, in a hospital context characterized both by a great complexity of relations and services, and by a great variety of users, from the anagraphic, social and cultural point of view.

Thence the aim is to define criteria and guidelines for the individuation, articulation and design (functional, conceptual, structural and relational) of possible reliable “paths” for a “Health Care of the Spirit”, on the background of the design modes related to Health Care and Science City of Turin. The starting point is the state of the art of the master plan; meanwhile, hospital paths already proposed for the “Cultures and Religious” project at the Molinette complex in Turin will work as a model for the realization of the Halls of Silence.

The incentive to the development of the analytic and elaboration process related to these themes comes from the specific concern, expressed by Don Marco Brunetti (Director of the Diocesan Pastoral Health-care Office of Turin). In the actual process, he has seen the opportunity to identify the models and criteria to realize a “Health Care of the Spirit path” (or even more paths) in the “City”, on the base of the individuation and analysis of the various religions (meaning also the condition of laicality) to be taken as a reference.

Apart from the catholic places of worship, there is the need to evaluate the possibility to realize Halls of Silence, multi-faith places, or even places dedicated to specific forms of worship. On this account, places of worship will have to take into consideration the various needs and features of the users, for which they exist; and to find their correct localization, towards functions and activities located in Health Care and Science City of Turin.

Considering the general objectives and background, the theme related to paths and places of “Health Care of the Spirit” must be connected to the wider theme of “communication systems”, meaning not only specifically informative aspects, but the modality of organization and transmission of contents and sense. In particular, the last one is a very complex matter, due to the users diversity and sensibility, only in part referable to the theme of humanization of the Cure.

In this respect, while securing criteria and examples of spatial-functional organization and characterization, the design guidelines (whose elaboration has been object of the agreement between AReSS and DAD) will not do without finding possibilities and modes to favor intercultural and inter-faith dialogue. Among the inspiring ideas, the Pastoral [2] had particular relevance, especially when it says that: “beyond differences among the various Nations of the World, and in front of the great number of defies in the sector of Health Care, the Church and the christians are called to bring loving cure and assistance to all people, and to convey the message of hope, finding their source in the God of Life, Love and Mercy”, and this can be said for any place of worship.

The guidelines elaboration and the proposal of possible solutions of general design will have to leave aside – as already stated – the overall organization and distribution of the Molinette hospital complex, in order to pursue the objectives of the project described in the Master plan. In this respect, general criteria of design, related both to the functional configuration and to the modalities of localization, spatial organization and relation with the context, will be likely taken into consideration.

Hypotheses of plan and volume articulation, which have been taken as a reference (developed by AReSS and Metropolitan Urban Center), will not be considered as strict design bonds: they will act as possible modes of interpretation and actuation of the intervention policies and guidelines stated in the Master plan (even in relation to operative and organizational needs regarding the planning and programming of the works).

Inside the past experience, considering what has been stated up to now, the concept and value of the “Path of Mind and Soul” has been strongly confirmed. It will not only gather people needing recollection, reflection and meditation in a specific place, but also “Irradiate Spirituality” in the whole Health Care and Science City of Turin. The idea of “Sustainability of the Spirit” is then strengthened: sustainability is not only ecologic and/or technologic, but ethical and cultural. In this context, the dimension of Mind and Soul is a strong experience, constant and shared, not limited to just a few moments during the day or the week. This dimension helps us to accept the personal difficulties of Life, adding spiritual value to our existence; to find common values in the collective dialogue, respecting the complex system of religious differences; and to “act as a community”. This is education to condision, framed along a pathway which might be divided in the following phases: to inform, to know, to understand, to share. For these reasons, while planning the guidelines, the author meant to entitle the project “Anima valens in corpore aegro”.

3. Itineraries of the Spirit in Health Care places: research and design

The author was responsible for the scientific coordination of the project, assisted in this work by a group of research composed by DAD PhD fellows, PhDs and graduates, among who Gaetano De Simone, Serena Abello, Rossana Netti, Chiara Cannavicci and Paolo Ceresa can be named. The research results have been published on the volume entitled “Anima valens in corpore aegro. Luoghi dello spirito nella Città della Salute di Torino. Percorsi di cura dello spirito. Sale del silenzio, sale

multiculto, chiese” [1]. The text is organized in seven chapters, leading from the project premises to the definition of some guidelines, derived from methodological approaches and in-depth studies.

In a first introductive phase, the project of the Halls of Silence for Health Care and Science City of Turin has observed the formal context, defining the main objectives. The general features of the operative background were described, with a specific focus on indications and information given by previous initiatives at a regional level. A series of preliminary analyses allowed to trace the formal features of the functional and structural context, leading to the comprehension of the actual status and of the possible variances to the project.

In this respect, some researches related to the definition of a repertoire of theories and experiences, as an initial reference, have been made. These have been catalogued according to the related case-studies, suitably selected (figg. 1-5).

The spotting of guidelines among design and analysis methods, criteria and parameters was made by monitoring the targets, derived from the inspirational principles of the “Cultures and Religions Project”, which originated the general criteria for the definition of the “Needs Framework”.

The “Halls of Silence” project was worked out according to the general features of the complex, respecting the specific context of application, outlining the level of priorities and hypotheses definition and hierarchy, and never neglecting the relation between the Halls of Silence and the whole complex. Everything was done without forgetting the dimension of sustainable building, and of an overall sustainable approach. The volume recalls the main normative orientations, mainly for what regards the use of sanitizing colors, according to European rules. The design approach analysis ends with the spotting of the first guidelines for the definition of a procedure for the preliminary analysis and design. Metadesign is originated in the context of these first analyses. Its development takes into consideration commands and suggestions, derived from rules and experiences of already realized projects (fig. 6).

The scientific connotation of the research could not do without the description of documentary apparatus (bibliography, list of rules related to hospital, and glossary). In the same way, some paragraphs derived from design experiences, already performed by the author, together with her group of research, in relation to themes like vision, color and decoration. These features can not be considered as random factors in architectural design, particularly dealing with hospitals. Among the approaches and the methodological in-depth analysis, some parts have been devoted to the following subjects: color, color in motion and decoration, psycho-geometric/gestaltic modes of vision, neurosciences, vision and therapy, sustainability.

4. Paths of Faith in the humanized hospital

A strong point is represented by the “Inspiring principles: a decalogue”, also defined as the “Commandments”, approved and widely accepted by the ministerial commission. These are the “rules” which any “new Hospital” must respect.

1	HUMANIZATION	Centrality of the Person
2	URBANITY	Territorial and urban integration
3	SOCIALITY	Belonging and solidarity
4	ORGANIZATION	Effectiveness, efficiency and noticed ease
5	INTERACTIVITY	Completeness and aid-continuity
6	APPOSITENESS	Correctness of health-care and use of resources
7	RELIABILITY	Security and peace
8	INNOVATION	Diagnostic, therapeutic, scientific, technologic renewal
9	RESEARCH	Inducement to intellectual and clinic-scientific in-depth examination
10	FORMATION	Professional and cultural updating

Any informative principle is made clear in different modalities, and can be expressed in various actions. The first principles shows a very important concept, according to which a new hospital must be conceived on a human scale, focused on the person and his/her needs (especially if sick, than feeble); it must be a Place of Hope, of Healing, of Cure (if healing is not possible), of Welcome and Serenity related to trust.

The difficulty lies in harmonizing the complexity and technology of a “machine” – that might appear totally hostile and unmerciful – and aspects like the human dimension, trust – not fear – reception, health care, in other words “Humanization”.

Privacy, Comfort, Reception, Hearing, Orientation, Transparency, Communication, Information must be granted. Fight against pain in all its form has to be secured as well. The current idea of hospital as a place of pain, suffering and death will have to be transformed in that of “open” hospital, meaning a place of hope, fight against grief and suffering relief, healing or cure. In this respect, there is a need to

guarantee to the users not only an adequate sanitary answer, but also a psychological, social and religious one. Religious assistance is among the integrative services that the hospital must give itself. Among its primary objectives, religious assistance has to guarantee the possibility of worship in one's own religion, with active assistance by the faith ministers. On the other hand, the possibility of granting adequate spaces of worship for the different religions – especially for the main ones – is privileged among the design guidelines. In this respect, the projects tends towards the idea of “multi-faith” halls, which flank the catholic chapel, as already seen in other social contexts, such as the airports.

In addition to this, we have to cite article 4 of the “Intesa fra la Regione Piemonte e la Conferenza Episcopale per il servizio di assistenza religiosa presso le strutture di ricovero del Servizio Sanitario Regionale”, which reminds of the kind of service requested for religious assistance. In the definition of the object of the service, it is said the religious assistance includes: the institutional cooperation of the National Sanitary Service for the inclusion of religious assistance in the therapeutic path of the patient; the relation of psychological assistance, at a human and social level; the spiritual ministry, executed in individual and/or common form (with means of communication used in ecclesial activity, respecting the needs of the hospital environment) through the celebration of the divine cult, the Sacraments, the catechesis, the organization of pastoral, cultural and religious activities; the ethical and religious contribution in ethical committees and in the formation of the personnel in activities of service; administrative services for office organization and needs (certifications, correspondence, archive, care of chapel, liturgical furniture...).

The ultimate users, meaning those which will use the building during its lifetime, can be divided in three main categories (targets): users, patients and internal workers. The first can be divided in: “temporary” users, that is, using the structure for “temporary” services, sometimes repeated in time; users needing continuity and completeness of assistance from the social and sanitary point of view; users needing first aid with continuity during the day; healthy users, looking for periodical checking; users involved in burocratic duties; users, whose health is compromised by illness. Among the internal workers, we can remember: social and sanitary professionals; local doctors (general practitioners, pediatricians...); specialist doctors; nurses; social workers; students and postgraduates; technicians. Other categories of personnel involve administrative, front-office and auxiliary workers.

5. The Project Implementation

The idea of “Anima Velens” has been vividly appreciated both in general and in the sector of Health Care, so much that it has deserved a specific initiative of dissemination: the project described above was presented on December 3rd, 2013, at a convention, in the lecture hall of the Molinette facility of the Unversitary Hospital Firm “Health Care and Science City of Turin”: on this occasion, the theme of the “Paths of the Spirit” has been exposed, with particular focus on design ideas presented for the Health Care City of Turin. Among the interventions, we might remember the greetings of the intervening authorities, the introductive considerations by Monsignor Nosiglia (archbishop of Turin), the description of the State of the Art by doctor Angelo Del Favero (former general director of the Hospital firm), and, in particular, the contribution of doctor Mario Airoidi, regarding the experience and results brought by the project “Halls of Silence” inside the division of Oncology, and by the “Paths of the Spirit” in hospital context, thought and realized under the scientific coordination of the author (who has exposed the related results on that occasion).

The meeting had a gratifying outcome, both because it resonated with the words published on “La Stampa” and for the invitation by Monsignor Zygmunt Zimowski, President of the Pontifical Council for the Pastoral Care of Health Care Workers, to present the results of the work on January 14th, 2014, in Vatican City. On this occasion, all the themes related to the description of the project have been faced: Introduction and Opening (Brunetti, Di Marco); The Outcomes in the Legislation: Regione Piemonte's Protocol and Resolutions for the Institutional Actuation (Lombardo); The Accrual of the Shared and Compared Experience. Architectural Design for the Paths of the Spirit in Health Care Places: “Anima valens in corporea aegro” (Marotta), involving the “Discussion of design themes related to the quality of life in hospitals”. The meeting was over with an agreement on the “Possible future outcomes in the territories of Mind and Soul: the dialogue among specializations and institutions, nations and cultures”. In particular, hypotheses bound to bilateral cooperation to continue initiatives and researches have been developed, with evaluation of contingent requests of funding at a national and European level. Moreover, the possibility has been advanced, to promote a series of national and international conventions, which might be followed by publications.

After the Vatican meeting (at the presence of Don Marco Brunetti, and doctor Mario Lombardo and Lia Di Marco), doctor Angelo Del Favero, had the occasion to present the initiative to the actual Minister of Health, Beatrice Lorenzin, who showed interest for the great potentials of the project and its possible results.

Among the possible outcomes related to the themes of the “Paths of the Spirit”, it was possible to introduce another project, which joins different fields of research, in which the author and her group of research are versed. Our Pope Bergoglio bears the same name has the district, which now hosts the

Citadel of Alessandria. In this respect, this second project involves this important fortified complex of Piedmont (free from military occupation) in a proposal, which intends to convert a site of war in a place of Peace: a sort of museum, dedicated to multi-faith, tolerance and spirituality, through the realization of a Path of the Spirit, not different from that conceived for the Hospital. It is based thence on some main principles: information, knowledge, comprehension, condision.

6. First conclusions

How might these paths develop? Some design proposals expect the insertion of information point (according, for instance, to different Feast calendars), symbology of the various religions, temples and houses of pray, thanks to the realization of digital interactive projections, which might involve the users in multicultural experiences, with great affective sharing.

Among the first references, we might remember the Nobel Centre for Peace, which has its seat in a former railway station in Oslo, host the Nobel Field, a suggestive installation of Art, which symbolizes a garden (fig. 7). This is composed by a thousand sharp light beams, forming a sort of radiant lawn: various monitors emerge from it, showing the story of the winners of the Nobel prize; the soundtrack of the installation changes according to the moves of the visitor. "it's a garden in evolution – say the directors of the Centre – whose fruits are the ideals which the Nobel prize winners leave as a legacy: this is the right place to reflect on the idea of Peace".

Another example – which cannot be forgotten – is the Centre for peace (Peres Peace House) of Jaffa, commissioned in Israel by Simon Peres (Nobel prize for Peace), whose design is due to Massimiliano Fuksas (fig.8). The center was conceived as a place, destined to become the main seat of discussion of arab-israelian initiatives, in the perspective of a gradual process of appeasement in the Middle East, promoting projects for the empowerment of local groups and individuals. The first event taking place in the building was the ceremony for the graduation of twenty-one women, most of them Arabic. This example implements the idea of Peace through the alternation of layers of concrete and layers of translucent glass. In this way, the structure is enlightened during the day, to give the light back during the night, offering an almost magical image, which convoys the spiritual message expressed by architecture. "I thought of a stratification – says the roman architect – of a building which could represent Time and Patience (...) a stone basement, which keeps the building lift over the meeting place, from which one enters through two long staircases to a place of rest, in which dimensions, height and light coming from above help us to forget earthly troubles, and put us in the right, positive mood to meet other men and women". The Centre of Peace is a parallelepiped, obtained by the stratification of irregular plans of concrete and glass, founded on a monolithic basement, on which edges the entrances for cars and pedestrians open. The six floors are served by stairways and elevators.

As a concluding remark, if architecture can be "therapeutic", it can be inclusive as well and can (must) be a place to build peace; peace of the soul, but not only individual. This can be achieved through the Itineraries and Paths of the Spirit, that – for now – have been proposed in the Health Care Places, but could be implemented in other situations involving the collective.

We may agree with Gandhi, when he states: "Maybe it will take time, before the Law of Love is adopted in international affairs, but if we want to save ourselves and give an important contribution to the progress of the World, we must tread with determination the Way of Peace".

PERCORSI DI "CURA DELLO SPIRITO". SALE DEL SILENZIO, SALE MULTICULTO, CHIESE

Capitolo
02

Repertorio delle schede con i casi studio individuati e criticamente selezionati

2.1. UNA SCHEDA PER L'ANALISI E IL PROGETTO

La scheda-tipo oggetto di questo capitolo è strutturata per campi e keywords: quando non compilata, costituisce già un primo indirizzo per l'organizzazione del lavoro – fra analisi e progetto – di messa a punto delle Sale del Silenzio. La stessa dovrà essere integrata dalla "Procedura" consigliata al capitolo 4.

Per converso, è risultata un utile strumento per organizzare i dati di alcuni casi studio individuati e criticamente selezionati, ovviamente passibili delle più ampie integrazioni e implementazioni.

Segue la schedatura di esempi internazionali e nazionali di Sale del Silenzio, luoghi multiculto e altro. Tra quelli nazionali si citano il caso torinese delle Molinette e quello ferrarese di Cona. Da questi è stato possibile estrapolare aspetti positivi e negativi, possibili criteri e parametri di progetto da confermare e assumere nelle fasi di rielaborazione progettuale.

2.2. SCHEDATURA DEI CASI STUDIO

Il repertorio che segue è preceduto da una "scheda-tipo" non compilata che potrà risultare utile per affrontare ogni eventuale fase di analisi e di progetto.

1. Cappella multiculto e centro per attività religiose in Campus Universitario, Cambridge, Massachusetts, USA, 1955;
2. Sala del Silenzio presso la Porta di Brandeburgo, Berlino, Germania, 1994;
3. Luogo multiconfessionale di preghiera e raccoglimento in complesso ospedaliero, Marsiglia, Francia, 2000;
4. Cappella Evangelica, Monaco, Germania, 2000;
5. Spazio per la Preghiera e il Silenzio in aeroporto, Monaco, Germania, 2003;
6. Scultura, installazione. Progetto per uno spazio di tranquillità e riflessione, Berlino, Germania, 2005;

7. Sala per incontri interculturali in Campus Universitario, Francoforte sul Meno, Germania, 2009;
8. Stanza del Silenzio. Ospedale Molinette, Torino, Italia, 2009;
9. Sala del Silenzio in complesso per uffici. Thyssenkrupp-quartier, Essen, Germania, 2010;
10. Sala multiconfessionale in complesso ospedaliero, Hartford, Connecticut, USA, 2011;
11. Sala del Silenzio in edificio adibito a biblioteca, Stoccarda, Germania, 2011;
12. Sala senza rumore: installazione in centro commerciale, Londra, Gran Bretagna, 2012;
13. Progetto in concorso per una cappella multireligiosa in Campus Universitario, Jacksonville, Florida, USA, 2012 (progetto);
14. Spazio di preghiera interreligioso in complesso ospedaliero, Annemasse-Bonneville, Francia, 2012 (progetto);
15. Progetto per uno spazio di culto multireligioso, Berlino, Germania, 2012 (progetto);
16. Spazio di tranquillità e riflessione in complesso ospedaliero, Palo Alto, California (in costruzione);
17. Sala del Silenzio in aeroporto, Berlino, Germania (in costruzione);
18. Installazioni in un progetto per uno spazio di tranquillità e riflessione, New York, USA;
19. Progetto per una Stanza del Silenzio in complesso ospedaliero, Cona (FE), Italia (progetto).

Sono inoltre state analizzate recenti realizzazioni di nuovi ospedali italiani con lo scopo di individuare i criteri adottati per la localizzazione dei luoghi dedicati al culto religioso ed alla spiritualità. Il repertorio di esperienze, illustrato mediante sintetiche schede di analisi, è il seguente:

20. Nuovo ospedale Sant'Anna di Como (2007)
21. Nuovo ospedale di Vimercate (2010)
22. Nuovo ospedale di Pistoia (2013).

The Valencia Region La Luz de las Imágenes Foundation: a specific way of managing heritage

Carmen D. QUINTERO¹

⁽¹⁾ Fundación de la Comunidad Valenciana La Luz de las Imágenes, Valencia, Spain
carmen@laluzdelasimagenes.com

Abstract

The Valencia Region La Luz de las Imágenes Foundation was created in 1999 with the aim of restoring and disseminating Valencian cultural heritage. However, the most distinctive aspect of our Foundation is the manner in which it manages this heritage. It follows a model that is not based solely on restoration. It not only focuses on the restoration of works of art and buildings in short periods of time (usually less than one year) in order to provide Valencian citizens with a return on the investments carried out within the shortest possible time. It also strives to disseminate information relative to the work carried out as part of each restoration campaign undertaken by the Foundation.

Throughout the ten restoration campaigns undertaken in the last 14 years, this institution has recovered 57 buildings, including the main architectural sites in the Valencian Region, and 2,976 artworks (paintings, silverwork, documents, sculptures, etc.). It has organized 10 exhibitions in different towns throughout the Valencian Region in order to advertise and promote this vast array of heritage and which have been visited by almost 4,000,000 people. Motivated by its vocation to educate, the Foundation has organized workshops to demonstrate the importance of restoration work and the need to preserve heritage. As part of this objective, it has published dozens of works, such as catalogues, restoration books, audiovisual and music cds, etc.

In addition, our Foundation encourages the towns in which its campaigns are developed to become involved with the heritage in question in order that it may occupy a central place in the area's cultural tourism and create wealth, not only with the arrival of visitors to the exhibitions, but also with the recruitment of local staff.

This intervention model, combining heritage and social profitability, enhancement of cultural heritage and the improvement of local economies, was awarded by the European Union's Europa Nostra Awards for its exemplary contribution to the preservation of cultural heritage in 2009, and the International Cicop Award for exceptional and relevant work in the field of World Cultural Heritage in 2012.

Keywords: heritage, restoration, exhibitions, management, social profitability.

Introduction

The Valencia Region La Luz de las Imágenes Foundation was created in 1999 as an ambitious, exciting project aimed at recovering the Valencia Region's movable and immovable cultural heritage. Under Article 5 of its Statutes, "the purpose of the Foundation is the restoration of movable and immovable assets representing the historical and artistic heritage of Valencia, as well as the organization of exhibitions and displays of artistic and historic character, obtaining, by means of the same, the collaboration of all the public, ecclesiastical and corporate stakeholders for the dissemination of the region's rich heritage among ITS citizens."

This is a project that has, from the outset, worked with a multidisciplinary team to address the task of enhancing the value of the Region's main buildings and works of art, not all of which are well-known

and recognised, but which hold an emotional or sentimental value for THE inhabitants of the towns and villages to which they belong.

Thus, some 14 years ago La Luz de las Imágenes set off on a long journey, during which it has shed light on the Valencia Region's main architectural and artistic treasures with the aim of involving the largest possible number of stakeholders in the project. We consider the implication of the greatest possible number of institutions and individuals in the recovery of the heritage an asset.

On the other hand, the manner in which we deal with the recovery of our heritage is not limited to the restoration of movable and immovable assets, but rather from the beginning we have made a great effort to raise awareness not only of our work, but also of all the heritage recovered through exhibitions, publications, the organization of training workshops and the participation in conferences.

The factor that we believe sets us apart from other institutions or organizations dedicated to the protection and restoration of heritage is the manner in which we manage that heritage. The sum of heritage and social profitability is fundamental to us. That is, that the restored heritage becomes an economic engine within the area in which each action is undertaken, especially during the time in which we keep the exhibitions open, and also upon their conclusion: on numerous occasions we have been able to place hidden villages and remote locations that were relatively-unknown to the majority of the Region's citizens on the map and seen how, following their involvement with the Luz de las Imágenes, they have become attractive destinations for potential visitors.

1. La Luz de las Imágenes Foundation: 57 buildings and 2976 movable assets restored

In 1999, the Valencia Regional Government decided to launch the La Luz de las Imágenes Foundation with the aim of "organising artistic and historical exhibitions in different points throughout the Valencia Region in order to disseminate the Region's rich heritage among its citizens. To this effect, the successive editions of the same shall be itinerant throughout the Valencia Region".

During this 14-year period, La Luz de las Imágenes has restored a total of 57 religious and civil buildings and 2,976 movable assets, including paintings, sculptures, documents and jewellery, and artistic heritage "in situ", such as keystones, frescoes, sculptural decorations and altarpieces in the buildings in which the actions have been carried out in 123 locations within the Valencia Region. Some 100 million Euros have been invested to date, and the restoration campaigns carried out during this period have included the participation of 954 restorers, 179 architects and engineers, 43 archaeologists and 606 historians.

Fig. 1: Restoration of a large canvas in the Church of Saint Mary in Alcoy (Valencia)

The actions carried out by La Luz de las Imágenes have returned the splendour to authentic architectural gems from the Valencia Region, including the cathedrals of Valencia, Segorbe (Castellón), Orihuela (Alicante), the co-cathedral of Saint Nicholas in Alicante, the collegiate basilica cathedral of Saint Mary in Xativa (Valencia), and the archpriest church of Vinaròs (Castellón), architectural examples that have subsequently served as temporary headquarters for the exhibitions organized by the Foundation upon completion of its restoration campaigns.

In addition to religious buildings, La Luz de las Imágenes has also carried out work on various civil buildings. In such cases, the interventions are always carried out in agreement with the buildings' owners, usually institutions such as town councils, which indicate the future use to be given to the properties. The actions undertaken are thus adapted to these uses, with the aim of reaching a dual objective: that the Foundation, upon the conclusion of the action, may use the buildings as part of its expository itinerary (for example, as a visitor reception centre or as a venue for educational workshops), and that the owner has access to a finished space that is adapted to the intended use, with the social benefit that this represents. In most cases these properties, upon which we have acted in many cases after they have remained abandoned and closed for many years as a result of a lack of municipal funds, are converted into municipal museums or conference centres following restoration, thus forming part of the Valencia Region's cultural circuit. In this way, they contribute to increasing the cultural offer within our geographical area.

In the case of movable assets, La Luz de las Imágenes has its own Movable Assets Conservation Centre, which is located in the town of Bétera (Valencia). The centre works with a complete technical team of restorers who are specialised in painting, sculpture, gold-leaf, jewellery, paper, woodworking, etc., and who apply the most advanced restoration methods suitable in each case. From museums, private collections, churches and convents, after being located and selected for one of the Luz de las Imágenes' exhibitions, after exhaustive research by the exhibitions' curators, in the majority of cases these movable works are transferred to the centre, although in others, due to their size, the interventions are carried out by the specialist restoration team in the locations in which the works are situated. The same applies to cases of restoration of artistic heritage "in situ", when the geographical mobility of La Luz de las Imágenes' team is constant. The restoration teams spend weeks travelling to locations in which their restoration skills are needed.

On the other hand, La Luz de las Imágenes does not limit itself to restoration carried out as part of its own campaigns. Its scope goes beyond this limit. During 2012, the Foundation was charged with the restoration of the church of Saint Christopher in Lorca (Murcia), which was severely affected by the earthquake that struck the city in May 2011 and left the temple out of service. This was an act of solidarity to which the Foundation assigned a budget and staff (architects and restorers), and which allowed the temple to be reopened in 2013. It has also carried out the restoration of the walls of Xativa (Valencia) and Segorbe (Castellón), the castle at Vall de la Gallinera (Alicante) and the Valdecríst Charterhouse in Altura (Castellón), all financed by the 1% Cultural programme of the Spanish Ministry of Culture.

1.1 Ten restoration campaigns in fourteen years

La Luz de las Imágenes Foundation develops its work through restoration campaigns that usually last between 10 months and 1 year. One of the Foundation's maxims is to minimize the length of the interventions on heritage. Once the budget has been approved and the contract awarded, agreements are reached with the different professionals - builders, restorers, architects, etc. - in order that they may carry out their work within a predefined period (never exceeding one year) subject to the opening date of the exhibition which closes the campaign.

For La Luz de las Imágenes, the social profitability of the work carried out is fundamental, i.e., that the investments effected provide the quickest possible return for the region's citizens in the form of the opportunity to contemplate movable and immovable heritage that has been restored in the shortest time possible as part of a process that places great priority on the complexity of the interventions and their implementation in accordance with rigorous standards. It is a well-known fact that, on many occasions, actions of this kind can be never-ending. With this in mind, the Foundation operates with a further objective: the search for consensus between all the technicians and institutions involved in each case, in order that the processes may be carried out quickly and the final result of the investment is available for the public's contemplation and appreciation in the shortest possible time. The only factor that can lead to delays in the restoration work are contingencies that may arise during archaeological excavations.

Those responsible for the Foundation (the Foundation's manager, the head architect responsible for the works and those responsible for restoration of works of art and movable assets) subject the progress of each project to a weekly control. On scheduled days they visit the works and those responsible for carrying out the same in order to obtain first-hand knowledge of the progress and to ensure that there are no deviations from the schedule. This coordination and detailed monitoring also allows the Foundation to fulfil another of its objectives: cost control, aimed at avoiding budget deviations. We must never overlook the fact that the work we carry out is financed via taxes, that is to say, it is the citizens of the Valencia Region that enable us to reach our goals and, therefore, we scrupulously manage these funds in order to provide results within the deadlines and budgets established.

These efforts to meet our deadlines and to work in accordance with our budgets have enabled the Foundation to complete 10 restoration campaigns in 14 years. These campaigns have culminated in the following 10 exhibitions:

"Sublime" (Valencia, February - August 1999): 398,463 visitors

"Desconocida, Admirable" (Segorbe, September 2001 - August 2002): 204,321 visitors

"Semblantes de la Vida" (Orihuela, March 2003 - April 2004): 532,448 visitors

"Paisajes Sagrados" (Sant Mateu, March 2005 - January 2006): 510,975 visitors

"La Faz de la Eternidad" (Alicante, March 2006 - January 2007): 548,722 visitors

"Lux Mundi" (Xàtiva, March 2007 - January 2008): 574,232 visitors

"Espais de Llum" (Castellón, Borriana, Vila-real, October 2008 - August 2009): 250,000 visitors

"La Gloria del Barroco" (Valencia, December 2009 - October 2010): 572,658 visitors

"Camins d'Art" (Alcoy, March 2011 - March 2012): 232,000 visitors

"Pulchra Magistri" (Culla, Catí, Benicarló and Vinaròs, December 2012 - in progress).

In total, the exhibitions staged by La Luz de las Imágenes have been visited by nearly four million people.

An innovative aspect introduced by the Foundation in the last three years is the fact that it is the institution's workers themselves who are responsible for the creation of the design and installation of each exhibition, taking into account the expository narrative previously defined by the exhibitions' curators. This has enabled cost savings, since the materials (exhibition panels, structures, etc.) are reused and adapted to the demands of each new design, and the transfer of the works is controlled directly by the Foundation, which has its own vehicle and expert staff for the handling of each exhibit.

1.2 Dissemination and education

The exhibitions staged by La Luz de las Imágenes represent only one of the visible aspects of the work undertaken to bring the region's citizens into contact with their cultural heritage. In addition to the exhibitions, which are always organized in buildings that have been previously restored, thus increasing the visibility of both the restored works and the buildings themselves, the Foundation uses two other ways to engage citizens with their heritage: the organization of educational workshops and publication of different works.

Each exhibition offers educational workshops, usually in one of the restored areas, aimed at all audiences, and especially at young people and children. Through the use of manual and multimedia tools, attendees discover the details of the restoration processes and are able, through various activities designed specifically for each exhibition, to put the skills learnt into practice. Since 1999, some 370,000 users have attended these educational workshops.

Fig. 3: Visitors to “Camins d’Art” (Alcoy-Valencia) (left) and educational workshop held during “Lux Mundi” (Xàtiva-Valencia)

Moreover, since 2012, La Luz de las Imágenes has run a permanent educational workshop in its Movable Assets Conservation Centre in Bétera, which is operative during the periods between exhibitions and is overseen by the Foundation’s own restorers. When attending this permanent workshop, users are able to obtain first-hand experience of the restoration of works and to carry out complementary manual and multimedia activities related with a chosen area of interest (gold-leaf, stone sculpture, wood carving, chromatic repair, mural painting, artistic and textile techniques).

This contact between the uninitiated and the tasks associated to the restoration work is fundamental to the Foundation, as it enables users to understand the importance of investing in the conservation of heritage, as well as allowing people without expertise in this area of knowledge, and especially the young, to discover for themselves that this investment in heritage and, therefore, in culture enables citizens to continue to enjoy that which already belongs to them.

Since its inception, the Foundation has also published dozens of works, including those corresponding to the various restoration campaigns and the catalogues detailing the movable assets that have been restored as part of each exhibition. In total, the Foundation has published:

- 10 catalogues corresponding to each of the exhibitions.
- 15 books about the architectural and artistic restorations carried out during each campaign and on different aspects related to each exhibition.
- 10 Cds of early music performed by the Choir of the Generalitat Valenciana.
- 17 DVDs on the restoration work carried out and on diverse historical and artistic aspects related to each exhibition.

The contents of these publications, especially the restoration books and the catalogues, are created by the historians involved in the selection of pieces for each exhibition and by the architects and restorers who carry out the architectural and artistic interventions. The coordination, translation, layout and publishing of each publication is carried out by the Foundation’s staff. In this way, the institution is able to control and monitor the entire process.

2. Heritage and social profitability: an internationally-recognised management model

After 14 years of work, the Valencia Region’s La Luz de las Imágenes Foundation has managed to create a multidisciplinary team of experts representing more than thirty occupations, including architects, restorers, archaeologists, stonemasons, glaziers, gilders, goldsmiths, historians, archivists, documentalists, administrative staff, journalists ... all of whom are highly-skilled and capable of proposing technically-appropriate solutions that are respectful towards the heritage and adapted, in terms of budget and deadlines, to the problems that may arise when addressing heritage interventions. During this time, La Luz de las Imágenes has been able to complete a circle that allows it to manage the assets in a comprehensive manner: project-restoration-dissemination-socio-economic profitability. The last aspect is the factor that differentiates our institution from other agencies involved in heritage management.

In 2011, Valencia University’s Inter-University Local Development Institute produced a report on the “Socio-economical impact of the recovery, intervention on and dissemination of heritage by La Luz de las Imágenes based on the “Camins d’Art” case” (“Camins d’Art” is one of the exhibitions staged by the Foundation). According to this report, in the case of “Camins d’Art” public expenditure of 7.8 million Euros, primarily financed through taxes, generated wealth in the Valencian economy to the tune of 8.3 million Euros, which represents a rate of return of 6%. These same ratios, when applied to previous years and under the conservative assumption that the effects on tourism are more or less the same, give an average rate of return on public spending of 11%. This means that, on average and over the

period considered, for every Euro of public expenditure on the Foundation's activity, an increase in wealth of €1.11 has been generated in the Valencia Region's economy.

Thus, according to the report on the generation of wealth, the activities derived from the restoration processes, the production of the exhibition and the attraction of visitors activate, through the payment of salaries, the acquisition of assets and the contracting of services, economic processes which generate income and employment in an incremental manner, in accordance with the forward (clients) and backward (suppliers) links. These effects manifest themselves in direct, indirect and induced ways due to the income effect. Therefore, in addition to the overall effect of 8.3 million Euros in terms of wealth, almost 300 (296) jobs were generated.

In the case of the "Camins d'Art" exhibition, the aggregated multiplier effects of La Luz de las Imágenes' activity were 4.0 for added value and 5.1 for employment. The contribution of tourism to the overall effect was 19% for added value and 30% for the generation of employment.

According to the report, the aggregate effects can be used to demonstrate that the sector that obtains the most benefit from the Foundation's economic activity is the cultural sector (57.4%), followed by the business services and the industrial sectors. By contrast, the main benefactors in the case of tourism are logically the areas of hotel and catering and retail trade (63.6%).

This report allowed us to corroborate that the Foundation's heritage management enables the investments made to be re-channelled into society and that such investments in culture are worthwhile. This is the line that the Foundation has intuitively followed since its creation as, although such scientific data was not available until 2011, the feedback obtained from local institutions pointed in this direction.

A great many municipalities request interventions by La Luz de las Imágenes centred on their heritage and the staging of exhibitions. As mentioned, the Foundation makes a direct investment in movable and environmental heritage that enables us to enhance their value and, therefore, their reuse. And sometimes even to put certain locations on the map. This is possible because our institution acts not only in big cities, but also in small towns, thus enabling them to enter the cultural and touristic circuit.

Given that the restored assets serve not only as attractions for visitors during the exhibitions staged by La Luz de las Imágenes (let us remember that each exhibition attracts an average of 400,000 visitors), but that they remain in their places of origin and that, following the conclusion of the exhibitions, the local authorities continue to exploit their presence. This provides a direct benefit for local shops, hotels and restaurants. Most of the time these establishments become fully involved in the exhibitions, offering special hotel rates and menus for visitors to the exhibitions.

The collaboration of local institutions and companies with the La Luz de las Imágenes has always been positive, as they recognise the economic benefit they obtain. By means of an example, we may consider the case of Sant Mateu, a village of less than 2000 inhabitants, which was one of the hosts of the "Paisatges Sagrats" exhibition between 2005 and 2006. According to data provided by the Sant Mateu Town Council's Tourism Department, 'if before "Paisatges Sagrats" 30,000 people visited the town annually, now we receive 140,000 tourists. Between two and three bus loads of visitors arrive in Sant Mateu each day, a figure that is doubled at the weekends, when all the local hotel and catering establishments are fully-occupied. This was not the situation prior to the exhibition, and as such the presence of La Luz de las Imágenes has created a direct impact in the life of the people living here'. [1] Similarly, the press also highlighted the impact of La Luz de las Imágenes on the tourism industry. On July 27, 2005, the journalist Emili Fonollosa published an article in the newspaper *El Mundo* in which he stated "the municipalities that host "Paisajes Sagrados" exhibition venues have seen a considerable increase in the number of visitors since the opening of the exhibition". [2]

Fig. 4: "Pulchra Magistri" exhibition in Catí (Castellón) (left) and "Lux Mundi" exhibition in Xàtiva (Valencia)

Fig. 5: *Mare de Déu Chapel, Alcoy (Valencia) before (left) and after the restoration carried out by La Luz de las Imágenes*

Furthermore, during the restoration works, La Luz de las Imágenes attempts, in so far as is possible, to contract the services of local companies in order to produce a return on the investment in the community.

Local staff for the venues, guides, maintenance and security staff, etc., are also contracted for each exhibition. In accordance with the number of venues employed for each exhibition, between 20 to 30 people are contracted for the duration of each project.

Another aspect to be noted is the presence of La Luz de las Imágenes in the media throughout the each restoration campaign. The Foundation has its own press department that issues weekly reports on the progress of the work undertaken and which creates interest in upcoming exhibitions as the respective inauguration dates approach. Press releases are issued on the progress of the work and press conferences are held over several months to report the latest news. Following the inauguration of each exhibition, domestic media sources are invited to guided visits, which in turn give rise to press articles and audiovisual presence throughout the Spanish territory, increasing the dissemination of our work throughout the state.

In order to raise interest in the exhibitions, the last restoration campaign was the first occasion on which the works were opened and free, guided visits were organised under the supervision of the architects participating in the project. This line of action enables visitors to receive accurate, technical information adapted to a public that does not always possess expert knowledge of our activities. The experience has been extremely positive and all the scheduled groups were fully booked.

This is another aspect on which the Foundation places great importance: the attraction of segments of the public that are not related to the art world. We are able to capture the public's imagination and interest in heritage through the previously-mentioned educational workshops and with initiatives such as the guided visits to the works and the organisation of concerts in the exhibition venues in order to present the music that we have recovered. By means of example, during the "Espais de Llum" exhibition we organised an organ concert during which pieces that were selected for the occasion were interpreted and which saw, for first time after many, many years of silence, the Baroque organ of the archipriestal church of Vila-real (Castellón), constructed by the Salanova family in 1724 and considered the best example of a baroque organ from the ancient Kingdom of Valencia, played once more in public. The organ had previously been restored by La Luz de las Imágenes.

Recent years have seen La Luz de las Imágenes' commitment to the region's heritage and its constant work aimed at the dissemination of knowledge about the same recognised in the form of two important international awards: the Europa Nostra Award 2009, in the category of "Dedicated Service", in which the jury highlighted the Foundation's exemplary contribution to the conservation and diffusion of information about heritage, and the CICOP Foundation Award 2012, endorsed by the UNESCO Forum, for its exceptional and relevant work in the field of World Cultural Heritage.

As part of this congress, three further communications will be presented providing greater detail on certain of the aspects outlined in this communication.

Conclusion

Since its creation, the Valencia Region's La Luz de las Imágenes Foundation has striven to bring cultural heritage closer to the region's citizens in order that they may feel it as their own and through it recognise their own symbols of identity.

The conservation and restoration of movable and immovable assets for their own artistic interest and that of other, less tangible assets or those of lesser artistic importance but equally deserving of being preserved by virtue of the esteem in which they are held by the region's citizens, precisely because they represent certain symbols of identity, is the first step. However, if we are unable to capture the

interest of all sectors and publics from an educational and inclusive perspective, in order that they may interiorise the fact that without heritage there is no past, the considerable investments required will not be understood, and less so in the current situation of economic crisis, and society, and specifically the sectors without expert knowledge of this field, will turn their back on history and lose the opportunity to discover their roots in today's current, ephemeral world.

La Luz de las Imágenes has demonstrated that heritage can be managed in such a manner as to educate and to interest, and that the corresponding investments are not only reflected in the conservation actions, but also in the social and economic revitalisation of the towns and villages in which the Foundation acts. There is no doubt about our commitment to heritage, but we are also committed to society, with those who are not experts in architecture, painting, restoration, etc., because, if we do not include these citizens, we will lose the opportunity for all of our projects to be understood and supported.

Abstract

The archipriestal church of Vinaròs is the latest building to be restored by the Valencia Region La Luz de las Imágenes Foundation to host the “Pulchra Magistri. The splendour of El Maestrazgo in Castellón” exhibition. This building was built at the end of the 16th century to fulfil the dual role of a parish church and a fortress in order to protect the town of Vinaròs from possible attacks of Berber pirates.

The restoration of the building is based on three intervention principles: the consolidation of the external image of the church, the recovery of the unity in the central nave and the recovery of the ambulatory for cannons. The outstanding feature of this church as a fortress makes this building special and different from the vast majority of the contemporary churches.

In the exterior of the church, the intervention has consolidated the strong image of the fortress wall which is completely polychromed with a trompe l'oeil architecture, unique in Spain. The interior of the church is very heterogeneous due to different interventions carried out in the past century. These interventions weakened the coherent contemplation of the central nave, so the unity of this space has been recovered through a global intervention and individual actions in the lateral chapels.

Regarding the ornamentation, the important sgraffiti on the walls and in the lateral chapels were recovered. The frescoes, with great artistic value and in poor conservation status, were also restored in several chapels. In the exterior, the Baroque entrance door was also restored bringing out its compositive aspect made of several kind of limestone.

Keywords: architecture, restoration, trompe l'oeil, church-fortress

Introduction

Vinaròs is a small coastal town in the north of the Valencia Region. In 2013, the city's main building was restored by the *Fundación de la Comunidad Valenciana La Luz de las Imágenes*, which researched the remains found on the site in order to restore their original historical and artistic value.

1. Vinaròs Archpriest's Church: the architectural duality of a temple-fortress

1.1 Vinaròs, a border city

Located at one end of what was the old village of Vinaròs and marking the beginning of the main street leading to the sea, we find the stunning archipriestal church of Our Lady of the Assumption. The power of the monument remains intact despite the passage of the years: it is a sturdy-looking building, which both acted as a key element in the defence of the old town and served as a focus for the

Fig. 1: The archipriestal church and its development alongside the defence system: a. 18th century; b. mid-16th century; c. 1586 _construction of the temple

inhabitants' spirituality. A monument whose history and transformations have always been linked to the town's urban and historical development.

In Vinaròs' old street layout (which is still evident today in the distribution of the streets, if not so much in the architecture), the temple stands as a border element, located at the northern end of the town and forming part of its defences since the end of the 16th century.

In its origins in the early 13th century, the town was located in reconquered Christian territory and was characterised by the standard morphology of this type of *exnuovo* settlement, based on a grid of small, perpendicular and parallel streets. The main thoroughfare, Calle Mayor, ran across the town from northwest to southeast, running from a small square in the extreme north that was host to the present archpriest's church and ending at the sea. From the beginning, it was surrounded by defensive elements of varying quality designed to protect the territory, as its condition as a border town represented a determining factor in its urban development.

Coinciding with the refortification campaign carried out in the Valencia Kingdom, the walls were extended during the 16th century, followed by the posterior construction of the church. This represented a significant development along the entire coastline of the Kingdom of Valencia, as evidenced in 1579 by the engineer Bautista Antonelli when referring to Peñíscola, situated a few miles south of Vinaròs, and the great concern relative to the seafront boundary:

(...) it is surrounded by its enemies, the Tagarins of Aragon and the Moors of the Kingdom (...), it lies five leagues from a Muslim port, from which those on land could be serviced by sea. [1]

1.2 The temple/spiritual vs. fort/defence duality

(...) a church that has been built in the fashion of a fort, necessary both for divine service and worship and for protection against the enemies of our Catholic faith (...). [2]

This quotation from the builders responsible for the new church explicitly describes the programmatic duality of the temple from its conception. A temple designed by Joan d'Ambruesa, in a style typical of the religious architecture of the time, whilst at the same time successfully incorporated into a fortress. Complying equally well with both requirements (religious and defensive), as if it were a mechanism, the archpriest's church of Vinaròs is an interesting typological example of hybrid architecture capable of combining two uses and two aesthetics in a single body: the exterior, compact and prepared for the defence of the town from attacks; and the interior, devout, perfectly designed to accommodate moments of divine worship and created in the style of the time.

1.3 Formal reality of a church connected to the defensive system

The archipriestal church was built in 1586 on new foundations, precisely in response to its dual requirements: a large temple capable of hosting the faithful living in the town, which had seen a significant increase in its population, and the need for an icon to complete the city's defensive system. Much of the new temple's surface was constructed outside the city walls, thus leading to an alteration of the defence system upon its completion. This fact would determine the monument's exterior image, above all in its northeast and northwest facades, which were placed beyond the walled city and which resemble those of a fortress more than of a temple. The corners were equipped with guard posts and a double strategic and defensive area for the protection of the city: a semi-exterior walkway along the building's perimeter on top of the lateral chapels, from which artillery was deployed, and a flat roof connecting with the wall and used for changing the guard. The rooms in the tower, which was built at a

later date, offered a connection to the walls, with the tower itself serving as the main observational point due to its great height.

The interior, dedicated to worship, has been designed in a formal, "Roman" style, highly-characteristic of Valencian architecture of the period, with the nearest vaults finished in the region's characteristic Gothic style.

Thus, the archipriestal church represents the town's most important and best preserved monument. The outer strength of the building, which became a key point for the town's defence, remains virtually intact: the passage of time has taken its toll on its surfaces, but the walls' morphology remains unchanged. The interior, more disjointed and altered over the years, required a study and investigation, which in turn revealed the successive layers deposited throughout history on the temple.

1.4 The meaning of the present and the recording of the past

Prior to an architectural intervention in this type of building, it is the knowledge of the past that reveals the manner in which to carry out the project. The definition of a series of operative guidelines becomes the *modus operandi* that establishes the form of the intervention.

The intention of enhancing the programmatic duality has governed the process from the beginning of the project. It is precisely the defensive exterior of the temple that converts it into a unique type of building, a character that has been conserved despite the different alterations carried out during its history.

The operational form of the project's development and its subsequent implementation has been closely linked to the research into and the knowledge of the building. The learning process, the construction stages of which were related to the historical context, has marked the course of the project's development. The passage of time has been incorporated into the strategy, enabling the discovery of the monument's historical reality to serve as a means of reflecting its past, whilst simultaneously conditioning and enabling the incorporation of new installations more closely linked to the present.

2. The interior intervention

2.1 The initial image and understanding of the order of the interior spaces

Prior to the intervention, the interior of the temple presented a heterogeneous aspect due to the overlapping of different periods and previous elements and decorative styles. The central nave presented an image dating from the early 20th century, with many plastered elements, structural elements with marbled strips decorated with pastel-toned borders and plasterboard-covered keystones. The chapels, the majority of which were damaged during the civil war, had been refurbished with paintings and emergency alters that did not respond to the building's character. And finally, the presbytery had been subject to a restoration several years earlier, during which layers of stucco and paint had been removed in an attempt to reconstruct building's possible original image.

Therefore, the exterior of the building represented an amalgam of hastily-executed actions, eclectic decorations and restorations that conferred a banal aspect to the elements they were intended to recover.

Once the elements necessary for establishing criteria and targets had been understood, and aware of the relevance of each of the decorative layers, work was begun on interpreting the treatment to be applied in order to enhance the building. The image of the central nave had to respond to a criterion of unity, capable of being understood as an indivisible element in which the globality of the whole dominates. This is the spine from which the lateral chapels are articulated, the latter in turn requiring consideration as individual, unitary elements: whilst each chapel maintains its own unity of elements, it is not necessary that it maintains unity with the adjacent chapels. And for this system to work, every new element introduced must be neutral and fully discernible from the surrounding context.

2.2 Study and determination of different surface layers

Thus the building's hierarchy was established and its parts were located within the scheme of the actions to be undertaken. The different layers present in each of the elements determine the final image, with those of greater value (historical and artistic) determining the nature of the intervention. Two predominant layers were found in the central nave: the layer of stucco, paintings and borders from early 20th century, and the layer of original decoration lying below, consisting of lime mortars with painted lines in the manner of false ashlar, together with the bare stonework of the structural elements. The decorative layer dating from 1916 had been badly damaged by damp, and in some sections it had disintegrated due to the presence of salts. In order to visualize the original lines on the stone facing as a whole, check their condition and determine the extent to which they could be recovered, a series of stratigraphic tests were conducted to determine the viability of their restoration. Practically all the sections of the vaults that had not been exposed to excessive leaks of water were

Fig. 2: The initial and final condition of the nave

found to have preserved almost all the grooves and brushwork associated with these decorations. The masonry of the ribs, arches and pilasters, meanwhile, was found to be in excellent condition.

The situation in relation to the side chapels was different, with each chapel presenting a different type of decoration and different periods reflected on their surfaces. The predominant style, however, was that of eclectic post-war compositions, in which very poor quality paintings and heavy altars and retablos were mixed with loud plinths made from inappropriate materials. Thus, each chapel was a jumble of objects and colours that were hardly representative of the temple's essence. During the study process, a decorative style which was found in almost all the chapels was studied. It was based on a layer created in the 18th century using the sgraffito method, with a thin layer of plaster standing out over an earth-coloured lime base.

Two chapels contained baroque pictorial compositions painted by local maestros, whilst another was decorated with gold leaf. As occurred in the nave, a strict research protocol, based on soundings carried out in various parts of all the chapels, was implemented in order to determine the conservation status of this level and the degree to which the previous layers had been lost. The results showed that the above-described model had been used to cover all the vaults and the bases above the ledges, whilst below there was a border running the entire length of the gold leaf up to a supposedly original plinth.

2.3 Management and combination of ornamental layers

As such, each of the layers applied to the temple's masonry over time were defined and analysed, revealing their degree of preservation, extension, qualities and historical and artistic importance. In view of the combination of all the different layers, the whole was treated as a model of overlapping architectures, each covering one another whilst allowing those decorative elements or details that were deemed interesting to be visible, under the provision that they did not distort the overall picture of the temple or its surrounding elements. A second level hierarchy was thus established, based on a decorative, global background, peppered with curiosities in the manner of archaeological traces. Therefore, reintegrations or additions were treated from a neutral perspective, avoiding their affecting or breaking the unity of their surroundings whilst allowing them to remain discernible from the original parts.

Based on this knowledge, on the combination of the different layers, an order was established for each, with a decision taken on which was to predominate and how they were to be arranged, in order to understand the hierarchy between the elements that simultaneously endowed the space with unity and complexity. All the superficial layers were eliminated from the central nave until the base was reached, thus creating the global image of the central area, composed of bare stone and lime mortar plastering in imitation of ashlar masonry. In certain points, evidence of the presence of soft-toned pictorial remains which decorated the front sides of the bases of the former arches and spandrels in the form of borders and bossages were left.

A decision was taken on which of each chapel's layers was to be treated as predominant. A disassembly protocol was established for the layers that had suffered the greatest degree of disintegration, coinciding with that of the second half of the 20th century. The operation carried out was very similar to

that of the main nave, consisting of cleaning the stone in order to reveal the structural elements and consolidating the predominant, representative decorative elements, which were highlighted by virtue of the neutral treatment applied to the rest. In the absence of intermediate layers between the sgraffiti and the subsequent decoration, it was decided to reveal the decorative element as the most dominant element within the space.

As opposed to the original decoration of the central nave, a large proportion of these coatings were missing, in some cases representing more than 50% of each of the gold leaf sections. Therefore, the action implemented was defined as a stylistic operation on how to treat missing sections. Following the criteria established for the overlapping of different layers, the missing sgraffiti was considered as the base level and treated as such, neutral and with a smooth finish and dull background, highlighting the baroque decoration as the main image. In this way, the traces of the drawings were submerged in an atmosphere in which, more than the details of the forms, the general texture was highlighted.

2.4 Reintegration and addition of new components

Once the walls and their coatings had been consolidated, and following the definition of the image of the temple's decoration, it was necessary to determine the manner in which the new elements were to be introduced, as well as the character with which they were to be endowed. The removal of the surface elements and the stripping of the layers in the areas that interfered with the understanding of the space and which distorted the interpretation of the relevant decorative elements was limited to specific areas, with the determination of a system composed of discernible layers related to each other within a global environment, and with the premise that they would be highlighted by the building itself. These additions acted as links between parts of the overall space, enabling the holistic understanding of each of the proposed levels of hierarchy. The new layers, overlaying the ornamental layers, revealed simple, neutral and light forms, occupying a second level as objects subject to the architectural consistency in which they reside. In this manner, both the treatment of missing elements and the addition of new components formed the final layer of the system of overlaps employed during the project. An additive character which time bestows on buildings, without overlooking the effects of different époques or intentions, exposed as a sample by which to understand the temple's experiences and the moments of growth and decline of the society of which it formed a part.

3. The exterior intervention

3.1 The ambulatory and the roof

The ambulatory is the space above the church's side chapels and the sacristy's rooms. It is a long, continuous volume that borders the temple's main nave, separating spaces by means of the buttresses. These rooms are covered with barrel vaults following the longitudinal axis of the nave, and are made from rough stone masonry.

Fig. 3: (Left) Old wooden window used for ventilating the nave, together with the cable duct above the ledge. The window is interrupted by the vault and the ambulatory roof. The lower section of the window was deprived of direct light from the exterior. (Right) Windows after the restoration.

Fig. 4: (Left) The ambulatory prior to the intervention. It was unpaved and the upper surface of the lower vaults can be seen. The wall bears cabling trays and the attachment elements of obsolete facilities, which reduce the space for passage between the buttresses. (Right) The ambulatory after the restoration.

The ambulatory was created in accordance with a defensive function, converting the building into a church-fortress. The fortress facade was of a regular form hiding the structure of the religious building, akin to a huge canvas. Large openings give onto the exterior between the buttresses. They were used for firing larger artillery. This same facade includes a series of smaller openings located at different heights and used for different types of weapons.

Access to the ambulatory and to the roof is gained through the tower's spiral staircase, which is attached to the south-westerly corner of the church. There is evidence of the original access from the interior of the nave, which connected the church to the ambulatory and the flat roof, located within the west wall. This access, which is currently walled in, was used until the tower was built some years later. In the second half of the 19th and the early 20th centuries, the first rooms next to the tower were used as the bell-ringer's accommodation. They were paved with clay tiles. The rest was unpaved, with the upper surfaces of the vaults visible. Subsequently, the ambulatory ceased to be used and was abandoned, remaining as a storage space littered with large amounts of rubble derived from previous works and repairs, pigeon droppings, dust and dirt.

The walls were host to the remains of the fastenings of now-obsolete installations, whilst the corridor was occupied by a cabling duct that semi-obstructed the passage between the buttresses. The larger holes facing the exterior had been sealed with chicken wire to keep out the pigeons. In the interior wall of the church nave there was a series of small wooden windows that served for ventilation, as well as ducts for the cabling supported on the temple's ledge.

Above them, the large windows opened in the walls as part of an earlier restoration process were partially blocked by the vault and the ambulatory's roof. They shed a heterogeneous light between the upper section, which received direct light from outside, and the lower section, which was obscured by the ambulatory roof.

The interventions focused on the removal of debris, the levelling of the floor, cleaning the earth floor tiling and the subsequent paving of the entire surface, the removal of inappropriate elements and obsolete installations from the walls, the installation of grills on the exterior openings, the replacement of windows below the stained glass and the recovery of a homogeneous light in the same.

The new flooring was separated from the original work by means of steel plates anchored to the walls. This metal strip served as formwork for the interior ballast and as a base for the installation of the lighting. Continuous LED were positioned either side of the rooms separated by the abutments to illuminate each of the vaults. The passageways and window sills were surfaced with lime mortar. The interiors of each of the rooms between the buttresses were filled with sandy earth. Continuous layers of lime and sand were applied: the mix was watered and manually tamped down with wooden mallets. The stones that made up the original windows that were replaced when the stained glass windows were installed were embedded in the flooring as historical remains.

The original openings in the facades, which had been sealed with rough stone, were reopened, their dimensions unified, the sills recovered with restoration mortar, creating a flat, sloping, waterproof surface to favour drainage.

Small openings were created in the junctions between the vaults and the stained glass in each room in the form of chamfers to facilitate the entry of light from the outside along their entire surface. Irregular polyhedron-shaped, etched, tempered glass skylights were installed to cover the openings in the ambulatory roof.

The small windows under the stained glass were replaced and woodwork elements measuring the same width were installed. The sections visible from the interior replicated the decoration visible in the nave, homogenised the surface and are barely noticeable from the nave. They all have an opening in

their lower sections that serves as ventilation. The openings in the facade were sealed with wire mesh attached to uniform steel-plate frames anchored to the walls.

3.2 The exterior facades

What began as a conventional restoration of facades, adapted to a standard protocol, became, almost immediately, a fascinating adventure that presented us with the challenge of enhancing the value of the most extensive group of wall paintings that exists in the Valencia Region.

The use of scaffolding enabled us to detect the presence of certain lines and coloured stains that we were unable to identify. The first decision was to completely clean the surface, removing all the stains created by fungi and lichens. After cleaning, the number of lines and the extent of the coloured stains was seen to increase, although now certain forms and figures were discernible.

It was decided to employ the same technique used for the graphic survey of the paintings to collect data, consisting of the mapping all noticeable incisions. Once the initial data had been collected, and even with the absence of some segments, the compositional elements of each wall were revealed. A temple was discerned on the west facade, complete with pilasters and a classical order, together with an entrance with a door ajar.

Before the start of the restoration work, the presence of these traces had been lost. Their memory forgotten, these remains were only revealed at certain times when the rain soaked the building's walls, giving rise to the popular belief that the facade had been painted by a patron saint, St. Christopher, together with what appeared to be a globe on the northern facade. The popular imagination had been fuelled largely by the writings of local historians.

During the cleaning process, the areas with and without pictorial remains that matched areas that were very exposed to rainwater were determined, especially in the areas beneath the gargoyles, where even the mortar facing had been eroded.

The cleaning process chosen involved the gentle projection of aluminium silicate in those areas without chromatic remains, and manual cleaning for the areas that did. These operations completed the data collection, with the assignment of the original colour detected in each area. The end result clearly revealed the perspective of a temple with domes at its corners, the buttresses of the new figurative apse.

As the cleaning work progressed, the problems associated to dating the remains arose. At what point in the 18th century were they created? They were carried out via indirect procedures, as there is no associated written documentation. The conclusion was determined by their location, since the paintings were integrated into the expansion of the Communion Chapel, leading us to suppose that they were carried out following the chapel's construction and during the existence of a workshop capable of successfully undertaking such a task. All the indications lead us to believe that they are the work of the Guilló's workshop, which was in a position to carry out such a request. Therefore, we can assume that they were created during the first decades of the 18th century.

The 18th century enjoyed an economic boom following the conclusion of the War of the Spanish Succession and the end of Berber attacks, leading to the growth of the city and the consolidation of several settlements outside the city walls. The church's military functions were no longer necessary and it was used solely for religious purposes, becoming the most important building in Vinaròs. This iconic character was enhanced with the painting of its facades and an architectural programme aimed at presenting the church as a reference in the eyes of the new society of the Enlightenment.

This extensive composition was carried out by applying a fine layer of plaster over the initial defensive stonework, upon which the auxiliary lines and those which were to define the architecture that was to be represented were drawn, whilst simultaneously defining the masses of colour that enabled the

Fig. 5: Photo-drawing of the west facade with trompe l'oeil architecture, initial (left) and final condition

creation of perspective. The remnants of colour, more than at first believed, have provided highly-precise knowledge of the range of colours employed (different tones of ochre, Indian red, black and white) and the syntax of their use, which in turn served to enhance the different architectural elements. The decision to enhance the paintings as a whole gave rise to the difficult balance of presenting observers with the original colours without forgetting that the time that has passed since the creation of the paintings has altered the sensitivity of their perception. The pre-existing idea of seeking the solution in modern painting and, more specifically, in the informalists, led us to focus our attention on Jean Foutrier, a French painter and sculptor who was not involved in the Cubist experience, but who experimented with other forms of abstraction that placed him in a leading light when appreciation was first shown for the work of the informalists around 1945, shortly after the end of the second world war. There was a clear awareness of the intention to recreate an 18th century theme with 21st century sensitivity. Foutrier's working method was well-suited to the concept governing the recovery of the paintings. The colour leaps beyond the limits imposed by the lines, in the manner of Kandinsky in certain of his *Improvisations*, a line which in turn is measured in tone and thickness to enhance specific aspects of the work. The use of colour with texturing, renouncing flat colour, working it by density to obtain depth, at times merging with the adjacent colours, as in the art of watercolour. The control of colour required the use of natural pigments mixed with lime paint, which affords a wide range of resources, densities, fading, tones, etc., although these were achieved at the expense of longevity, as we know that the protective measures employed cannot alter the technique's finite nature.

Facing this challenge, the recovery of a painting covering more than 1500 m², was akin to the work of Diego Rivera and Siqueiros and had to be conceived as an act of collective painting in which it was necessary to shed the role of hegemonic management and integrate oneself as another member of the team. Each member of the team, together with the restaurateur who participated in the project and following the general guidelines issued, was called upon for their own, personal poetic contribution, giving rise to a necessary cultural intermesh and, thus, enriching the intervention.

The result has satisfied those who were involved, and it is hoped those who contemplate it, too.

The exhibition “Pulchra Magistri. The splendour of El Maestrazgo in Castellón”, captures the uniqueness of this border territory which, for centuries, was the northern stronghold of the old Kingdom of Valencia, an area of experimentation and cultural exchange between the neighbouring Kingdom of Aragón and the Principality of Catalonia.

To do so, a mechanism composed of interconnected explanatory levels has been employed, allowing the visitor to participate in the whole narrative, from the restored buildings to the qualities and curiosities of certain of the artworks that cannot be seen at first sight. In this way, all the elements within the exhibition’s itinerary, including the towns themselves, are part of the exhibition as a whole.

Therefore, the system used to generate the spaces connects the several levels of information, adapting the content to the spaces and creating connections between the different exhibition venues. The elements are rapidly and easily deployed throughout the space, allowing all the material to be reused once the exhibition is over.

The system is composed of a modulated structure, with scaffolding supporting DMF panels by means of attachments made from recycled material. The furniture is also made of elements that enable them to be adapted to different spaces and situations.

In addition, accessibility to all the areas which, by virtue of their interest, are an indispensable part of the exhibition, is granted by using a system of platforms and access ramps.

Each element is linked to the overall space, forming part of one of the system’s levels, related, through the different pieces (graphic, artistic or architectonic), to the socio-cultural importance of El Maestrazgo of Castellón and its relationship throughout history.

Keywords: exhibition, educational, systems, scaffolding, formats

Introduction

The exhibition “Pulchra Magistri. The splendour of the Maestrazgo in Castellón” represents the tenth edition of a global project organised by the Luz de las Imágenes Foundation aimed at the conservation, restoration and dissemination of the artistic and architectural heritage of the Valencia Region. The symbolic nature of this edition has determined the focus of a design centred on explaining the heritage of the Maestrazgo area of Castellón, a border territory within the Valencia Region that has been historically characterized as an area of experimentation and cultural exchanges with neighbouring Kingdom of Aragón and the Principality of Catalonia.

The design of this edition’s exhibition has been conceived in accordance with a very clear objective: to enhance its informative nature in order to increase the interest of visitors in an exhibition that offers more than three hundred works in seven different exhibition spaces in four different villages and towns in the Maestrazgo: Culla, Catí, Benicarló and Vinaròs.

1. Expository discourse. The didactics of a route

1.1 Concept, requirements and geographical factors

After the exhibition "*Paisajes Sagrados*" (Sacred Landscapes) held in 2005, La Luz de las Imágenes returns to the Maestrazgo, a Valencian territory of special significance and characteristics, and this time it does so with a different approach. While La Luz de las Imágenes' last two exhibitions were held in only one village, the exhibition "*Pulchra Magistri. The splendour of the Maestrazgo in Castellón*" was born from the desire to function as a powerful bond between two parts of this territory: the Alto Maestrazgo, located inland in the northern extreme of the Valencia Region, and the Bajo Maestrazgo, a coastal area directly related to the communications between the main cities of Valencia and Catalonia. Despite the geographical proximity of the two regions, each has very different constraints. Thus, while the Alto Maestrazgo is formed of small mountain villages, and its main attraction resides in ecological and adventure tourism, the Bajo Maestrazgo is characterized by the beach tourism offered by the larger coastal towns.

The dialogue between these two related, but differentiated, territories is the main determinant of the current exhibition, conscious of the articulating power and socio-cultural and economic importance that the exhibitions staged by La Luz de las Imágenes represent for the towns and villages in which they are held. Thus, the exhibition "*Pulchra Magistri. The splendour of the Maestrazgo in Castellón*" has been conceived as a unitary whole located in four different municipalities: Culla and Catí in Alto Maestrazgo, and Benicarló and Vinaròs in Bajo Maestrazgo.

The geographical fragmentation of the exhibition represents a very demanding starting point in logistical terms and determines a fundamental aspect: the exhibition must offer an interpretation of the whole in order to create the necessity to visit each of the venues whilst, at the same time, it must allow a certain degree of independence between the spaces in order that they may be visited at different times. In this context, the didactic facet has been developed as necessary element in the conception of the exhibition project, as it is the global awareness of the narrative that allows the visitor to understand the relationships that exist between the different spaces and the different exhibits.

1.2 Expository discourse

The main characteristic of the exhibition project, developed by the curators Victor Marco and Josep Alanyà, is the enhancement of the artistic expressions of the Maestrazgo territory which, traditionally, have been relegated to the background. Thus, in addition to bringing together key works from the medieval period, which are normally associated with the history of this area, the exhibition also displays works of art of great relevance belonging to other periods, such as the Modern and Contemporary Ages, as well as the Prehistory. The exhibition "*Pulchra Magistri. The splendour of the Maestrazgo in Castellón*" provides, for the first time, a complete picture of the evolutionary development of the area's art, bringing to light several artistic periods that have remained relatively unknown until today, and without which this global interpretation would be impossible.

The ample time-period covered by the exhibition is complementary to its fragmented nature. Thus, a logical dialogue between the content exhibited in each venue and its geographical location is established. In chronological order, the exhibition shows visitors the evolution of the area's art in consonance with the geographical evolution of the municipalities involved. Thus, the artistic expressions ranging from prehistory to the Middle Ages are located in Culla and Catí, key populations

Fig. 2: Different explanatory formats. Brochure and guide for visitors

during the formation and early development of the historic Maestrazgo, whilst the works derived from the Renaissance to the Modern and Contemporary eras are displayed in Benicarló and Vinaròs, municipalities which experienced their peak precisely in these periods.

This approach gives rise to a relationship between the exhibited works, locations and periods of great interest that is intended precisely to enhance the dynamic connection between the Maestrazgo's two regions. Thus, inland municipalities are host to those medieval and prehistoric works with which the public is initially more familiar, whilst Benicarlo and Vinaròs, which possess an inherent attraction for tourists throughout most of the year due to their coastal location, are host to lesser-known artistic manifestations which nevertheless are highly-relevant in terms of obtaining a global vision of the region's art. The result is a balance between the artistic content and the geographical and architectural containers hosting the exhibition which maintains its interest throughout its chronological development.

1.3 Three explanatory lines. The educational condition of a public investment

In the combination of the need to explain the exhibition as a whole in relatively distant locations and the relational interpretation between works from different periods, education represents a key element. The use of multiple explanatory tools that accompany the visitor along the itinerary is one of the exhibition's fundamental aspects. In this sense, the design team, in constant communication with the exhibition's curators, has developed an educational system divided into three interconnected explanatory lines. The main intent is to enable visitors with very different cultural experiences and artistic interest to obtain a global interpretation of the exhibition. To this end, there are multiple layers of information that allow visitors to voluntarily select the elements that are of greatest interest to them.

1.3.1 Line 1. The exhibition's articulating instruments

The first educational line has been developed within a global order and serves to explain the exhibition "Pulchra Magistri. The splendour of the Maestrazgo in Castellón" as a whole. This first layer of information enhances the interpretation of the exhibition as a socio-cultural instrument of the highest level and serves to relate its artistic content with the different contexts in which it is located, with emphasis on the necessary link between the artistic manifestations and their place of origin and exhibition. The design developed by the project's team for all the exhibition's graphic elements represents a key factor in the implementation of this premise: this initial educational line is mainly composed of printed and digital content that is external to the venues themselves.

Different formats have been employed in such a manner so as to, directly and simply, explain the exhibition as a whole and, particularly, in terms of the content exhibited at each venue. On one hand, a brochure has been designed to be available in all the exhibition areas in order to explain the fundamental aspects of the exhibition as a whole. This triptych highlights the content of each of the venues and enables the visitors to become aware of the relationship between the exhibition's different contents. As a complement to this initial didactic element, the team has created a guide for each space which presents a detailed explanation not only of the exhibition's artistic content, but also the buildings that have been restored for the exhibition and the most relevant aspects of each municipality.

These two graphic elements, supplemented with a catalogue of the exhibition and the information available via La Luz de las Imágenes different digital platforms, offer visitors a comprehensive view of the exhibition and its relationship with the municipalities in which it takes place.

1.3.2 Line 2. Architectural and artistic content of each venue

The second educational line is developed within each venue and serves to explain to visitors the most relevant artistic and architectural aspects of the expository narrative. Within each of the buildings hosting the exhibition there are three main elements whose content has been developed jointly by the exhibition's curators and the design team. Each of these elements serves to explain the fundamental aspects of the selected works on display and their relationship with the exhibition's chronology. Firstly, an audiovisual display located at the beginning of the itinerary presents the exhibition's main characteristics and emphasizes the most relevant factors in each venue. Secondly, a series of vertical text panels accompany visitors at various points along the itinerary, explaining the most relevant artistic content of the works on exhibit. Finally, a series of horizontal panels set on wooden stands display information on the main aspects of the host venue and the architectural restoration processes that have been carried out.

These three media have been designed to offer visitors an overall picture of the material on exhibit in each venue, relating the exhibited works to the exhibition's narrative and linking the exhibition to the restored architectural heritage.

1.3.3 Line 3. Specific characteristics of each exhibited works

The third explanatory line represents an innovation with respect to previous Luz de las Imágenes exhibitions, and forms part of the goal to create dynamic, highly educational exhibitions. This third line runs parallel to the exhibited works and serves to explain, briefly and directly, certain of their curious characteristics and notable aspects. Texts of around sixty words in length are displayed on specially-designed horizontal supports situated at the foot of each work. These texts emphasize certain curious aspects of each work, increasing the visitor's emotional attachment to the artist's work.

By means of this third educational layer, further support is given to an exhibition that maintains the visitor's interest throughout the entire itinerary. The combination of the three explanatory lines presented here forms an open system that allows every visitor to choose the level of information in which they are interested.

1.4 New explanatory mechanisms

The three lines that characterize the educational approach of the exhibition "Pulchra Magistri. The splendour of the Maestrazgo in Castellón" are accompanied by two innovative instruments. In the form of guided visits of the works during their restoration and a 360° presentation showing the buildings before and after the process.

Between July and October 2013, and in collaboration with each of the municipalities hosting the exhibition, visitors were offered guided visits that enabled them to witness the restoration work carried out in each of the venues. With the contribution of the technicians responsible for each project, the public was afforded the opportunity to participate in the criteria and the works carried out, thus facilitating a greater understanding of the importance of the recovery of immovable heritage as one of the main characteristics of the work of La Luz de las Imágenes.

Fig. 3: Explanatory elements located at the foot of the exhibits

Complementing these guided tours, a new digital tool has been introduced into the current exhibition that enables visitors to contemplate, in real time, the relationship between the initial state of the restored buildings and their condition today. This mobile application offers a 360° view of the space in which the visitor is situated. Depending on the point on which the mobile is targeted, visitors are able to see the building's pre-restored condition on their screens, whilst contemplating the final work with their own eyes. This application is also accessible from the Luz de las Imágenes website, thus making it possible to experience a virtual tour of the exhibition.

2. Exhibition design. The expressiveness of the system

2.1 Project. System and adaptability

The expository narrative of the exhibition “Pulchra Magistri. The splendour of the Maestrazgo in Castellón” is based on a fundamental concept conditioned by the factors described in the previous sections: the construction of spaces which are both analogous and different that enable a joint interpretation of a design adapted to the specific characteristics of each building. The support of the artistic works, which play an undeniable leading role in the exhibition, has been conceived as an element by means of which to enhance the overall interpretation of the exhibition's itinerary in the different host towns by means of a clear, constructive identity. The system's legibility offers visitors a clear view of the project, independent of the space in which they find themselves, and as such the construction of the expository support acts as a means of articulating the narrative in the different venues.

The choice of the system developed was based on an additional goal: the construction of a support that created the smallest possible impact on the host venues in order to enhance the visibility of architecture restored by La Luz de las Imágenes. The restored buildings are thus incorporated into the exhibition as fundamental elements of the same by means of a design that aims, by virtue of its unobtrusive nature, to establish a discourse between the container and the content that enhances the value of the exhibition as a whole. The fact that an art exhibition is staged in a religious building increases the interest of a space that combines architectural representation with the artistic significance of the exhibits. The design of the expository media thus becomes the common thread that unites the different elements and gives rise to a new kind of cultural space.

Together with identity and unobtrusiveness, the third of the concepts that define the expository project's objective is adaptability. This premise becomes evident if we consider that the exhibition takes place in seven different buildings, ranging from small municipal spaces Culla and Catí to large churches in the towns of Benicarló and Vinaròs. The multiplicity of scales in these seven containers converts the concept of flexibility into a necessary requirement for the proposed system. In addition to the diverse morphology of each of these spaces, the nature of the exhibits requires media of a different format. This is due to the presence in the exhibition of pieces of very different character, ranging from paintings and small items of jewelry to textiles and documents. This multiplicity of formats requires the design of a highly versatility media.

The combination of these three requirements lies at the centre of a design based on the following constructive elements: a light structure of scaffolding covered with medium-density wooden panels serving as the main vertical support, and a series of horizontal pine elements that resolve the expository requirements of the items of jewelry and the documents. The use of these two main systems, which share the same constructive base but which are deployed in different forms in each

Fig. 4: View of the exhibition in the archpriest's church in Vinaròs

venue, facilitate a clear interpretation of the design's identity whilst creating a diversity of spaces adapted to the morphological conditions of each of the buildings.

2.2 Elements of the constructive system

2.2.1 Vertical structure. Scaffolding and medium density (MDF) wood paneling

The use of scaffolds for the resolution of the exhibition's vertical supports is, undoubtedly, the most distinctive design element. Through the use of this system, it has been possible to create a space that combines functionality and expressiveness via the repetitive use of standardized elements. In addition to the versatility of this light system, another key factor in its use is the economisation obtained through the elimination from the project's equation of the need to store the constructive elements following the conclusion of the exhibition. To this economic optimisation we must add the reduction in the time required to assemble the system, a necessary factor when taking into account the narrow time margin available between the completion of the restoration work in the different venues and the exhibition's official opening date. In this regard, it is noteworthy that all the design's structural elements were mounted in less than a week.

This light structure is used to support medium density wooden panels that are raised above the floor in order to enhance the unobtrusive nature of the exhibition's support media. Through direct collaboration with the company responsible for the installation during the project phase, these panels were installed with great ease on the scaffolding structure using a attachment system that was specially-designed for the occasion. By avoiding the use of mechanical joints, the work involved in the installation and removal of these panels is greatly simplified.

2.2.2 Horizontal elements

Within this category we may distinguish between three different elements, all of which have been resolved with pine wood to achieve a unified image for the exhibition as a whole: the supports for sculptures and items of jewelry, the elements containing explanatory texts located at the foot of the exhibits and the flooring employed to facilitate access to raised surfaces, such as the side chapels in the churches. The material identity which the pine-wood confers on these three elements contrasts with the pure condition of the vertical surfaces, facilitating a direct understanding of the relationship between the two systems. Thus, while the vertical structure forms a unitary element which occupies a large proportion of the space in each venue, the horizontal elements are arranged in a more relaxed manner in the spaces set aside for the circulation of visitors.

Despite the intended difference between these two systems, it is noteworthy that a lightness was also sought in the design of the support pieces through the use of steel substructures to raise the wooden panels, thus minimizing their impact in relation to the existing container.

2.2.3 The shop. A paper lamp

A special feature of the exhibition is the shop, present only in the two larger venues. As an element that is extraneous to the artistic narrative, but necessary in the configuration of any exhibition today, in this exhibition the shop appears as a lamp located at the end of the itinerary, an enigmatic light that must be traversed in order to leave the exhibition. This volume of light is constructed of fabric hanging from a substructure supported by scaffolding. Given its larger scale, the store becomes a reference for visitors throughout their itinerary, although they do not discover its true role until the end.

2.2.4 Installations

The resolution of the exhibition's lighting and audiovisual installations bears a direct relationship to the scaffolding system employed. Thus, the structure's elevated bracing elements have been used to conduct all the electrical wiring, thus avoiding the appearance of linear obstacles on the flooring. The support system's general height of four and a half metres also serves to obtain the ideal positioning of the lights and projectors needed for the exhibition. In this sense, mention may be made of the fact that the exhibition's lighting also employs the building's own lighting in a complementary manner as a result of the need to facilitate the contemplation of the architecture restored by La Luz de las Imágenes.

2.3 Educational workshops. An added factor

Educational workshops have been created in the Catí and Benicarló venues aimed at enabling visitors to learn about, research and play with the techniques and materials on exhibit. These spaces are part of Foundation's dissemination methodology, describing restoration processes using virtual software or carrying out the gold- or silver-plating of materials, such as stars, in situ. These workshops are aimed not only at schoolchildren, but at all visitors to the exhibition, having been met with great acceptance and satisfaction.

Fig. 5: Aerial view of the exhibition in the parish church of Benicarló

3. Installing the exhibition

3.1 Implementation period. Coordination prior to installation

The installation of the exhibition “Pulchra Magistri. The splendour of the Maestrazgo in Castellón” was marked by the tight deadline imposed by the need to open the exhibition during the second week of December 2013 and the completion of the restoration work of the various exhibition venues in early November. This left only four weeks to implement the assembly in the four municipalities involved in this edition. For this reason, the coordination work prior to the installation was centred on compliance with the scheduled deadlines. In this sense, mention may be made, firstly, of the high degree of definition of the exhibition project and, secondly, the coordination work in the workshop with the company responsible for undertaking the work.

In anticipation of the necessary presence of the design team as part of the on-site coordination of the exhibition installation process, the exhibition project, drafted during the three months preceding the start of installation, was conceived as a comprehensive document in which all the design elements are perfectly defined. The measurements of all the elements to be created were technically defined in this document in order to avoid the need for global decision-making relative to the project during the intense weeks of the installation. This also allowed the majority of the horizontal pine elements to be produced in the workshop prior to the beginning of the work at the different venues while the assembly of the scaffolding structure was begun. This operation was fundamental for the success of the installation as it resulted in the initial schedule being reduced by one week and enabled the teams responsible for the installation of the exhibited objects to avoid working at the same time as those responsible for the more aggressive construction work.

The constant coordination between the design team and the company in charge of the installation also enabled, through prototyping, the suitability of the proposed construction systems to be tested prior to their final construction. This interaction led to the introduction of specific modifications to certain models on the indication of the company’s specialist carpenters and to improvements to the attachment systems which resulted in direct reductions of the installation time required.

Specifically, during these meetings the anchorage system for attaching the medium density wooden panels to the scaffolding structure was implemented, enabling the optimization of the design and facilitating considerably the posterior assembly process.

3.2 Assembly Coordination of the work

The unique fragmented nature of the exhibition “Pulchra Magistri. The splendour of the Maestrazgo in Castellón” created the need for special planning and the design of an ambitious logistical support for its installation. Given the distance between the inland municipalities and those on the coast, various working teams were required in both areas. Thus, two general teams were created, one for the inland municipalities and one for the coastal towns. Each team was composed of professionals from all the areas to be developed. Thus, it was possible to undertake the works simultaneously and carry them out in parallel, reinforcing those tasks required by the installation.

This division into blocks of work also gave rise to the need for intense coordination by the design team, whose members were also split into groups in order to establish a constant presence in each of the venues. The need for on-site coordination of the works became evident, above all, during the last

Fig. 6: View of the exhibition in the parish church of Catí

two weeks of the installation phase, during which the works of art were installed at the same time as tasks such as the installation of the graphic elements were being carried out.

In chronological order, the exhibit's installation works were carried in the following order over a period of four weeks. During the first week, almost the entire scaffolding structure was assembled in the venues, with the design undergoing certain modifications in its adaptation to the existing spaces. As these structures were being assembled, they were covered with medium density wood panels, with the work, including painting, being completed in the second week. During this second week, the wooden flooring was also installed in the corresponding areas so that, as of the third week, the specialists from La Luz de las Imágenes were able to begin work on the layout and assembly of the works of art. The furniture that was made in the workshop was also installed during the third week, with all the exhibition's support elements in place within the scheduled deadline. During the fourth and final week of installation, the main efforts of the various teams were focused, on one hand, on the installation of the works of art which, in many cases, required the installation of protective glass, and, on the other, on the deployment of all the exhibition's graphic elements. In this category, in addition to the elements described in the first section of this article, a number of advertising banners were installed in each of the municipalities.

With, when taking into account the exhibition's geographical and logistical conditioning factors, an extremely tight deadline to meet, it may be said that the correct implementation of the works on schedule was possible thanks to the collaboration and constant dialogue between the three main agents involved in the process: the design team, the professional team working for the company responsible for the installation work and the restorers of La Luz de las Imágenes. The success of the exhibition lies in the dedication of all those involved in its installation process.

Benefits of a global project about movable heritage

Abstract

The importance of the Valencia Region La Luz de las Imágenes Foundation's restoration campaigns lies in the fact that they protect the local cultural heritage belonging to regions of influence in each exhibition.

Ideologically the project is not only focussed on the most notable pieces from cathedrals and museums or on artwork created by well-known artists, but it goes further as it reaches the closest heritage: local artwork from all the towns, even the smallest ones, and heritage hidden in convents, vestries or hermitages. La Luz de las Imágenes targets pieces which have not only conclusive artistic and historical value, as the importance of many cultural assets worth conserving, i.e., restored, may lie in other values: devotional, emotional and symbolic in nature. Therefore, the aware of local people towards their heritage is raised, as La Luz de las Imágenes recovers and restores pieces to which they feel close and which are suitable for inclusion in the exhibition narrative defined by the curators of each season.

A multidisciplinary team (architects, archaeologists, religious operators, historians, politicians, owners, users, and restorers) works on each restoration campaign and provides the necessary data in order to define the most appropriate intervention. This allows the mapping and cataloguing of works that were previously unknown, and on many occasions we make surprising discoveries about authors or dates.

Throughout the 10 restoration campaigns run by La Luz de las Imágenes, 2,796 works of art belonging to 123 different towns have been restored; around a hundred in each exhibition, including documents, silverwork, paintings, sculptures and frescoes.

Keywords: movable heritage, values, conservation, interests

1. Different approaches to the restoration of movable cultural assets

The Luz de las Imágenes cultural project is aimed at disseminating the cultural heritage located in different areas throughout the region by means of large-scale artistic exhibitions. Simultaneously, it is a valuable tool for the recovery, preservation and restoration of movable cultural assets and property.

The importance of the movable cultural assets restoration campaigns lies in the preservation of the local cultural heritage belonging to each exhibition's areas of influence.

During the 10 seasons of restoration undertaken by La Luz de las Imágenes, some 2,976 works of art from 123 different towns and villages have been restored, representing some 100 pieces per exhibition. These objects include documents, jewelry, easel painting, sculptures and murals. This has enabled the cataloguing of works hitherto unknown and, in many cases, the discovery of surprises related to their authorship and dating.

Ideologically, the project not only focuses on the major works of museums and cathedrals that have been perfectly identified, it goes further, reaching the most familiar heritage, local assets from all towns and villages, independent of their size, to the heritage hidden in convents, chapels and vestries, as well as assessing the needs of each work, taking into account the target of the work and priority of

Fig. 1: From left to right, initial condition of the St. Agatha altarpiece, discovering a hidden scene and final result of the scene discovered in the attic

the values to be preserved. For these reasons, each campaign is equipped with a multidisciplinary team.

A clear example of this is a work that is kept in a small mountain village with only four inhabitants, a work that is hidden away inside a small temple that opens only two days a year, a work that is stored in very poor environmental conditions: the altarpiece of Saint Agatha, in La Pobleta de Alcolea (Castellón).

For years, the few inhabitants of this village flatly refused to allow the restoration of the altarpiece for fear of its permanent removal from the village. Following an intense campaign based on raising awareness and on demonstrating commitment, and through the mediation of the diocese's heritage delegate, the regional director of Culture, the director of La Luz de las Imágenes and the local priest, these reservations were overcome. And the work has been restored for the exhibition "Pulchra Magistri".

As a work of great artistic and historical quality, the interventions to which it had been subject in response to changes in fashion, and even as a means of preventing theft, as well as its having been embedded, had given rise to numerous pathologies that endangered its conservation and prevented its enjoyment. The panels of the late-Gothic altarpiece had been relocated, changing their original distribution on a gypsum structure, in the neoclassical style. The intervention has drawn attention to an extraordinary work that was hidden from the eyes of the region's citizens, as well as revealing an unknown scene in the upper section, hidden under a thick coat of paint that mimicked a marbled effect. Naturally, further deterioration was avoided, the original interpretation was returned to the piece by means of its reassembly in the manner in which it was conceived, and finally it was able to register the work within a specific corpus of works upon the discovery of similarities with other pieces.

La Luz de las Imágenes also focuses on assets whose value is not limited to their historical and artistic worth, as the importance of many cultural assets that deserve to be preserved and restored may lie in other values: devotional, emotional or symbolic.

Not only those assets which were formerly considered worthy of conservation, those which were held in historical-artistic consideration due to their belonging to the classical arts, are subject to restoration, but also those which, as the result of human activity, are granted significant value by a person or a group, from a Renaissance masterpiece to an industrial object, including even a pen used to sign a relevant document.

The Charter of Krakow 2000 defines heritage as:

(...)a complex of human works in which a community recognizes its particular and specific values and with which it identifies. Identification and specification of heritage is therefore a process related to the choice of values.

Therefore, if we grant a different value to that of its nature, the most important of its qualities will naturally be the conservation of the symbolic value, the added value that makes an object relevant. And this is what we have to keep in mind when intervening on an object.

Many of the works in which La Luz de las Imágenes intervenes are devotional objects and acquire the consideration of restorable, the consideration of heritage, due to their being granted an emotional value by a more or less numerous group, even when the object has scarce artistic or historical value.

Our priority is the maintenance of these values above all other considerations. Each intervention must be very controlled, no additions that enhance the interpretation can be removed, and the image will always be reinstated when so required by the object.

A clear example can be seen in the process carried out on the Christ of Salvation in Almudaina (Alicante), a polychrome sculpture of very scarce artistic quality, but one which is highly venerated by

Fig. 2: Final condition of the Christ of Salvation, Almudaina (left) and final result of the St. Bartholomew, Villahermosa del Río

the local people. Even before the transfer of the object and during the packaging process, we were accompanied by religious chants. The importance of this sculpture, the main value which it holds, is its relevance as an icon, and as such our project is obliged to place this quality above any other. The piece had been completely repainted, and it is this repainting that is present in the collective memory of the faithful. As such, the process consisted of adapting the current interpretation of the image without the removal of any additions.

On numerous occasions, devotional images are found to have suffered from changes in fashion and styles over time, human interventions that have gradually hidden the original polychromes in favour of the tastes of the moment. Furthermore, there are cases in which the simple need to enjoy the image made certain adaptations “necessary”, and in most cases these adaptations are found to be unsuitable and to have been carried out by people whose good intentions outweighed their technical knowledge. The problem arises when we add an object's value as a religious icon to its historical and artistic quality. In such cases, the decision of what to do is reached by taking into account the opinion of the object's users, as well as its conservational requirements, the actions that are necessary in order to avoid the asset's deterioration. Thus, our judgment at the crucial moment of the intervention determines the guidelines to be followed.

Such was the case with a wooden polychrome image of Saint Bartholomew in Villahermosa del Río (Castellón), dating from the early 14th century. The documentation corresponding to the veneration of this splendid medieval carving had been conserved in the village shrine, of which Saint Bartholomew is currently the patron, since 1333. After analyzing the work in detail, different paint layers were detected. The work had been repainted twice throughout its history, thus making it essential that we assess the factors of greatest weight: the historical data of the object's material evolution throughout the years, its devotional value relative to its current veneration, or the search for the original colour through the elimination of previous values.

The most recent polychroming, that of the venerated image, was stylistically very close to the original, had a certain historical value, was of a certain quality and did not generate any negative pathologies in the work, and as such it was decided to maintain the current image.

In contrast to this case, the intervention carried out on a 16th century Christus Patiens from Valencia's Royal College and Corpus Christi Seminary, from which the surface repolychromy was removed.

After carefully analyzing the work with relevant studies, and especially when performing different cleaning tests, we observed that the original layer was of high quality. The studies were presented to the owner, and it was agreed that the most appropriate course of action would be to allow the enjoyment of the work in the manner intended by the artist, taking into account that it not an object subject to worship and that the current polychrome was of low quality.

Fig. 3: Initial condition and final result of the Cristo Patiens

Fig. 4: Initial and final detail of the Cristo Patiens

Fig. 5: Initial and final detail of the Cristo Patiens

The decision making, the judgement, would not be correct without the participation of all concerned, without the collaboration of a multidisciplinary team (architects, archaeologists, religious, historians, politicians, owners, users or restorers), capable of providing the data needed for the selection of an appropriate treatment.

An example of this teamwork can be seen in the intervention carried out by the Foundation on the mid-15th century altarpiece of Santo Domingo de Guzmán de Valentín Montoliu, from the village of Vallibona (Castellón). This work arrived at the workshop for a review of aesthetic criteria following an intervention carried out some 15 years previously. The criteria employed in the first intervention was broadly disapproved of by the villagers, the owner, and even the heritage inspectors.

Although the decisions taken were correct, they perhaps did not take into account the needs of the other stakeholders involved, as the object was the village's most important cultural asset and was also subject to great devotion. The problem was therefore how to solve the significant losses of paint layers that hindered the interpretation of the object as a whole. A museum criteria was initially chosen: neutral colour retouching was applied, despite the access to archive documentation indicating the nature of the missing fragments. The missing segments were considered to represent too high a percentage of the whole work, and therefore impeded the reconstruction of the object.

When it was delivered to the workshop and analysed in accordance with strictly technical criteria, taking into account solely the requirements that we, the specialists, apply to such work, an intervention was considered unnecessary, except for the fact that the method and tone employed to resolve the neutral colour retouching were considered susceptible to improvement. From among the wide range of possibilities that we have as specialists to resolve the reintegration of the image, the most aseptic was chosen. However, if we analyse the work taking into account the needs of historians, members of the religious fraternity and, especially, the users, the missing segments took on a leading role and prevented the transmission of the message: their requirements are not met.

Was the distance between these different requirements capable of being bridged?

Aesthetic concerns (how will we be able to enjoy the asset for decades?) must never take precedence over the conservational requirements; as technicians, we can never reduce the technical demands as a result of external pressures. However, the aesthetic needs can and must be accommodated as far as possible to the requirements of the majority of those involved in the project, without, of course, crossing the boundaries of the hypothetical or disrespectful.

The decision was taken to reconstruct the missing fragments of the drawing and the colour, aided by archive photographs and carried out using a technique that is discernible at close range, thus

Fig. 6: Initial condition of the St. Domingo altarpiece, Vallibona (left) and archive photo

Fig. 7: From left to right, detail of the initial condition of the St. Domingo altarpiece, Vallibona, archive photo, and final result

attempting to unite the positions of both parties and to satisfy the needs of the citizens of Vallibona in relation to their most valuable asset.

Cultural heritage in our society raises great interest among the majority of citizens, it is our symbol of identity, the element that differentiates us from other peoples in an increasingly globalized world. Therefore, any event related to heritage has a special impact, and the different groups of specialists are considered the legitimate guardians and defenders.

The economic interests of collectors, the devotional interests of the parishioners, the catechetical interests of religious groups, the publicity interests of politicians, the functional interests of architects and the didactic interests of historians sometimes collide head on with the artist's interest in preserving the work in the form most similar to that in which it was created. Giving priority to any one of these interests can also become a fatal error.

This does not mean that the restorers must be deaf to any information coming from the outside. On the contrary, we must use the information supplied to us in order to assess all the data we have within our reach, attempting to maintain all the added values held by the cultural asset. The correct critical judgment can be reached if we have access to all the data. Alternatively, if we censor the information in our own interest, we may make a fatal mistake.

2. Conclusion

The events experienced by the works, and the manner in which they are reflected, not only provide us with information about the effects of the passage of time on the works, they also speak to us of the predominant culture at any given time, of taste, of the appreciation of art, devotion, etc. These data are often deleted in the search for the initiatory moment, the moment of creation, the proto-condition, without evaluating other considerations, overlooked in the search to the work's supposed truth.

When we intervene in the restoration of an image, we must take great care to avoiding deleting historically-valuable information, information that is valuable for the memory of the users, as heritage assets are extremely important documents that indicate where we come from and who we are.

By working with an interdisciplinary team, the Luz de las Imágenes Foundation is able to bring together these different sensitivities towards cultural assets and, as a consequence, undertake interventions that would not be considered interesting a priori, carrying them out at the same time with respect for all their values.

Abstract

The present study deals with a very important but not very well-known cultural heritage area, which is located in Southern Italy, in the municipality of Ascoli Satriano (in the Foggia province). The area represents the vestige of one of the principal settlements of the Daunian peoples (VI-IV century B.C.). In this area, the Carapelle Valley represented an ancient communication route between the Campania Region and the Apulia "Tavoliere", ever since a very fertile territory, where many flourishing rural communities established themselves. On the "Collina del Serpente" (the Snake hill) systematic research of the University of Innsbruck allowed to locate the remains of the ancient town of *Ausculum* as well as a large *Necropolis* (IV century B.C.) with very rich funeral furnishings. Not far away, in the Carapelle valley, at the Faragola site, the archaeological excavations unearthed a beautiful luxurious "*domus romana*" of late ancient times (IV-VI century A.D.). Based on the principle that preservation of cultural/archaeological heritage starts from recognition and measuring of the opus, the work presented here treats the first phase of the study of the whole archaeological area. This research proposes the establishment of a GIS (Geographic Information System) which classifies all the information already collected by various study groups, in order to be able to present a "virtual museum" useful for utilization by more extensive audience.

Keywords: GIS (Geographic Information System), archaeological survey.

1. Introduction

The area of Ascoli Satriano (in the Foggia province, Southern Italy) is located in the North of the Apulia region bordered by the Sub-Apennine hilly area and the "Tavoliere delle Puglie" plain (**Fig. 1**). The site has been home to human settlements and burial from the sixth to the fourth century BC, organized according to a criterion of "occupation spread" over a wide area (about 80 hectares). The burial areas were adjacent to those living with spaces left free for agriculture and livestock. Most likely the "Collina del Serpente" (the Snake Hill), corresponding to the maximum altitude (456 m asl) was the reference of local communities between the fifth and fourth centuries before Christ and was the seat of the houses of the aristocracy of that time. On the "Collina del Serpente" is located the Daunii Archaeological Park, where systematic research conducted by the Universities of Innsbruck, Foggia and Potenza and the Superintendence for Archaeological Heritage of Puglia allowed to locate the remains of the ancient town of *Ausculum* as well as a large *Necropolis* (IV century BC) with very rich funeral furnishings. Since the end of the 19th century, the hill of "Collina del Serpente" is a privileged field for archaeological research on Daunia pre-Roman times, but a little more than a decade, the territory is returning finds that also belong to the age of the Roman republic and empire. The sanctuary, a place to gather and ceremonies pertaining to the cult of the dead, lies within the sacred and dates back to the sixth and fifth centuries BC. The most luxurious funerary objects found in

Fig. 1: geographic area (IGM – 1:50000).

the tombs are now exhibited in the Diocesan Museums “Polo Museale”. Of great interest is also the wide pavement with beautiful mosaics of river pebbles, considered a unique by scholars. Some of the most important archaeological sites of the area of Ascoli Satriano were placed in a first draft of GIS as shown in Fig. 2.

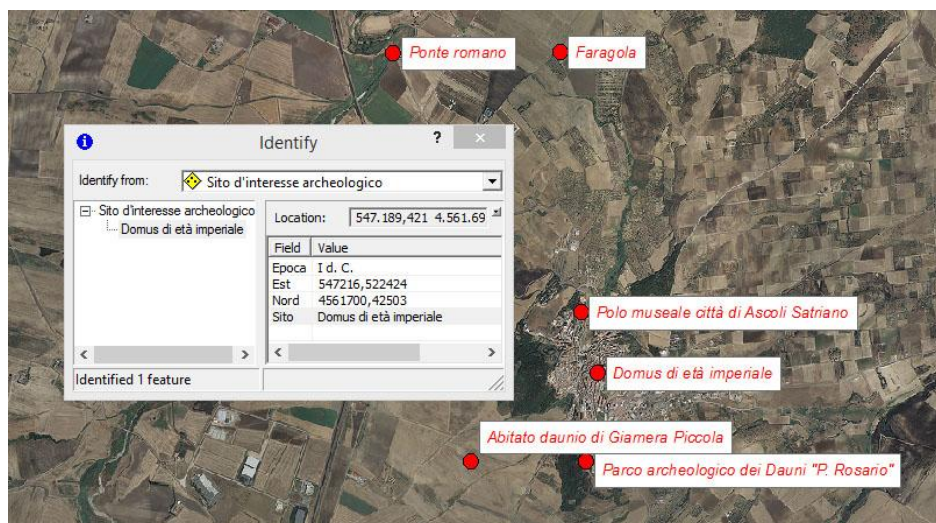

Fig. 2: screen shoot of GIS: archeological sites.

2. “Collina del Serpente” (the Snake Hill)

The hill of the Serpent was a landmark for the community Daune, used as a necropolis between the sixth and fourth centuries BC was affected by the construction of a large building for public meetings and religious services. It was affected also by burials of local aristocrats as evidenced by the tombs of the "Princess", of the "Warrior", et alii, rich in finds and funeral ornaments, now exhibited in the Museum Centre. One of these tombs, with its access corridor (Dromos) is displayed in next Fig. 3

Fig. 3: dromos of askos canosino: grave.

3. Polo Museale "Diocesan Museums"

The extraordinary collection of polychrome marbles, exhibited in the Museo Civico - Diocesan of Ascoli Satriano, consists of a support table (*trapezophoros*) with two griffins attacking a deer, a ritual basin (*podanipter*), in which is depicted the scene of transport weapons that Hephaestus forged for Achilles at the request of his mother Thetis, a couple of shelves, a large crater marble that not only retains traces of polychrome, but also the negative footprint of a gold decoration that has been recognized as a vegetal decoration with ivy leaves. The uniqueness of these products is due to the vibrant polychrome decoration, high quality marble, the crystalline and transparent tunnel dug in the island of Paros the Greeks reserving to the masterpieces of sculpture, the presence of the paintings, so rare in marbles come down to us, and especially the history of the discovery of these pieces. To these objects of daunian age is added a valuable statue of Apollo from the Roman period (second century AD), also stolen from a Roman villa of the territory of Ascoli Satriano. The "TRAPEZOPHOROS" with "GRIFONI" and "CERVA" (325-300 BC) (Fig. 4) is an integral part funeral objects of a Macedonian tomb and is the only example of a marble group, whose quality and pictorial decoration which were spared by time and odysseys sustained during all these centuries. The unique sculpture, which is the support of a ritual table is 95 cm high. and 148 cm long., consists of a pair of "Griffins" in the body of a lion and the dragon's head crest on the head of a purple-red color and blue wings unfurled upward, and are in action while hunting stuck in the ground with a hind claws that emerges with his nose, lying on the ground with their front legs bent and the rear completely stretched out.

Fig. 4: trapezophoros wiht “grifons and cerva”.

In the '70s (perhaps between 1976 and 1977) were carried out illegal excavations by grave robbers in the local area of Ascoli Satriano. The findings were immediately dismembered. Some of them, fragmented, were seized by the Guardia di Finanza and stored in boxes in warehouses of the Superintendence in Foggia, where they sank into oblivion, waiting for the trial. Other pieces, the most valuable, the trapezophoros and podanipter, were sold by grave robbers to a famous art dealer living in Switzerland. The invaluable pieces finished, then, through a well-known international drug trafficker, in the collection of M. Tempelsman, a Belgian-American mining magnate and diamond merchant. Afterwards, the two extraordinary objects of the IV century BC, paid respectively 5.5 and \$ 2.2 million, were sold together with the statue of Apollo (paid U.S. \$ 2.5 million) to the J. Paul Getty Museum in Malibu, California.

Meanwhile, one of the grave robbers, Savino Berardi, seriously ill, shortly before his death , in 2002 , pointed to the Police of Ascoli Satriano the site of origin of the furniture in the municipal territory and asking the military to bring the Griffins back to Italy, informed them of the existence of other material that was confiscated at the time.

The police then began a complex investigation in the archives of the former Magistrate's Court of Orta Nova, until, in May 2006, the two events once again intertwined: as part of a process for illegal trade of archaeological finds dr. Angelo Bottini (then Superintendent Archaeologist of Rome) recognizes the high quality of the artifacts found by the Police and establishes a connection with the items purchased by the Getty Museum. After protracted negotiations conducted by the Italian Ministry of Heritage and Culture, 22 years after the purchase made in 1985, the artefacts were returned to Italy on August 1, 2007. In June 2010, the Ministry has authorized the ' homecoming ' of these extraordinary objects that can be admired today in the Museo Civico - Diocesan of Ascoli Satriano.

4. “Domus Imperiale”

Pavement works in the Piazza del Plebiscito in the historic center of the town have uncovered an old "Roman Domus" dated to the first century AD. Mosaics identify three different rooms with characteristics nobiliary residence, as evidenced by the one visible in Fig.5.

Fig. 5: imperial domus mosaic.

5. “Faragola”

The Faragola site is located approximately three kilometers south-west of Ascoli Satriano in the fertile valley of the Carapelle river. The building complex was built up in a strategic location, midway between the two major villages of Ausculum and Herdonia, in an area rich in water, thanks to the presence of the Carapelle river and of numerous springs. Long known, it had already been reported in the course of archaeological surveys conducted in the early 90s by the University of Bologna. Later, preliminary investigations were conducted by dr.Francesco Paolo Maulucci on behalf of the Superintendence for Archaeological Heritage of Puglia, which led to the constraint area, then partly acquired by the Municipality of Ascoli Satriano.

In July 2003 started a campaign of excavations, preceded by geophysical surveys, under the scientific direction of Professor Giuliano Volpe, University of Foggia, in collaboration with the Superintendence for Archaeological Heritage of Puglia and the City of Ascoli Satriano. The results achieved so far are of great interest in the locality Faragola was, in fact, investigated an extended and articulated rural settlement from the Roman period and Late Antique, which is notable for the significant exhibitions of luxury (Fig. 6).

Fig. 6: Faragola “cenazio room”.

Some residential environments of a rich villa have been partially brought to light, of which has so far been documented especially the Late Antique period (IV-VI century AC). In particular, it has been uncovered a large room, probably identifiable with a summer dining room, the “*cenatio*”, with a fountain decorated with a relief dated to the early imperial age with the depiction of a female dancing and a snake and a floor of marble slabs, all of reuse, enriched by the insertion of luxurious carpets in “opus sectile” made with plates of various marbles and colored glass paste (Fig. 7).

A few meters away from this luxurious dining room were identified other rooms in the residential sector, paved with fine polychrome mosaics with geometric decoration.

The villa is also equipped with a handicraft sector: it was, in fact, also investigated a kiln for firing bricks, part of a larger group of manufacturing facilities. It is a discovery of great importance for the understanding of the organization of the countryside not only in the territory of Ausculum but in the whole Puglia: in fact, although several other Roman and Late Antique Villa were known in the territory of the Daunia, that of Faragola that like one of the most luxurious manifestations of this type of building so far known in rural southern Italy. It is obvious that the villa belonged to a person of high rank, owner of large estates in land area, further proof of the vitality of the agrarian economy dell'Apulia in Late Antiquity.

Furthermore, the presence of numerous materials reused (figurative relief, marble slabs, funerary inscription of the Augustan age inserted into the floor of *cenatio*, etc..) also raises the issue of both a pre-existing settlement in the same site and the detection of other settlements and monuments in the territory from which the materials were recovered.

The area surveyed so far, covering a surface of over 3000 m², is only part of a much larger, extremely articulate rural complex: it is assumed a total area of about three hectares. The site of Faragola was occupied for many centuries, with different ways of life. Archaeological research has so far allowed us to reconstruct the following steps:

- Daunian Village (VI/V – IV/III B.C.)
- Roman Farm (I B.C. - II A.C.)
- Late Antique villa1 (III – metà IV A.C.)
- Late Antique villa 2 (late IV – late VI A.C.)
- Early Medieval village (VII – IX A.C.)
- Agricultural use (IX – XXI A.C.)

Fig. 7: Faragola “cenazio room” render.

6. “Ponte Romano”

The construction of such a structure refers to the roads in the territory dauno, can be placed between the first and second centuries AD, relative to the nearby city of "Erdonia" and "Aecae" fig. 8

Fig. 8: roman bridge.

7. “Giarnera piccola”

In the valley of Carapelle the excavations conducted by the University of Innsbruck have uncovered a large village of daunia age, with houses, buildings and extensive pebble mosaics as road surface, and religious buildings with architectural decorations (Fig. 9)

Fig. 9: mosaics of river pebbles.

8 Conclusion

Many authors show that the presence of a "Virtual Museum" encourages the curiosity of the web users, who will be induced to visit the "real" places entered into the system.

The present paper in this perspective provides some information on the possibility of establishing a GIS regarding the various archaeological sites of which is particularly rich the Municipality of Ascoli Satriano.

In this regard we would like to thank the Mayor of Ascoli Satriano and especially the Head of Culture dr. Biagio Gallo, for its exquisite competence and availability during the site investigation.

The Barco Chigi in Ariccia

Mario PISANI

ARCHITECTURE and INDUSTRIAL DESIGN DEPARTMENT LUIGI VANVITELLI SUN
Second University Naples, Aversa, Italy
E-mail mario.pisani@unina2.it

Abstract

Usually the restoration work concerns an ancient church, a historic building, a monastic complex. I want to talk to a park, the barco Chigi. This garden park has recently been restored and given a new lease of life by Virginio Melaranci after five patient years of dedicated work, carried out between 2006 and 2010, at the cost of over one million euro. Originally planned by Gian Lorenzo Bernini for the Chigi, the project was further enriched by Carlo Fontana with additions typical of classical Italian garden layouts. These interventions included the installation of a Barco (an area reserved for hunting) surrounded by a form of sacred forest which echoed antique Greek models. Thanks to the Grand Tour, many travellers had the opportunity to visit and admire the areas. These included Turner, Corot, Goethe, Stendhal, Sand and D'Annunzio. Post its restoration, the place has now been reinterpreted as a walled garden with the installation of a lawn. The starkness and simplicity of which contrasts with the organic plastic qualities of the whole complex. The borders which define the area feature decorative plants such as acanthus, various species of fern, rhubarb, hydrangeas and palm trees which in their autumn colours contrast strongly with the grey tones of the walls covered with capsicum plants. The restoration was how to amalgamate and unify the historical, botanical and forestry aspects of the whole area while retaining the overriding order of its vegetal aspect. The choice was between the previously untamed and natural characteristics of the garden and one of recreating the image of what the park would have looked like in the 19th century based on photographic images of the time. Today, on visiting the park, the imagery certainly evokes the atmosphere of those times while the aromas, the silence, the light and colours which now characterise the project were certainly aspects which would not have been present in the original layout but which would have developed and materialised in the passage of time through different epochs.

Keywords: Barco, Gian Lorenzo Bernini, Park, Chigi, Ariccia

1. Section

Most restoration projects usually relate to historic churches, palaces, and monastic complexes. In this case I will be discussing Barco Chigi which exhibits notable differences from the classic Italian garden. This park has been diligently restored and given a new lease of life by Virginio Melaranci. The restoration project was implemented between 2006 and 2010, for a total capital outlay of one million euro.

The *Barco* was originally planned by Gian Lorenzo Bernini for the Chigi, a powerful family of bankers. The project was further developed by Carlo Fontana with later additions interpreted in a typical classical Italian garden layout. These interventions included the establishment of a *Barco* (an area reserved for hunting) which was surrounded by a sort of sacred forest or Eleysian fields reminiscent of ancient Greek models. The park itself also created a strong relationship with the surrounding natural

environment, creating a fine balance between the formal layout of the forest itself and undomesticated terrain around it.

Fig. 1. Jean Babbtiste Tierce, Chigi Park, 1776, watercolor on paper, Private Collection

In 1661 the Chigi family acquired from the Savellis the feudal title of Ariccia. Within the next fifteen years they embarked upon a series of important works restoring the park and incorporating the existing aviary dating to Roman antiquity and converted in 1682 under the patronage of Bernardino Savelli, Duke of Castel Gandolfo, Marquis of Rocca Priora. In the period 1661-1676, improvement works on the *barco* were undertaken. The imposing and visually appealing aviary constructed from ancient Roman quarry lava stone by Savelli dates to 1628. During the fifteen year period of improvement works, the Chigis created a fishpond now destroyed, an extraordinary complex of cells and caves for the storage of food, decorative fountains and an archaic system of rainwater collection system for the channeling of spring water, various pathways, a *ragnaia* comprising a dense coverage of high trees intended to support the placements of nets to capture birds.

Sigismondo Chigi (1736-1793) insisted that the park should always retain a natural picturesque quality reminiscent of a wild forest, with trees which had fallen due to the impact of strong winds or had decayed and dried-up over time, being left to stand in their derelict state. During the late- nineteenth and early-twentieth century the Chigi family continued to adhere to this philosophy. We have confirmation of this from some vintage views that show the park in its informal picturesque state. The Chigis were committed to respect the *zeitgeist* and *genius loci* of the place favouring an aesthetic sensibility that prevails today in conceptualizing these type of gardens. In synch with these principles is the new image conceptualized for those parts of the *barco* such as the square of the masks, the aviary or the new garden.

These evoke nineteenth-century types such as the intervention in the square where the masks conform to the desire not to disturb the romantic atmosphere of unspoiled nature, the net result of centuries of historical over-layering with traces from the past and with minimal gestures such as the planting of two Sequoias and a Cryptomeria in the middle of a clearing places in front of two fountains dating to the seventeenth century. These serve to update the figurative context of the site.

As a result of the Grand Tour from the seventeenth to the nineteenth century, several foreign travellers had the opportunity to visit and admire this park. The personalities included Turner, Corot, Goethe, Stendhal, Sand and D'Annunzio. In 1787, Goethe wrote as follows

Fig. 2. The aviary to the 900

Fig. 3. The aviary in two images today

“we paused at the entrance of a park which seemed well kept but not controlled by its owner. Strangely enough the proprietor, Prince Chigi seemed keen that visitors should only get glimpses of this private natural environment. In fact, it appeared more as a tangled assembly of trees, roots, and other plants which grew without any form of control. All bushes, shrubs and other vegetal growths were allowed to dry, fall and even rot. The whole ambiance evoked nature and appeared almost as a powerful painting conceived by a great artist.”

During the second half of the nineteenth century and the beginning of the twentieth century, the concept of the *barco*, the aviary and the new approaches in landscape architecture strongly evoked the zeitgeist of the age following a philosophy that one should not in any way intervene or disturb the romantic ambiance of untouched nature which manifested the layering and stratification of its evolution over many a century.

The practice of planting exotic trees in relation to man-made architectural features is most evident in this complex at the piazza next to the aviary where a large cypress tree was placed adjacent to the Viale dei Leoni, together with a series of sculptures in terracotta on the side of the arch which marks the entrance to the old Roman remains. Another cypress tree rises at the beginning of the passageway leading to the Barco, while a series of Chamaerop palms are evident in the Giardino Nuovo on the hillock on the route to the aviary.

Subsequent to its restoration, the place has now been reinterpreted as a walled garden with the installation of a lawn, the starkness and simplicity of which contrasts to the organic qualities of the whole setting. The borders which define the area feature decorative plants such as acanthus, various species of fern, rhubarb, hydrangeas and palm trees which in their autumn colours contrast strongly with the grey tones of the walls covered with capsicum plants.

The restoration was based on the premise of amalgamating and unifying the historical, botanical and forestry aspects of the entire area while retaining the primary character of its vegetation.

Fig. 4. Chigi Park from the satellite, the source Google Earth

Fig. 5. Views of the Chigi Park today

The choice of the architecture was between the previously untamed and natural characteristics of the garden and one based on recreating the image of what the park would have looked like in the nineteenth century on the basis of photographic records from that time. Today, when visiting the park the imagery certainly evokes the atmosphere of that era while the scents, silence, light and colours which now characterize the project were certainly aspects which would not have been present in the original layout but which would have developed and materialized with the passage of time through different historical epochs.

International researchworks about energy efficiency of historical heritage

Concetta GIULIANO,¹

Abstract

The actual normative on the energetic efficiency of the buildings stung to performances thought above all for the construction of a new concept. It deals with values which are not easily obtainable over the existing one that requires high impact interventions and often at odd with the spirit of the conservation of historic buildings.

Speaking of retraining of historical buildings, one must remember that every building is unique for its history and above all for its constructive and environmental characteristics and, therefore, different interventions will be made case by case. For this reason, different studies have been conducted to national and international level in theme of energetic retraining, that they propose to appraise the best procedures of development of the energetic efficiency that are compatible with the guardianship of the asset at the same time.

In this contribution is effected a critical analysis that puts in prominence how much these studies ducts give a valid contribution to this search. They are treated either individually or as a whole.

Keywords: Energy Efficiency, Sustainable Use, Historical Heritage

1. The normative outline of reference

The energy upgrading of historic buildings is become more and more a very important professional practice. At present, it is less considered by the current legislation on energy efficiency, because this one points at performaces thought especially for the existing or new building without a particular historical-architectural prestige, where it is possible to implement high-impact interventions which are often in contrast with the spirit of the conservation of historic buildings.

The aim 20-20-20 required by European Union directives, 20% reduction in greenhouse gas emissions compared to 1990 levels, energy consumption by 20% compared to the levels expected for 2020 and the increase of the use of renewable sources for 20% of total energy production, requires both existing buildings, including historic, than on new construction, as recent studies have corroborated that it is not possible to achieve these objectives by applying consumption limits only to new construction.

Currently, the national legislations, following application of the Directives issued by the European Community, report explicitly that *"Sono escluse dall'applicazione del presente decreto le seguenti categorie di edifici: a) gli immobili ricadenti nell'ambito della disciplina della parte seconda e dell'art. 136 comma 1, lettere b) e c) del decreto legislative 22 gennaio 2004, n. 42, recante il codice dei beni culturali e del paesaggio nei casi in cui il rispetto delle prescrizioni implicherebbe una alterazione inaccettabile del loro carattere o aspetto con particolare riferimento ai caratteri storico artistici"* [1], expecting to go in derogation of compliance with the minimum requirements of the law not only for monumental complexs but also for some valuable property landscaped with an explicit reference to the historical centers. However, the reference to the exception is viable only to those interventions that could damage the valuable characteristics of the material and formal of the Cultural Heritage.

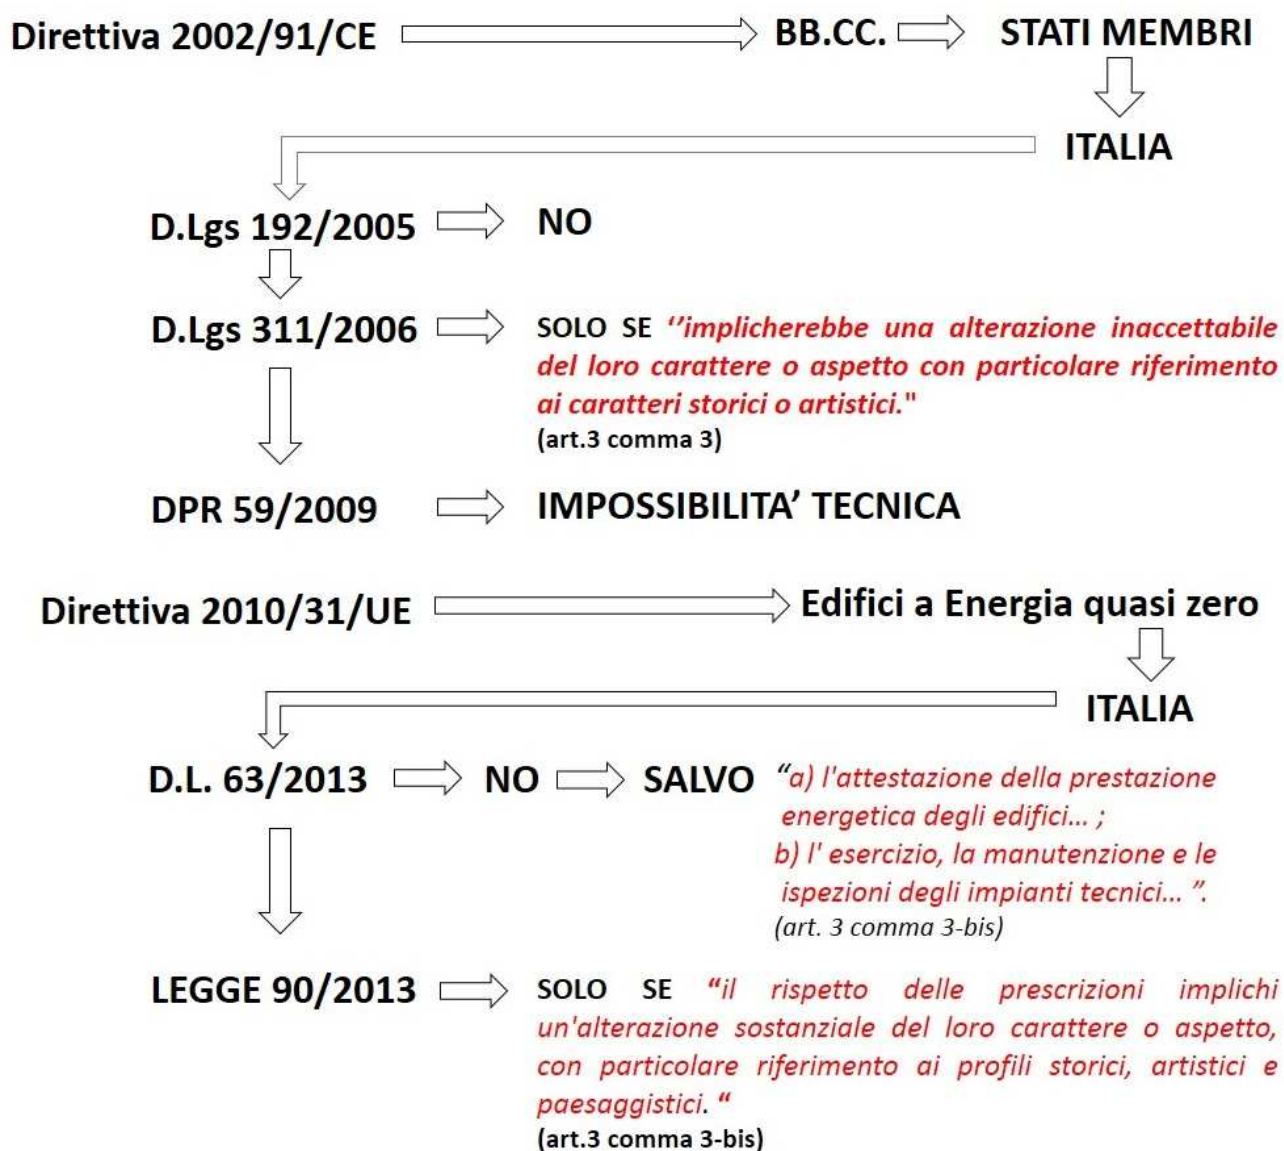

Fig. 1: Schematic summary of the regulatory framework.

The excessive costs in terms of energy consumption make it impossible to manage, and then an appropriate conservation of such buildings.

Not undergoing any type of surgery, in terms of energy efficiency, these buildings continue to have excessive leakage which could affect the already uneven public budgets (since the majority of these goods is to use / public property). Especially for unique goods and irreproducible, the ever more pressing need expressed by both the professional world and from a scientific is to identify design solutions that have as their objective to generate a dialogue between permanence and adaptation energy.

2. Projects

The topic of research is in a constant state of experimentation and this is proved by the numerous national and international research in progress.

You can see different types of approach which show Italy led by a more appropriately performance method, while the Anglo-Saxon countries tend to a practical application through the publication of manuals and guidelines. These are turned to designers and the general public with the aim of clarifying the practice of conservation and management of heritage and the most appropriate solutions for energy improvement.

All this is achieved as a result of studies carried out in different buildings located in different areas and with different technical characteristics. Below we will discuss the salient features of the most

significant and innovative research projects carried out in Europe on upgrading the energy efficiency of historic centers. In particular, we analyze:

- 3encult;
- Effesus;
- New4Old;
- Sechurba;
- Brita in Pubs;
- Restart.

The project 3encult - Energy Efficiency for the European Cultural Heritage funded under the Seventh Framework Programme of Research and Development for the period 2010-2014, is born with the purpose of developing and testing innovative solutions to improve the energy efficiency of historic buildings in urban area, with the intent to demonstrate that energy efficiency, occupants comfort, structural protection and preservation of cultural heritage are elements correlated in energy retrofit project [2]. The project is oriented to the creation of a manual with guidelines for design and a pool of technical solutions to designers as an alternative to conventional measures of thermal insulation and replacement plant [3].

The EFFESUS project studies the energy efficiency improvement of historic centers in Europe built before 1945, they are not necessarily protected by the law of cultural property. It identifies new technologies and products that do not affect the integrity and authenticity of the property with the intent to reduce the environmental impact of the historical heritage through significant improvements for energy efficiency and optimize the sustainability of the well retaining their architectural, historical, artistic and cultural heritage. These technologies are supported by software tools like MDSS (Multicriteria Decision Support Systems) for the assessment of energy improvements in historic districts [4].

Of great interest is also the project "New4Old - New energy for old buildings. Promoting the integration of RES & RUE background in historic buildings" that aims to promote the integration of renewable energy technologies and energy efficiency in historic buildings, by initiating the creation of a network of homes Renewable Energy (REH). During the project technical guidelines have been collected for architects, designers and developers on the methodologies for the integration of renewable energy and the spread of a more rational use of energy. In them are spelled out the problems that are created in old buildings, such as the critical issues, principles of operation, offering suggestions and possible solutions for action on the structures and systems [5].

The project SECHURBA has instead highlighted the possible actions towards sustainability that can be achieved by respecting and preserving the cultural heritage. It was launched to authenticate the historical centers play an important role in contemporary society, helping to reduce carbon emissions and become more sustainable. The objective of SECHURBA is to notify, through the results obtained from the case studies, opportunities and potential offered by sustainable energy interventions applied in historic urban areas (communities, towns, monuments blocks) in order to disseminate new technologies into future energy policies and local development programs [6].

The integrated project BRITA in Pubs (retrofit Bringing innovations to application in public buildings) is one of the 4 integrated projects financed which is part of project Eco-building, under the 6th Research Framework Programme of the Commission U.E.

The project Brita in pubs aims to increase the market penetration of efficient and innovative solutions for the retrofit of buildings, with the purpose of improving energy efficiency and developing the use of renewable energies, additional costs contained. The whole structured into eight work packages that include research studies also socio-economic character, such as the identification of the real needs of planning, design and financing strategies, evaluation of guidelines for the design, the development of a tool for the evaluation of retrofit measures, a tool for quality control to ensure good long term performance of the building and systems [7-8-9].

The project RESTART (Renewable Energy Strategies and Technology Applications for Regenerating Towns 1997-2002) is a demonstration project sponsored by the European Commission and coordinated by RESET (Renewable Energy Strategies for European Towns) in collaboration with the city of Barcelona, Glasgow, Lyon, turin, Rotterdam, Copenhagen, Porto and Dublin.

The project aims to achieve several redevelopment able to reduce the primary energy demand of buildings through the reduction of environmental impacts and the use of renewable energy sources.

The project has drawn attention not only on the more technical aspects of the intervention but also on economic and social aspects of these locations, involving the population, encouraging the penetration of new technologies and rationalizing the use of resources [10].

In Italy, instead, the studies aim to identify areas for performance improvement that relate to the individual technical element of the building envelope.

Interesting is the research carried out by ENEA, completed in 2011, which had as its objective the identification and evaluation of interventions that would ensure, at the same time, the energy improvement and preservation of morphological characters, material and architectural features of historic buildings, giving as a result of a path that would make schedografico immediately usable and transferable research conducted and the results obtained. As a case study was chosen the *Molino del Cantone*, inside the grounds of the Royal Palace in Monza [11].

Fig. 8: Example of cards Enea (by BORIANI, GIAMBRUNO, GARZULINO, 2001)

At the same time energy and environmental certification schemes are being studying such as the Green Building Council Italy which on the basis of protocol Leadership in Energy and Environmental Design dedicated to the historic buildings is developing the "Protocol LEED Historical Building." The intent is to change the traditional methods of design, construction and management, with the aim to create places in harmony with the environment, healthier and improve the quality of life. The Protocol LEED HB is a complex system of environmental assessment, which takes into account variables on an urban scale and construction. As for the "Protocol LEED New Construction " LEED for HB areas of concern regarding the sustainability of the site, the efficient management of water, energy and atmosphere, materials and resources and indoor environmental quality. For each category, there are the key indicators that allow us to obtain the environmental credits. What we want to achieve is consistency between the policies of sustainability and urban reuse that takes into account the reduction of waste in land management, the implementation of a retrofit adaptable to their reusability future and the importance assigned to managing sustainable energy. At the time this instrument has been tested on Foscari Palace, a historical palace of the sixteenth century, house of the prestigious University of Venice Ca 'Foscari.

Fig. 9: Categories of environmental impact according to the certification LEED

A new rating system for existing buildings has been developed by the Climate House of Bolzano that work on the issue of energy efficiency in buildings. It had achieved a certification protocol for new construction but, nevertheless, the application of the method to the House Climate Remediation work has highlighted some limitations of the protocol used for new construction so much that this method can not be used for assessment of restructuring measures. For this reason, the project Climate House R had to create an evaluation system that takes into account the peculiarities that characterize the

interventions on existing buildings. In the experimental phase of the project have been subjected to a process of evaluation of 32 projects, during execution, planning or construction, they had to take into account both the technical feasibility of the interventions that legislative requirements that in many cases turn out to be inadequate.

The Protocol Climate House R is aimed to become a technical instrument perfected for the designer, supported by a verification protocol transparent, allowing spot checks organized for the purpose of wanting to get a seal that certifies the quality of the entire construction process of the intervention recovery ranging from design to installation in order to achieve the goal of a true energy efficiency.

Finally, the project ATTESS ended September 30, 2010, is the result of an ' agreement of cooperation between the Veneto metadistrict green building, the Venetian metadistrict of cultural heritage and the regional directorate for cultural heritage and landscape of the Veneto, in the terms expressed in Memorandum of Understanding signed in Venice June 10, 2010.

The aim of the A . T.T.E.S.S. is to improve the energy and environmental performance of historic buildings, taking into account the performance criteria of the restoration of the criteria of green building. The search result ATTESS was the creation of guidelines for the knowledge of the historical building, to determine the method of approach to the project, through the application of new technologies, which seek to operate through the decisions sustainable and less invasive operating a careful evaluation of the existing in order to preserve the value of the housing stock and assess adequately the potential from the point of view of energy-environment [12].

3. Conclusions

From all this it follows that increasing attention is given to the historical buildings, in which the project must take into account a variety of aspects related to the cultural, historical and artistic building, use, length of time, but also to 'energy efficiency and management. The number of data points from all of these projects can serve as a useful guide for professionals, businesses, organizations and citizens to take part in a historic building without altering its value, but taking into account that as well use (public or private) must also be able to follow the rules of economy and efficiency in management.

Castra of Benedictine origin in territory of Cassino and in the Upper Volturno Valley

Camilla DI FALCO¹

⁽¹⁾ Department of Architecture and Industrial Design "L. Vanvitelli" - Second University of Naples
Aversa (CE), Italy
camilladifalco@gmail.com

Abstract

South and Central Italy saw the birth and the development, initially under the Longobardic domination and subsequently under that Frankish, of a series of monastic foundations of Benedictine order. Between them, the predominant role from the socio - political and economic point of view is surely to attribute to Montecassino and S. Vincenzo al Volturno Abbey, tied by an almost analogous history for timespan of the dark ages. On the vast possessions accumulated throughout the course of the centuries thanks to the longobardic and carolingian donations, and described as the Terra Sancti Benedicti and the Terra Sancti Vincentii, starting from the X century they put in place the model of territorial organization of the *incastellamento* constituted by inhabited centralized and strengthened situated at the top, called castra or castles, that became centers propellers of local economies, directed to the recolonization and the reconstruction of the areas. They are born in such way installations with similar characteristics that are still to the origins of the existing urban centers in Cassino and Molise's area. The contribution analyzes the territorial structure from the historical and urbanistic point of view and the development of such installations.

Keywords: Molise; Benedettini; Montecassino; Volturno;

1. Introduction

One of the dominant features of the rural Italian landscape consists of a concentrated and strengthened settlement, usually high ground. Historians and geographers over the years have deepened the institutional, political and socio -economic features analyzing the origins, development and transformation.

Demonstrations of this process of settlement are recognized in a large space that includes the Iberian world, southern France and Italy, in different ways and strong temporal differences between countries: in France for example it shows up between the X and the XII century, in Italy and Spain instead it's more precocious, it's already in place in the ninth and tenth centuries[1].

The historic French medievalist Pierre Toubert was one of the first to shed a global light on the phenomenon of *incastellamento*, which is the key to the structure, development and organization of Mediterranean societies of the Middle Ages: a theme still widely discussed after forty' years from the publication of his hypothesis[2].

The *incastellamento*, defined by Toubert as la *révolution castrale*, is the cornerstone and foundation to analyze the process of deep transformation that occurred in particular in Southern Italy: in Lazio between the tenth and eleventh centuries, but which had been previously caught by other scholars, primarily by Mario Del Treppo by social and economic analysis life of Terra Sancti Vincencii [3], and even earlier by Henri Pirenne that distinguishing between *chateau*(seat of power) and *bourg* (businesses seat surrounding the castle) had drawn up a profile of ' urbanization in medieval Europe [4].

The organic model of battlements identified by Toubert locates in the castle the main structure of the system of organization of rural areas; castles, with all the ambiguity of the term, or even castrated,

meaning fortified villages who settled in areas previously unoccupied by becoming centers of concentration of populations and essential reason for the disappearance of the scattered settlement that retraced an arrangement referable to the Roman era until the tenth century [5].

In essence, this phenomenon represents the transition from one dispersed habitat to a habitat concentrated in castles, grouped towns, fortified and situated at the top, a step that occurs through the convergence of three elements: the centralization of the population, fortification of the town and the formation of *territorium castri* around the site [6].

In Lazio, as well as in Campania, the concentrated and fortified town replaces the scattered rural settlement and agrarian structure space, revealing a kind of planned foundation, an intervention of rural planning[7] .

Actually in the process of fortification three separate historical processes converge[8]:

1. *incastellamento* itself, the fortification of existing settlements, or the construction of fortifications more or less close to them;

- 2 . the creation of territories and legal location associated to the castles [9];

- 3 .concentration, the concentration of the settlement, through the creation of new settlements or the convergence of the old ones: normally inside the castles (i.e. fortifications) as in the classical analysis of Toubert.

The *incastellamento* was in central and southern Italy conducted very frequently by the monasteries, mainly by the Benedictines of Montecassino and San Vincenzo al Volturno, but also by Farfa and San Clemente a Casauria, whose monastic and territorial organization is documented and recorded in the diplomatic sources, cartularies codes and *chronica*: The Religious acted in harmony with the owners of neighboring curtes and rural communities. In this regard *castrum* and *ecclesia*, *incastellamento* and enchurchment, cannot be opposed, as if they were models in competition. Anyway, the ecclesiastical institution seems to have taken a structuring role in the long term [10].

1.2. The Cassino territory

The territorial domain of the Abbey of Montecassino sees its real beginning with the donation of substantial portions of properties located in the area next to the monastery by the Lombard Duke of Benevento Gisulfo II, in 744. Prior to that date the Cassino territory consisted in assets dating back to the late Roman Empire and the funds of wealthy local families, descendants of the gentes Paccia , Ummidia, Tutia, Luccia who lived in *Casinum* during the imperial era[11].

The land donated to the monastery in the eighth century included a flat area between the rivers Rapido and Liri - Garigliano, and part of the mountain composed of hills to the north (Abruzzi Apennines) and on the southern side (Aurunci mountain) [12] .

The abbot Bertario, in 857, was the first to carry out a proper fortification of the territory, act to defend the abbey from the impending Saracen threat: an impressive complex of towers and walls of protection around the Monastery of the Savior, first called Eulogimenopolis , and subsequently San Germano [13].

Despite this intervention, the Saracen raids around 883 caused the abandonment of the monastery while the monks found refuge first in Theano, then in Capua, the territory was plundered and destroyed by the invaders. The tenth century was therefore marked by a severe social loss, a deeper crisis than the rest of the peninsula, from which derived in consequence the retreat of arable land and a significant alteration of the urban fabric [14].

The return of the monks and the abbot Aligerno to Montecassino in 949, was the *ubi consistam* for a total renovation and unprecedented and caused the reconfiguration of the abbey heritage. When the period of the building industry of the cellae was over it began the period of the fortifications of towns sprang up around the monastery: the entire earth of St. Benedict, as well as works for cultivation, land reclamation, and fortifications, was affected by a new judicial organization and by the onset of a new administrative system: the *incastellamento* phenomenon began [15].

In 967 the abbot Aligerno , through the contribution of the *Ius Munitionis* granted by Pandolfo Capodiferro and his son Landulf III , [16] obtained the right to freely fortify the entire inhabited territory by facilitating the reconstruction of the destroyed churches and the creation of new ones[17] . Around these farmers would settle, to whom the abbot gave soils with balanced contracts.

Dealers of land were bound to soils with long-term agreements that guaranteed the exploitation of land, while remaining the property of the monastery. In exchange for the freedom to settle in the land received and the opportunity to build homes both for themselves and for the employees , they were bounded to build the castle (*castellum tan veins juxta et ratione*) , with staff provided by Monte Cassino, the so-called *magistri fabricatores*. By placing their houses around the churches, they formed thereby those that can be defined the first rural villages, which were built on high ground before uninhabited.

The new settlement units was represented now by the *castrum*, a term that in most of the peninsula indicates a cluster of houses enclosed by fortifications, and often protected by a fortress built inside the perimeter wall, with agricultural areas positioned concentrically in the surrounding space. But the

castrates were also supporters of local economies, aimed to the reconstruction and repopulation of the territorial organization.

With the implementation of balanced contracts, lasting twenty-nine years and renewable, the vast territory of Monte Cassino , an area of nearly four square miles, was divided into small possessions that could not be moved unless within the same monastic community, which represented properties , although restricted to the payment of contracts.

1.3. The area of upper Valley of Volturno.

The territory which occupies the upper valley of the Volturno River, straddling the modern regions of Abruzzo and Molise, has always been inextricably linked to the role that the Abbey of St. Vincent played on it, from its definition that identifies itself with the foundation of the Vultur monastery .

The Abbey of St. Vincent was founded in an area protected by Mainarde of course , which marks the border with Lazio and Abruzzo , not far from the headwaters of the river Volturno, by Lombard will and in conjunction with the Benedictine expansion throughout the country.

The tradition, linked to the events narrated in the *Chronicon Vulturense* [18], says that it was founded in 703 by three nobles Benevento Paldo Taso and Tato, who came from the Abbey of Farfel, and chose to stay in that site where there was already a chapel in ruins dedicated to St. Vincent.

At the time of its foundation, the three were sponsored by Gisulfo The first Duke of Benevento , who gave them a vast expanse of land , about 300 square kilometers of land, the nucleus of what would later be the land of Sancti Vincentii [19] .

It should be emphasized that the foundation of the first monastery of St. Vincent foreruns about fifteen years before the restoration of the abbey of Montecassino by the Petronace of Brescia, which occurs precisely with the help of the community of Volturno ,distant only twelve miles of walking alpine [20].

Since the foundation the development of the abbey had to proceed at times, now facilitated by the growth of the monks, now damaged by the Saracen invasions and earthquakes, but at the end of the eighth century the monastery, with a small cloister located in the south of it, occupied an area of half a hectare and housed little more than 100 monks [21].

Over the years through numerous donations , particularly that one of Arechi II during the years 758-60, the monastery had become the owner of a large area of over 400 square kilometers bordering the territory of Monte Cassino , who trained at the same time thanks to similar ducal donations but with a much higher extension.

The *Chronicon Vulturense* of monk John, dating from the twelfth century , and the first source for the reconstruction of the monastic history of the monastery of San Vincenzo al Volturno , contains a series of documents that attest to the formation of the assets of the abbey.

The formation of the Vultur estates contributed , to varying degrees but equally significant, the private and public munificence . The flow of donations from the first half of the eighth century formed the basis of monastic power, was accompanied by the granting of such immunity rights that acted as a distinctive element of that power [22].

Internal organizational structures of the area are not documented nearly up to about 914-916 , a period when the monks returned after the looting and destruction of the monastery by the Saracens . The situation changed completely in the early ninth century when ,under the initiative of the abbot Joshua , it was decided to launch a broader project of urban planning .

The abbots conciliated between Lombard and Carolingian power , placing the abbey as a watershed between two spheres of influence. According to Marazzi, only in the tenth century, the influence of the Carolingian was consolidated and the abbey became a sort of outpost in central and southern Italy.

Throughout the Molise between the ninth and twelfth centuries an extensive process of fortification is documented. The castles are born in the Volturno area in the ninth century, and again in the tenth century their fortification around the abbey is attested. In the following century the arrival of the Normans increases the widespread implementation of fortified and walled towns.

The Normans impose themselves by repressing the push for autonomy of the local lords . The occupation is accompanied by a work of fortification so punctual that they introduce the castles in the city as a characteristic of their original process of territorialization .

The hilly terrain makes it difficult to adopt appropriate solutions to the countryside, to the geomorphological characteristics , exploiting any previous settlements [23].

Until about the middle of the eleventh century the settlement forms had little consistency , being scattered within the entire area of the valley, but in these areas are developed the settlements which are the origins of those countries that still exist in the Valley of the Volturno.

1.4. Conformation of the centers: some significant cases.

For proper evaluation of any historic urban core it's essential to look specifically at the territory which is the basis originator , along with all those physical, hydrological , cultural, settlement factors which variously affect its education , as the streams , vegetation and climate , thus acquiring a greater

awareness of the environment that characterizes the place where you place the single architectural object.

The centers who depend from the abbeys of San Vincenzo al Volturno and Monte cassino extend between Cassino and the plain of the western slope of Molise , neighboring territories which show very similar orographic and environmental features.

The same Cassino and Vultur settlements, being of course the result of the encounter between a geographical site and a settlement pattern, present in the majority of cases, a common urban planning.

Types of settlement of this territory are divided into two categories : the spindle of the acropolis one and the winding one (partial or total): however, the plants of Vultur centers have a greater readability , as they were unchanged in their shape after the loss of power of the abbey of St. Vincent determined an arrest in the development, both for their isolation ; Cassinensi centers throughout the centuries have changed their shape better because of the increased religious impulse and consequently to frequent and severe earthquakes that have always interested the area and often have totally and irreversibly destroyed structures .

A case that's particularly interesting in its conformation is the Vultur fief of Castel San Vincenzo , in the province of Isernia.

The village is situated on a spur in the south of the Rio Omero, 749 meters above sea level . Because of its dominant position and the proximity to the Abbey of St. Vincent the village has assumed a supervisory role over the lands of the monastery, following the historical fortunes until the middle of the fifteenth century.

Actually, what is the present-day town was formed by the union of two centers , one -time independent named Castellone and St. Vincent, the first with total winding type, the second type with a spindle of acropolis , joined in the south Eastern Europe.

The core of Castellone wraps around the St. Stephen's Church, built in the twelfth century, which can be reached along the way of the Church that meets in the square now named Vittorio Emanuele III and on which the church faces .

The village of San Vincenzo develops itself following the linear Via Roma, with the monumental entrance to the west door of St. Philip (XII century), Which is also dedicated to the eighteenth-century church of the same name , located in the square that welcomes those who arrive in the country . The road runs through the village , opening in the center in a rectangular square with the church of St. Martin already existing in the inhabited area in 819.

The village appeared walled around the perimeter but did not have other defensive elements. In fact it isn't indicated the presence of either a castle or tower to protect the population.

Unlike the case of the town of Fornelli: situated on a rocky ridge in the central part of the high valley of the Volturno , encloses an area of approximately 60 x 75 meters a set of small inhabited units into a wall which was once surrounded by a moat [24]. In Angevin era the walls were expanded with six cylindrical towers that disrupt the continuity of the walling .

The church of St. Michael the Archangel is still in the center of the fortified nucleus, with the residential center which is distributed radially around [25].

In the Cassino area in the same setting is recognizable for example in Castelnuovo Parano, in which the village is spread concentrically around the Church of Sant'Antonio Abate, contemporary with the construction of the fortified plant (XI century).

Although several seismic events, since the earthquake of 1349 , we have definitely changed the look , a trace of the original plant of the settlement is recognizable in a small circular tower with a shoe.

Until the seventeenth century there were still three doors , a square tower with three rows of rooms, and a round tower. What still can be seen now, on a rocky outcrop , is a square tower of which remains standing one side, surrounded by a wall of elongated shape inside in which was placed a residential building.

ANCIENT POMPEII SIGHTSEEING: INTANGIBLE IMMERSIVE TECHNOLOGY AND EMOTIONAL MAPS

Marco BORRELLI

Department of Architecture and Industrial Design, Second University of Naples, Aversa, Italy
marco.borrelli@unina2.it

Abstract

Pompeii has always been the destination of a continuous flow of tourists from all over the world, who come to see first-hand the archaeological patrimony inherited from the past that has elevated Italy to the rank of the “*Bel Paese*” as the guardian of the beauty and charm of the past. Unfortunately, this basic condition also includes the negative elements of the political, social and cultural degradation that have not encouraged the sustainable development of the entire territorial system that now includes the archaeological excavations, the religious complex as well as the attached museums.

In line with central government initiatives (see DL “Cultural Value”) undertaken in 2013 and aimed at the preservation, development and enhancement of the cultural heritage and activities of Pompeii, the current research test a *cultural* tourism project today *alternative* to the *mass*, which is processed through a **model of reciprocal systemic and relational exchange** between the tourist-traveller, the local community and the wealth of beauty inherited from the past.

Addressing an immersive almost pervasive path, through interactive technologies and environmental devices carried out with augmented reality, means fostering a retrospective reading of the space, as an occasion for inner enrichment for the 21st century tourist-traveller, who from simple day-tripper, penetrates into an innovative experience in the perceptual optical field in the same way as experienced by the romantic model of *Flâuner*. Through the use of **emotional maps** translated into new models of control and understanding of the space with a series of inspections of the emotions, it allows an individual to expand the knowledge of a place and explore the sphere of intimate man

Keywords:

Heritage: Collective Identity, Memory, Communication for Cultural Heritage.

Architecture: Modification Project

Landscape : Government of the territory, Sustainable development, Social Sustainability

1. Introduction

This research can be placed within the current historical context that is characterized by a period of economic decay, a slowing of production on the verge of a **recession**, not only economic but also political and social, which tends in contrast to founding a fertile ground for a new cultural revival.

In general, this situation can be extended to the entire **planet** since man has abused the natural resources for too long and has particularly focused his activities on mere economic profit excluding any extended benefits to the community in the social and cultural spheres.

Specifically, the current American crisis is dragging Europe behind it, changing the direction of the global economy, while at the same time shifting the economic and productive barycentre from the US-European axis to the archipelago of new emerging countries such as **Brazil, Russia, India, China and South Africa**, identified with the acronym **BRIC(S)**.

Unfortunately, **Europe** will have to wait a little longer so that the unification process of the **European Community** can comply with an overall programmatic intervention including the different systems and economic models, articulated and complex, of development and growth, finally considering all the countries currently participating as a true community.

Unfortunately, **Europe** has always been considered the old Continent since it is too conservative and anchored to old models of development, a process of unification of the nations that is too slow and merely based on the introduction of a single currency and therefore too limited.

In fact, this approach has not favoured a broader process of unification and development involving more heterogeneous areas ranging from sociology to politics, starting as a basis for a development model focused on culture understood by **Richard Florida and Maurizio Carta** as a “**cultural reset**”.

[1]

Starting from the assumption that development through *culture* and *creativity* should be primarily focused as a tool to re-start from a state of serious decline, it means focusing on young people, their creative force and the opportunities offered by social exchanges as well as cultural and ideological premises that can favourably interact in the global village. [2]

In fact, the solution to the crisis intended as a reversal of the route will only be viable if it is based on the application of certain factors that promote innovation and progress expressed in the theories of **Richard Florida and Maurizio Carta** capable of promoting cultural development through a model based on the **3T and 3C** (Technology, Talent and Tolerance + Culture, Communication and Cooperation). [3]

Fig. 1: Saverio Della Gatta, Bottega di antiquario napoletano, gouache (1798)

First form of for example the distribution of the product archaeological inside the store

The theory tries to highlight some aspects of these factors of cultural progress by applying them to the territory of Campania, a region rich in archaeological and artistic artefacts that for decades represent a source and resource of cultural tourism, aimed at demonstrating that in the XXI century, there has been a reversal of values so as to assert that "... culture has exceeded technology as an engine of innovation, particularly in consumer goods ..." based on studies developed by *Judith Mühlenhoff*. [4] In fact, *Italy* cradle of culture for the stratification of signs, thoughts and products, which are also identified in its archaeological and artistic environment, has always had the possibility to invest in an economic system for **tourism** in an attempt to combine the relationship between **tradition** and **innovation** into a relationship that is not to be considered confrontational but symbiotic and antithetical. [5]

Starting from L. De Biase, with tradition defined as "... a source of knowledge for a society geared to make things right ...", development based on traditional roots intended not as an archaic model but as a base to which to refer to for the production and creation of a growth process that bases its pivotal point on creativity, in fact, tradition must express the meaning of things, the truth and it must establish itself as a source of knowledge from which to actualize technologies, service devices and automation systems useful in obtaining "smart" performances and innovations.

Many Smart City projects on the lines of **cultural and archaeological tourism**, especially in the cities of art, that hold a wealth of testimonies and secular values, revolve around the concept of "*heritage driven*" [6] while drawing from digital technologies as well as the intangible assets of Web 2.0.

If the orientation of economic policy management is changed by passing from "emergency" interventions to structural and strategic initiatives, there will be a radical change based on investments that tend to an opening of a creative nature without neglecting the creative and innovative contribution of young people who are more open to the contamination of knowledge.

Unfortunately, on the contrary, in recent decades, we are witnessing, disheartened and demoralized, the decay and abandonment by the institutions of cultural tourism destinations such as the archaeological excavations of **Pompeii and Herculaneum in Campania** as well as for the Imperial Forum and the Colosseum in Rome. Despite the growing tourist flow being mainly foreigners who visit the places of memory and tradition of classical civilization, policy initiatives tend to avoid the question of innovation thus marginalizing the contribution of **Cultural Creative Enterprise ICC** [7] with a short-sighted attitude.

Apply digital interaction systems through increased reality and the immersive reality directly connected to cloud computing, i.e. in close contact with records that can be stored and archived through the Open Source tool typical of the Web 2.0 era, means starting from a concept of creativity closely related to that of culture that by using advanced technologies can promote the material culture and social quality.

In the **tertiary production** sector, a formula for **cultural tourism** that is attached to the mass tourism, historically a driver of our economy, has grown in the last few years.

Establishing systems of economic development on a model intended as a magnifying glass based on actions and reactions, means promoting tangible and intangible products and services on the territory capable of promoting a **scenario of sense**, of aesthetic value in addition to a complement to the mere function of products and services in line with recent directives of the "White Paper on Creativity" by Walter Santagata. [8]

2. Vision and Scenario

The current line of scientific research addresses some design themes developed during the course of "*Company Museum*" in the second year of the **Master's Degree in Design and Innovation** at the Department of Architecture and Industrial Design "Luigi Vanvitelli" SUN, oriented at furthering the experience of a user interacting with digital technologies when visiting an **Interactive Museum and/or the Company Museum** the value of which is to transmit digital content. Everything starts with an analysis of the value chain of the cultural and creative industry, based on the definition of the **creative economy** that is understood as an economy based on knowledge and talent, traditionally associated with areas such as architecture, art, music and painting.

Today, however, this new dimension of the **knowledge economy** is also contaminated by scientific and technological activities capable of building a relationship that is a useful both for the interfacing of transmissible scientific research as well as the development of new forms of entrepreneurial projects. Progress and development depending on the production of culture means to leverage this wealth of knowledge stratified in our civilization and in every expression of the historical and artistic heritage and at the same time means that the scenario and context for creativity understood as a value that holds each individual to solve any problem by optimizing resources and time.

This position promotes economic development through digital technologies contaminated with culture as historical and artistic heritage, and thus the creative atmosphere or territory represents the pivot and at the same time the foundation of ongoing research reported in the international conference "XII

Forum International Le Vie dei Mercanti 2014” about the theme Heritage-Conservation-Management best practice from the world to Pompei.

Starting from some scientific positions reported in the “White Paper on Creativity” produced by the Commission of creativity and production of Culture Ministry of Culture in Italy MiBAC (2009) under the chairmanship of Walter Santagata [9] and the European Digital Agenda for Culture (reported in the Green Paper “The cultural and creative industries unlocking the potential”).

Specifically from the **Green Paper on Creative Industries**, there is an essential reference to the principle that “... *the culture becomes a creative input to the process of production of goods and services* ...” sometimes not necessarily only cultural. They are accompanied by activities attributable to forms of cultural expression a method of contamination with a creative and expressive dimension of the handmade design product expression of traditional manufacturing. While in the **White Paper on Creativity**, the model assumes a principle according to which: “...*the basic skills of creativity*...” the factor that offers guarantees of development in terms of innovation lies in governing the processes of communication, financial management and fundraising as well as market access strategies .

In Italy, the nation of art and beauty, the opportunity we have today to promote an economic recovery is offered by the opportunity to promote the creative and cultural industries contaminating immersive technologies as well as those of augmented reality derived from a “*technology –driven*” position with the values, cultural and artistic, described by the existing pattern of development such as “*heritage-driven*” , all to promote a process of continuous transformation where innovation and culture are the right mix to follow a line of frontier economic development and highly symbolic and intangible cultural tourism.

Specifically, the Italian tertiary tourist production sector with all the cities of art, archaeological sites and excavations of Pompeii and Herculaneum, testimony to a strong interest in classical civilization of communicative and cultural, bases its appeal on a model that promotes and disseminates values that are focused on culture.

If an aspect of creativity that focuses on communication technologies, innovations and industries of content is added to this precondition, a model of creative development that promotes the production of cultural content is obtained, capable of providing a complete service to cultural districts and tourist museums. Today, **Smart Phone** are diffusing interactive digital applications, new ways of sharing content and images that applied to the creative and cultural sector of the company, promote an active participation of a museum, customizing paths, impressions and emotions to be transferred in real time via cloud computing to friends, relatives, colleagues in remote locations based on the concept of a united global location GLOCAL. [10]

(In both images Gouaches you can see the tourists who visit the excavation cultured)

3. Technological Tourism and Emotional Maps

In Campania, tourism has always played a leading role in the tertiary production sector due to the presence of an archaeological and environmental heritage that attracts many foreigners from Europe as well as other continents. Unfortunately, this opportunity is no longer sufficient and not enough to support the history and environment, it is therefore necessary to implement a strategy that involves planning and business institutions, local associations, the research universities and business realities according to a model of continuous innovation as a factor of competitiveness for economic development (*Triple Helix Model* [11] which allows Political Companies and Universities to interact).

However, local institutions, given the economic crisis and very few structural funds, have never concretely adopted in the configuration of an innovative **Cultural District** because the central government has always coped with relief interventions and commissioning safety, and because they have never considered cooperating, systematically involving different actors and people capable of exploiting the wealth of local creative businesses.

The definition of **Cultural District Museums** and the consequential distinction of several other forms of museum network or Museum System refer to research and scientific texts of scholars in economics and management, who recently addressed through careful critical reading the development of industrial districts in Italy. [12]

Specifically, the cooperative work in progress with some business networks and associations involved in tourism in the city of Pompeii based on the European Framework Programme for Research and Innovation **Horizon 2014/2020** so that an integrated funding for competitiveness can be implemented and the application of digital technologies, the author is considering some design strategies to revive the tourism trade based on creative and cultural companies applied to the “*Open air Museum*” within a broader archaeological cultural district of **Company Museum in Pompeii**. The objective is to imagine the extent to which within a district cultural archaeological “open-air museum” is it possible synergistic intersect systems in the form of service and immersive technologies aimed at improving the quality and quantity of experience of archaeological space, improve services relating to the supply and consequently increase the number of visitors and improve the relationship between the public user/visitor and offer new products and services prepared on the basis of a system of interaction or immersive and interactive journey.

What form of twenty-first century tourism is preparing to materialize?

If industrial production has historically favoured the spread of a commodity and specialized monothematic product, today in the twenty-first century technological and digital developments tend to the *dematerialization* [13] of the product, which applies to the cultural district museum of Pompeii and Herculaneum and should incorporate a principle diffusion of externalities, i.e. intangible values and elements expressed in complex systems and multi-services for the integration and completion of the pre-existing cultural museum product. Investigating tourism through creativity and technology at the service of culture is to imagine systems of interactive technologies capable of constructing a scenario of meaning, where the space and time of the visit in the archaeological excavations becomes the relational platform for a new dimension of perception based on the experiential testimony to a feeling and immersive emotion as the result of a dialogue between the virtual and real, between the imaginary and imaginative obtained by overlapping and/or juxtaposition of a hologram that fully integrates with the existing historical and archaeological environment. Furthermore, the technologies of augmented and immersive reality allow the individual user of the service to interact with the information apparatus overwritten by customizing experiences translated into a path as the suggestion in the form of programmed self-management of continuous information.

Today, among the “digital natives”, there is a pervasive use of interactive digital content aimed at offering a sensory journey that responds to the needs, dreams and expectations translated into a narrative in the form of “storytelling”. The individual memory of that particular physical location can be so easily stimulated through the active participation of the user in addition to finding valid information cataloged, prepared and properly organized. It can personally expand the cultural matrix with creative contributions and interpretation.

Everything is entrusted to the contribution of the individual viewer, protagonist in relation to his experiential travel path defined in the era of post modernity by **Giampaolo Fabris** [14] as consumer-Actor, but with the dimension being critical to be referred to, namely that human, in reference to the issue of involvement and behaviour will need to determine a measure through which to create reference guides capable of collecting data, stimuli and responses by organizational structures and museums together with the entire community in the form of cloud computing.

The system of archaeological excavations, contaminated with immersive technology, distorts the behaviour of tourists in the exploration of the space and search for information phases, which, obtained by a technological approach applied to the existing architecture of the past, increasingly blurs the boundary between physical and digital, between real and unreal loading the cultural experience of intangible and emotional values, stimulating the participation and interaction of tourists through its emotional component.

The tourist traveling through a *promenade*, in the manner of Baudelaire's *flâneur*, activates the emotional sphere in a playful and exploratory path, favouring a mental process in which the emotional involvement increases the more the tourist bases his journey through an appropriation of space in an haptic manner rather than optical, where the investigative path is not based on a faraway look, a stranger to his own person, in the manner of **Giuliana Bruno's** *voyeur* [15], but on a look that is more like a tactile vision, in which the body is involved through all its senses in the total complexity of the experience of using the space, with the whole system of perception through the sensory sphere. So that the simple consumption of images becomes living complete and complex in archaeological

spaces and museums, where the simple visual delight of an incomplete and ruined architecture becomes the desire to fruition through the perception of those places as real emotional journeys; the rigid optical vision is replaced by an inner journey that begins with a haptic approach to the outside world through the eye, passing through all the sensory fields of the body and turning into a real emotional journey, where the external journey enters into a relationship with the inner journey, and the physical journey with the virtual, in which places become defined as **Giuliana Bruno** [16] *mnemonic palimpsest*, i.e. rewriting the memories and the journey instead of a discovery in a territory as real as the interior, giving visitors the opportunity to write their own **emotional geography**, linked to this new way of looking and coming into *contact* with the space, which becomes a place of representation through mind maps.

Draw maps results in writing sentimental places, a psycho-geography, where maps become an intermediary between the physical reality and the inner life, and where emotions are influenced by the space within which it moves the memory formed through haptic and emotional experiences, which allow to model the architectural *promenade* of the tourist according to different emotional situations, giving rise to a continuous re-mapping of the space of the museum.

In this vision, the *yoyageur* of the museums of Pompeii moves away from the figure of the common tourist *voyeur*, simultaneously addressing a travel route connecting an emotional feeling inside and outside, public and private, where the *promenade* is transformed into an emotional and experiential narrative, in continuous evolution, recountable and transmitted through a new form of narrative or storytelling media within an architectural space.

Seeing and travelling, to explore the museum and archaeological reality, from life and body to an inner landscape that interbreeding with the new digital technologies of augmented and immersive virtual reality allow to roam as if the *flâneur* in time but in most other places and spaces through a journey of discovery and wonder characterized by the movement that generates emotion, promotes a kind of participatory emotional, sensory and cognitive experience. Recent technological contributions of interactive devices connected to clouds, and the continuous exploration and application configurations can also interact through microchips in clothes (wearable-technology) between the physical reality of the archaeological excavation site and a virtual hologramatic world within which the tourist is "immersed", allowing for the construction of a *figurative syllogism*, an active emotional link between past and future, between reflection and action between mnemonic perception and design perception of the future. The tools of augmented reality allow to connect the state of places and ruins (archaeological) to a facsimile diachronic historical reconstruction in which the possible use inside through immersive technologies facilitates the multisensory and pluri-perceptive haptic journey.

4. Best practices

A look into the future to improve the past, to foster a better understanding of civilization and the testimony of the society that once was, a "technological" reconstruction of an immaterial part of the archaeological site is not retrieved, giving an added emotional value to the historical value.

A reference model is the case history of the **CHESS Experience** as a model for future testing of a project funded by the European Commission under the Horizon 2020 program whose aim is to offer two new alternatives in the enjoyment of a museum space that merges adventure and interaction with the technology of augmented reality and the world of digital applications.

Fig.4 Some representative images of regeneration projects and design in the tourism and archaeological sector BEST PRACTICE

CHESS (Cultural Heritage Experiences Socio-personal Interactions and Storytelling) adds to the world of the museum the following functions such as adventure, emotion, interactive participation, magic, exploration by combining the two dimensions of culture and technology that apparently seem antithetical. In connection with the current digital devices applied in this international project CHESS which involves various businesses, institutions and universities systematically collaborating to can capture the innovative and original aspects that promote the use of a user visitor to an open air museum in order to include in the range of services to the tourist an opportunity to promote a more complete experience and gratification as well as intellectual and cultural growth.

The tertiary cultural productive museum sector has more benefits in terms of opportunities and economic benefits thus increasing the value of the identity of the place that is home to such performance since the tourist would remain indelibly imprinted to the charm of the “Pompeii that was” cradle of civilization and classical culture, in addition to the conviction of a territory and a community to move with the times capable of investigating and using the various technologies in innovative ways that today characterize the processes of sustainable economic development by focusing on innovation as a competitive factor. Promoting the current models of local development, such as that of Pompeii and its catchment area in the field of mass tourism and cultural heritage, momentum towards development that is based on technological means to merge culture, history and technology in a creative atmosphere in a creative enterprise in line with current economic trends that in a situation of stable and continuous economic crisis could lead to a turning point and a revival similar to the emerging countries **BRICS** that base their innovative strength and growth, based mainly on the knowledge factory .

Fig.5 Some example about interaction design environmental devices to offer the traveler new opportunities for sharing. Application and new startup for the creative project

Palenque: The Maya Pompeii.

Giada LUIISO,⁽¹⁾

⁽¹⁾ Department of Architecture and Design, Seconda Università degli Studi, Naples, Italy

E-mail giada.luiso@gmail.com

Abstract

Palenque is one of the most important places of the pre-classic period, World Heritage Site since 1987. Located in the Mexican state of Chiapas, about 130 km south of Ciudad del Carmen, it still contains architectures and sculptures dating back to the fourth-fifth century BC. The work presented reconstructs, through documentary sources for the most unpublished, the history of the city "rediscovered" at the end of the eighteenth century by Don Ramon de Ordoñez y Aguilar, historiographer of Charles III of Spain, highlighting the contribution of the architect Antonio Bernasconi, pupil of Luigi Vanvitelli, who realized maps and drawing of the site, applying modern techniques experimented in Italy, during the Vesuvian excavation works. The king involved expert archaeologists in order to realize detailed explorations and excavations, because he was convinced that this place was, in large part, the key to the origin of the peoples of the New World: the Maya Pompeii.

Keywords: Palenque, Antonio Bernasconi, Chiapas, Carlo III.

1. The story of discovery of Palenque

The ruins of Palenque are located at the foot of the eastern highlands of Chiapas, bordering to the north with the coastal plain of the state of Tabasco. The importance of this Mayan city, which prospered during the Classic period, is represented mainly by its unique architectural beauty, which is evident both in the urban distribution of buildings, and in the particular aesthetic expression of its fine stuccos, carved tombstones, sculptures and its funerary and ritual complexes.

Thanks to these historical and cultural importance, this archaeological site has aroused the interest of many explorers and travelers, who have never ceased to visit it since its discovery in the eighteenth century, leaving several reports, studies and testimonies that make the city of Palenque one of the Mayan sites with the most complete archive of documentary information.^[1]

The historical context in which it occurred the story of the Palenque archaeological discovery in the eighteenth century is part of the wider historical and cultural context of the Spanish possessions in America, during the reign of the Bourbons.

However, considering all this interest caused only by the proximity of the important archaeological site and the fortuity of the discoveries would be highly restrictive. In fact, the involvement of Charles III in organizing, soliciting and keeping under control the excavations prove the opposite. The Spanish king didn't restrict himself only to boost economic investigations in order to enhance the area of Palenque but also choosed personally the names of technicians who, in some way, would gave him professional guarantee for the success of the work. It is evident that the name of Bernasconi, bounded, as we shall see, to the one of his idol due to the magnificence of the largest of his projects in Italy (Royal Palace of Caserta) and other architectural and engineering works, can not be only a matter determined by fate but a precise choice of quality made by the sovereign.

When Charles III became King of Spain, the archaeological interest in the ancient indigenous city in ruins increased significantly, because, as King of Naples, he was an enthusiastic supporter of the excavations of Pompeii. Under his influence, there has been a significant development of the study of

the ancient indigenous Mesoamerican city and, consequently, an increase in travels and scientific exploration.^[2] In the province of Chiapas, the first official program of investigations and explorations of the ancient city of Palenque begins, under the jurisdiction of the Governorate of Guatemala. During the government of General Gálvez, in 1783 the General D. Jose de Estacheria, Governor of Nicaragua, was elevated to the rank of President of the Assembly, Governor and Captain General of Guatemala. In April of the same year he took office and ruled with great integrity until 29 December 1789, when he left for Spain where he obtained the government of the square of Pamplona and the degree of Field Marshal.^[3]

Under his administration several works of public utility were realized in New Guatemala de la Asuncion, which became the new capital, after the destruction of Santa Marta due to the earthquake in 1773. The first news about the discovery of the ruins of Palenque date back to 1746, when Father Antonio de Solis, parish priest of Tumbala, was appointed priest of the People of Santo Domingo de Palenque, where he settled with his brothers and nephews. In relation to the missionary task assigned to him, De Solis arranged to boost the indigenous economy by encouraging the agricultural exploitation of the surrounding land. Sources report that during one of the visits undertaken with the intent of identifying areas suitable to plant new crops, the Father came upon some ruins in the territory, symbolically called by the natives "*casa de pietras*".^[4] This episode was reported after few years by a grandson of the Father to his classmate: the young Ramón Ordoñez y Aguiar later became the parish priest of the royal city of Chiapa.^[5] In this role, in 1773, Ramon sent his brother José Ordoñez in exploration with two other companions, Jose Esteban Gutierrez de la Torre, Alcalde Mayor of Ciudad Real, and Nicolas de Velasco, retired knight, in order to visit the ruined buildings and gather all the useful information on what will prove to be the archaeological site of Palenque. So it was thanks to Don Ramón Ordoñez y Aguiar if the interest of the Spanish crown to the ruins of Palenque awoke. So, the 28th of November 1784, the governor of Guatemala José Estachería ordered Don Joseph Antonio Calderón, Lieutenant of the Alcalde Mayor of the city of Palenque, to represent the Spanish government in the city and realize immediately an expedition to the ruins.^[6] The result of this first exploration, lasted only three days, was related in an illustrated report with four drawings in ink and sent to the Governor Estacheria, December 15, 1784. In the text Antonio Calderon said that after walking for a long time, he came to a place called "*casas de pietras*", where he could examine eight structures and a palace, which appeared to be the building of major importance for the structure and the size.^[7]

"... y despues de haver caminado las tres leguas llegamos a el parage tenido y nombrado aqui las Casas de piedra, y me fueron mostradas unicamte. por los referidos Yndios y Ladinis ocho Casas, y inclucive un palacio qe. por la constructura y magnitud no pudo ser menos; mas formando yo un concepto, bien fundamentado, qe. aquel gran Palacio precisamte. devio estar circunvalado de muchas Casas y que ahí devió de ser la corte"

(AGI, Audiencia de Guatemala, Exp. 674, Leg. 471, ff. 7r)

The Lieutenant, although impressed by the bulk of these ruins, which were called for the first time "the Great City of Palenque", stressed the difficulty of finding information about the establishment of the city.

"... no ha havido quien me dé razón de lo q^o. esto fue, o qⁿ. haya sido el fundador, para desvanecer así muchos pensamienrtos q^o. formo al verlo todo y han formado otros mui entendidos, sin qe. puedan deslindar el monte de dificultades q^o. le ofrece a la vista con los vestigios de la gran Ciudad Palencana: Lo que puedo asegurar sor. Ylustre es q^o. la obra es suntuosisima aunque Si tosca en su fabrica y por lo tanto de gran firmeza"

(AGI, Audiencia de Guatemala, Exp.674, Leg.471, ff.9v-r)

From his analysis a distinction is noticeable between the different types of structures that make up the core of the area. He began his path in the Palace and described the buildings he came across in relation to the two nearby rivers.

Similarly for the first time he assigned a specific name to all the ruins differentiating environments and architectural elements, categorizing them as towers, houses, patios, hallways, living rooms, niches, vaults, carved doors, stone beds, etc.. He described the stucco reliefs in the palace and in other buildings and defined them as: *"...figures carved very clearly on the wall of the palace (ibid., ff.10v)."* He realized drawings with ink. Calderon, however, did not refer to the location of the reliefs styled with all their characteristics. It is assumed that they could correspond to the relief of the pilaster B of the Temple of the Sun (Figure 1), to the plate of the Temple of the Sun (figure 3) and of course to the Tower of the Palace (fig. 4): it is important to note that in this first drawing of the Tower the upper body is covered by a vault, but two years later, during the expedition of Captain Antonio del Rio, appears collapsed along with a portion of the tower.^[8]

Fig. 1

Fig. 2

Fig. 3

Fig. 4

To get an idea of the difficulties Calderon came across when he realized this expedition, just take a look at the report when he talks about the number of homes and buildings (structures) reported in the village. He enumerates 216 buildings, including 197 homes, 18 buildings and a large palace, making specific reference to the state in which they were found. This was the first valuation of the consistency of the architecture of the site and the archaeological material.^[9]

"... pues lo demuestran con probantes a mi dictamen, muchos cimientos de Casas, ollas y ladrillos qe. cabando la tierra se ven quan en todo el distrito dicho; y no solo pero pudo tener dominio aquel Señor en todo Tabasco y los Rios de Usumacinta ..."

(AGI, Audiencia de Guatemala, Exp.674 , Leg. 471, ff. 8-9v-r)

Calderon sended its report to the President Estacheria in Nueva Guatemala in 19 papers, including four drawings in ink, on December 15, 1784. As a result of this report, 43 days later, January 27, 1785 Antonio Bernasconi, architect of the Royal Works of New Guatemala de la Asuncion, was appointed of a new investigation of the ruins of Palenque.

"...renuevese pr. el arquitecto de las Rls. Obras de esta Capital Dn. Antonio Bernasconi el reconocimiento. De los vestifiod de dha Ciudad en los terminos que el prevendr  por la circunstanciada Ynstruccion qe. el efecto se la pasar ..."

(AGI, Audiencia de Guatemala, Exp.674 , Leg. 471, ff. 11-12v)

We do not know any news of the life and works of the Italian architect Antonio Bernasconi, before his arrival to the Captaincy of Guatemala, when he was nominated architect of the Royal Works in the Capital. However, the information contained in the General Archives of the Indies in Seville about his recruitment as Architect of the Royal Works of New Guatemala, permits to recreate a blurry image of his academic career. Among the other drawings made by architect Bernasconi, there are here reported the projects of the map of the Archbishopric Palace of Nueva Guatemala de la Asunci n for Don Cayetano Francos y Montoy, in the perspective drawing that turns to the east of Piazza Maggiore, dated October 13, 1784 in New Guatemala (AGI, Audiencia de Guatemala, Exp.571, Leg. 2).

Also note the drawing of the fountain of the Main Square of New Guatemala with the equestrian statue of Charles III , submitted by the President of Guatemala in Seville with card Num.487 of 14 December 1786, a month and a half after the death of the architect Bernasconi, who did not receive the sacraments due to his sudden death on the 28 October of that year. The instructions for the second official shipment of the ruins of Palenque were given to Bernasconi, and were signed by Jos  de Estacheria, President of Guatemala, in the Royal Palace of Guatemala on 29 January 1785. These directives were collected in 17 chapters and they teached Bernasconi on how to guide his expedition to this place, with the request to draw the most interesting elements, as well as inviting him to gather peculiar objects of the place in order to bring them to the capital of New Guatemala.^[10]

"Ynstruccion de los puntos y particulares a que ha de dirigir el Arquitecto de las Obras Rls. de esta Capital Dn. Antonio Bernasconi y las observaciones, reconocimientos, examenes y medidas qe. por orden del d a le prevengo pase a executar en la arruinada Ciudad poco ha descubierta en el distrito de la Provincia de Ciudad Rl. de Chiapa y a distancia de tres leguas del Pueblo de Palenque.

Capitulo 10

Son obgetos de revision.

Primero: hacer merito de todo quanto pueda influir para formar idea de la antigüedad de aquella fundacion; y de lo qe. de luz para inquirir la Nacion, o gentes a quienes devi6 su origen.
Segundo: Qual fue la industria, Comercio, o medios con qe. subsistieron sus havitantes.
Tercero: que fatalidad, moción, o tragedia causaria la destruccion de aquella Ciudad y el exterminio de sus havitantes.
Quarto: Saber la entidad y magnificencia de ella.
Quinto y ultimo: Averiguar el orden, que a su Arquitectura señalan las noticias historicas de otra facultad; esto es, propias de que Nacion y tiempo fueron las reglas con que Se dirigió, por si fuere inferible, como acaso podrá ser esta cincunta. de la extensión de las piezas de los Palacios, su altura, torres, bovedas, subterraneos, escudos, estatuas, adornos y partes en qe. estan colocados"
 (AGI, Audiencia de Guatemala, Exp.674, Leg.471, ff.13v y r).

In another communication, dated January 30, 1785, the President Estacheria invited Joseph Calderón to accompany the architect Antonio Bernasconi in his investigations. Bernasconi traveled from Guatemala to Santo Domingo of Palenque, arriving on the January 25, 1785, where he was accompanied by Fr Joseph Antonio Calderon to the ruins.

"Haviendo en consecuencia de la Orden de V S de 29 de Enero de este año, llegado el 25 de Febrero inmediato al Pueblo nombrado del Palenque en el distrito de Ciudad Real de Chiapa, pase luego en compañía de Josef Antonio Calderon theniente de aquel Partido al reconocimto. que en dicha Orden se me mando hacer de las Ruinas y fragmentos que existen a la distancia de tres leguas del referido Pueblo del Palenque"
 (AGI, Audiencia de Guatemala, Exp.673, leg.645, ff.90).

Bernasconi brought with him the document in which the President Estacheria urged Josep Antonio Calderón.^[11] It's clear that Calderon was precisely the one who organized both the expedition and the path in the archaeological zone, thanks to the experience acquired during his first trip to Palenque and mainly for having taken an official position by the Spanish Crown lasted 30-year, which allowed him to establish a direct coexistence with its inhabitants (Latinos and indigenous Lacandones Choles), the same people who helped him in both missions.^[12] The result of this second expedition is the report the architect Antonio Bernasconi handed to the President Estacheria in the City of Guatemala (June 13, 1785), which consisted only of four handwritten pages along with four projects, the same ones that were sent to Spain by the President Estacheria on the 25 August. The description of the site by Bernasconi, as well as the one of its main buildings and the architectural elements, it's quite general.^[13]

Fig. 5

We are only talking of an explanatory text complementary to the maps he draws. Through these we can have basic archaeological information, which combined with the amount of information gathered during the first expedition in the eighteenth century, allow us to enrich the knowledge we have of the site.^[14] His report begins with a floor plan of the whole that is inscribed in a circle of "seis legas y mil

varas castellanas" 1 (fig. 5). Here are three panels representing the residential buildings (table 2-fig.6), the complex of the main building with the temples of Cruz and Sol (table 4- fig.7) and the various motifs decorating them. (table 3- fig.8)^[15]

Bernasconi's report was brought to the attention of the historian Juan Bautista Muñoz, chronicler of the Indies, who instructed him to gather more information on the site, making sure that the relationship was quite explicit and detailed in order to be presented to the king of Spain, antiquarian and passionate about archeology.^[16]

**Physical consistency and “immaterial life” of an architecture.
The *Amphitheatre of Pompeii*: an exemplary case-study**

Giovanni MENNA,

Department of Architecture, University of Studies “Federico II”, Napoli, Italy
giovanni.menna@unina.it

Abstract

In historiography the recognition of certain documentary materials - which are "spurious" with respect to the conventions of disciplinary tradition - and the extension of the "life" of an architecture beyond the cycle that proceeds from its concept to its completion and its transformation are closely linked problems. If it is accepted that the history of architecture should mean to reconstruct not only this cycle, but also its *use* as a social or cultural object and its changing of its consumption over time, then it requires the inclusion of new types of documents. Exemplary in this regard, it is the case of the Amphitheater of Pompeii, one of the most significant monuments of ancient roman architecture in Campania. Although there were no changes with respect to original conformation, it has condensed itself over the centuries a multiplicity of meanings that have taken place or juxtaposed. Aim of this paper is to tell the stratification of these immaterial consistencies and their installing into the collective memory or imagination through "documents" extremely different from each other: an ancient painting; a photograph; a 19th century specification document for restoration; a newspaper chronicle of a assembly of Fascist National Party; and a document of the psychedelic counterculture of the early 70's: a musical movie.

Keywords: Archeology; History of Architecture; Pompeii; Theory and Methodology of Historiography

1. Introduction

The reconstruction of the "history" of a building requires the historian to go beyond the identification of the elements that make possible the "story" of his fulfillment just as material object.

The "life cycle" of an architecture of which the historian must take into account goes beyond that process which starts from the client's original intentions and arrives through the project at its execution, and then proceeds to the possible transformations of its distribution structure as well as its tectonic and formal arrangement. Duty of the historian is to reconstruct all the multiple uses, both tangible and intangible, of that architecture, never forgetting that *every* built architecture - and in particular those ones related to the scale of the monument or of the masterpiece - is always also a *social object*.

Architectural historians never speak only to themselves, nor only for architects, but also to those who are rather much (and especially) interested in the way in which changes over time the usage, the perception and the consumption of architectures.

In fact the various uses - manifestly declared or secretly instrumental ones- of a certain building in a particular context or in a certain cultural climate move away over time from the inherent nature and original of that architecture and the reasons for which it was built.

An analysis which stops to a mere fulfillment of those questions which legitimately arise and motivate the historian of architecture work- dating, attribution and reconstruction of the original conformation etc.. - runs the risk of turning what is perhaps only the starting point into the final purpose of the historiographical research. Ignoring or even neglecting the polysemy of contemporary or later meanings can preclude the possibility of grasping the complex relationship between the individual and collective act of men who used or just interacted with a particular architecture, relegating it to a generic "context" (almost pure "ornament" or "ritual" introduction to the historical narrative).

This conception of history seriously endangers the interpretive analysis - the reason being of the historical work - leaving too narrow margins to pass the level of a tautology, albeit professional and technically flawless. This explains, for example, the failure of all structuralisms that, never "explaining" just one architecture from a historical point of view, are therefore useless from the historiographical point of view. In the lens of the historian the focus of the past and present shape of things should not lose sight of its true object of study: the men who used them. In the history of things - and thus of complex organisms such as architectures too- the changing of relationships between objects and men is always a function of a partial reconsideration or of a radical revision of their "meaning." Each new use is a function of a new "meaning" of the object, which places it in a different way the location previously occupied by it in the social space or in the collective imagination.

The recognition of this dynamic is one of the tasks of the historian of architecture and implies (and indeed claims) an extension of the traditional corpus of documentary and iconographic sources from which he draws from the materials of their work, including both those specific to other disciplines both the products offered by new communication techniques: photographs, newspaper articles, movies. Archaeology, in this sense, is an extreme limit, since some architectures "lost" their own use, but have been "woken up" to be enjoyed in a different way from the original function, and often only in an immaterial dimension. The amphitheater of Pompeii is, in this respect, an exemplary case study.

2. A paradigm. Chronology, location and basic characters.

The Amphitheatre of Pompeii is the biggest building in Pompeii, occupying an area of about 15,600 square meters. It plays an important role in the history of ancient architecture because it is the oldest public masonry building that's known as specifically intended for gladiators games.

It should therefore be considered as the *paradigm* of a typology typically Roman, one of the most original and characteristic element of architecture and of urban space in the Roman world. This conclusion is reached thanks to the information we have available in relation to the client. An inscription informs us that who lended the transformation of the preexisting structure (realized in terrain and wood) into a permanent masonry construction, were Marcus Porcius and, above all, Caius Quinctius Valgus. They had just recently built the *theatrum tectum* in Pompeii too, which they also probably lended. In fact the Odeion shows many tectonic and structural elements similar to those used in the amphitheater.

The inscription states that the construction was carried out when the two magistrates were in their fifth and final year in their office as *duumviri quinquennali*, which fell in a "census year", and that could be in 70 BC. We can therefore say that the building dates back to the age of Sulla and is in any case much earlier than the first amphitheater built (partially) in stone in Rome in 29 BC by Statilius Taurus.

This record is not surprising. First, because the fighting gladiators shows, born in the margins of private funeral ceremonies, begin to establish themselves as public performances just in Campania, as demonstrated by some funerary paintings found in Paestum and Capua. If Neapolis, however, in the ancient Roman world played the role of undisputed capital of cultural *otia* and, in particular, theater, dance and performances for the entertainment, Capua was the most important center of the Roman gladiatorial. Secondly, Campania has been a sort of laboratory research of new types and construction techniques as demonstrated, for example, by the testing of large vaulted concrete spaces produced in Campania before becoming part of the great roman architecture in the Imperial age.

The term "amphitheater" helps to clarify the genesis of this type of building, designating it not as a "double theater" (as it is sometimes still considered), but as a "theater that runs around" the arena, and it was introduced in the official use as in the common one long after the construction of the first amphitheaters. In the same Pompeii, even in the Augustan age, they still used the original term of *spectacula*. By this term is meant the plant that surrounded the arena where the games took place, usually realized by means of embankments, natural or artificial, and equipped with temporary structures and wooden seats.

The amphitheater of Pompeii should be considered as the "petrification" of an embankment cruising around the esplanade of the arena and was located in the extreme eastern edge of the city for many reasons. In the first place, it was still an area free from buildings, suitable for large public building around which developing social and commercial activities; secondly, it was in direct connection with the escape routes from the city, in an ideal position because the large influx of foreigners would not procure traffic problems and obstacles to urban life.

The area of sedime chosen also allowed to shift to the fortified walls of the amphitheater to the south and east, with a great saving of economic resources in terms of materials and structures and execution times. Finally, there was also a very important politically motivation. Earlier, the gladiatorial games, in fact, were held in the *Foro*, an area that with the Romanization of the Samnite city was "monumentalized" and devoted to Roman official cults (and then specifically imperial) that could not be "contaminated" by recreational or "transgressive" activities such as those linked, in various ways, to the consumption of *spectacula*, inside and outside the amphitheater.

The amphitheater was built by digging up to 9 meters below street level an elliptical arena with the major axis oriented north-south. As the contiguous *Palestra Grande*, it is then inserted seamlessly into the *grid* with which most of Pompeii was rationally urbanized, already in Samnite age. Around the arena the auditorium was elevated, in the three distinct overlapping sectors of *ima*, *media* and *summa cavea* which, on the east and south slopes leans on the walls and on the north and south sides on an artificial embankment. The embankment is supported by a scarp wall and 62 buttresses realized in Monte Somma lava stone, almost an *opus reticulatum* with the edges in blocks of Sarno limestone. These buttresses were connected by round arches with projecting cornice, placed at regular intervals (except at the access to the north and west). These arches are almost all blind and, on the occasion of *spectacula*, were used by street vendors such as kiosks. A top frame indicated the presence of the parapet of an open ambulatory, about 8 meters wide and paved in concrete, which is accessed through four stairs, two flights of steps in double rampant and two in single ramp. On this elevated ambulatory there is a *tambour* with 40 small elliptical arches inside which there was the covered *vomitorium* which led into the *summa cavea*. Above it there were the *palchetti* (separated by walls) that constituted the crowning top of the implant, together with the famous linen *velarium* that protected the public from the sun, supported by wooden pillars and sliding strings. This top of the Amphitheatre is in bad state of preservation because it was not covered by the eruption of 79 AD, remained for centuries as the only outcropping part of the entire buried city of Pompeii.

The entrance to the *media* and *ima cavea* was through the *Crypta*, a vaulted concrete gallery which was accessed from the outside through four sloping vaulted corridors (one in the north and three to the west). The *Crypta* also presented at the time of the eruption some arches of reinforced brick made after the strongest earthquake in 62 AD, most likely made by Caius Pansa Cuspius who statues affixed to the inputs were dedicated to. Other artworks were present in the Amphitheatre, such as the paintings that decorated the parapet that separated the arena from the auditorium, high a little over 2 meters and bordered by a frame in the shape of a prism shelled (such as of the *Odeion's analemma*). These paintings, now unfortunately lost, were placed in panels and were about various subjects: fights between animals; gladiators and hunting scenes; simple decorations and so on. The entrance to the arena took place directly outside the square through two long tunnels placed at north and south. They had a great architectural impact and were paved with large slabs of stone, realized for the obvious purpose of introducing wagons not necessarily with gladiators or wild beasts. The Amphitheatre, in fact, was not reserved for only gladiatorial shows, hosting feasts such as religious representations of Apollo, games and ludic choreographies, pantomimes with dancers, actors and buffoons and, even, military parades. These events were much loved by the masses and were taken, organized and financed by the political *élite* to build or strengthen popular support. These events were therefore exploited as means of identification or as real political struggle, such as that one which hardly opposed within the pompeianian establishment the new rich Roman colonies to the ancient Samnite oligarchies. We should not forget, in this connection, that the politicians who possessed more economic means, invested substantial amounts not only in the shows and in the construction, renovation or modernization of amphitheatres, but also in the gladiators, many of whom were personal properties, as well as the most prestigious schools of gladiators will be imperial property. So it played an important role as a "stone showcase" where were on display political glories and personal fortunes, a formidable container in which they set up public identities and, most important, conveyed messages to the masses. For this reason, the amphitheater was perhaps the first and most powerful *mass medium* in the authentic sense of the term.

The amphitheater then played another interesting role, as "representation" of the social order. The seats for the spectators were in fact strictly differentiated (stages of honor reserved antlers, *ima*, *media* and *summa cavea*; upper *palchetti*) and assigned to the spectators according to rank. Beyond the economic and organizational reasons, this subdivision crystallized into the stone the social hierarchy, "photographing" the status quo, ie the momentary balance among the power relations that determined the positions occupied by the various components of the social body into the Pompeian society at the time when those games were held. So, going on stage not only was the show, but around it, the Pompeian society itself. It must however, at this point, account for the occurrence of a singular and paradoxical social "short circuit". The undisputed protagonist of the urban scene, and the most loved, invoked, and acclaimed public figure, even outside of the show, is the hero of the Amphitheatre: the gladiator who, like the arena itself where he was performing, was indeed: *totius orbis desiderium*. Subject to individual (and often unmentionable) desires, and at the same condenser collective impulses, the gladiator is at the top of a popularity that can give him redemption and life, and yet occupies the lowest rung at the base of the social pyramid, forced to live in slavery and in almost bestial conditions. The first one is the latest. He is really "the walking dead", the slave condemned to live and die in the general indifference or in the glory of cheer popular, as cruel as ephemeral. And the imperfect circular amphitheater ellipse ends up hiring the allegorical image of a social mobility that is only virtual, and is screwed onto itself in that circularity slavery-redemption-death, within a general folding only in the fiction of the staging arena. The amphitheater is a perfect machine for a "society of

the spectacle", still archaic and still imperfect, but in which, however, we recognize without difficulty behaviors and dynamics typical of our contemporary civilization.

3. Document I. A painting (1st century A.C.)

The painting in question is a fresco realized in the second half of the first century AD, now preserved at the National Archaeological Museum of Naples, and coming from a private home located in the *Regio I* (3.23) known as the "Casa della Rissa nell'Anfiteatro" because of the subject represented. The painting depicts, in fact, the famous brawl which broke out in 59 AD during the gladiatorial games that were held in the amphitheater, and involving young people of Pompeii and a large group of spectators from the nearby city of Nuceria Alfaterna.

The rivalry between Pompeii and Nocerian originated by specific political reasons, attributable to the deduction of Nuceria a colony, which took place only two years earlier, as a result of which a portion of the cultivated soils pertaining to Pompeii was probably transferred to Nocerian landowners. The riot - which Tacitus also refers to (*Annales XIV, 17*) - made a great impression among the public, as evidenced by the fresco itself, but also by a graffiti in the *Casa dei Dioscuri* ("O Campani, you're dead together with Nocerini in that victory"). The fight had indeed dramatic results: sparked by mutual insults and accusations, it immediately degenerated into a stone-throwing and then in a real armed clash, after which counted some deaths and dozens of serious injuries, mostly among the ranks of the spectators from Nocera. The story had an immediate echo and also outside the city of Pompeii. The bloodshed was such as to induce Nero to ask the Senate harsh and exemplary punishment to the perpetrators, the largest of which was located in the organizer of the games, Livineio Regulus, who was exiled together with those who were identified as the leaders of both armed fronts. The gladiatorial games were banned in Pompeii and it was decided to close the arena to the public for ten years, though the sentence was reduced to two, according to some involvement of Poppea, that probably had a residence in nearby Oplonti, not far Pompeii. The amphitheater, however, did not have time to be reopened to the public because, as all the buildings of Pompeii, it also suffered from the severe damage inflicted by the strong earthquake of 62 AD.

The painting is as a valuable iconographic source not just to get the information required to reconstruct the original shape of the building, but because the way in which it is represented leads to some thoughts about both the consideration that it had the community who used it, both in relation to the relationships that it established with the context. It should be noted, first, that the work was made and then presented without any monumental architectural characterization.

Despite the large size and also the objective importance that covers not only to the local community but also offering hospitality to large groups of "foreigners" from outside of the city, the amphitheater did not pose architectural accents. Masonry structures are devoid of the element of most semantic connotation of classical architecture: the architectural orders, which, however, will become a central element in the formal qualification of the great ancient amphitheatres, and also in the *scenae frons* of roman theaters, as the central element in the apparatus of signification. The amphitheater is therefore not perceived or presented as a "monument" to exhibit, but as a pure service structure, part of the urban "armor" finalized to provision for social needs. It is significant, in fact, that in perspective deformation of the image of the amphitheater designed by the anonymous artist, the higher weight is given to the great double staircase through which access to the terrace above.

Fig. 1 *Rissa nell'Anfiteatro* (second half of the first century A.D.), Naples, Museo Archeologico Nazionale

This painting shows us that the task of "express" the building in an expressive and aesthetic dimension was assigned to a functional element of the apparatus of distribution. The amphitheater is seen more such as *social object* than an architectural masterpiece. In fact, there is not the building in the abstract dimension of a "backdrop" to the representation of a bloody clash in the streets - as the architectural *scenae frons* of a show or one of the square of virtual architectures so frequent in the various "styles" of the wall painting of rich pompeian residences - but the amphitheater literally surrounded by the urban social life. The amphitheater – which is joined by another important building of great importance for the life of the community: the Palestra Grande - seems to be part of an integrated system of social spaces consisting of a real square that opens up before you with its permanent kiosks or the temporary stalls of street vendors, the rows of plane trees and the swarming of men and women that we can easily imagine animating the area, not only during the days of the *spectacula*.

Another extremely interesting aspect is given by the point of view - not only "technical" - chosen by the executor of the painting to represent the amphitheater. The amphitheater is in fact taken from above, from a virtual station to allow the viewer to see what goes in and what goes out at the same time. It is a point of view that helps us to understand the dual nature of the amphitheater. On one hand the great void, the mere container that is filled with animals and wrestlers, actors and audience, both part of the same great show. On the other hand, the spectacularization, the sublimation and the exorcism of the violence that is in the gladiatorial games, seem at some point to be no longer containable in the form of the show as in the shape of the reservoir that must contain it, and that bursts and overflows outside. The amphitheater: a big "object" planed in the heart of urban space; a strong visual reference into the urban scene; an element that can transform an area on the edge of town, the peripheral extreme eastern limit of the city, into a powerful "attractor" the other pole of collective life. As a container and a condenser in a time of meetings and clashes, in its elliptical shape that dilates and contracts, the amphitheater seem to condense, overflow and then again collect the impulses and unresolved tensions of an entire community.

4. Document II. An accounting ledger for restoration works (1829)

The eruption of 79 A.D. that buried Pompeii was not able to cover the whole amphitheater and the part above the *summa cavea* remained for centuries, uncovered among the dense vegetation that grew on the layers of stone material that accumulated in that large bowl. It was the persistence of those structures to suggest the presence of a city in that place and that's why the entire area corresponding to Pompeii before being discovered in 1748 was named *Civita*.

The basin was not filled in full and the site once occupied by the amphitheater will take on the characteristic shape of a moat which explains the name assigned to that place for a long time: the *Scodella*. Its "discovery" occurred 26 October 1748 by Rocque Joachim de Alcubierre, an engineer and colonel of the Spanish Bourbon Genius, and marked the beginning of the slow return to the life of the whole city buried: mistakenly believed the theater of the city of Stabiae was finally identified as the amphitheater of Pompeii after 1763, the city which in turn finally ceased to be a faded as suggestive literary image for finally taking on the consistency of a real presence.

The Amphitheater - considered in its sole reality of architectural object, pure physical construction, observed and studied, measurable and convertible - refers to an iconographic document dating from the early XIX century and preserved at the Historical Archives of the Archaeological Superintendence of Naples. The manuscript is dated 1829 and signed by the architect Carlo Bonucci, a few months before designated "architect director" of Pompeii. The title is: *Misura ed apprezzamento del lavoro eseguito dal partitario Giuseppe Dell'Aquila per porre in veduta gli archi fondati nella periferia esterna dell'Anfiteatro, situato nell'angolo della settentrionale della distrutta città di Pompei, rafforzare con fabbrica le lamie dei vomitori; e indi rifare una porzione dei sedili nella parte interna del medesimo sul lato sinistro dell'arena qual lavoro si valuta, ed apprezza per materiale, e magistero, nel tenor presente*.

It shows the "final accounting" of the work of the first "restoration" of the amphitheater, which began more than sixty years after its discovery in 1813 and after a year and a half stopped, to be finally resumed in 1826. Being an accounting document, it is extremely meticulous and shows in detail the interventions, even the smaller ones, made on some parts of the amphitheater. They consisted essentially in the reconstruction of entire missing parts of the building, rebuilt in the "old style", such as nine external arches, the reinforcement arches at the intrados of the vaults of the *crypta*, and even the stone seats of an entire sector of the cavea.

The aim was twofold: to secure the building by eliminating the causes of potential structural instability and, above all, restore a plausible and possibly suggestive image, able to perfectly overlap in what was considered the *ideal-type* of the "Roman Amphitheater", ie a building that would have been a bellwether of the scene that was going to be rebuilt in the unearthing Pompeii, but considered in its autonomy of the subject with no reference to the social and cultural life which acted in. In the

restoration that the document describes, there was no concern to distinguish new parts from the original ones: on the contrary, the effort was to allow the new parts in *camouflage* with existing, offending the authenticity of the archaeological evidence. For this reason this accounting document is particularly valuable because it allows to distinguish between the original parts (including the restoration's works carried out in the aftermath of the earthquake of 62) from those built in *imitation* of the ancient and often performed with original materials found in site (not infrequently from other areas of the amphitheater itself), which pose today extremely serious problems of recognition.

Despite the cold objectivity of accounting work, the paper relates a lot more than those that explicitly tells. Through it, in fact, you can grasp what emerges as the prevailing attitude in the architectural culture of the time compared to the complex issues related to the conservation of the archaeological heritage. More: it is a document that exhibits a "mentality" that goes beyond the specific disciplinary restoration and on the contrary regards to the relationship that the culture of the time, in its broadest sense, has against the past and its "tracks". A past that must be able to materialize front of our eyes through testimonials forced somehow to be "living".

The illusion of being able to *reborn* the past, not figuratively but in the true sense of the term, passes through the certainty that a ruin is *useless* if it is not able to build a reliable and as much as possible "complete" image through the transition from conservation to alteration, even to legitimize the reconstruction "in style" and the *invention*. There is no doubt that in the late eighteenth-century mentality, which survives in the early decades of XIX century, an unburied object has a real value only if it can fully grasp its *integrity*, a *conditio sine qua non* for its appreciation: without it, all the neoclassical notions considered as central in the evaluation of an object of art or architecture - style, shape, materials and techniques - lose any "value" in archeological field.

Even before its importance or its aesthetic qualities, the decision to intervene and commit financial resources for this purpose - is the case of the Amphitheatre - is a function of the integrity of the evidence, or of the possibility of reconstructing the artefact. The persistence of this conception - which also boasted influential supporters such as Winckelmann - is at the origin of the arbitrary completions and the "reconstructions style" that characterized many archaeological restorations, not only in Pompeii.

That ancient arena where gladiators clashed became the battleground in which performing the violent battle between the proponents (usually scholars antiques) of an improper conception of the restoration and those (usually architects) who tried, with great effort but without success, to offer more correct and advanced positions in a still uncertain culture of architectural restoration, still looking for a statute disciplinary science. The document that meticulously describes and even quantifies this senseless restoration reveals a flagrant paradox: right there where the object is proposed as a physical and *real* construction, finally freed from the immaterial dimension of the Memory or the Imagination, it is subjected to an intervention that, in the end, deliberately denies the same physical reality and the status of archaeological evidence itself, trying to create, on the opposite, what is considered as *the* pure "ideal" image of the "amphitheater". In the rubble and dust of the yard, at the end, the object emerges as an *idea*.

5. Document III. A photograph (1848), compared with a vintage postcard

A town without men, with empty streets, lifeless architectures, silent stones: this is what evokes the first photographs taken in Pompeii. Among these pictures, an image of the amphitheater is of particular importance because it was perhaps on the first ever to be printed. It was created as a "calotype" by Reverend George Wilson Bridges (1788-1863), anglican clergyman, writer and photographer, archenemy of the abolition of slavery. The calotype - unlike the "daguerreotype" by Louis-Jacques-Mande Daguerre - allowed to print copies from a negative and is also known as "talbotype" by the name of William T. Fox Talbot, who began to experience this procedure around 1831, patenting in 1841, just two years after the daguerreotype.

The meeting with Talbot, around 1843, incited the rev. Bridges to approach this new kind of technical reproduction of images, which put to use in a long photographic campaign. From Paris, where he had bought the camera, he went to Malta and from there, between 1846 and 1852, he traveled throughout the Mediterranean, as far as Egypt and the Holy Land, taking about hundreds of negatives (for a total of about 1,700), which were then shipped to Talbot to be printed.

It is remarkable to note that the first building began to be excavated in Pompeii was also the first to be photographed, and the way in which the amphitheater is reproduced in this photograph calls considerations of some interest. First, the arena is not represented from the outside, giving up to bring to light the relationship with the urban context that the fresco of the brawl, on the contrary, put so strongly in evidence. Throughout the nineteenth century Pompeii is not perceived, moreover, as what remains of a city at one time full of life, but it is still considered as a summation of artistic or architectural isolated incidents and not as part of an integrated system of spaces, environments and architectures.

Fig. 2: left: Reverendo George Wilson BRIDGES, *The Amphitheater at Pompeii*, 1848;
right: The Amphitheater in 1926 ca. in a vintage photo

Bridges deliberately leaves out of view every other possible architectural presence, and the Amphitheatre applies to himself, returned by the recent renovations throughout its charm. The geometry of the elliptical amphitheater, however, is almost didactically emphasized, because Bridges places the lens on the end of the major axis of the ellipse. He offers a view of a classical monument in a front position, setting up a de facto staging that privileges the balance guaranteed by a frame perfectly symmetrical. The other photograph was taken instead around 1926, for a postcard. It conveys, on the opposite, a sense of dynamism, somehow even "anti-classical", which is explained by a kind of almost romantic sensibility by which the photographer had laid the eye lens on the disinterred city. Photography still imitates, despite all, painting. It seems to be still in the age of Romanticism, and the amphitheater is in fact put in relationship with the natural space. As in a XIX century gouache, in this second picture the amphitheater's glimpse is framed by a row of pine trees that border the upper crown and open the view of the landscape, referring to other more distant pines located in a countryside still not contaminated by the wild urbanization of the next century and, finally, to the absolute ruler: the peremptory profile of volcano.

This photo does not propose the Amphitheatre as a document of social history, politics and culture, and even as an exceptional testimony to insert into a repertoire of ancient Roman architectures. This specimen of the photographic document intends to perceive the perfection of the form of an object returned in its entirety from the depths of History, but again delivered in some way to that, beautiful and violent Nature, that once buried it.

6. Document IV. A newspaper article (1928)

The fourth document proposed is an article edited in one of the most important Italian newspaper: "La Stampa" of Turin. The item does not inform of an event of particular importance, and it is indeed an editorial relegated to p. 5. This is a correspondence from Naples who reported a political rally, which was held on Sunday 9 September 1928. It is, more precisely, an "adunata" of the National Fascist Party (PNF), which channeled several thousand workers from Naples and its province to Pompeii, with a consistent organizational effort, as special trains and buses set up for the occasion. The participants were all workers enrolled of the Party organized as "dopolavoristi" in some associations who managed their leisure under the complete control of the PNF. The reason of interest for this episode with no historical relevance - except as a gash on the social life in a nation totally controlled by a fascist party in a totalitarian regime - lies in the fact that this political event took place inside the 'Pompeii Amphitheatre.

This fascist celebration came to pass in the presence of guests at the highest political level as Augusto Turati, national secretary of the PNF for a little over a year, and Commissioner Michele Castelli, perhaps the most powerful man in Naples since 1925, accompanied by other civil, political and military representatives and by a marching musical band. To act as hosts were Amedeo Maiuri, famous archaeologist and the chief executive officer of the excavations of Pompeii, and Giuseppe Spano, a scholar of the amphitheater and subsequently more comprehensive author of the study dedicated the building. The article reports almost completely the short discourse given by Turati, also highlighting the points where it was interrupted by applause, cheers and chants. It was not, in fact, an assembly, as Turati himself explained in the speech held in the amphitheater: "we do not call you, and we do not call for you to "discuss" on politics, as the politics of the Italian people cannot be that the one of a Chief who commands and knows where to go. (...) We want to meet, but not within the four walls of a hall for one stupid game of words; among the repeated hosannas of a complaisant clique. We

want to meet together right here, with your face to the sun, at the edge of this ancient city that rises inch by inch every day and replay the charm of the beauty and of the past life, for looking into our eyes each other and see if we are good and worthy, and to repeat to ourselves that we'll never go back again." They were years in which the mass rallies in the amphitheatres were frequent enough to consolidate into a very pleasing habit to the Duce. One of the most spectacular fascist rallies took place into another ancient implant, the Arena di Verona, with choreographies and scenography extolling the Cape.

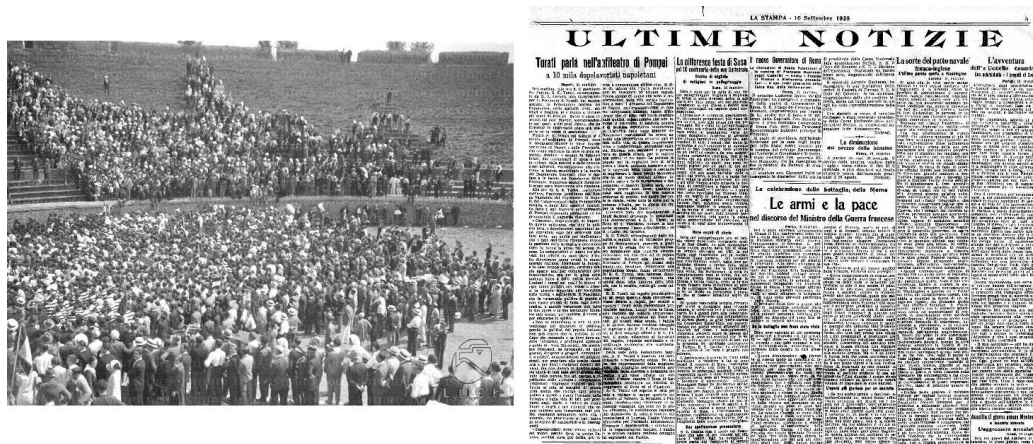

Fig. 2: "Adunata Fascista" in Pompei (09.09.1928, Istituto Luce).
On the right: the article *Turati parla nell'anfiteatro di Pompei*, "La Stampa", 10.09.1928, p.5

Sunday 2 April 1933, many of these workers will find themselves together into seven thousand, conveyed to Rome by seven special trains, rallied in the Flavian Amphitheatre and then greeted by the Duce himself. When at the end of the '30s the fascist authorities of Naples devised the great complex for the Esposizione Triennale delle Terre Italiane d'Oltremare, Mussolini asked to build a big "theater of the masses for the masses" for 20 thousand spectators, who will be significantly called "Arena Flegrea." The real "theater fascist" for littoria Italy was to be in fact - using the words of Mussolini himself - especially a "mass theater for the masses," and exacted those installations able to accommodate choral performances that were to represent, and indeed exalt "a collective consciousness that exceed the individual, overlapping the reality of the individual to that one of the crowd of which he is only a part. The mass must therefore be considered not as a sum of individual entities, but as a single indissoluble reality."

The choice of ancient amphitheatres as places of these "adunate" - despite the excellent alternatives offered by so many old and new Italian squares or by the new public buildings built by the Regime - is perfectly understandable, and maybe even obliged. The amphitheater, one of the most beautiful and best preserved architectural evidence of the greatness of the ancient world, in fact, well satisfies two specific needs. On the one hand it fits perfectly into the cult of the Roman world on which Mussolini built a large part of a cultural policy functional to the yearned new *renovatio imperii*. On the other hand it condenses specific instances of political propaganda, in years in which the new collective rituals of mass society - for more in a totalitarian regime - inevitably intersected with the "spectacularization" of politics openly researched by Mussolini as a fundamental instrument of consent.

The meaning and the role of the amphitheater of Pompeii are in this sense completely unrelated to the logic of archaeological tourism of mass that the regime itself had also encouraged, in Rome as in Pompeii. On the contrary, they are rather situated in a pantomime in which the two protagonists are the Duce and "his" people. At the time of its greatest popular support, Fascism has by now reduced the space for any political action to the mere presentation of a plebiscitary consent to a scheme that transforms the amphitheater in the ideal scenario, sumptuous and authoritative, new and old, and for this reason certainly the most appropriate for its ceremonies and its liturgies.

7. Document V. A psychedelic musical film (1971)

A completely different way of perceiving and then "using" the Amphitheatre of Pompeii is documented by a film production of the early 70's of the last century: the musical movie "Pink Floyd at Pompeii", filmed between 4th and 7th October 1971 largely in Pompeii, and in particular in the Amphitheatre, with inserts footage shot at the Solfatara of Pozzuoli, and then in Paris. The Pink Floyd, one of the most famous and influential groups in rock music history, had recently absorbed the painful exit from the group of its founder, the great visionary poet Syd Barrett, and they were a band ripe for the great international success.

Fig. 4: The PINK FLOYD, *Live at Pompeii*, 1972 (left: poster of the remastered digital edition of *Pink Floyd: Live at Pompeii: Director's Cut*, DVD Universal Music & Video, 2003; right: The Pink Floyd in the arena, october 1971)

The film marked a crucial step in this direction for the band's career because they were able to engage the remnants of the London counterculture of the Sixties in a rock music easily inserted into the logic of the profit music industry. Two years after the band recorded "The Dark Side of the Moon", the album with which they climbed the international sales charts, consecrating them as the undisputed protagonists of the world rock scene.

The encounter between the London-based group and the Cinema there had already been with the proposals for the soundtracks for the films of Barbet Schroeder; at the highest level, with Michelangelo Antonioni, who included three songs of theirs in *Zabriskie Point* (1970) and then, a few weeks before, with Stanley Kubrick who requested, unsuccessfully, their intervention for the music of *A Clockwork Orange* (1971). Creator and director of the movie in Pompeii was the Scottish filmmaker Adrian Maben, later the author of several documentaries on art history.

In the first version of the movie Maben filmed Pink Floyd playing at the center of the arena of a completely empty amphitheater, closed to the public for the occasion, with a special permission by the Archaeological Superintendence, thanks to Ugo Carputi, professor of the Faculty of Architecture in Naples, and a Pink Floyd fan. After the great mass gatherings characterized by the utopia of Woodstock but also by the violence of Altamont, where the hippy dream definitively broke, The Pink Floyd waive to autcelebrate through the exhibition of crowds of fans convened in a sort of oceanic assembly-concert. The relationship which The Pink Floyd seem rather seek with the listener-viewer aspires to be individual and personal, as the lysergic experience itself seems to suggest: a practice that begins with the others, through the ritual of taking collective psychotropic substances, but then proceeds as a journey - a *trip* - in the individual's mind, through stages of altered consciousness.

So The Pink Floyd could have placed the camera "everywhere", relying on the visionary power of their lyrics and sounds, or unleashing a blaze of psychedelic abstract figurations. Instead, they choose to represent themselves in an ancient amphitheater, with no special effects and no spectators. The Arena is enough in itself. This choice cannot be explained only with the objective influences exerted by the beauty of the architecture, since it expresses rather a parallel, if not a "cosmic connection", between the monument and the music of The Pink Floyd. The Amphitheatre, by virtue of its completeness of archaeological evidence belonging to a past world and yet still perfectly "working", seems to present itself in the double condition of the subject of *another time*, and yet belonging to *each time*. It is at once real thing and a mental thing, an object of scholarly study and "machine" powerfully attractive inserted in the circuits of mass tourism. Suspended among exotic imaginary, seduction of ruins, evocation of life and death, crowds and absence, the amphitheater evokes the poetics of an "elsewhere" as never far from the reality of the metropolis, but paradoxically constructed through the codes of urban culture contemporary art.

So also is the music of Pink Floyd: a *medium* between the abstract dimension, alienating, cerebral of the psychedelic universe that refuses a real or permanent placement in space or time, and that of mass civilization to which it belongs. It's not the sophisticated expression of a niche culture, but it's now an industrial product, designed, manufactured, promoted and distributed as an object of popular consumer products. The Amphitheatre emerges here as a "text", independent once again, both from its original nature of building mass spectacles, either from the current tourist attraction, a symbol of Pompeii in a few decades become one of the most attractive tourist destinations in the world. The building born to accommodate crowds for performances, thanks to the charm of its history and its shape shows itself with no crowd, becoming itself "the show."

The same ellipse of the arena, stylized in a series of concentric ovals, appears overlaid on one of the movie posters, as a logo which enters in dialectics with the colors and patterns like the psychedelic light show. At the center of the oval is a freeze-frame shot of Roger Waters ready to shoot a gong – archaic musical instrument par excellence and not by chance also used to promote in ancient civilizations the evolutionary processes of personality - which gives a symbolic start to the visual and musical in which the viewer is going to be swallowed. It is a journey into the depths of History and, at the same time, into the contemporaneity, as shown in the sequence plan that takes musicians between ancient stones carved by inscriptions or graffiti and gigantic amplifiers on which there is the inscription "Pink Floyd, London".

That trip had been opened with the beautiful slow sequence that framed the amphitheater from the arena to glide slowly and zoom on the musicians in action at the center of the arena, some of which, like ancient gladiators, are shirtless. It closes an hour later, with the same opening track (*Echoes*) and reverse sequence, with the last frame that returns the glam of an amphitheater offering the viewer (as well as the historian) a precious *Saucerful of Secrets*: a stoned enigma full of history and stories, enclosed into the geometric perfection of an arcane and modern Beauty.

Ordinary and emergency: a possible new order through productive poles. The case of Piana del Sarno.

Francesco COSTANZO¹

⁽¹⁾ Dipartimento di Architettura e Disegno Industriale, Seconda Università di Napoli, Aversa (CE)
francescocostanzo@gmx.net

Abstract

Which role can productive settlements' planning have in an exodus strategy?

And, inverting the terms of the discourse, can mobility system of escaping contribute to productive clusters renewal (and, through them, of the whole territory)?

In a reflection about an active sense of natural patterns, which capacity they have for structuring a new urban order?

We apply these questions to the complexity of Piana del Sarno, a huge area crossed by the Sarno river, composed by several middle size urban nucleos with different cultural potentialities (as Pompei archeological area), with a strong historical capacity to use agricultural quality and, above all, characterized by partially being in the "red zone" (the emergency area potentially invested by Vesuvium eruption effects).

So we want to describe a recent research project (PRIN 09) that defines shape and sense of productive condensations in the Piana del Sarno in a general thinking that intersects theme of exodus and the possibility of a urban order fixed by natural elements.

Today, old industrial areas (named PIP, ASI) are completely stopped in their evolution for many reasons (inadequate infrastructures, not organic structure, too expensive purchase and management costs). Our project goal is fixing few criteria that permit to develop new role of production and so defining new geographic poles. One of these criteria concerns the double quality of new infrastructure: productive framework in ordinary use, mobility escaping system in emergency phase.

These criteria could guarantee a renewal order's stability.

Keywords: urban order – production – emergency – infrastructures/framework

1. General Framework

This research has two distant issues as nucleus: production *clusters* and evacuation directions to use in case of seismic and volcano event. Both the issues are considered by the same point of view and it is about infrastructures in a possible re-thinking of urban and territorial structure of Sarno Valley study area.

Improvement of urban assets in productive existing areas – as occasion for polarization of existing industry, settled in fragmented way and grown in relatively recent history – and the on-going rethinking of Red Zone exodus directions general framework (in which a part of study area is located), are two questions this research wants to make in contact with the aim to show feasible solutions on the basis of shared infrastructural need.

Indeed, on one hand, the current stasis condition in which PIP areas lie, despite re-modulation made by STU - Areas seen as an unconvincing alternative to diffuse and unstructured realities, internal or adjacent to urban centres - highlights the need for rationalization and refurbishment following advanced criteria, but also the need for a strengthening of their polar role within the territorial

framework. This rethinking should allow PIP areas to be urban and geographical large-scale benchmarks solving the issues of infrastructure links, the variability over time of industrial spatial requirements, energy autonomy of productive sector, the need to revisit the issue of centralized-integrated services (equipment) related to logistics, first trading, processing and the review of public green's role provided by urban standards for D areas (L. 765/67).

On the other hand, if we think that actual evacuation plan (prepared by the Department of Civil Protection) must deal with infrastructural inadequacy with respect to the ordinary and emergency load, it is necessary to increase internal local connections along escape lines in connection with fast viability, as indeed pointed out by the Extraordinary Plan of Operations 2003 (PSO).

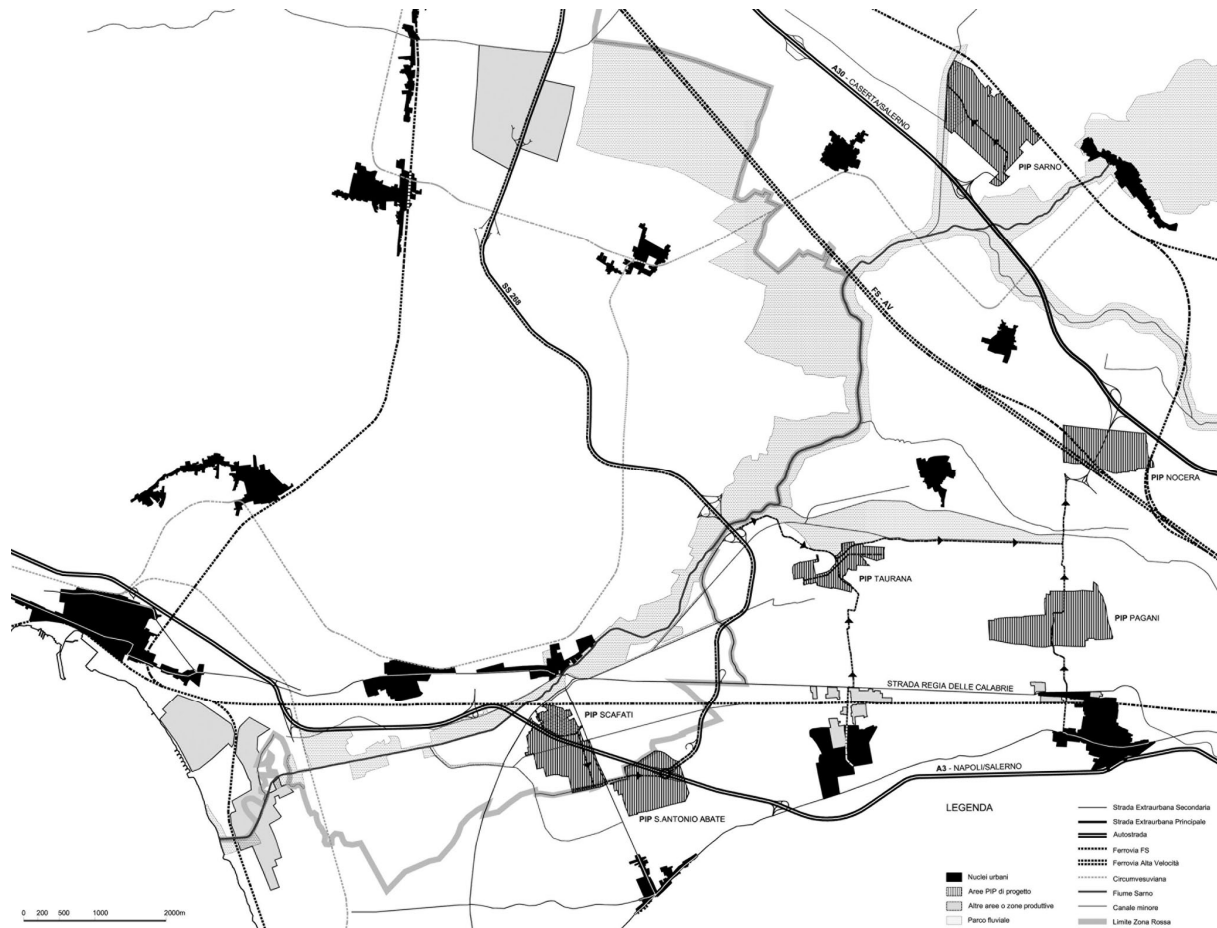

Fig. 1: Plan of Piana del Sarno – historical nuclei, productive areas, exodus directions.

1.1 Objectives - Purposes

The purpose of the research is to verify if rationalization of productive areas - through few feasible interventions - can be oriented to punctual redefinition of a structure that can be considered as an opportunity to build a new exodus frame. The locational criterion for PIP areas that regards proximity to the motorway junctions (which coincide with the "gates" of evacuation plan - manned places-filters regulating exiting evacuation flows) means that these areas are critical in the design of exodus.

In addition, it is evident that the rethinking about infrastructures in PIP areas, corresponding to a partial redefinition of urban structure of these areas, introduces the question of the revision of industrial buildings through a reflection concerning with urban morphology and aggregation of artefacts, but also the artefacts' architectural features. The natural features of Sarno Valley, in this reasoning, large scale elements as Sarno River have a central role, its system of canals, natural areas defined by flooding bands as well as the draft for River Park.

Finally, the indirect objective of this research is also to support the condensation of production in industrial areas - recognizing the value of intents proposed by Law 865 of 1971 which established implementation plans for production sites - to relocate industries actually present in urban centers, to promote the necessary separation of transport flows and the reduction of building density in the same centers.

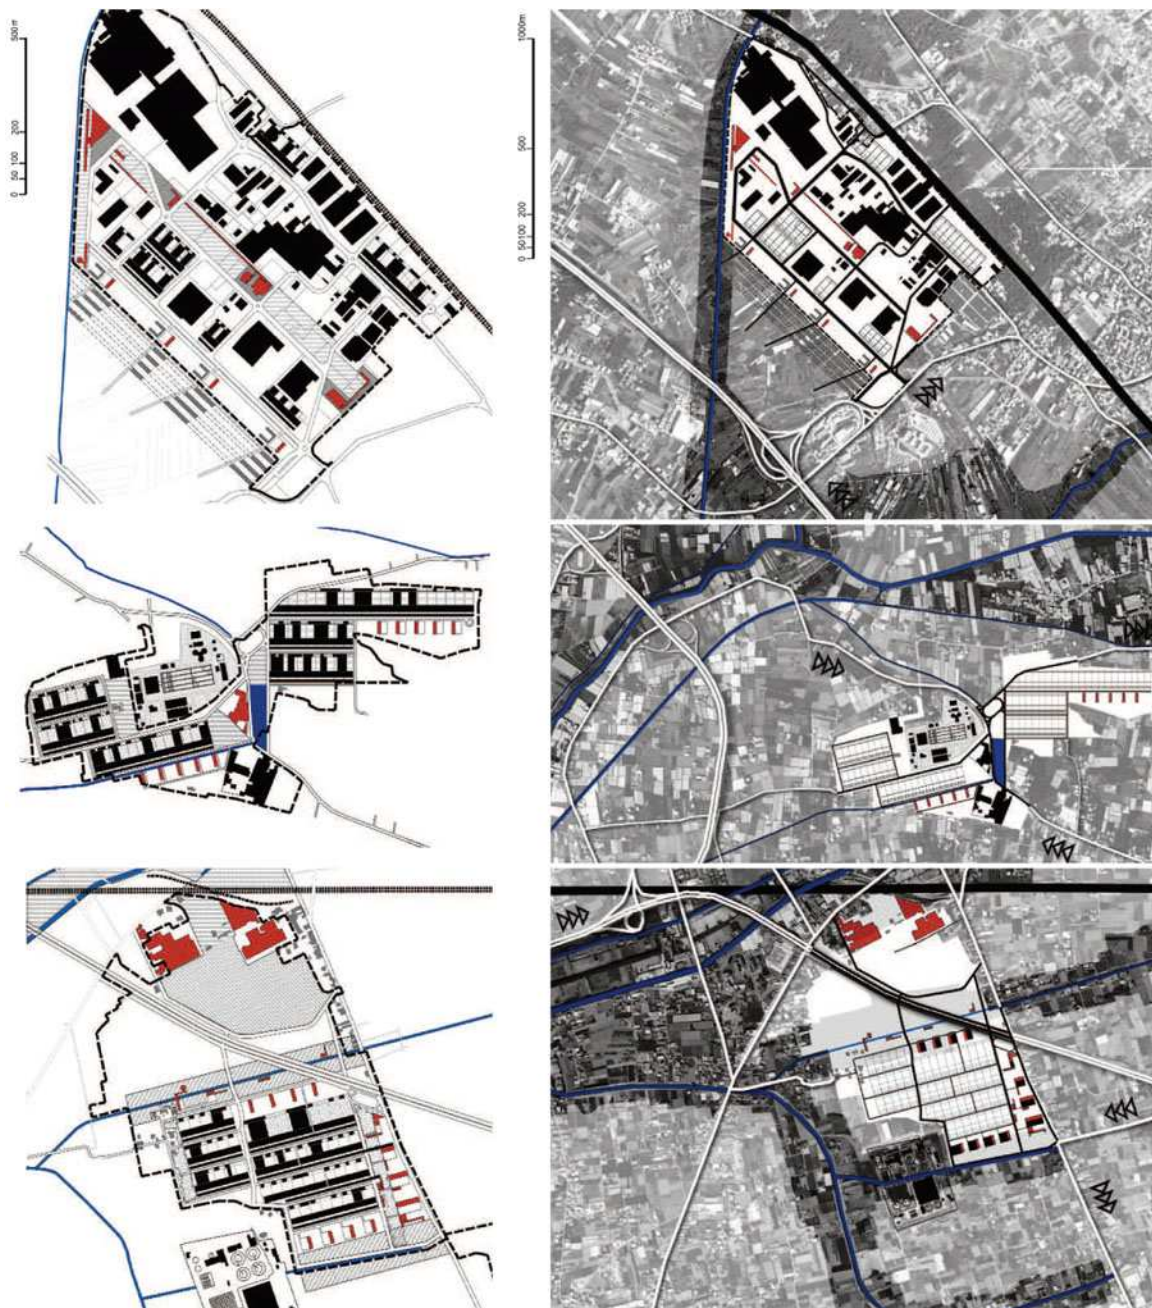

Fig. 2: PIP areas, projects: Sarno, Taurana, Scafati

1.2 The theme of exodus

The concept for exodus plan is exposed by the Strategic Plan that sets some interesting ideas for this research. In fact, the current P.S.O. highlights the need for a strengthening of infrastructural system to make the exodus more efficient in various stages of alert. The Strategic Framework (par. A1.a, Art. 3) describes some possible actions for the adaptation of escape routes net through the rationalization of infrastructural system.

In addition to intermodality criteria (relationship between several transport systems through interchanges) and multimodality (variety of transport systems), among the possible actions we highlight the actions promoting hierarchy and functional specialization of infrastructures and those actions that aim to organize the urban transport of goods "focused on regional interports and local logistics platforms focused for the collection and distribution of goods." In addition to these opportunities, some principles seem attractive – underlined in PSO Norme Quadro (Article 12) - such as the "redundancy in connections serving municipalities in the Red Zone" and the adaption of existing network "to different load conditions in ordinary and emergency situations (...) useful for both scenarios."

The general motive of the project is the need to redefine the urban structure of existing PIP areas starting from a new (or redefined) road in axial position with appropriate size to serve as a large

specialist infrastructure with secondary branches. In emergency regime this road becomes a fundamental element for the civil traffic in exodus direction. As shown in study cases described below, position and arrangement of this infrastructure is derived from traffic flows analysis and from the possibility of duplication of some existing axes with lower transport load capacity (as in the case of PIP Scafati).

In the hypothesis of restructuring productive areas as autonomous polarities (from the point of view of energy, logistics, services, through the establishment or strengthening of collective spaces and equipment), equipment-services system - already provided by the minimum standards allocate for this purpose - qualifies the entire production area as a polarity for the whole territory. We think this system can respond to the small farms' need to rely on consortia for products processing or logistics (see ISTAT data of these years related to agricultural enterprises, which shows a constant tendency to reduction of enterprise scale and the parallel proliferation of family farms).

The PIP areas rethinking is an opportunity to polarize the presence of productive artefacts, that actually are diffused and often inserted in urban fabric, to promote, in this way, their relocation reducing congestion in dense urban areas, lightening ordinary traffic and separating productive transport flows from ordinary ones. This orientation, which is one of the general and widespread positions in contemporary urban research, works in the direction of concentrating occupied lots to conserve soil and bring it to a "negative balance". We highlight the cases of Nocera and Angri where production areas are internal to urban fabric and there are congestion phenomena for the road Strada delle Calabrie.

Fig. 3: Project of productive architectures, plans

2. Applications

The applications concern three PIP areas interested by on-going new drafts for the modification of original projects (according to L. 865/71). These sites are located in geographical area near to Sarno River, to the River Park and considered in this PDR as potential benchmarks of an integrative infrastructural frame connected to the great main roads. These areas are: P.I.P. Scafati, P.I.P. Taurana, P.I.P. Sarno.

In the considered areas, in the last ten years PIP plans have been revised by Urban Transformation Company Agroinvest prepared by (STU are established by Legislative Decree no. 267/2000 as mixed subjects with the aim of implementing urban transformations). These re-modulation projects are approved (eg, PIP Sarno) or in the approval process (PIP Scafati). The lots reshaping - both industrial and artisanal ones - stems from the need of reducing lots' surfaces responding to the general reduction of the corporate's size happened during the last two decades (see Istat data on firm size).

The average lot - compared with the original provisions which included an area of 2000 sqm - is contracted to a surface of 1000 sqm. These projects do not alter, if not exceptionally, the system of

roads (often already realized). For this self-limitation, that do not discuss the roads structure, we can say that reconfigurations have a mere division logic. It establishes that areas geometrically defined by road network are "mechanically" divided in surfaces responding to the market's needs. In conclusion, in revisions there are no principles of hierarchy, structure, localization strategy for equipment.

2.1 The project of productive clusters

The project's guidelines lie in the roads hierarchy, in the definition of a more relevant role for nature, in the contribution of service central architectures defining the identity of industrial areas, in the redefinition of a productive type-building more congruent to changing needs and in the relocation of existing residential volumes. The projects include a structuring role for water systems and green areas - intended as places for service collective infrastructures or as energy infrastructures -.

Project involves different degrees of implementation, according to a progression considering logistical difficulties associated with the relocation of existing industrial buildings and, where applicable, the definition of a new internal roads system for industrial area.

The progression involves:

a *first degree* in which we define open spaces and we configure some new roads, a *second degree* involving the moving of some small and medium existing industrial activities and roads consolidation, *third degree* in which existing activities contained in large industrial buildings to be demolished or converted according to different uses are transferred and the final definition of roads network, of green areas and of eventual new water canals.

In function of the characteristics of the different areas, the construction of equipment may be provided in each of the three degrees of development.

Each project builds the new structure for PIP from a spine road (longitudinal or transversal) ordering the urban system. Equipment architectures are generally located on this road. It assumes a dual role:

- organizational and hierarchizing when it is considered as specialist infrastructure, or during ordinary working;
- as an integrative way for exodus during emergency in cases of earthquakes or volcanic and idrogeological risk.

The derivation canals of Sarno River and flooding areas are natural elements assumed as regulatory traces for urban system. Canals and lamination basins to be constructed to prevent flooding phenomena are an opportunity for energy production.

Identification of the Modal Properties of a Medieval Tower Next to a Landslide

Dora FOTI¹

⁽¹⁾ Department of Civil Engineering and Architecture, Polytechnic of Bari, Bari, Italy
E-mail dora.foti@poliba.it

Abstract

In this paper dynamic identification techniques for a non-destructive evaluation of the dynamical characteristics of cultural value buildings are applied to the medieval Normand tower of Craco (Matera, Italy) that is built next to a landslide area. As a consequence the little medieval town was abandoned starting from 1968 when the effects of the landslide on the buildings were more pronounced. The tower is one of the few building still standing as it is built on a fixed stiff ground. More in detail, the paper presents the in-situ tests results and the preliminary finite element model of the tower.

The tower was built in the XI century for defense against enemy attacks. It has a symmetric square plan, with dimensions 11 m x 11 m, and it is 20 m tall. Inside a cistern in reinforced concrete was placed in 1949. It has no interaction with the structure of the tower; nevertheless it makes more difficult to install the sensors of the testing set-up.

The results of the experimental tests have been analyzed to estimate the modal parameters through Operational Modal Analysis. The results will give indications about the health status of the tower in order to assess its effective risk of collapse and prevent the structure from the damage due to dynamic forces and the close landslide movements.

Keywords: Masonry Tower, Structural identification, Forced Vibrations, Operational Modal Analysis.

1. Introduction

The neglect status suffered by many minor historic centers in Italy and abroad, whether they are the result of a translation of the settlements as a result of a disaster, whether they have been evacuated to a different motivation, is an opportunity to reflect on the meaning and reasons of the restoration of the forgotten villages. Their slow and gradual disappearance requires urgent conservation and proposals to assign a new role and meaning, without excluding a-priori a possible conversion into places of contemplation and sedimentation of collective memory.

Studying ancient villages means increasing the interest and promote the operational skills related to the preservation of historic buildings, the typological, formal and constructive values, which are the signs of identity of an urban organism with its unique value, so as to safeguard its transmission to future generations.

The preservation of architectural heritage becomes of fundamental importance especially in presence of dynamic phenomena and forces acting on the buildings. In these cases it is important to assume a correct dynamic assessment and design of rehabilitation techniques and risk mitigation interventions [1,2]. The dynamic identification techniques allow a non-destructive evaluation, which is very important in the case of architectural heritage.

In this paper, the study is focused on the medieval Normand tower of Craco (Matera, Italy) that is built next to a landslide area. This is the reason why the little medieval town was abandoned starting from 1968 when the effects of the landslide on the buildings were more pronounced. The tower is one of the few building still standing as it is built on a stiffer and more stable ground.

The paper presents the in-situ tests results to compare with the preliminary finite element model of the tower.

More in detail the test campaign was conducted on the tower with the aim of a direct monitoring of the environmental vibrations. The results have been analyzed and compared with the data obtained from the visual inspection and the preliminary numerical model of the tower [3]. The acceleration data obtained during the tests will be, in fact, used for the Operational Modal Analysis (OMA), which allows knowing the modal parameters of a structure by mean of non-destructive tests, because, like in our case, the structure has a cultural-historical value. This technique is particularly suitable for slender structures such as towers [4,5] because, as explained in the Italian guidelines [6], if they are subjected to vibrations even of low intensity, generally produce very clear signals. Sometimes, on the contrary, difficulties arise due to the geometry of old masonry towers and buildings, which often are not accessible to the upper levels [7,8]. On the contrary the monitoring of these levels is preferable as the response vibrations are clearer and stronger [9,10]. The behavior of masonry buildings and towers is also highly influenced if they are connected to other buildings or are built in aggregates [11,12].

The actual boundary conditions of the tower and the mechanical properties of masonry could be defined through the dynamic identification based on the recordings of a experimental samplings in-situ, which include the use of only ambient vibrations. This represents, through input of an environmental nature, a solution to evaluate the characteristics of the materials and the constraint conditions of the structure, in order to define reliable numerical models, through updating procedures, and to validate the vibration modes, the natural frequencies and the damping ratio on real data. In this way it is possible to define suitable intervention solutions for structural repair and strengthening [13]. With this aim, in parallel to the dynamic identification, a 3D finite element model for a linear simplified analysis is implemented and developed.

In this work experimental data obtained from environmental vibration and recorded during the in-situ tests are shown and discussed: the test set-up is described in detail and the first results of the experimental campaign are reported together with the first considerations and comments relatively to the state of conservation of the structure. Also the results obtained in-situ are compared with the results obtained from the preliminary FE model of the tower.

2. Historical information on Craco

Craco is just one of many centers abandoned in Italy for danger of landslides, which are likely to be physically deleted because of the progressive deterioration, inevitable consequence of the absence of daily use and a constant action of maintenance. But it is the state of disrepair of Craco that, paradoxically, has attracted the attention of scholars and visitors; they have been attracted by the unquestionable charm exercised by the ruins of a village made of poor constructions, but firmly tied to the extraordinary natural landscape of the region (Figs. 1, 2).

a)

b)

Fig. 1: a) South-West view of Craco; b) East-North top view of Craco.

Fig. 2: Top view of Craco.

The history of Craco is documented only from fragmentary and insufficient sources. The settlement is mentioned for the first time in a document dated 1060, where *Cracum* appears among the possessions of the Bishop Arnaldo Tricarico whose diocese counted, between the XI and XII century, thirty Universitas (municipalities). The first feudal lord, Eriberto of Craco, is mentioned in a document drawn up between 1154 and 1168, while Roberto Pietrapertosa is the name of a royal executioner who holds Craco between 1176 and 1179. Another document records that in the XII century Craco, along with Cagnano, was among the fiefdoms of the principality of Taranto.

A century later, in 1239, Godfrey, lord of Craco, appears in the list of the barons to which Federico II had given the job of guarding some Lombard prisoners. It is likely, therefore, that the first nucleus of what local historians call the "castle", presumably encompassing or coincident with the tower, perhaps with confinement cell, was the seat of the feudal lord.

From an architectural and engineering points of view re-tracing the historical events of the urban organism and the individual buildings (including the typological structure), recognizing the materials, analyzing the techniques of historic buildings, studying the characteristics of the built, assessing the state of preservation, is to understand the current state of ruin, which does not mean fatalistically accept the status quo, but to evaluate the possibility of developing a project for the preservation and enhancement of the entire built heritage, differentiating the degrees and impact of individual interventions.

The state of degradation of the medieval village can offer a starting point for an overall project, unitary and coherent, that readmitting the urban organism in the circuit of the use, in line with the municipal strategies oriented to the recovery of their ancient heritage building, it respects the character enhancing the functional vocations. The idea starts from the conviction that it is possible, for one side, to exploit the criticalities of Craco and turn them into strengths, and, on the other side, to exploit the other local resources.

The study of Craco is aimed at safeguarding and revitalization, which provides, in the first instance, a monitoring program of the buildings of the historic center to increase the knowledge of those that need restoration, enlarging the limits of direct observation that, on the other hand, remains an indispensable step of investigation.

3. The survey aimed at restoring

The planned survey, conducted with the utmost caution, has been preceded by a careful analysis that, starting from a scrupulous relief (this is understood as one of the tools of historical knowledge and then restoration), gave information on the geometry, materials, equipment, construction techniques, recording anomalies and irregularities useful to the overall understanding of the building.

But the study takes advantage of the survey intended also as a means equally effective for the analysis and evaluation of the cracking pattern, which can be extended over time in the form of monitoring, i.e. constant monitoring of the evolution of the phenomenon of degradation, such as to facilitate the reading and interpretation of landslides.

Knowledge, therefore, is a prerequisite both for the purpose of a reliable assessment of the current security, both for the choice of an effective and at the same time respectful restoration.

The knowledge of the materials and construction techniques is certainly useful to discern the weak points of the structure in order to properly consolidate both what has now become dilapidated and what has been heavily tampered. The purpose of consolidation is to return the building the static-structural requirements lost over time, taking into account the ethical limitations imposed by the historical and aesthetic implications which, in achieving a newfound technical efficiency of the building, are placed to guarantee the preservation of a symbol of the collective memory.

4. The Normand tower of Craco

The Normand tower is located in the highest and more stable part of the hill where the old town was built (Fig. 3). It is the tangible evidence of the first settlement developed at first along the ridge path, the current Via Alfieri, up to palace Carbone, and then progresses down the South-West slope favoring the level curves.

The tower is the first defensive building carried out in Craco for strategic control of the territory. The documents so far traced do not say anything about the exact date of foundation that, based on what previously mentioned, is attributable to the first half of the XII century. Nor do we know if the tower was originally isolated, or if it was equipped with secondary service constructions, not communicating with the tower, placed in adherence to the portion of the first level, and was built, at least initially, for purely military needs. It is also unknown if it pursued the dual function of residence and administrative center of the feudal lord as well as city fortress of the lord from which to impose the payment necessary to guarantee the safety of the small cultivated lands.

The tower has a symmetric square plan, with dimensions 11 m x 11 m x 20 m (height). Actually, the part that stands free from small buildings at contact on two parallel sides is about 17 m tall.

Inside a cistern in reinforced concrete was placed in 1949 (Fig 3b). It has no interaction with the structure of the tower; nevertheless it is an obstacle for installing the sensors of the testing set-up. Moreover it should be evidenced that to install the cistern a barrel vault inside the tower was removed, probably producing the failure in the upper part of the wall, only visible from inside (Fig. 4).

5. Experimental study

The experimental study consisted in ambient vibration tests and recordings of acceleration time-histories in specific points of the tower. For the tests 16 piezoelectric accelerometers with a sensitivity of about 1000 mV/g have been utilized. The results of the experimental tests will be analyzed to estimate the modal parameters through Operational Modal Analysis [14,15,16,17]. The results will give indications about the health status of the tower in order to assess its effective risk of collapse and prevent the structure from the damage as effect of dynamic forces mostly due to the close landslide.

Fig. 3: a) East-West view of the Normand tower; b) inside view of the tower and the r.c. cistern.

Fig. 4: Inside view of the Normand tower with the cracks on the wall down the vault.

5.1 Test set-up and data acquisition system

The geometrical survey and the visual inspection have been followed by the monitoring phase. The monitoring system consists of several elements properly connected:

- 1) acquisitions units, or piezoelectric accelerometers of PCB National Instruments, each one with a sensitivity of about 1000 mV/g. Appropriate rectangular blocks were designed and realized in order to ensure the perfect orthogonality of the accelerometers in each point of application, directly applied to the masonry: the accelerometers were inserted with screws on the threads realized on the perpendicular faces of the blocks (Fig. 5a),
- 2) data acquisition system or DAQs positioned at the levels to be monitored. The control units consist in acquisitions modules of the National Instrument, each one is divided into 3 channels; for each DAQ two modules were used, so overall there are 6 channels (Fig. 5b),
- 3) co-axial cables with low impedance and with a length variable from 4.0 m to 15.0 m;
- 4) a laptop where an Acquisition software of NI is installed.

The management of the data acquisition and archiving is done through a software developed in a Lab view ambient [18]. The program automatically converts electric units to engineering units, and stores the signals acquired on the Hard Disk.

The signals post-processing system, an FFT Properties-Signal Analyzer [19], has been chosen in order to obtain characteristics of precision during the signals acquisition.

The piezoelectric accelerometers have been installed on two levels, the only ones accessible from a narrow staircase (Fig. 6a). The difficulty to install more accelerometers at other levels was principally due to the presence of the r.c. cistern inside the tower, as previously described. Fig. 6b shows the plan view at a quote of 10.5 m and the position of the accelerometers; it is possible to notice the presence of the cistern inside the tower, very close to the structural walls. Fig. 6c shows the position of the accelerometers on the terrace at the second level of the tower to be monitored.

Fig. 5: a) example of piezoelectric accelerometers, PCB National Instruments; b) acquisition modules (DAQ).

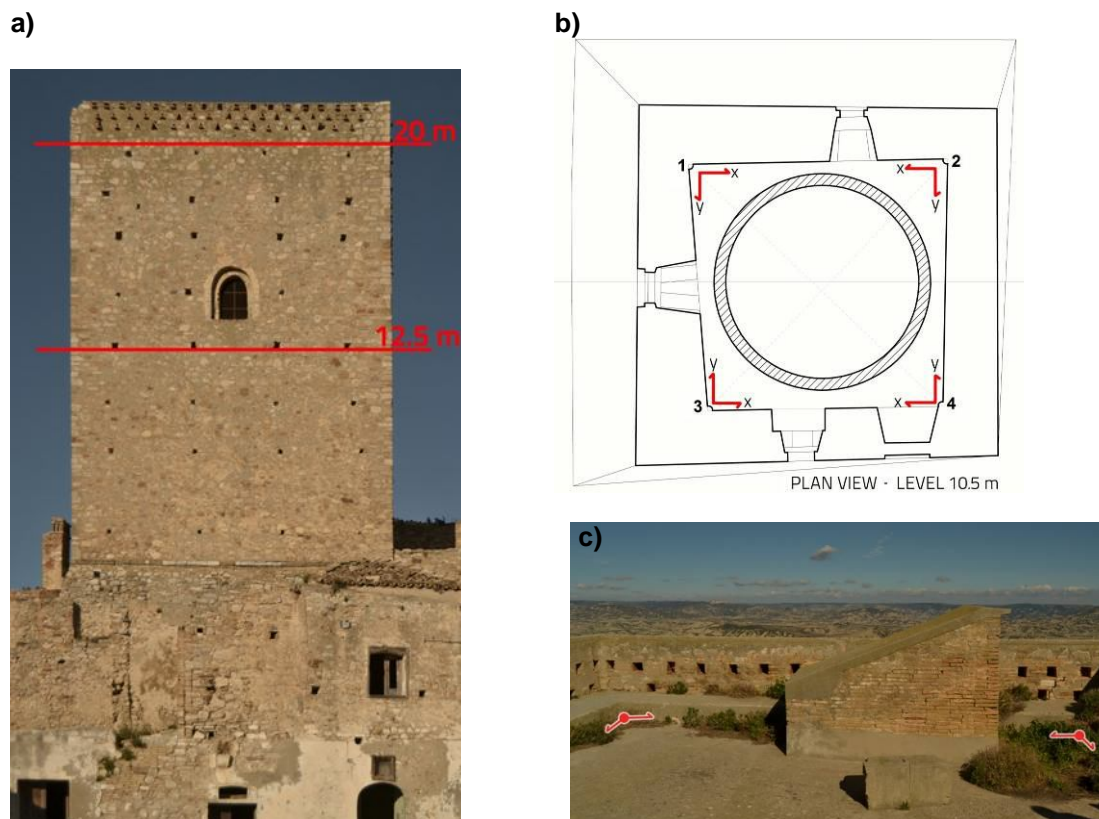

Fig. 6: a) positioning of the accelerometers (in red); b) plan positioning of the accelerometers (in red); c) positioning of two accelerometers at the second level (quote 20.0 m).

5.2 Tests Results

The accelerations have been recorded in 8 different points at two levels, at quote 12.5 m and at quote 20.0 m from the base. In Fig. 7 the time-history of the acceleration at the first level, in correspondence of accelerometer n. 3 is plotted.

Fig. 7: Accelerometer 3 in x direction at quote 12.5 m.

The acquired time-histories of the accelerations at the eight sensors will be utilized to identify the real frequencies, mode shapes and damping factors of the tower. They will be compared with the numerical results obtained on the preliminary model (see par. ...) in order to update it. The updated model will be utilized to study a reliable retrofitting of the structure, also considering the effects of a close landslide.

6. Preliminary numerical 3D finite element model

The data obtained from the archival study, the geometrical survey and the visual inspection have been utilized to develop a preliminary three-dimensional finite element (FE) model. In this way it has been possible to obtain the dynamic characteristics of the tower to be compared with those obtained from the test campaign.

6.1 Description

The numerical finite element model of the tower has been made with Straus7 software for finite element model analysis [20]. The tower has been modeled with 3-node plate elements with a uniform mass distribution along the height of the structure. The cistern has been considered in the model because it stands in contact with the tower's walls, even if there are some simplifications. Fig.8a shows the final model of the tower and the cistern inside, consisting of 50 vertices, 3170 nodes and 5909 plate elements. The base has been considered totally fixed.

The different constraint conditions that characterize the structure on the NW and SE sides in contact with other small structures, have been considered as local elastic springs.

The mechanical properties of the masonry utilized for the preliminary FEM analysis are the elastic modulus (E) equal to 800 MPa, the Poisson's modulus (ν) equal to 0.2 and the material density equal to 1800 Kg/m³. It was assumed a linear elastic mechanical behavior during the calibration. The value of the stiffness of the springs (K) has been assumed equal to 900 N/mm. These values have to be updated following an iterative approach until a satisfactory level of agreement is obtained between the numerical and experimental frequencies. In this particular case the iterative process will be carried out varying the Young's modulus (E) of the masonry and the value K of the springs.

These values will be updated in a future analysis. As a consequence, the finite element model of the tower shown here is only preliminary and cannot be completely defined as the aforementioned uncertain parameters may not be chosen.

6.2 Results of the numerical analysis

The preliminary results obtained from the analysis with Straus7 software are shown in Tab. 2, which collects the first five frequencies obtained from the preliminary FE model. The correlated mode shapes of vibration are shown in Fig. 8.

The first mode corresponds to a bending mode in E-W direction, the second to a bending mode in N-S direction and the third mode is a torsional one; the fourth and fifth modes are bending modes of a level higher than the first two.

It is expected that the first two frequencies, the bending modes, should be very close having the structure an almost square plan. But even if the tower has a first natural frequency in the same range of any other similar case presented in the scientific literature [4-5], the presence of the small one-floor one-room structures in contact with the lower part of the tower on two parallel walls made the 2nd frequency quite different from the 1st one. This is explained by a higher stiffness in one direction due to the presence of the constraints.

Tab. 2 shows the first five frequencies obtained during the experimental acquisition tests.

After the acceleration recordings the characteristics utilized in the preliminary numerical model will be updated following an iterative approach until a satisfactory level of agreement will be obtained between the numerical and experimental frequencies. It will be then possible to perform a stress analysis and determine the most stressed part in the tower where it will be necessary to design a structural reinforcement.

Tab. 2: The preliminary frequency values of the F.E.M

Mode	Frequency (Hz)	Frequency (rad/s)
1	3.35696	21.09
2	4.41093	27.71
3	7.03589	44.21
4	7.75742	48.74
5	10.71	67.26

Fig. 8: a) Finite Element model; b) c) d) e) f) Modal shapes of vibrations of the Finite element model.

7. Conclusions

The present paper shows the first results obtained during in-situ investigation on the Normand tower of Craco, which, indirectly, is subjected to the movements of the close landslide. Geometrical survey, visual inspections and environmental accelerations recordings are the techniques utilized to determine the characteristics of the structural masonry walls and the modal parameters of the tower (frequencies). In parallel a numerical analysis has been conducted on a preliminary model of the tower with the aim of updating the in-situ recordings by mean of OMA techniques and define a reliable model for next study of the stress distribution in the structure.

Heritage discretize: the Regional Park of Matese.

Luigi CORNIELLO

Department of Architecture and Industrial Design Luigi Vanvitelli, Seconda Università degli Studi di Napoli, Aversa, Italy
luigi.corniello@unina2.it

Abstract

The protection of the heritage of the Park of Matese, associated with innovative technologies through which you can observe, document and preserve the relationship between nature and architecture are the values that have made a path of knowledge in the lush nature of the extreme site of Province of Terra of Lavoro on the border between Campania and Molise. This territory quoted by Polibio are a homogeneous composition between built and natural environment between then complemented by geological and karst with iridescent colors which overlooks the green forests and propose actions for the protection of economically productive rural villages not devoid of architectural such as castles and convents on the remains of the classical age. The research is based on the belief that the action of the protection and enhancement of the places can not be separated from an activity based on the discretization of multidimensional knowledge and measurement of assets. The various formal and aesthetic aspects of nature and the built facing historical reasons, the relations between factories and housing facilities for agricultural used in the geographical context give life and character to the landscape, the roots based on the multidimensional representation, in which each component, material and immaterial returns the territory as a dynamic entity constantly evolving.

Keywords: Matese Regional Park, multicriteria analysis, representation

1. The rural heritage of the Matese

The reading of some archive images and contemporary have in common the structure, shape perception, the compositional geometry useful to make the reading of the signs of historical systems and networks, where the perceptual nature of the compositions is drawn. To the operations of research in Documentary, are added references to the naturalistic theme that, in relation to architecture, expose the beauty of structural and compositional territory. The latter characteristic is essential for the implementation of measures to protect the causes of degradation are many and varied in relation to the natural and made environment in which they present their functional characteristics and perception. The development of the itinerary is contained in the following stages: the first concerns the perception of places and architectural structures in the landscape and the urban environment. Take advantage of these images means acquiring the historical value and the current reality. The visions of the architectural reality in dealing with shapes and colors of the social structure are acquisitions that belong to the detector and the designer through graphical documentation.

The second segment of the research develops a comparative study of documents of different age and origin, whose expressive language shows pictures compared of the territory and the current reality, both played with the detection of the places. The review outlines the common images of Ailano, Castello del Matese, Cusano Mutri, Faicchio, Gallo Matese, Letino, Piedimonte Matese, Pietraroja, Prata Sannita, Raviscanina, San Gregorio Matese, San Lorenzello, San Potito and Valle Agricola documented by representations analyzed to compared in order to achieve the interpolation knowledge and aimed at the conservation and protection of places from which resource landscape.

This territory is mentioned by Polibio that after describing the plain around Capua adds that it is strong and difficult to access, "and it limited on one side by the sea mostly by high mountains and

uninterrupted, through which the hinterland leads to the plain only three steps narrow and bitter, respectively Lazio, the Irpinia and Sannio". The present vision of the places manifested a homogeneous composition between built and natural environment among their integrated with geological and karst with iridescent colors which overlooks the green forests and propose measures for the protection of economically productive rural villages not devoid of architectural like castles and convents of sediments of the classical age. The different formal and aesthetic aspects of nature and the built facing historical reasons of the relationship between housing and facilities designed for agricultural use in the context geographic characteristics and give life to the landscape; designs based on the roots of the natural environment in the cultural life of the region studded with children living in the suburbs architectures prevalent in rural vocation, pursuing an analytical knowledge through discovery. To graphically document the human environment and natural images are compared aspects of nature such as trees, rocky elements, water sources and structures related to the production of the soil.

Fig. 1: The Matese Regional Park: view from the east.

2. Discretize the heritage: research methodology

The beautiful natural landscape of the Park of Matese offers unpredictable a scene, in which between rich forests of beech and maple trees, between different species of animals and plants of the Apennines, also rare, you can see the springs, caves and lush valleys, together with traces of prehistoric civilization , Italic and Roman. Of particular charm are the testimonies of monastic hermitages and caves that demonstrate the presence of zones of medieval worship, along with the discovery of small rock sanctuaries. The research is based on the belief that any action for the protection and enhancement of places can not be separated from an activity based on the discretization of multidimensional knowledge and measurement of assets. The measure, therefore, is the basis of knowledge and representation of the values of all physical and intangible assets of reality and documentary traces of man in his biological evolution as a function of the environmental context in which they live. Measure and capitalize the infinite reasons of nature, as we recommended Leonardo, is to recognize the genetic heritage, the identity of places, the founding of the ongoing process of restoration and regeneration as a modification against any notion of transformation: transform involves action dictated only from a technological need for conduct going beyond the limit imposed by knowledge. The instruments of knowledge allow us a multidimensional representation, in which each component, material and immaterial, returns the territory as a dynamic entity constantly evolving. The methodological system it is not given by the sum of the individual single-issue knowledge, but from a integral of knowledge that any information is qualitatively and quantitatively itself.

Fig. 2: The Matese Regional Park: view of the Matese lake.

Each point is described by a range of information that analyze the characteristics of material and immaterial triggering an ecogeometric approach that allows you to "measure the complexity", ie to recognize characters founding by reading the signs. It is the most effective means not only to analyze a territory, but also to program the management calling a hierarchy of actions. In applying this method to the territory of the Regional Park of Matese, analyzing a large and heterogeneous place, where knowledge is consisted of the reading given to the understanding of all the complex aspects that contribute to determining the form, not only as appearance exterior, but also as a carrier of immaterial values related to the history, culture and traditions over the centuries have stamped their marks to the environment by initiating a knowledge of the territory so to speak genomics.

3. The Matese Regional Park: surveys

The protection and enhancement of the heritage of the Park of Matese, represent a path of knowledge in the luxuriant nature, the far site of the province of Terra di Lavoro, on the border between Campania and Molise. The Matese Regional Park is a protected natural area of Campania, established by the Campania Regional Law n. 33 of 1 September 1993 and came into operation in the year 2002. the territory mainly includes the mountain massif of Matese and is made up a chain of calcareous mountains mainly located between Molise and Campania, where towering the Mutria Mount, the Gallinola Mount and the Miletto Mount. The park occupies an area of 33.326,53 hectares along a North – East, South - West, by the valleys of the rivers Sava and Lete, runs for about 50 km up the valley of the Tammaro River, in the province of Benevento.

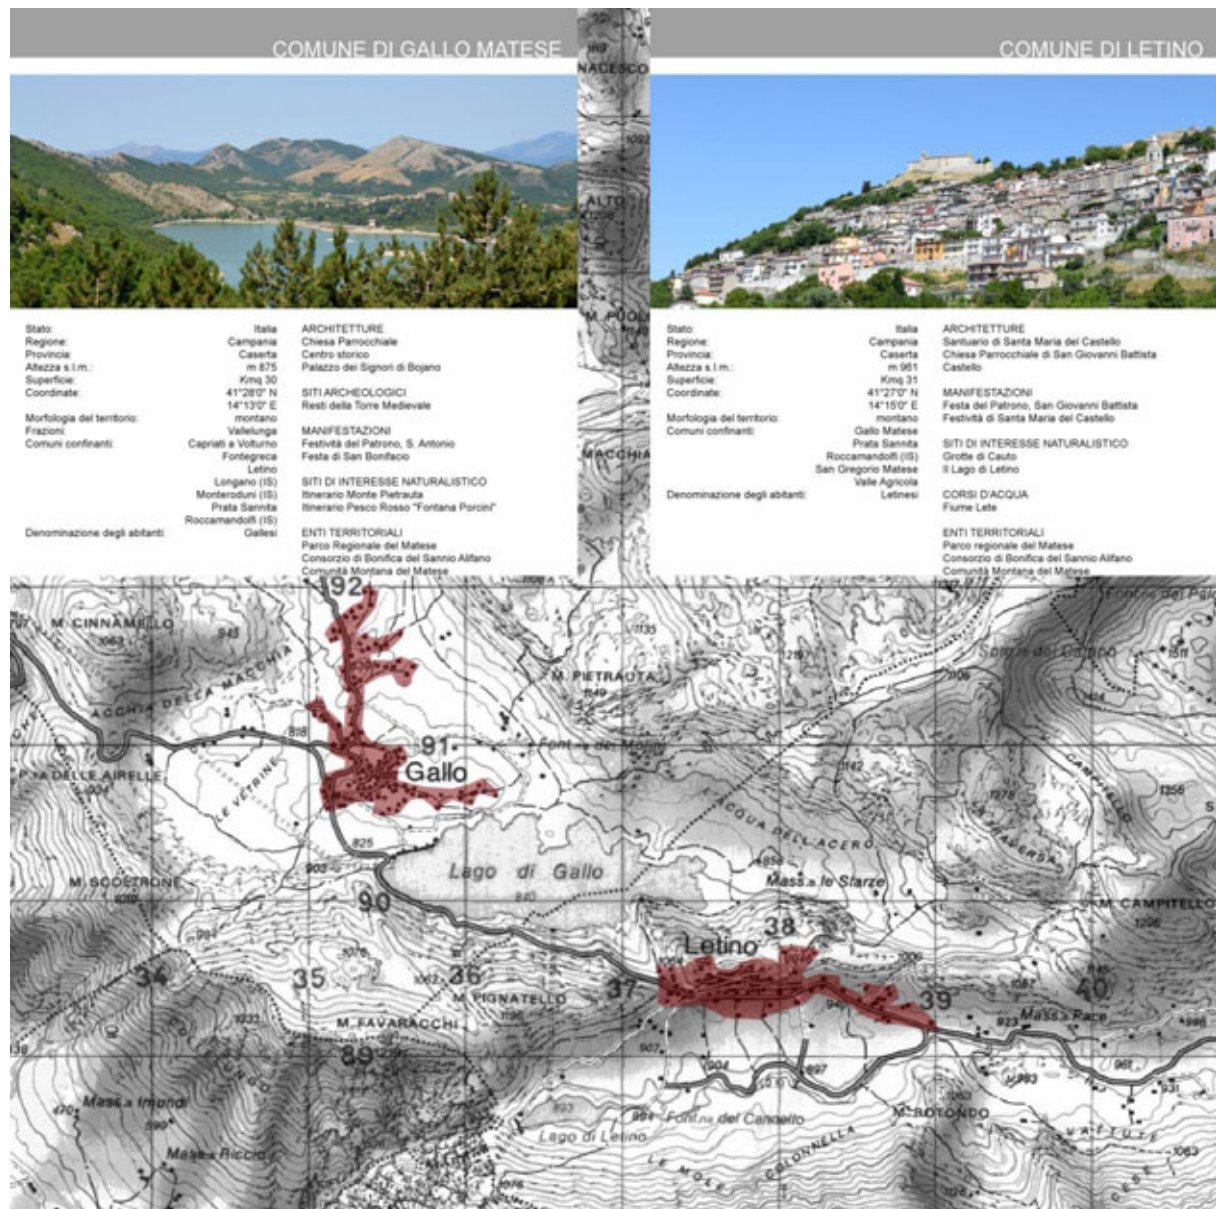

Fig. 3: The Matese Regional Park: thematic map on the towns of Gallo Matese and Letino.

The presence of castles, city walls, towers, fortified villages is characteristic of the landscape of the Matese and offers a fascinating place full of history. Gentle landscapes with lakes from the blue waters which reflect the summits of the mountains, well-preserved historical centers, relations between the Romans and Samnites, led to the designation as a Special Protection Area, in accordance with Directive 79/409/CEE. Most of the villages still perfectly the ancient medieval structure: access doors, the walls, the mansion, the churches. One of the most significant examples is the castle of Prata Sannita, built in the twelfth century, perfectly preserved, is part of a small town is still surrounded by its walls and stands on a rocky ridge that slopes toward the river Lete.

In the Iron Age, while the Tyrrhenian coast is affected by Greek settlements, inland areas are of Etruscan dominion of Capua and make their main center.

The Matese is a stronghold of the Sanniti who resist the disruptive power of Rome. In the late - ancient of these lands pass the Goths, the Vandals and the Lombards, who settled in the inland areas. Even today, with monuments and sacred caves dedicated to the cult of San Michele Arcangelo and the Matese bears the mark of the presence Lombard. The centers entrenched and fortified monasteries tell of the arrival of the Saracens. The period of Normanno Svevo and Angioino buildings still, villages, rock caves as signs of splendor and of ups and downs, of wealth and splendor. During the fifth century BC, the population descends from the mountains of Abruzzo directed to the most fertile plains of Irpinia and Puglia: the Sanniti, which occupies the hinterland, pushing in some cases up to Neapolis, Herculaneum and Pompeii. According to the author Tito Livio, referring to the invasion of the Sannita people in the Campania region, defines the Sanniti were a fierce people, military and predator, not at all interested in the activities of production and exchange. This description suggests a people perched on the mountains and dedicated exclusively to the practice of farming. However, the archaeological finds attest to a high degree of civilization. The Sannitic wars, which last 343-290 BC and they see quite a few defeats by the Roman, as in the case of the Forche Caudine in 321 BC. The traces left by the Romans on the territory are remarkable. Alife with its walls in random length it is a wonderful example. The town still retains its urban layout, with four doors typical of the castrum, at the intersection of the roads that connected to Caiatia Bovianum through the Matese, and Venafrum to Telesia. The crisis of the Roman world and several outbreaks of plague and malaria, which are decimating the population, facilitate the invasion of the Goths and Vandals in the fifth century AD.

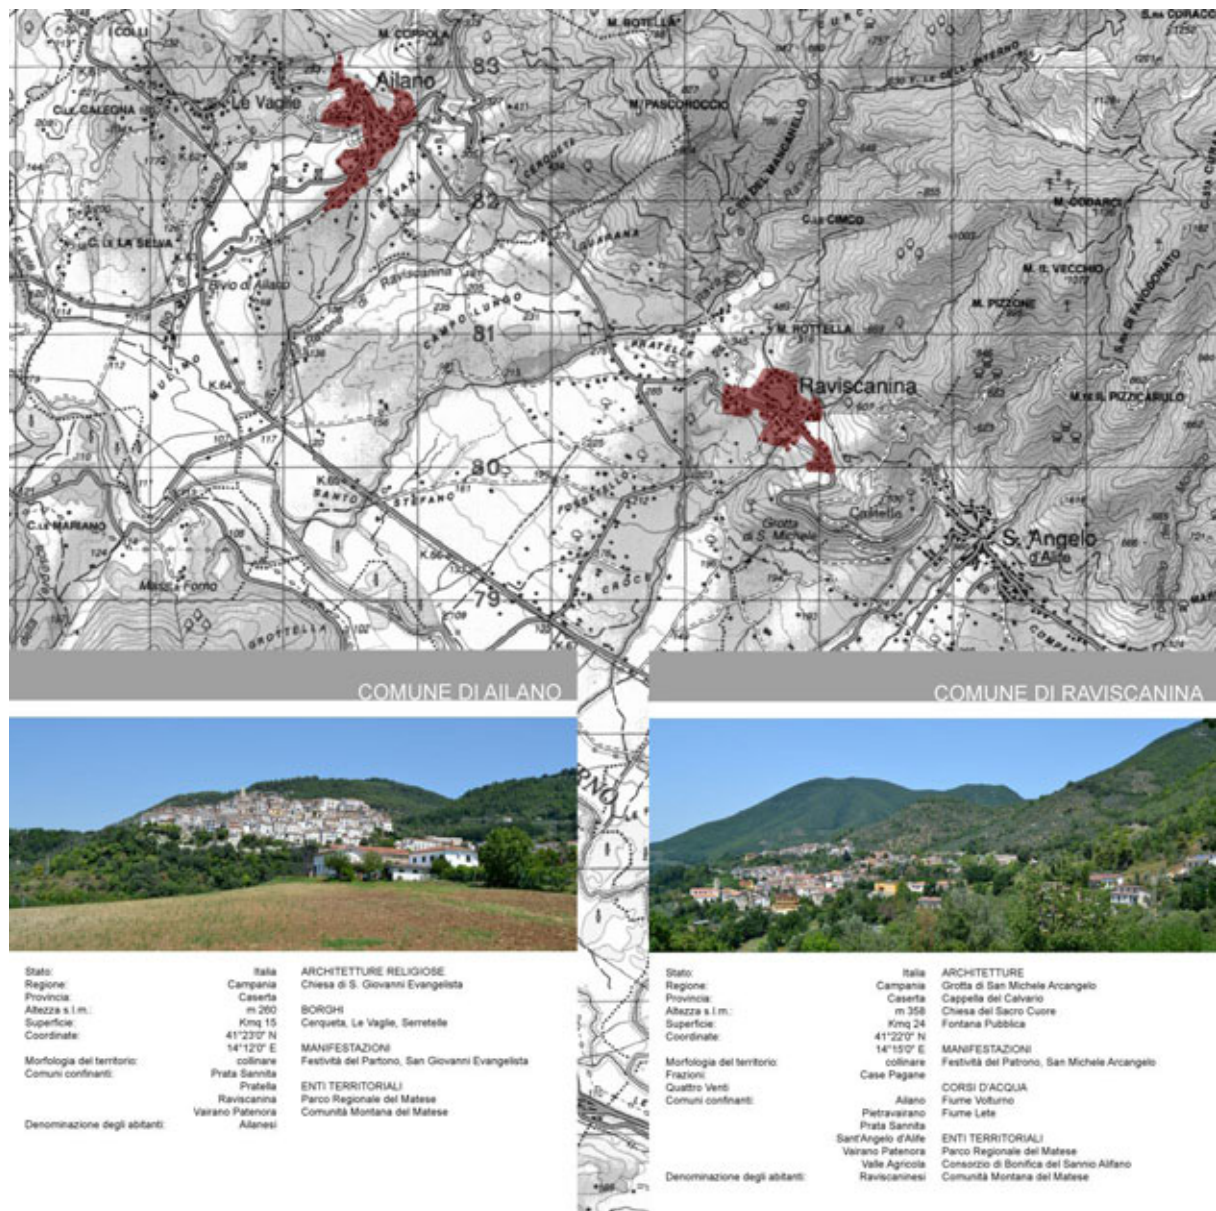

Fig. 5: The Matese Regional Park: thematic map on the towns of Ailano and Raviscanina.

A century later, are the Lombards, who settled in the inland areas of Campania, to reorder politically throughout the area. The caves, the great protagonists of these mountains, are treasures of history and art. The imprint of this period is especially evident in caves such as Curti located in Gioia Sannitica, or those of Raviscanina and Faicchio, adorned with altars and important frescoes. With the coming of the Saraceni, the whole area undergoes a profound transformation: the centers are perched on the hills, in the more sheltered positions, and even the monasteries are fortified. The refugees in the city of Alife founded numerous centers built against the hills or along the sidessuch as Castello del Matese and San Gregorio Matese, Prata Sannita, Pratella, Ciorlano and Piedimonte Matese. All the Volturno Valley, moreover, is rich in castles, the legacy of the next The period also Norman, Swabian and Angevin. The whole area bears the signs, buildings and works of art, style prevalent at the time of the Spanish domination. Cerreto Sannita, for example, is located in a place other than that of the previous city, mentioned by Livio and Polibio as Cominium Ceritum. Razed to the ground in 1688 by a terrible earthquake, it was rebuilt with a new facility, free of walls, typical of urban conception of the eighteenth century. On orthogonal streets are lined blocks to plug in court and block, and beautiful buildings are adorned with limestone fillers in soft colors. A typical example of a noble residence is the Filangieri Palace de Candida Gonzaga in San Potito Sannitico. Built in the eighteenth century by the family of Sanillo on the remains of a Roman villa, of which it retains an aqueduct, was expanded during the nineteenth century by the Count Gaetani.

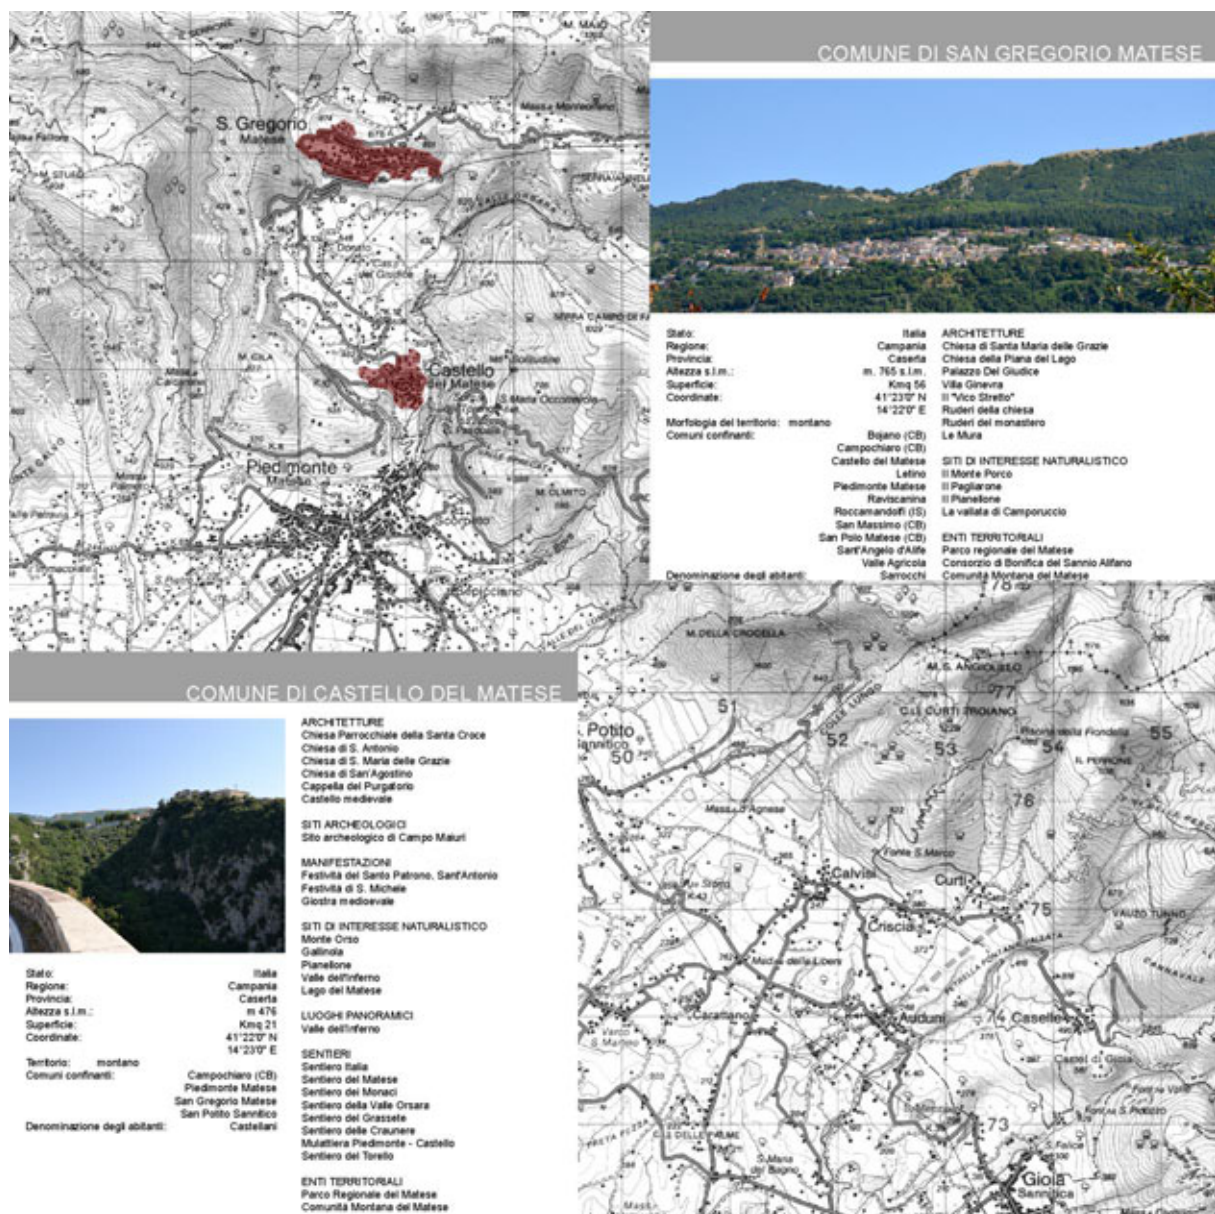

Fig. 6: The Matese Regional Park: thematic map on the towns of Castello del Matese and San Gregorio Matese.

5. The Matese Regional Park: some municipalities under investigation

The town of Piedimonte Matese is the gateway to the natural mountain massif. The area, located on the slopes of Mount Matese and Mount Cila, at the end of three valleys, one of the Paterno, one of the Rivo and that of Torano, looks like a green and uncorrupted nature, bathed by the Torano river, a tributary of the Volturno river. A pre-Roman historical testimony are the remains of the megalithic walls of Mount Cila consisting of three city walls, with a thickness of two meters. Part of the sannitiche fortifications became were destroyed by the Saracen invasions.

The town of Castello del Matese is surrounded by nature and framed in the charming mountain range, enriched with caverns, caves, streams and springs. The Norman period, the Castle is an imposing building with five towers, two of which are still visible. In the oldest part of the settlement, the presence of remains of megalithic walls of ancient Samnite period attest to how much the settlement was chosen in pre-Roman times as a defensive place thanks to the existence of natural ravines.

The town of San Gregorio Matese is located at 750 m. above sea level, on a majestic limestone wall of the Matese Mount, between the lake of the same name, and the step of Miralago is set in a typical rural landscape, including extensive farming and herding traditional woods of beech and maple. The trails lead through historical era Samnite tombs of warriors Italic until you see a particular Christian settlement of the Sixth Century.

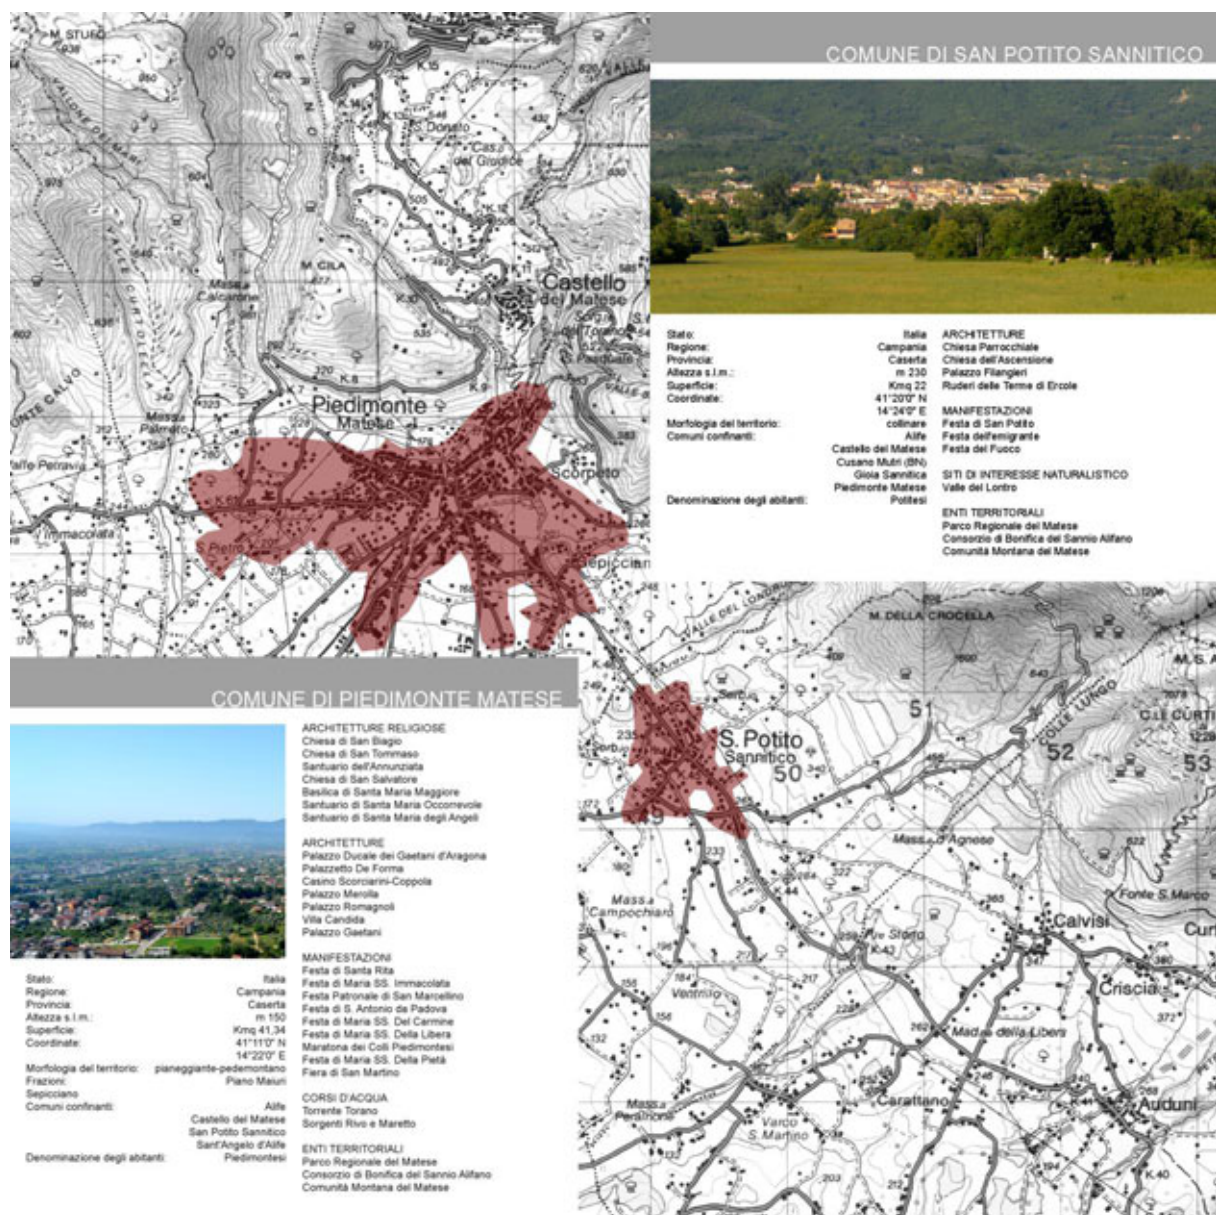

Fig. 7: The Matese Regional Park: thematic map on the towns of Piedimonte Matese and San Potito Sannitico.

The town of Valle Agricola is a charming village with copses and beeches, which lies near the ditch Rave Secco, a tributary of the River Lete. The place is dominated by pine forest of Monte Cappello, dominated by an ancient tower the Samnite, and the Scavenara hill, overlooking the valley of the river Ravone. After the Saracen invasions Valle Agricola has been in possession of the Barony of Prata, and then become, in the Norman period, a feud of many noble families. One of the four towers that were part of a fortification of medieval origin, of a square, had risen to defend themselves from the attacks of rival lords. The tower, whose origin is the Lombard period, is visible in the town that has incorporated over the centuries.

The town of Gallo Matese is a settlement of ancient memory. The extraordinary discovery in 1979 of the remains of Homo Aeserniensis in the Pineta area, on the border with Isernia, certifies that the place was already inhabited around a million years ago. Gallo became, in Roman times, an important line of communication to the plain of the Volturno, on the side of Venafrò, up the slopes of Mount Pesco Rosso, passing the ditch of Marangoni. The site is home to the Lake of Gallo, a reservoir created a few decades ago that feeds the hydroelectric plant of Capriati a Volturno.

The town of Letino is a picturesque mountain village that is located on the Matese and is on a hill over a thousand meters above sea level, between green fields and rich woods. The town sprang up following the permanence of shepherds in winter. The Church of Santa Maria dell'Arco and that of San Pietro picked up their first settlements. The Norman castle is the most obvious evidence of the medieval period. The artificial lake was built by to support the central SME of Prata Sannita in 1911.

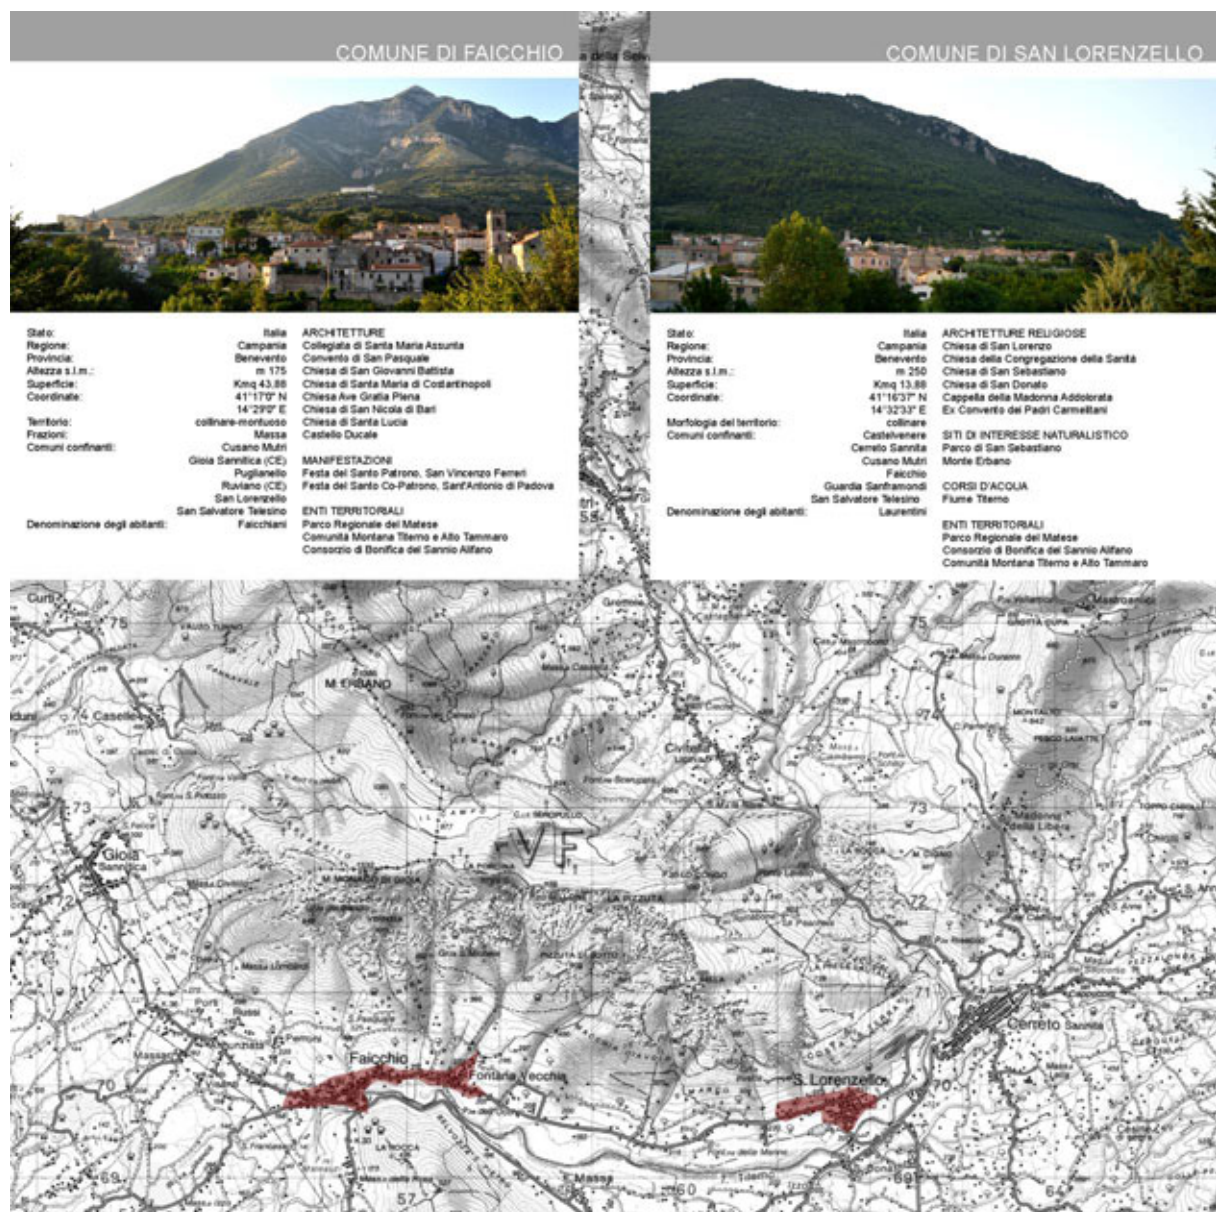

Fig. 8: The Matese Regional Park: thematic map on the towns of Faicchio and San Lorenzo.

The town of Raviscanina is located in the unspoiled rocky ledge at the foot of the Matese Mountains, and has always taken advantage of a strategic defense and control over the area. The forests of beech trees, widespread and rich Mediterranean maquis undergrowth, the large presence of various species of wild animals and the presence of small settlements has facilitated numerous caves of prehistoric man, witness the discovery of pottery from the middle and late age of Bronze. The territory was the subject of several settlements, first of all the Samnite and subsequently that of the Latins. Then became part of the possessions under the feudal duchy of Benevento.

The town of Ailano is perched on a rocky hill feature. Retains the medieval street pattern, flanked by the river Lete and pristine pastures and woods. Of Samnite origin, is an important archaeological site.

The town of Prata Sannita is placed at a height of 400 m. the rocky slopes of the north-western side of the Matese, comprises two settlements: Prata Superiore and the characteristic medieval village of Prata Inferiore. The megalithic walls testify that the first settlement was founded by the Samnites. The Roman era saw the heights of these tragic clashes between the Romans and Samnites. After the dominion of the Lombards that made Prata feudal possession of the duchy of Benevento, the city fell under the control of the monastery Montecassino. The fortress was built in the ninth century. and has a rectangular plan that is built around a courtyard whose floor covers a large tank designed to collect rainwater. The entrance to the village is made up of a majestic arch through which you reach the access ramps of the Castle. The nineteenth-century portal is valuable. The three is storey while the north tower contains a fresco of the Annunciation.

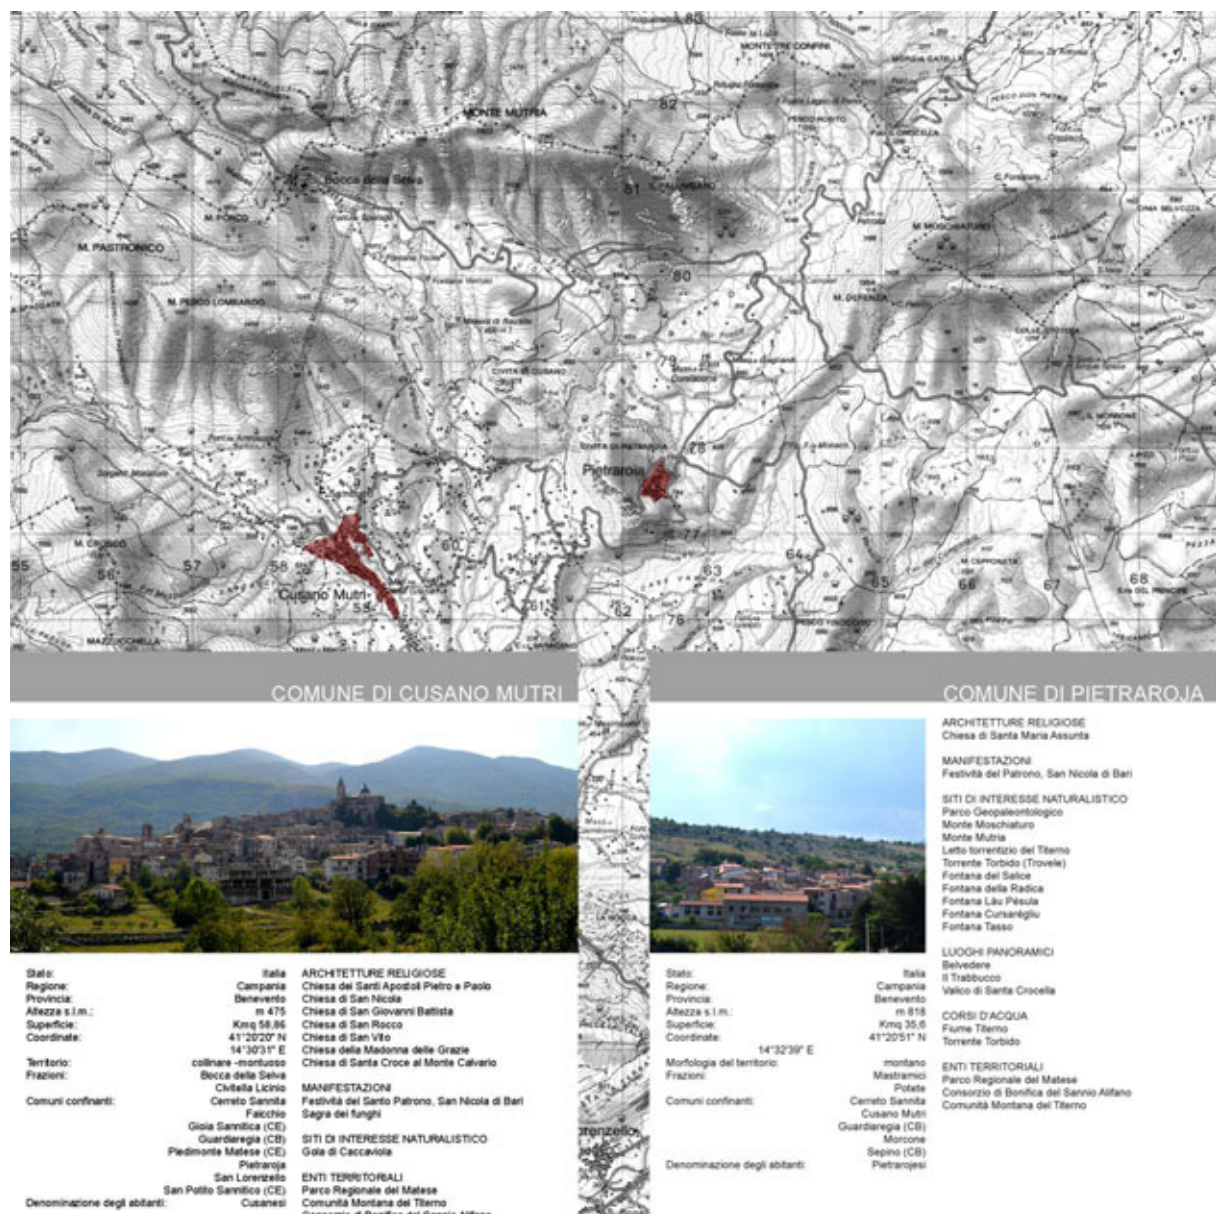

Fig. 9: The Matese Regional Park: thematic map on the towns of Cusano Mutri and Pietraroja.

6. The Matese Regional Park: tradition

The Matese is also a wealth of history, traditions and legends, many of whom still live as an expression of local folklore, closely connected to the daily life of farmers and shepherds. In the villages, perfectly preserved, where you live in a state of tranquility and serenity, but at the same time, you experience the hardships, difficulties and loneliness of mountain life, it is possible to walk through narrow cobbled streets that history: the history of transhumance pastoralism, the story of the robbers after the Italian unity, the history made by the cycles of nature.

The towns are Matese cradle of art and crafts. The land and trees, simple elements, provide the raw material for local handicrafts, based primarily on ceramic, stone and wood. Within the protected area, the centers of Cerreto Sannita and San Lorenzello constitute a single artisan in Italy, dating from the seventeenth century. Walking through the streets you will come across laboratories master potters. Here transform the clay into precious works; matter takes shape as if by magic by turning on the lathe manual, and is then baked in the oven according to ancient techniques.

Other materials worked by craftsmen Matese is wood. This art is flourishing in San Potito Sannitico, Letino, Ailano, Pratella, Gioia Sannitica, and Cusano Mutri. The main products are benches and stools, or kitchen tools such as shovels and multibucket oven. From stone, carved by hand, you get construction elements and authentic pieces of art. With the woven wicker baskets are of various shapes and sizes. Gallo and Letino possess valuable traditional costumes, made by the women of the country and enriched with embroidery bobbin, which with a patient and painstaking work allows you to get very elaborate lace.

The diffusion of the triconch churches in the Mediterranean world*

Danila JACAZZI

Department of Architecture and Industrial Design
Seconda Università degli Studi di Napoli, Aversa, Italy
E-mail: danila.jacazzi@unina2.it

Abstract

In recent years, the archaeological documentation has furnished new interesting elements about the diffusion of the triconch typology in the whole Mediterranean area.

The birth of the Christian art in the period immediately subsequent to the Edict of Milan of the 313 A.D. coincides, in fact, with the formation in the Mediterranean world, particularly in Roman Africa, of a new society and of a new culture that imposes the adoption of renewed architectural models diffused in the dawning monastic centers.

Even if with suitable differentiations, the new oriental paleochristian churches adopt typologies in which Hellenistic and imperial survivals, Byzantine and Syrian influences coexist with technical and formal elements derived by the local tradition.

The existence of cultural and religious common circuits could explain the great diffusion of unitary formal models that is recorded, beginning from the IV century, in centers at times very geographically far.

Keywords: History of Architecture; Christian archeology; Triconch churches; Mediterranean world

1.

Territorial dynamics and cultural plans about the diffusion of the triconch typology in the paleo-christian's basilicas refer to the relationships established among the first christian communities between the IV and the V century in the Mediterranean area, which united the values about the ascetic isolation with the principles about the cenobitic life.

Generally, the rising monastic aggregation took advantage of articulated structures where, in addition to the sacred spaces – basilicas, sanctuaries and burial-places – there were monk's cells, locations addressed to host the pilgrims, sometimes libraries and *scriptorium*, mills, kins, oil-mills, wine-cellars, storehouses, apart from cisterns and shafts.

In the Mediterranean area, new spaces devoted to new functions took new architectural configurations in which survived hellenic and imperial elements and byzantine and syrian influences, coexisting with technical and formal elements resulting from the local tradition.

To better understand the birth of the basilical model with *trycore*, it's necessary to briefly trace out the origin, the process and the symbolic value about the triconch, since its earlier architectural utilizations, starting from Krautheimer's assumption that is so say that the paleo-christian art is not the prelude to the medieval art, but essentially the last phase of the late antiquity art, about the architectural conceptions that dominated western world centers, eastern areas and the Mediterranean coastal areas [1].

Although deriving from greek *τρίχωρος*, the term has been used in his latin version *tricornium* or *trichorum* to identify an architectural element.

Starting from the II century, the sources report the term referring to urban and sunurban mansions, with a peculiar monumental and representative character.

Fig. 1: The Tricorythos of Villa Adriana in Tivoli (II century).

The triconch's utilization in the architecture concerning the late-empire mansions and its diffusion all over the western areas, is confirmed by Irving Lavin in his many statements in Gaul, Spain and Africa (Tunisia), where it is very popular in structures datables between the end of the III century and the beginning of the V century [2].

Initially, the triconch appears as a *triclinium*, that is like a dining room for special events, but soon it become one of the most representative location of imperial roman apode, addressed to official ceremonies. A similar utilization is documented by Villa Adriana in Tivoli (II century), and by one of the most emblematic building of the late antiquity age: the mansion of Piazza Armerina in Sicily (beginning of IV century) that, starting from the models of the private building by that time, (peristyle mansion with an apsidal courtroom and a triconch room), clearly reveal influences deriving from the North of Africa [3].

The triconch is very popular even during the age of the paleo-christian architecture, where it is chosen thanks to its symbolic value: the *triclinium* become, according to the triconch typology, the emblematic location addressed to the Eucharistic meal.

The ritual that took place in the imperial buildings was, in fact, considered as a religious rite *sancti palatii ritus*, and the building itself was considered as the emperor's temple of worship.

After the christianity's foundation as the cult of State, many of its ceremonial aspects were perceived on the basis of imperial terms, with a symbolic meaning, seeing Christ as the Emperor of Heaven and the paleo-christian church as the house of the Lord.

Consequently, the Liturgy and the architectural definition of its spaces, started to obtain an increasing number of elements about the official ritual, roman and imperial. After all, the most frequently used term concerning the paleo-christian church, *basilica*, shows a clear regal derivation. Similarly, Paolino di Nola describing the church founded by himself for the Cimitile's Christian community, uses the term "palatium": *omnia circa nos lucere ut aperta videntes, cuncta putaremus flammis correpta cremari ipsaque sanctorum simul igne palatia tanto fervere* [4].

Even the sources show, starting from the IV century, developed a metaphorical equivalence between the royal or imperial *palatium* and the Christian basilica. These observations could justify the introduction of the church's model with the triconch typology in the paleo-christian architecture, but the most recent archeological discoveries and the new interpretations about some known buildings, permit to obtain new elements about the apparently well-established historiographical contest.

Fig. 2: Piazza Armerina (Sicily - early IV century) from Heinz Kähler, *Die Villa des Maxentius*, 1973.

The Edict of Milan in 313 A.D. deeply turned the official approach of the roman state towards the church, most of all in relation to the religious practices and to the free veneration of martyrs and, then, to the realization of specific places of worship, ratifying the integration of the Christianity in the culture of the classic world [5].

In this context arose Costantine's architecture, in which, architectural elements connoted with ideological values shaped with imperial mold. Recent critique considerations help to specify the role played by late roman villas for the definition of the new monastic locations, through the examination of the Christian communities founded between the IV and the V century, respectively from Sulpicio in Primuliacum, from Martino in Marmountier and Paolino in Cimitile [6].

Many biographical analogies band the three in common experiences: they have never traveled to oriental landscapes and they have never lived in a monastery. Moreover, they belonged to the army or to the provincial aristocracy that performed official charges at the imperial court.

In regard to Sulpicio and Paolino deal with rich landowners who choose to lead a monastic life in structures that inherit spatial models and organizational manners from the villa's example.

The conversion to the ascetic practices and to the cenobitic life redefined, in effect, the role of the *dominus*, definitively ratifying the passage from the *otium ruris* to the *contemptus mundi*.

Fig. 3: Cellae trichorae of San Callisto's Catacombs (Rome - IV century).

The sharing about the theological and constructive choices recorded in the conformities between Sulpicio Severo and Paolino could be symptomatic of a common attitude to the founders of the christian communities with epistolary relationships among them.

At the beginning of the V century all the empire's territories developed, in effect, monasteries and convents were used by the first cenobitic communities in place of the villas.

Indeed, as is known how "a warp of continuities and analogies associates the Mediterranean world between the IV and the V century" [7].

Between the IV and the V century the first christian communities become vital centers for the spread about the monastic principles and the community life in the west. Is remarkable a substantial homogeneity about the implementation of specific planimetric systems also recurring in different territorial areas, which lead to the circulation of reference models – also by artists – through the Mediterranean areas, Egypt, Syria and balkan, dalmatian and istrian regions up to Italy and Gaul.

Of course, every single case has to be analyzed in their peculiarity, but the literary sources seem to confirm the role of the late roman residential buildings about the definition of paleo-christian monastic spaces.

First of all, the *Epistolae* and the *Carmina* written by Paolino permit to recreate the origin of a sacred place at the beginning of the IV century and furnish proves about the intense theological and epistolary relationships that the *monasterium* founded by himself in Cimitile, had with the more important christian exponents and with the greater bishops, members of the greater seat of Italy, Aquitaine, Gaul and the christian Africa.

Ambrogio (bishop of Milan but hailing from Treviri in Gaul), Girolamo (Bethlehem's ascetic), Delfino and Amando (bishops of Bordeaux), Pammachio (member of the roman aristocracy, founder of the *xenodochium* in Porto next to Ostia and of a monastery in Bethlehem), Vitricio (bishop of Rouen), Fiorenzo and Alezio (bishops of Cahors), Onorato (founder of a center of monastic spirituality in Lérins, similar to the Nola's one), Melania senior (roman patrician, a Paolino's relative, guest in Cimitile after the journey to the Holy Land where she sojourned for 27 years), and Rufino Turannio (hailing from Aquileia, then moved to the Egypt where he met ascetic and cenobitic communities in the desert that he had passed through with Melania senior, with her he founded a monastic community in Jerusalem), Sulpicio Severo (member of the rich aristocracy gaul-roman and founder of the scetic-monastic community in Primuliacum, next to Tolosa, similar to the one of Martino in Marmoutier, to which inspired also Paolino), Niceta di Remesia (who conducted an evangelization of the danubian region and visited Cimitile two times during his journeys from Gaul to Dacia), they all are friends of Paolino [8]. Among his epistolary contacts there are also the bishops of the important African seat:

Aurelio of Carthage, Agostino of Hippo, Alipio of Tagaste, Profuturo of Cirta (now Costantina), Severo of Milevi (now Mila).

Furthermore, many famous men at the time, travelling from East to West, visited the ascet Paolino [9], spreading monastic models tested in the ascetic and cenobitic communities of Egyptian desert, and promoting its imitation [10].

Trying to identify the matrix and the reason of the adoption of the triconch typology for the christian basilical churches, is necessary to consider that the *trychora* was used in pagan architecture for the construction of mausoleum and cemetery rooms [11].

Numerous studies have proved the diffusion and the popularity all over the Mediterranean basin where, during Christian epoch, was used as the funerary model. Among the first testimonies there are the two *trycorae* cells of San Callisto's catacombs.

In Cimitile, the triconch is directly linked to the cult of the martyr Felice and to the presence of relics, specifically recalled from Paolino in his works. It is probable that the model adopted by the Nolan at the beginning of 400 A.C., represented the prototype of comparable planimetric configurations which constitute an homogeneous sequence in the places of the first Christian communities of the V century. The theme of the central space fused with the longitudinal compartment is solved with the recourse, even symbolic, to different planimetric structures melt in an uniform organism: the triconch - tied to the cult of the martyr's relics, to the simbology of the *martyria* and of the mausoleums, to the authentic cimital function, and also to the imperial ceremonials – the naïve with axial development, correlated to the liturgic functions and to the requirements of devotional pilgrimages' itineraries.

The *trycora* in Cimitile, covered with marble and with the vault adorned by mosaics, assumes through Paolino's words an evident symbolic value, highlithened by the lines which describes the painting: *Pleno coruscat trinitas mysterio: Stat Christus agno, vox patris caelo tonat et per columbam spiritus sanctus fluit. Crucem corona lucido cingit globo, cui coronae sunt corona apostoli, quorum figura est in columbarum choro. Pia trinitatis unitas Christo coit habente et ipsa trinitate insigna: Deum revelat vox paterna et spiritus, sanctam fatentur crux et agnus victimam, Regnum et triumphum purpura et palma indicant. Petram superstat ipse petra ecclesiae, de qua sonori quattuor fontes meant, Evangelistae viva Christi flumina* [12]. In Paolino's lines clearly appears the symbolic depiction about the Trinity, which alludes the shape of the triconch apse, that marks how a *martyrium*, the place dedicated to the custody of Apostles and Martyrs' holy relics, located under the altar inwards the *trycora*: the *sancta sanctorum* with the fragment of the wood of the Cross, granted from Melania to Paolino, as said to the *titulus* placed under the frame.

Fig. 4: Mosaic in the apse of the basilica in Cimitile (reconstruction by Charles and Georges Rohault de Fleury, *Les Saints de la messe et leurs monuments*, Paris 1900).

Fig. 5: Basilica *vetus* and basilica *nova* in Cimitile (401-403 a.C.) reconstruction by Tomas Lehmann, Paolino di Nola: poeta, architetto e committente delle costruzioni, 1998.

The today's San Giovanni's basilica, built in the XIII century, uses the apse and a part of the central naïve of the basilica *nova* built by Paolino. The largeness of the central naïve is now recognizable by the identification of the visual axis fixed by the ancient arcades, comparables with the alignment of the survived plinths setted *in situ*; but originally the living-space was occupied by three longitudinal naives detached by arcades. Two sequences of columns made of colored marbles, green and grey, which re-used some of the most ancient materials of I-II centuries A.C., separating the three naives cobbled with big sheets made of white marble. The employment of the sheets made of marbles and the bases of the columns, and also the apside's *opus sectile*, made possible to suppose the presence of workforces operative in the roman basilica of San Paolo fuori le mura in Cimitile [13].

The *basilica nova*, through the re-utilization of marbles and columns, gives back the "image of an imperial tradition still alive, with its need of uniformity concerning the architectural order", by the utilization of colonnade lines with similar materials for the naïve (cipollino and bigio venato), and breccias coralline for the chancel to mark, even through the different chromatic effects, the transition from a setting to another one [14].

The structure undoubtedly obey to symbolic and functional decrees: at the same time, it is a *martyrium* – built in a place aim of particular devotion, as a space linked to the worship of the martyr Felice's remains and of the relics of the real cross given from Melania senior to Paolino – but also a basilica, center of devotion and pilgrimage.

The insertion of the *basilica nova* inside the basilical compound and the relationship with the martyr's grave, which imposes an inversion of the usual basilical orientation east-west, it pushes back to other eastern models. The new structure, in effect, is built on the basis of a north-south axis. This orthogonally inserts to the space of the basilica named *vetus* through a *triforium* opened on a courtyard, so that it is possible to see the altar of the new grave's construction, located along the basilica's naïve, *vetus*.

The connection among different basilical structures related to a specific devotional space, refers to eastern examples, probably dependent on the prototype of the SS. Apostoli in Costantinopoli's church, perceived as an imperial mausoleum with the portion destined to the *martyrium* placed at the centre of the structure [15]. The great church built on the grave of the Apostle Giovanni (beginning of the V century) on the original squared *sacellum* in Efeso, there were inserted four basilical buildings organized as a cross, and in the greatest syriac compound of San Simeone Stilita the old *Qal'at Sim'an*, built at the end of the V century, converged towards the central space four basilicas organized as a cross.

Fig. 6: San Giovanni (Efeso) and San Simeone in Qal'at Sim'an (Syria).

In both cases the examined structures were part of an ample organisms provided with conventual buildings and locations addressed to groups of pilgrims.

Pasquale Testini identified with the *trycora* of Paolino one of the most interesting element in a basilical compound. Cimitile represents, according to the popular academic, «the summary of the architectural evolution of a great martyrial center, arose among a pagan funerary center and thanks to some elements – triconch, iconostasis of the second half of the IV century – is related to the Orient and in particular to Egypt» [16].

The archeological investigations, during the last years, has produced new interesting elements about the spread of the triconch typology all around the Mediterranean area. Certainly the most immediate reference, remain the Egypt with its great desert as indicated by Testini, since in the Christian Egyptian architecture the basilical map and the triconch apse knows a specific diffusion. The basilicas with a triconch presbytery represent, in effect, the expression of the local egyptian tradition, developed as an alternative to the themes and the models imported [17].

For example, the churches of the two coptic convents of Sohag, White (Deir el-Abyad) and Red (Deir el-Ahmar), built at the beginning of the V century, and the Christian church of Denderah built in the VI century using the temple's room of Hathor [18]. Here, the planimetric model with three naives presents a great apse tripartite deeply connotative, according to Grabar nearly an autonomous aedicule, derived by the models of the Hellenic style buildings and by the funerary tradition of roman mausoleums, attributable, in particular, at the idea to insert a location at the naïve's extremity with the role of *martyrium*, which utilization was popular in the Christian architecture in eastern area [19].

This aspect is recognizable, for example, in the basilica of Ras Siyagha (Monte Nebo) in the triconch cell of the V century located in correspondence to Moses's grave, set under the apse. Even in Sohag, the presence of a triconch local is ascribable to the founder's sepulture, the Coptic monk Schenudi (Shenoute), archimandrite of the monastery of Atripe next to Sohag [20].

Another great Egyptian sanctuary is located in Hermopolis, in the basilical church of El-Ashmunein, founded in the V century (430 ca), which proposes an analogous model. But, in this specific case, the triconch typology is absorbed by the orthogonal disposition of the naïve, configurating itself as a transept with a hollow end, differently from the connotation of an autonomous ambience recognizable in the *trycorae* of Sohag and of Cimitile. Also in Hermopolis, the crypt underneath the apse was intended to preserve the remains of a saint [21]. The Christian basilica in Marea (V-VI century A.C.) shows a similar treatment, nearby Alessandria, with a triconch typology composed by two lateral apses with a colonnade that act like transept and central apse with smaller dimensions, with a crypta and adjacent *pastophoria*, as underlined by the excavations made in 2003 by the équipe of academic guided by Hanna Szymańska [22].

It is interesting to note how, even in the basilica of Cimitile, is adopted the same solution that has been adopted in the convents of Sohag and in the church of Denderah, that is the introduction of two columns laying on the triumphal arch to solve the conflict between the presbyterial space and the naïve [23].

Fig. 7: View from above of *trycora* in Julia Concordia.

Fig. 8: Paleo-Christian buildings in Invillino, Colle Zucca (Italy – First half of V century)

Fig. 8: Basilica in Knossos (Crete – Greece - early V century)

In regard to the naïve, the apse is elevated like many churches in the northern of Africa and Tripolitania, using the term of Sant'Agostino *gradate* [24].

The structure of the *basilica nova* in Cimitile shows on the triconch apse's sides, in correspondence to the lateral naives, two locations with different liturgical functions, *prothesis* and *diaconicon*, following the example of the Syrian-Palestinian, revealing in the *trycora* architectural structure "the presence of eastern influences penetrated into the traditional fabric of the latin basilica" [25].

The two compartments, especially present in the paleo-christian churches of the first religious communities in Tunisia, Algeria and, generally, in the paleo-christian basilicas in the roman-Africa, were addressed to contain the saints' relics (*prothesis*) and used as sacristy (*diaconicon*).

Archeological sources and specific studies, have registered remarkable progresses during the last decades, extending, with renovated attention, the strengthened historiographical referential model.

Starting from Julia Concordia to the recovery in Friuli [26], up to the Illyricum territory, have been discovered paleo-christian showing the existence of common intention or the derivation from a common tradition, as the basilica in Cnosso (early V century) with three naives preceded by a narthex, an atrium and a triconch presbytery, and the Sant'Andrea church in Betika in Istria, datable at the beginning of the V century [27].

The adoption of the *trycorae* characterize the north-eastern Italy that, between the IV and the V century, resulted included in the diocletian provinces of *Venetia et Histria* [28].

Unfortunately, the limits of this contribution doesn't consent to examine all the highlighted cases in the most recent studies, but it's obligatory to remind, although fleetingly, the basilicas in Pannonia, in the actual Hungary and in the Balkan territories, where Niceta, a friend of Paolino, conducted an intense activity and that can be considered as the channel of occidental influences in the regions of the Danube.

Finally, through this analysis emerges how, extending the strengthened historiographical model and underlining the connections among the expressions of the architectural paleo-christian tradition in the Mediterranean world, the Christianity of the "suburban" regions doesn't appear as an isolated phenomenon, but as the expression of strengthened relationships among the greatest centers of Christian art and the numerous local realities.

Abstract

This paper presents the outcomes of the multidisciplinary study carried out on the tower of Mongialino in Mineo (Sicily), a complex architectural heritage today reduced into ruins. The site has a strong landscape and territorial value, the vestiges of the donjon rise on a rock promontory that dominates the valley of Margi, already inhabited in ancient greek age. The unstable conditions of the building, affected by important collapses and lesions, require a safeguard intervention and that implies a deep knowledge and understanding of the construction. The first step of this process is a suitable documentation and representation of the artifact through the integrated use of current technologies of surveying able to provide a metrically accurate three-dimensional model of the architectural object. The circular planimetric shape of the donjon and its towering position require to solve both the problems related to the 3D data acquisition and those related to the representation of a cylindrical shape object. In this paper we propose a multidisciplinary approach concerning both the reading of the technological, typological and material elements that constitutes the constructive apparatus of the building (masonry, ribs, ring-like vault), and the geometric analysis addressed at the virtual reconstruction of the original shape. The peculiarity of the object, perhaps an unique case in Sicily of a cylindrical tower with inner cylindrical nucleus, its status of ruin immersed into a context of remarkable environmental value, encourage this cross-disciplinary approach. This way it is possible to catch the essence of the object to protect and therefore to foreseen the necessary interventions that will be able to pass it down to future generations.

Keywords: Digital Cultural Heritage, 3D modeling, geometrical analysis, building technology

1. Introduction

Nowadays data acquisition research on cultural heritage concentrates increasingly on the identification of rigorous methods of investigation, which must be able to define a suitable methodological approach for the creation of more detailed guidelines. For this reason the study of the castle of Mongialino in Mineo, Sicily, has been carried out using a method which involves the integration of specific investigations aiming towards the documentation of the architectural element in its complexity and its totality. This research has analysed the historical-documental, geometric-spatial and typological-formal aspects of the defensive structure, interesting scholars from different interdisciplinary fields of study. Its typological features as well as its severe state of decay and danger have made it necessary to carry out a survey using a 3D Laser Scanner, which was the most appropriate method for its conditions and provided a synthetic drawing which includes the various investigations of the scholars involved.

The study, in fact, uses a three-dimensional model obtained from laser scans as a model of objectively accurate research, through which it is possible to identify the geometric rules as well as the classification of the materials and of the building techniques – both traditional and imported – in order to validate the historic-documental theory.

Moreover, the 3D model obtained gives us an appropriate analysis of the wall structures and of their textures in order to define their state of conservation as well as being able to achieve reliable results about the level of their stability. This provides an accurate evaluation of the state of conservation of the architecture and, the fundamental components being known, guidelines for an intervention plan for its renovation, which will be more coherent since there is the opportunity to analyse carefully the result, understanding its principles and the criteria which document the data acquisition process.

2. Reading the signs: historical and territorial overview

Mariagrazia Salerno

Sicily is a territory of castles. The island, which is a flourishing land in the heart of the Mediterranean, has been, in its history, the crucial set of fighting between kingdoms which competed for the control of the *Mare Nostrum*.

The fortified architecture in Sicily is an important testimony of the history and of military and constructive techniques: in the island, that was in a permanent state of siege, the defensive constructions changed appearance or maintained partly functional elements, reflecting the *modus operandi* of new lords; all this leads to a diversification of the fortress theme.

Numerous castles arose: next to and in the towns, often equipped with sighting towers with protective walls; others are located along the coast or protecting ways that connected the urban sites [1].

The south-eastern Sicily, like the rest of the island, has been cradle of civilization since prehistoric period. In the centuries various dominations, from the Greeks to Northern Europe people, have followed: not only the lands were fruitful, therefore suitable for agriculture and human settlement, but the particular physiognomy of the (Catania) Plain, surrounded by the southern foothills of Erei and, in the north-west, by Mount Hyblaeon, makes these locations strategic for the control of major waterways and terrestrial ones. In this study, Mineo's territory is analyzed, in which, throughout the medieval period, there are several defenses guarding a portion of the Plain called "valle dei Margi". Here rises the Tower of Mongialino, placed to protect the territory and the internal road that connected the stronghold of Mineo with the Agrigento one. The fortalice, otherwise referred to Montalfone or Griffon or Falcone or Gaffone or Montecaffuri, because of the different naming it took over the centuries, is located on a rocky and steep spur (315 m above sea level) overlooking the valley of Casalgrismondo, ploughed by the Pietrarossa river, a feeder of the Monaciand Gornalunga rivers, which, introducing in the Iron River, flows, after a long arcuate path, into the river of Margi. At the foot of the rocky outcrop rose a small village and a religious complex, which is ruined too.

The date of construction of the manor is uncertain: Gambuzza [2] and Tomarchio [3] reported that the building was constructed in the period of Arab incursions: in 829 the Arabs conquered Mineo and its lands, in which they erected the "Malgia Khalil". The first mention of Malgia Khalil is that of the Arab chroniclers Ibn 'atir, An Nuwayrî and Ibn Haldun. They narrated the Muslim conquest of the Byzantine fortress, which was stripped of the peripheral elements of defense (we do not have any information of the consistence of this previous fortress) and reduced to a garrison of secondary importance. The signs lead approximately to the location of the castle. Near the castle, there was a large farm, preceding the birth of the castle as reported by the Arab chroniclers and subsequent notary deed until the frederician age; De Spuches asserts that the castle was built by Manfred, lord of Butera, who was proclaimed lord of Mongialino in 1143; it has recently been suggested that the construction of the fort

is due to the presence of the Cistercians in the territory of Mineo; it is assumed that the two churches of the feud of Mongialino were dedicated to S. Cataldo and some architectural elements, placed in the way of other more recent ones, show a typical Cistercian craftsmanship [4]; finally, a last hypothesis is that the manor is dating back to the Angevin age [5]. Indeed in 1273 Charles of Anjou established a commission to assess the condition of defensive garrisons in the area; the commission began its work in Mineo in April 2 and ended in June 18 of the same year in Enna. Their objective was to assess existing safeguards to reorganize, renovate and build new ones where there was a need or a garrison destroyed.

The historical reconstruction has proven that the life of the castle was closely linked to that of *Vetustissima et Jucundissima* Mineo. The town of Mineo took part at the Catania Emirate and followed its destiny until the Normans occupied the island.

It is supposed that Count Roger, between 1062 and 1063, has occupied the fortified places in the interior of the island, and among these Mineo and surroundings. The feudal catalog from 1320 reveals that since the foundation of the Norman kingdom were instituted the feuds of Mongialino, Serravalle, Balchino, Camemi, Lamia, Bucalca or Bucalta (today Buscialca), Anicara (today Nicchiara) [6]. These populated feuds did not become part of the state property of Mineo, but they were linked to it because the officers of the city extended their authority or jurisdiction over there, and finally because the feuds were subjected to the payment in cash to take advantage of civic uses. Vast estates of the territory of the state property of Mineo, however, were granted to knights, who became direct vassals of the crown. The feud Mongialino was never divided in other lordships, and was composed of the following subfeud: Casalvecchio, Frasca, Serri, in the territory of Mineo, Pietrarossa Soprana, Pietrarossa Sottana, San Cataldo, and Montecaffuri, where today stands the ruins of the castle. Several feudal lords succeeded in Mongialino but the long-lasting dynasty was that of Enrico Statella, who in 1408 came into possession until the end of 1800. This feud, under Charles V, was still subjected to the city of Mineo and so forced to comply with the dictates of civic uses; this is confirmed by the acts referring to the Civic Council of 1530, year in which were established the "feghi dell'Università". The 1693 earthquake, which destroyed many towns of the Val di Noto, caused extensive damages to the dungeon. The time and the carelessness of the owners have accentuated the decline, but nevertheless it is possible to understand its features.

From 1800 until 1988 the castle and part of the feud became property of privates.

Only in that year the town of Mineo bought the castle of Mongialino to build there a Museum of defensive garrisons and of the sacredness of the landscape.

3. Reading the signs: digital survey and the project for knowledge

Mariateresa Galizia

The medieval castle of Mongialino lies on Mount Alfone, an inaccessible promontory in the territory of Mineo, Sicily, which overlooks the whole valley of the Margi and is so perfectly integrated with the surrounding area that a survey of the whole territory is seen as necessary for the graphical representation of a part of the rock on which it rises. Access to the castle is possible by means of a steep ramp following the lines of slope of the terrain, which leads to the top of the limestone elevation. In the lower part of the fortress there is a religious building with a church with two small rooms on the ground floor and one room on the upper floor. A barn and a henhouse formed part of it as well. The church, which dates back to 1600, was in use until 1800. Services were held for the people coming from the surrounding countryside.

The planimetric map of the architectural unit shows a 'whistle-shaped' cylindrical tower overhanging both the north-west side and the south-west side where it is possible to observe what remains of the polygonal surrounding walls, which are instead clearly visible on the north-east and south-east sides.

In the upper part the polygonal surrounding walls, of which we can see the remains of the first ring along the hilly path, enclose a courtyard with warehouses and pens. On the walls it is possible to see the merlons, the putlock holes placed at equal height, which make us imagine the existence of a walkway to guard the territory, and the arquebus embrasure to protect the castle.

From the digital survey the circular dungeon shows a huge wall thickness of about 2 metres with a widening at the base: a section with an embankment which ensures the stability of the building. A central column unit, which is hollow inside and concentric with the tower, was used as a tank for collecting rain water.

The inner room is a ring-shaped corridor about 4 metres wide. On the wall surface it is possible to see some holes which leads us to assume the existence of a wooden stairway accessing the upper level. It seems that its floor lay on a stone stringcourse, placed at a height of 3.90 metres, overhanging the inner walls onto which it is fixed. The ring-shaped barrel vault is arranged in pointed arches with two centres placed radially. Through a narrow square passage which opens onto the vault it is possible to access – once probably by using a ladder – the upper floor (third floor). This covers only half of the circumference of the base of the tower, and leaves the other half uncovered forming a terrace, thus giving the defensive structure what is defined as a 'whistle shape'. Moreover, evidence of this shape is to be found on the third floor in the toothing between the wall surfaces which are placed at right angles to one another, and in the upper part of the drainpipe, which is built into the brickwork and placed at the base of the top floor parapet (which has a regular height).

From a vertical viewpoint the cylindrical front of the tower shows, on the second and third floors, two different types of openings: splayed and straight loopholes (some of them having a seat). In all likelihood at the time of the construction there were only the splayed loopholes and, over time, some of them were rearranged and turned into windows fitted with seats. This hypothesis is supported by the interruption of the stringcourse where the windows with seats are, as well as the lack of plastering by these openings. Two of the three splayed loopholes have been damaged by the collapse of the structure, and now it is possible to see only partial traces (one of the two has been walled, so it is possible to see it only from the inside). The third loophole is in fairly good condition and is placed at about the middle of the arches supporting the vault.

The instrumental survey of the geometric-spatial, static-conservational and environmental characteristics of the place was conveniently carried out using the 3D terrestrial laser scanner Riegl VZ-400 [7,8,9]. The phase of the in situ survey took into account a territorial and architectural scale approach. The data acquisition project involved a total of twelve stations, five of which were placed along the driveway lying under the fortress and at a distance of about 550m between each of them for

the territorial scale representation, and 7 additional scans were placed near the object for the architectural scale representation. During the phase of acquisition homologous points were used for the following union of clouds instead of targets. In addition, during the scanning phase high resolution (Mpixel) photographic images were obtained from a Nikon D 700 Fx format -14 mm release, integrated with the instrumentation. The obtained data were processed using Riscan Pro software for the alignments of the clouds and, then, they were exported onto Cyclone, where layers were created for each scan, by choosing different colours for the single clouds. On these clouds slices were carried out on the model using vertical, radial and horizontal planes. The model thus obtained was cleared of intrusive elements so as to make the graphical representation on Cloudworks more accurate.

This digital model came to represent a collection of information which was decoded through single fields of study related to each other. Indeed, it represents a simulation model still open to further research in order to carry out more detailed structural exams, which will be able to clarify some doubts about the interpretation of certain formal and constructive elements, thus providing the basic principles for a rigorous construction theory of the architecture. The outcome of the digital survey is a 3D representation model forming the basis for a computer reconstruction of the castle according to the principles of the London Charter [10], which established that digital heritage visualization has to be both intellectually and technically rigorous (reliability, documentation, intellectual integrity, sustainability and access). The obtained model is the result of a logical process in which the various sources for the reconstruction theories to be put forward (material remains, current and previous graphical documentation, current and previous photographic documentation, written sources, iconographic apparatus, typological comparisons, metrical observations, stylistic observations) were used and made public.

The result obtained to date represents a product to be included in a possible Cultural and Environmental Heritage databank: a digital archive with 3D information which can be shared by scholars in this field, is open, can be constantly updated and integrated with other types of data, or can simply be used for study and for the dissemination of knowledge.

Furthermore, as required by the London Charter, the model of 3D visualization makes it possible to devise a strategy which may ensure the long-term sustainability of the documentation and of the results of digital visualization concerning cultural heritage in order to prevent loss in mankind's cultural, economic, social and intellectual heritage.

4. Reading the signs: the geometric interpretation of the architectural shape

Cettina Santagati

The interpretative process aimed at understanding the architectural shape of Mongialino's Tower has taken into account the few written sources that describe the consistence of the castle [12,3] and, above all, the metric and spatial data by 3D laser scanning survey. The several collapses have largely affected the structure so now it is difficult to get a unitary spatial reading of the architectural text, indeed essential for its proper understanding and, therefore, conservation.

The digital model of the tower – its virtual replica – has been an effective and irreplaceable research tool in this phase, as it allows in real time: -the close exploration of inaccessible or dangerous areas easily subjected to collapses; -the control of the geometrical/spatial interpretative hypothesis that have been formulated; -the volumetric quantification of the masonry portions that have been spoiled; - the virtual anastylosis of the collapsed pieces still present on site.

The first step of our approach forecasted the geometrical study of the circular plan of the tower [12]. At a first metrological examination, we confirmed that the planimetric dimensions are compatible with the ancient local measurement unit – canna (about 2,062 m) – according to multiples and sub-multiples. As previously described (Section 3), the external diameter is 20,64 m (almost 10 canne), the thickness of the masonry is 2,06 m (almost 1 canna), then follows a ring-like vaulted room and the central cylindrical core whose diameter is 8,18 m (about 4 canne) and that holds inside a cavity used as holding tank.

Furthermore, we also have verified that the radial arches that support the ring-like vault divide the plan in uniform circular sectors. The theoretical geometric reconstruction of the collapsed area brings to a plan divided into twelve parts, according to a regular dodecagon structure. The dodecagon is one of the principal regular polygon and it is done by dividing the circle by number 3. This is a geometric shape whose tracing is very simple, because it is based on the construction of equilateral triangles with side equal to the radius of the circumscribed circle.

Often, in castle's architectures we can recognize symbolisms linked to numbers mystique. In this case the number 12 could be linked to the time and to humans (like 12 months, 12 zodiacal signs, 12 hours, 12 doors of heaven), to the divine trinity, to the multitude, to the 12 apostles.

Fig. 10: Studies on the plan: a) metrological analysis; b) geometrical analysis and plan reconstruction of the first two elevations; c) geometrical analysis and plan reconstruction of the third elevation.

In the second step we investigated the shape of the inner room to have proofs on the Vito Amico description. The presence of a cantilever stone stringcourse of about 3.90 m of height on both sides of the walls brings to the supposition of a wood planking level and so to the division into two levels. The stringcourse is made by supporting and decorative ashlar. The firsts act like cantilevers, pierce the solid wall and support the floor frame, the others give continuity to the floor. Furthermore, the presence of a planking level is beyond confirmed by the sings of some holes at different height that leads to imagine a stair that connected the two mentioned levels. Among these, 4 holes placed from one side to the other of the room, at the same height and under the only intact splayed arrow loop, lead to hypothesize a halfway landing.

The openings of the tower belong to two different typologies: splayed arrow loops and right-angle arrow loops (some of them have a seat). It seems that the planimetric distribution of the openings does not comply with a strict symmetry: some of the openings are in axis with the dodecagonon sides, others are not. We could assume that in a defensive architecture the opening of an arrow loop should respond more to some functional needs than to aesthetic ones. Nevertheless, if we consider the intrinsic symmetry of the used circular shape and the division in twelve parts, the choice to not have a balanced succession of plenums and voids, it disadvantages the stability of the building and, maybe, it has started weakness mechanisms.

The next step was the geometrical study of the ring-like vault [13]. This is a toric surface supported by radial pointed arches whose ratio between span and rise is $4/7$, with a division in modules M of about 60 cm (that corresponds to the double roman feet unit). The springline is at about 5.40 m from the ground (9M) and the distance between the stringcourse and the springline is equal to 1.50 m (2,5 M). The vault directrix profile is a segmental arch whose springline is at about 7.00 m from the ground and whose centers are at the same height of radial pointed arches springline.

As regards the upper level, it is likely the access had place through small passages into the vault. The reduced dimensions of the only surviving passage leads to imagine the use of a retractable stair. The current impossibility to access this level and the few surviving ruins do not allow to recognize the two other elevation described by Vito Amico, but only one of them.

We suppose that the plan of the upper level was a semi-cylinder, that corresponds to the collapsed zone, with a terrace. Some of the still present signs confirm that hypothesis: the traces of a radial wall that closed the upper level, the continuous parapet of the terrace, the logline for the water disposal that is placed at the end of the parapet and is build in the masonry.

Some further checks on the digital models highlighted that the radial wall of the upper level lies on the vault rather than on the supporting pointed arches and the entrance to the tower is perfectly in axis with the pointed arches. These two circumstances are not so optimal from a static point of view.

Finally, we studied the geometry of the upper level vault by using the few surviving parts. The first thing that we noticed is that the upper radial supporting arches are not in axis with the lower ones. The absence of other elements of reference does not allow to carry out a deeper check that could help to understand if this is a building tracing mistake. Furthermore, starting from the existing traces of the vault we can suppose another toric surface supported by pointed arches and whose directrix is a buttress arch with springplane staggered of about 1.50 m (2,5M).

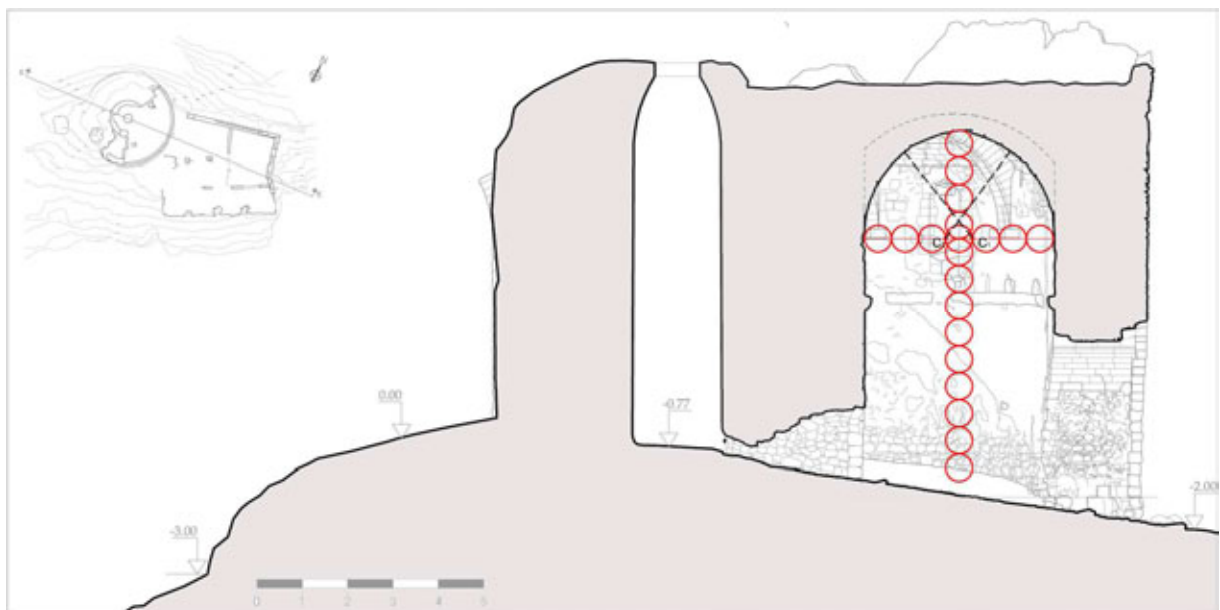

Fig. 11: Cross section and geometrical analysis of the supporting radial pointed arch.

The geometrical studies and the proofs highlighted up to the present allow to propose a first hypothesis on the original shape of the tower: a cylindrical building whistle-like, with terrace. On the base of these evidences and interpretations we are working on the virtual reconstruction of the Mongialino Tower.

Our reconstruction hypothesis and their representations will be guided by London [10] and Seville Charter [14] on Cultural Heritage Computer – Based visualization principles. In particular, we are applying and verifying the principles that deal with Authenticity (principle 4), Historical Rigor (principle 5) and Scientific Transparency (principle 7). Due to the weakness of the sources, the methodological approach will attempt to follow a rigorous path highlighting all the estimated choices sharing and making them visible also to the community. The goal is to make the methodological approach visually transparent the both to the scientific community and also to non experts [15,16].

5. Reading the signs: materials and constructive techniques

Alessandro Lo Faro

The massive bulk of Mongialino's tower binds strongly on the rocks on which it stands through the use of construction materials also. All the building elements that constitute the dungeon are in fact made using the limestone carried out Mineo's territory. Probably the same rock on which the tower is has contributed to its construction. The sands of the nearby rivers were mixed with lime for mortar that bind the masonries and plasters that cover them.

We interpreted the masonry of the dungeon through the detailed examination of the portions of walls now ruined and the laser scanner acquisition: the arrangement of the ashlar is largely readable as it is detached from plaster. The eminently defensive function justifies the massive thickness of solid masonry with an obvious variation between the tower and the outer fence, perhaps built later and reshaped several times.

Analyzing the masonries according a constructive point of view, we are recognized 3 different typologies of walls, that we call M1, M2 and M3.

The tower has a cylindrical outer thickness of about 206 cm; the columnar inner core is equal to 308 cm. In both cases it is possible to distinguish a cobblestone wall, called M1, consisting of 2 outer irregular coursed rubble wall, with visible face of approximately 25x30 cm.

These sets have containment function and thickness varying from 30 to 50 cm. The core of both walls is constituted by a conglomerate in mortar and rubble limestone of small size (average size 3-30 cm). The settlement is every 50 cm, generally. They seem completely absent squarely dressed stone having function of ligament: the external sets are without necessary bond.

In the upper part of the dungeon, in correspondence of the third elevation, is possible to recognize another typology of wall, which we define M2. Its thickness decreases by 2 rows of ashlar, reducing about 140 cm. It is always a cobblestone wall, with outer surface thick from 30 to 40 cm and concretionary core of rubble and mortar. Compared to the type M1, the beddings are highlighted by narrow joints with fragments of tiles and bricks placed at each row of blocks.

The surrounding walls and the buildings near the tower have been realized using an additional type of walling, here called M3. Its constructive technique is particularly poor and close to described masonry previously: a double surfaces in unsquared dressed stone, with a core of limestone mortar and rubbles. The thicknesses ranging from 70 to 100 cm, with particularly thick mortar joints. Greater care is found only at the corners, where are readable the dressed stone having ligament function.

The different types of wall texture find here are all cobblestone wall: the impressive thicknesses (up to 3 meters in the columnar core) are a consequence of the defensive function of the tower but above all by the walling technology. It requires considerable thickness, with a massive behavior of masonry, against the ineffective bond between the blocks and the weak cross connection between the outer sets.

The horizontal closures of the intermediate elevations, as recalled by Vito Amico, were wooden floors, of which today remains the stone shelves and the traces of the scaffolding holes: there the timber joists supporting the continuous timber flooring, with a wheelbase of about 90 cm.

The second and the final elevation of the dungeon are defined by an annular vault realized in dressed ashlar supported by polycentric arches, set at a distance of about 320 cm [17]. In the first elevation the arches are composed of a succession of blocks, according to the sequence $(a/2 + a/2) - a - (a/2 + a/2)$, i.e. a parallelepiped of dimensions 45x50x (7 ÷ 20) cm, then with variable height (Fig. 12).

The arches, whose visible edges are slightly grooved, resting on stone cantilevers, just deeper (60 cm) than other ashlar. The laying of the arcs occurred initially placing the cantilevers inside the wall, and the first of these blocks over them, while also the masonry rises to a 30° inclined plane. The barrel vault rises from this height. Thanks to the instrumental survey, it was possible to trace both the shape of the support arch than that of the vault. It has the geometry of a segmental arch because its centre is about 4 meters below the impost.

The barrel vault in the first elevation is realized using dressed blocks of tender limestone, organized according the rowlock course. The height of ashlar is generally 30 cm, variable width (11 ÷ 18 cm)

and length (30 ÷ 55 cm). The courses have staggered joints, about ¼ of total length, i.e. 13 cm. They are also occasionally used blocks having lateral squared surface to compensate for any unevenness. The support arches and barrel vaults do not have any bond from each other. At the surfaces of contact between the arch and the vault, you can see traces of the ribs, i.e. the housing for the wooden joists on top of the arches. Set up the centre, that is tracked stone arches, these are placed on the shutterings for the assembly of the blocks that form the barrel vault [18]. The abutment, as stated clearly due to the collapse, is made up of "heavy" materials: rubble stone tied with plenty of mortar, following the principles inherited from the Roman *caementum*.

We have no trace of the vault that closed the last elevation, with the exception of the supporting arches, of which some remains ashlar abutment.

Fig. 12-13: Detail of the vault system: 1) blocks of the barrel vault; 2) ashlar of support arch, so called *a*; 3) cantilever stone block; 4) M1 masonry; 5) outer set of M1 type masonry. On the right a view of the ruined vault.

The *modus construendi* of this vault is similar to that of the lower level, although its geometry is different: it rested about 150 cm higher than the impost of the supporting arches. The vault's ashlar have more regular size, equal to 24x (30 ÷ 40) x 30 cm. The support arches are resting on brackets slightly protruding, of which only traces remain evident in the columnar core. Here also decorative pieces seem to have assumed, by their strength, functional value.

The poor and unadorned simplicity of the adopted solutions, both spatial and constructive models, seem to recall the first French Romanesque, specifically the large common rooms and the cloister's aisles of the Cistercian abbeys. In those spaces the use of the barrel vault, (round and / or lancet arch) interspersed with reinforcement arcs of stonework, was the technological solution most frequently adopted. Here in Mongialino the working technique of stone blocks appears cruder and have a variability in size cannot be found in the examples of France. The function to compensate for the irregularities of the stone shall be entrusted to the mortar joints. In medieval fortified architecture the Cistercians workers were well estimated by contemporaries, so that the Emperor Frederick II came to entrust them with the construction of its castles [19]. It well designed, that is, the power of their logic and essential art. The lesson widespread in Sicily by Frederick architectures (Castle Maniace in Syracuse, Tower of Frederick in Enna) about the stoneworking according to the canons of stereotomy, however, appears in our tower still far away.

6. Conclusion

This study is important not only for a proper historical/typological placement of the building, which is unique in the Sicilian landscape, but also for its preservation and transmission to future generations. The 3D model becomes an essential tool for the understanding of the static behavior of the structure, of the causes that led to the collapse and the proper conservation project. The reading of the cracks and understanding of damage mechanisms give some necessary indications to the choice of rehabilitative therapy [20]. The apparent symmetry of the plan tower's collides with its inherent weaknesses, which partially justifies its current state of ruin. Among these we highlight: the presence of openings (the entrance, some loopholes) close to the impost of the supporting arches, i.e. where the thrusts are concentrated; the third elevation masonry stay directly on the vault; the weak cross-connection between the sets of masonry; the heavy abutment; the lack of connection between vaults and arches of reinforcement, are just a few examples.

The present study would have these future outlooks: analysis of typological and formal models of the tower; the virtual reconstruction of the object; verification and measurement of the cracks.

Acknowledgment

Authors would like to thank Microgeo srl (Simone Orlandini, Enrico Cabrucci, Vincenzo Ippolito) for their support in the surveying phases.

Abstract

The diffusion of Image-based 3D modeling techniques, through image-based free, low cost and open source software, have increased drastically in the past few years, especially in Cultural Heritage domain (Architecture, Archeology, Urban planning) [2, 3]. Computer vision techniques use photographs from dataset collection to rapidly build detailed 3D models. The simultaneous applications of different algorithms (MVS), the different techniques of image matching, feature extracting and mesh optimization are inside an active field of research in computer vision. Computer vision techniques - Structure from Motion (SfM)- allow to fulfill detailed 3D models from photos dataset collections. The results are promising: the obtained models are beginning to challenge the precision of laser-based reconstructions. This research investigates the limits and potentialities of 3D models obtained by using image based techniques in Architectural Heritage field, in order to verify the applicability of the method for the perspective return of the solid perspective of the artistic repertoire in my territory. My approach to this challenging problem is to verify the reliability of the 3Dmodels by Autodesk 123D Catch (web-based package). This paper aimed to demonstrate the efficiency of 123D Catch to obtain an accurate 3D model to operate the perspective return of artistic models.

Keywords: Image-based modeling, 3D reconstruction, Photogrammetry, Computer Vision, Architectural/Artistic Heritage

1. Introduction

Image-based modeling method can be employed to extract original texture and illumination directly from images for visual 3D modeling [21], without the need for complicated processes, such as geometry modeling, shading and ray tracing. These techniques – named Structure from Motion (SfM)- are usually less accurate, but offer very intuitive and low cost methods for reconstructing 3D scenes and models [1, 9, 10, 11]. There are now a number of software packages that offer the ability to acquire 3D models from a set of images without any a priori information about the scene to be reconstructed. 3D reconstruction from images has undergone a revolution in the last few years [12, 13, 14]. Thus, there is a growing attention among academics and practitioners due to the great potentialities of these systems [24]. Among all available web based software (ARC3D, 123D Catch, Hyp3D, my3Dscanner) I have chosen 123D Catch for the easiness of use, the visual quality of the reconstructed scene and the possibility to interact with and develop the results. Furthermore, Catch 3D mesh is suitable for all 3D modeling software. This web-based package exploits the power of cloud computing, allowing to carry out other tasks but it works like a black box and the user does not have the possibility to interact with the software in order to improve the outcomes [25, 26].

I will use 123DCatch on the bronze tile in S. Caterina urn in Dome of Palermo.

2. 123D Catch Model

123D Catch is a web-based, at present time free, package of Autodesk. It overcomes Autodesk's Photofly project launched in 2010 summer, using technology developed by Realviz [8, 22]. The used approach underlying 123D Catch technology is well described in [20].

Exploiting the photogrammetric approach and the algorithms of Computer Vision, 123D Catch is able to reconstruct internal parameters of the digital camera and the position in space of the homologous points from a number of correspondences between sequences of photographic images, suitably taken [17].

The 3D coordinates of all points of the scene have been found and the polygonal model has been reconstructed through the correspondence pixel-pixel.

To use 123D Catch you have to:

- 1) Capture a photographic sequence of convergent photos of the object with an overlapping of about 70%;
 - 2) Upload the photos to Autodesk cloud (user can decide whether to wait the 3D reconstruction or to be advised by email);
 - 3) Improve the results by manual stitching of homologous points on triplets of images and submit again the scene to the cloud;
 - 4) Create a video;
 - 5) Export the 3D polygonal model thus obtained in OBJ format and use it in other 3D packages.
- In professional field, 123D Catch has carried out good results both under metric and visualization output and both on large and small architectural scale.

To use 123D Catch you need:

- 1) A pc with a low Ram profile also, for example 3 giga and a fast internet connection (the mesh elaboration takes place on cloud);
- 2) A camera with resolution range of 6/12 Mpix.
